

Functional Diagram

### Absolute Maximum Ratings

(All voltages referenced to GND, unless otherwise noted.)

V <sub>CC</sub> .....	-40V to +40V
V <sub>P</sub> .....	MIN: the higher of -0.3V and (V <sub>CC</sub> - 0.3V) MAX: the higher of 40V and (V <sub>CC</sub> + 40V)
LDOIN.....	-0.3V to +40V
V <sub>5</sub> .....	-0.3V to the lesser of (V <sub>LDOIN</sub> + 0.3V) and +6V
LDO33.....	-0.3V to the lesser of (V <sub>5</sub> + 0.3V) and +6V
V <sub>L</sub> .....	-0.3V to +6V
DIO, DO.....	MIN: the higher of -40V and (V <sub>CC</sub> - 40V) MAX: the lesser of +40V and (V <sub>CC</sub> + 40V)
Logic Inputs	
LIO, DODIS, DIOEN, LO, $\overline{CS}$ ,	
SDI, SCLK.....	-0.3V to (V <sub>L</sub> + 0.3V)

Logic Outputs

RX, $\overline{WU}$ , SDO, $\overline{IRQ}$ .....	-0.3V to (V <sub>L</sub> + 0.3V)
UV.....	-0.3V to +6V
Continuous Current Into V <sub>P</sub> .....	±50mA
Continuous Current Into Any Logic Pin.....	±50mA
Continuous Power Dissipation	
TQFN (derate 27.8mW/°C above +70°C).....	2222mW
Operating Temperature Range.....	-40°C to +105°C
Maximum Junction Temperature.....	+150°C
Storage Temperature Range.....	-65°C to +150°C
Lead Temperature (soldering, 10s).....	+300°C
Soldering Temperature (reflow).....	+260°C

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### Package Thermal Characteristics (Note 1)

TQFN

Junction-to-Ambient Thermal Resistance ( $\theta_{JA}$ ).....	36°C/W
Junction-to-Case Thermal Resistance ( $\theta_{JC}$ ).....	3°C/W

**Note 1:** Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](http://www.maximintegrated.com/thermal-tutorial).

### DC Electrical Characteristics

(V<sub>CC</sub> = 9V to 36V, V<sub>L</sub> = 2.3V to 5.5V, V<sub>GND</sub> = 0V; all logic inputs at V<sub>L</sub> or GND; T<sub>A</sub> = -40°C to +105°C, unless otherwise noted. Typical values are at V<sub>CC</sub> = 24V, V<sub>L</sub> = 3.3V, and T<sub>A</sub> = +25°C, unless otherwise noted.) (Note 2)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
V <sub>CC</sub> Supply Voltage	V <sub>CC</sub>		9		36	V

Typical Operating Characteristics (continued)

( $V_{CC} = 24V$ ,  $LDOIN = V_P$ ,  $V_L = LDO33$ , DIO and DO in push-pull configuration,  $T_A = +25^\circ C$ , unless otherwise noted.)

Pin Configuration

Pin Description

PIN	NAME	FUNCTION
1	LDOIN	5V Linear Regulator Input. Bypass LDOIN to GND with a 0.1µF ceramic capacitor.
2	V <sub>5</sub>	5V Power-Supply Input and 5V Linear Regulator Output. Bypass V <sub>5</sub> to GND with a 0.1µF ceramic capacitor for 10mA load capability. Add the recommended compensation network to increase the source capability to 30mA. See the <i>5V and 3.3V Linear Regulators</i> section for more information.
3	LDO33	3.3V Linear Regulator Output. Bypass LDO33 to GND with a 1µF ceramic capacitor.
4	IRQ	Active-Low Interrupt Request Output. IRQ is a push-pull output referenced to V <sub>L</sub> .
5	SCLK	SPI Clock Input
6	CS	Active-Low SPI Chip-Select Input

