4K x 8 Dual-Port Static RAM and 4K x 8 Dual-Port SRAM with Semaphores

Features

- True dual-ported memory cells, which allow simultaneous reads of the same memory location
- 4K x 8 organization
- 0.65 micron CMOS for optimum speed and power
- High speed access: 15 ns
- Low operating power: I_{CC} = 160 mA (max)
- Fully asynchronous operation
- Automatic power down
- Semaphores included on the 7C1342 to permit software handshaking between ports
- Available in 52-pin plastic leaded chip carrier (PLCC)
- Pb-free packages available

Functional Description

The CY7C135/135A[1] and CY7C1342 are high speed CMOS 4K x 8 dual-port static RAMs. The CY7C1342 includes semaphores that provide a means to allocate portions of the dual-port RAM or any shared resource. Two ports are provided permitting independent, asynchronous access for reads and writes to any location in memory. Application areas include interprocessor/multiprocessor designs, communications status buffering, and dual-port video/graphics memory.

Each port has independent control pins: chip enable ($\overline{CE}$), read or write enable (R/W), and output enable ($\overline{OE}$). The CY7C135/135A is suited for those systems that do not require on-chip arbitration or are intolerant of wait states. Therefore, the user must be aware that simultaneous access to a location is possible. Semaphores are offered on the CY7C1342 to assist in arbitrating between ports. The semaphore logic is comprised of eight shared latches. Only one side can control the latch (semaphore) at any time. Control of a semaphore indicates that a shared resource is in use. An automatic power down feature is controlled independently on each port by a chip enable ($\overline{CE}$) pin or SEM pin (CY7C1342 only).

The CY7C135/135A and CY7C1342 are available in 52-pin PLCC.

Pin Definitions

Left Port	Right Port	Description
$A_{0L–11L}$	$A_{0R–11R}$	Address lines
$\overline{CE}_L$	$\overline{CE}_R$	Chip Enable
$\overline{OE}_L$	$\overline{OE}_R$	Output Enable
$R/\overline{W}_L$	$R/\overline{W}_R$	Read/Write Enable
$\overline{SEM}_L$ (CY7C1342 only)	$\overline{SEM}_R$ (CY7C1342 only)	Semaphore Enable. When asserted LOW, allows access to eight semaphores. The three least significant bits of the address lines determines which semaphore to write or read. The I/O_0 pin is used when writing to a semaphore. Semaphores are requested by writing a 0 into the respective location.

Figure 8. Write Cycle No. 2: R/W̄ Three-States Data I/Os (Either Port)[18, 21]
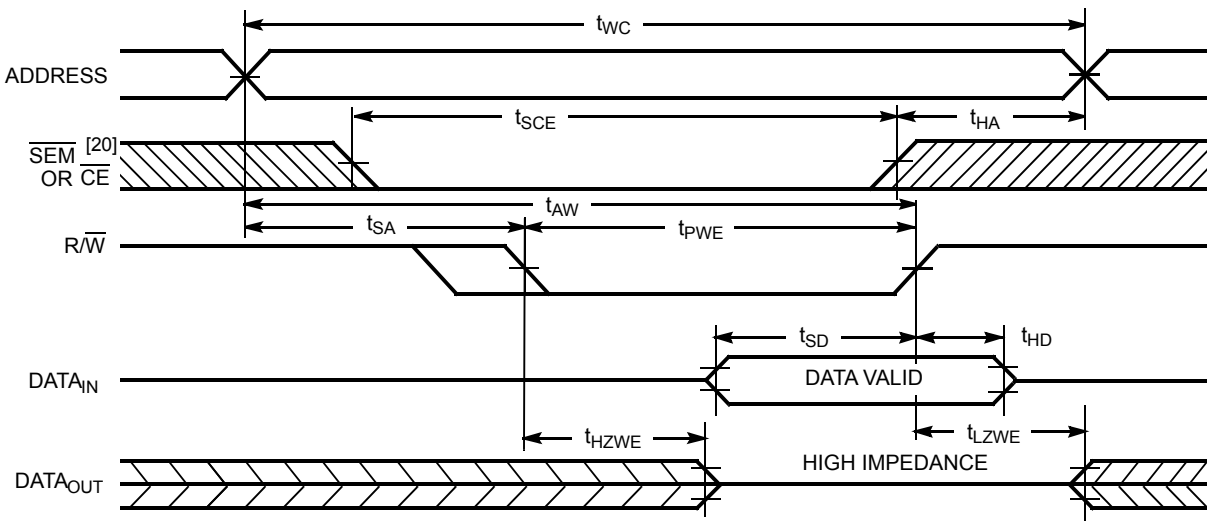