## Pin Description (continued)

PIN	NAME	FUNCTION
7	SDO	SPI Serial-Data Output
8	SDI	SPI Serial-Data Input
9	$V_L$	Logic-Level Supply Input. $V_L$ defines the logic levels on all the logic inputs and outputs. Bypass $V_L$ to GND with a 0.1 $\mu$ F ceramic capacitor.
10	I.C.	Internally Connected. Connect to $V_L$ or leave unconnected. It is recommended to connect to $V_L$ .
11	DODIS	DO Driver Disable Input. Drive DODIS low to enable the DO driver. Drive DODIS high to disable the DO drive.
12	LIO	DIO Input. The logic on the DIO output is the inverse logic level of the signals on the LIO inputs.
13	DIOEN	DIO Driver Enable. Drive DIOEN high to enable the DIO transmitter. DIOEN is referenced to $V_L$ .
14	RX	DIO Output. RX is the inverse logic level of DIO. RX is always high when the RxDis bit in the DIOConfig register is set to 1.
15	$\overline{WU}$	Active-Low Wake-Up Output. $\overline{WU}$ is a push-pull output referenced to $V_L$ . $\overline{WU}$ pulses low for 50 $\mu$ s (typ) when a valid wake-up pulse is detected on the DIO line.
16	LO	Logic Input of the DO Output. LO is the logic input that drives DO. LO is referenced to $V_L$ .
17, 19	N.C.	Not Connected. Leave N.C. unconnected.
18	UV	Open-Drain Undervoltage Indicator Output. In case of an undervoltage, the UV open-drain transistor is off.
20	GND	Ground
21	DIO	Driver Input/Output. Drive DIOEN high to enable the DIO driver. The logic on the DIO output is the inverse logic level of the signals on the LIO. RX is the logic inverse of DIO. The DIO driver output level can be set by the LIO input or programmed by the Q bit. The level on DIO can be read by the RX output or the $\overline{QLVL}$ bit.
22	DO	24V Logic-Level Digital Output. DO is the inverse logic level of the LO input and can be digitally-controlled through the DIOConfig register.
23	$V_{CC}$	Power-Supply Input. Bypass $V_{CC}$ to GND with a 1 $\mu$ F ceramic capacitor.
24	$V_P$	Protected 24V Supply Output. $V_P$ is one diode drop below $V_{CC}$ . $V_P$ is reverse-polarity protected and can be used as a 24V protected supply to the sensor.
—	EP	Exposed Pad. Connect EP to GND.

## Detailed Description

The MAX14836 is a dual-sensor driver. The device contains two 24V digital outputs. Two internal linear regulators generate common sensor voltages.

The device detects short-circuit wake-up conditions on the DIO line and generates a wake-up signal on the  $\overline{WU}$  output. The DIO and DO drivers are independently-configurable to any one of three driver output types: push-pull, high-side (pnp), or low-side (npn).

The device is configured and monitored through an SPI™ interface. Extensive alarms are available through SPI.

### 24V Interface

The device features an IO transceiver interface capable of operating with voltages up to 36V. This is the 24V interface and includes the DIO input/output, the logic-level digital output (DO).

### Configurable Drivers

The device features selectable push-pull, high-side (pnp), or low-side (npn) switching drivers at DIO and DO.

Set the DIO\_N/P and DIO\_PP bits in the DIOConfig register to select the driver mode for the DIO driver. When configured as a push-pull output, DIO switches between  $V_P$  and ground. Set the DIO\_PP bit to 1 to select push-pull operation at DIO. Set the DIO\_PP bit to 0 to configure the DIO output for open-drain operation. The DIO\_N/P bit selects npn or pnp operation when DIO is configured as an open-drain output.

Set the DoN/P and DoPP bits in the DOConfig register to select the driver mode for the DO output. When configured as a push-pull output, DO switches between  $V_{CC}$  and ground. Set the DoPP bit to 1 for push-pull operation. The DoN/P bit selects npn or pnp operation when DO is configured as an open-drain output. Set the DoPP bit to 0 to select high-side or low-side operation at DO.

### DIO Driver and Receiver

The DIOEN input enables the DIO driver. Drive DIOEN high to enable the DIO driver. Drive DIOEN low to disable the driver.