Notes
17. The internal write time of the memory is defined by the overlap of CE̅ or SEM̅ LOW and R/W̄ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input setup and hold timing should be referenced to the rising edge of the signal that terminates the write.
18. R/W̄ must be HIGH during all address transactions.
19. If OE̅ is LOW during a R/W̄ controlled write cycle, the write pulse width must be the larger of t_{PWE} or (t_{HZWE} + t_{SD}) to allow the I/O drivers to turn off and data to be placed on the bus for the required t_{SD}. If OE̅ is HIGH during a R/W̄ controlled write cycle (as in this example), this requirement does not apply and the write pulse can be as short as the specified t_{PWE}.
20. Semaphore timing applies only to CY7C1342.
21. Data I/O pins enter high impedance when OE̅ is held LOW during write.

[+] Feedback

Switching Waveforms (continued)

Figure 9. Semaphore Read After Write Timing, Either Side (CY7C1342 only)[22]
Figure 10. Timing Diagram of Semaphore Contention (CY7C1342 Only)[23, 24, 25]
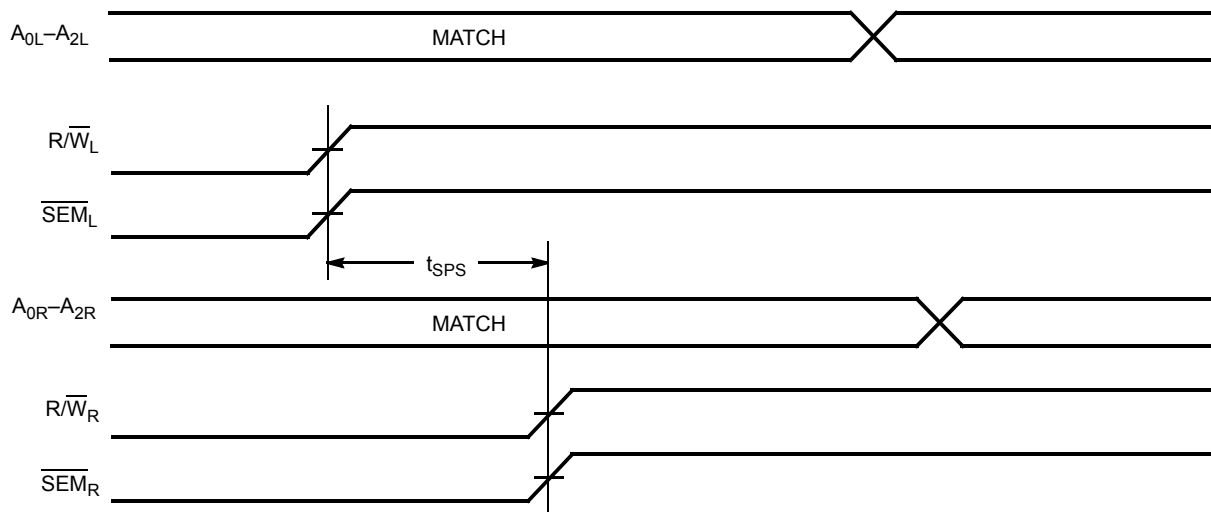

Notes
22. $\overline{CE}$ = HIGH for the duration of the above timing (both write and read cycle).
23. $I/O_{0R} = I/O_{0L}$ = LOW (request semaphore); $\overline{CE}_R = \overline{CE}_L$ = HIGH.
24. Semaphores are reset (available to both ports) at cycle start.
25. If t_{SPS} is violated, it is guaranteed that only one side gains access to the semaphore.