The device's DIO driver is specified for 200mA to drive current to large capacitive loads of up to 3 $\mu$ F and dynamic impedances like incandescent lamps.

The DIO receiver is always on. Disable the RX output through the RxDis bit in the DIOConfig register. Set the RxDis bit to 1 to set the RX output high. Set the RxDis bit to 0 for normal receive operation.

The DIO receiver has an analog lowpass filter to reduce high-frequency noise present on the line. Set the RxFilter bit in the DIOConfig register to 0 to set the filter corner frequency to 250kHz (typ). Set the RxFilter bit to 1 to set the corner frequency of the filter to 500MHz (typ). Noise filter is present on the DIO receiver and controlled simultaneously by the RxFilter bit.

### DIO Fault Detection

The device registers a DIOFault condition when it detects a short circuit for longer than 650 $\mu$ s (typ). A short condition exists when DIO driver's  $V_{OH}$  or  $V_{OL}$  exceeds 2.8V (typ).

When a DIOFault error occurs, the DIOFault and DIOFaultInt bits are set,  $\overline{IRQ}$  asserts, and the driver is turned off 650 $\mu$ s (typ) blanking time after the start of the fault condition.

When a short-circuit event occurs on DIO, the driver enters autoretry mode. In autoretry mode, the device periodically checks whether the short is still present and attempts to correct the driver output. Autoretry attempts last for 770 $\mu$ s (typ) and occur every 26ms (typ).

### DO Fault Detection

The device registers a DoFault event when a short-circuit is present at the DO output for 440 $\mu$ s. A short condition exists when the DO driver's  $V_{OH}$  or  $V_{OL}$  exceeds the 2.8V (typ). When a short-circuit condition is detected, the DO driver enters autoretry mode. In autoretry mode, the device periodically checks whether the overcurrent is still present. Autoretry attempts last for 440 $\mu$ s (typ) and occur every 26ms (typ). When a DoFault error is detected, the DoFault and DoFaultInt bits are set,  $\overline{IRQ}$  asserts, and the driver is turned off 440 $\mu$ s (typ) after the start of the DO faults.

### Reverse-Polarity Protection

The device is protected against reverse-polarity connections on  $V_{CC}$ , DIO, DO, DI, and GND. Any combination of these pins can be connected to DC voltages up to 40V (max). A short to 40V results in a current flow of less than 500 $\mu$ A.

Ensure that the maximum voltage between any of these pins does not exceed 40V.

### 5V and 3.3V Linear Regulators

The device includes two internal regulators to generate 5V ( $V_5$ ) and 3.3V (LDO33). LDO5 is specified for 10mA total external load current (i.e., LDO33 +  $V_5$ ) when bypassed with a 0.1 $\mu$ F capacitor to ground. Add the compensation network shown in Figure 5 to draw up to 30mA of total external load current from the 5V LDO. LDO33 is specified at 20mA. The input of  $V_5$  (LDOIN) can be powered from  $V_P$ , the protected 24V supply output, or to another voltage in the 7V to 36V range.

If the external circuits that are powered by the linear regulators require an input bypass capacitance larger than 100nF for 5V or 1 $\mu$ F for 3.3V, a compensation network must be added on  $V_5$  and/or LDO33. The compensation network consists of a 10 $\Omega$  series resistor and a capacitor equal to the value required by the external circuit, as shown in Figure 6. The capacitors C33 and C5 in Figure 6 represent the capacitance required by the external circuits. Figure 6 does not show any protection diodes for simplicity.

When the internal 5V LDO is not used,  $V_5$  becomes the supply input for the internal analog and digital functions and, therefore, has to be supplied externally so that the MAX14836 operates normally. The 5V LDO can be disabled by connecting LDOIN to  $V_5$ . Apply an external voltage of 4.75V to 5.25V to  $V_5$  when the LDO is disabled.

Use the LDO33Dis bit in the Mode register to disable LDO33. See the *Mode Register [R1, R0] = [1, 1]* section for more information.  $V_5$  and LDO33 are not protected against short circuits.