[+] Feedback

Architecture

The CY7C135/135A consists of an array of 4K words of 8 bits each of dual-port RAM cells, I/O and address lines, and control signals (CE, OE, R/W). Two semaphore control pins exist for the CY7C1342 ($\overline{SEM}_{L/R}$).

Functional Description

Write Operation

Data must be set up for a duration of t_{SD} before the rising edge of R/W to guarantee a valid write. Because there is no on-chip arbitration, the user must be sure that a specific location is not accessed simultaneously by both ports or erroneous data could result. A write operation is controlled by either the $\overline{OE}$ pin (see Figure 7) or the R/W pin (see Figure 8). Data can be written t_{HZOE} after the $\overline{OE}$ is deasserted or t_{HZWE} after the falling edge of R/W. Required inputs for write operations are summarized in Table 1.

If a location is being written to by one port and the opposite port attempts to read the same location, a port-to-port flowthrough delay is met before the data is valid on the output. Data is valid on the port wishing to read the location t_{DDD} after the data is presented on the writing port.

Read Operation

When reading the device, the user must assert both the $\overline{OE}$ and $\overline{CE}$ pins. Data is available t_{ACE} after $\overline{CE}$ or t_{DOE} after $\overline{OE}$ are asserted. If the user of the CY7C1342 wishes to access a semaphore, the $\overline{SEM}$ pin must be asserted instead of the $\overline{CE}$ pin. Required inputs for read operations are summarized in Table 1.

Semaphore Operation

The CY7C1342 provides eight semaphore latches, which are separate from the dual port memory locations. Semaphores are used to reserve resources which are shared between the two ports. The state of the semaphore indicates that a resource is in use. For example, if the left port wants to request a given resource, it sets a latch by writing a zero to a semaphore location. The left port then verifies its success in setting the latch by reading it. After writing to the semaphore, SEM or OE must be deasserted for t_{SOP} before attempting to read the semaphore. The semaphore value is available $t_{SWRD} + t_{DOE}$ after the rising edge of the semaphore write. If the left port was successful (reads a zero), it assumes control over the shared resource, otherwise (reads a one) it assumes the right port has control and continues to poll the semaphore. When the right side has relinquished control of the semaphore (by writing a one), the left side succeeds in gaining control of the semaphore. If the left side no longer requires the semaphore, a one is written to cancel its request.

Semaphores are accessed by asserting $\overline{SEM}$ LOW. The $\overline{SEM}$ pin functions as a chip enable for the semaphore latches. CE must remain HIGH during $\overline{SEM}$ LOW. A_{0-2} represents the semaphore address. OE and R/W are used in the same manner as a normal memory access. When writing or reading a semaphore, the other address pins have no effect.

When writing to the semaphore, only I/O_0 is used. If a 0 is written to the left port of an unused semaphore, a one appears at the same semaphore address on the right port. That semaphore can

now only be modified by the side showing a zero (the left port in this case). If the left port now relinquishes control by writing a one to the semaphore, the semaphore is set to one for both sides. However, if the right port had requested the semaphore (written a zero) while the left port had control, the right port would immediately own the semaphore. Table 2 shows sample semaphore operations.

When reading a semaphore, all eight data lines output the semaphore value. The read value is latched in an output register to prevent the semaphore from changing state during a write from the other port. If both ports request a semaphore control by writing a 0 to a semaphore within t_{SPS} of each other, it is guaranteed that only one side gains access to the semaphore.

Initialization of the semaphore is not automatic and must be reset during initialization program during power up. All semaphores on both sides should have a one written into them at initialization from both sides to assure that they are free when needed.
Table 1. Non-Contending Read/Write

Inputs				Outputs	Operation
CE	R/W	OE	SEM	$I/O_0 - I/O_7$	
H	X	X	H	High Z	Power-down
H	H	L	L	Data out	Read semaphore
X	X	H	X	High Z	I/O Lines disabled
H	L	X	L	Data in	Write to Semaphore
L	H	L	H	Data out	Read