### Power-Up

If  $V_L$  is connected to  $V_5$  or to LDO33, the DIO and DO driver outputs and the UV output are high-impedance

when  $V_{CC}$ ,  $V_5$ ,  $V_L$ , and/or LDO33 voltages are below their respective undervoltage thresholds during power-up. If  $V_L$  is not connected to  $V_5$  or to LDO33,  $V_L$  needs to be powered up before or simultaneously with  $V_5$  or LDO33 in order to ensure that the DO output is high impedance at power-up. UV goes low and the drivers are enabled when all these voltages exceed their respective undervoltage-lockout thresholds.

The drivers are automatically disabled if  $V_{CC}$ ,  $V_5$ , or  $V_L$  falls below its threshold.

### Undervoltage Detection

The device monitors  $V_{CC}$ ,  $V_5$ ,  $V_L$ , and optionally LDO33 for undervoltage conditions. UV is high-impedance when any monitored voltage falls below its UVLO threshold.

$V_{CC}$ ,  $V_5$ , and  $V_L$  undervoltage detection cannot be disabled. When  $V_{CC}$  falls below the  $V_{CCUVLO}$  threshold, the UV24 and UV24Int bits are set, UV asserts high, and  $\overline{IRQ}$  asserts low.

The SPI register contents are unchanged while  $V_5$  is present, regardless of the state of  $V_{CC}$  and LDO33. The SPI interface is not accessible and  $\overline{IRQ}$  is not available when UV is asserted due to a  $V_5$  or  $V_L$  undervoltage event.

When the internal 3.3V LDO regulator voltage ( $V_{LDO33}$ ) falls below the LDO33 undervoltage lockout threshold, the UV33Int bit in the Status register is set and  $\overline{IRQ}$  asserts. UV asserts if the UV33En bit in the Mode register is set to 1.

The UV output deasserts once the undervoltage condition is removed. However, bits in the Status register and the  $\overline{IRQ}$  output are not cleared until the Status register has been read.

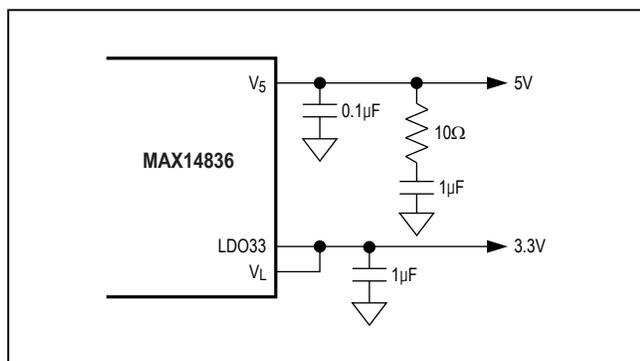

Figure 5.  $V_5$  Compensation Network

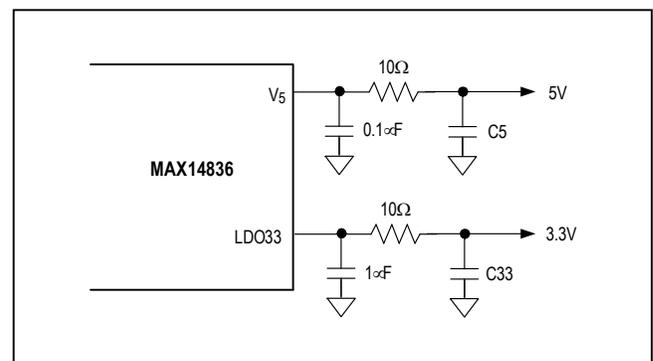

Figure 6. Larger Bypass Capacitance for Powering External Circuits

### Wake-Up Detection

The device detects a wake-up condition on the DIO line in push-pull, high-side (pnp), or low-side (nnp) operation modes. A wake-up condition is detected when the DIO output is shorted for 410 $\mu$ s (typ).  $\overline{WU}$  pulses low for 50 $\mu$ s (typ) when the device detects a wake-up pulse on DIO (Figure 3).

Set the WuIntEn bit in the Mode register to set the WuInt bit in the Status register and generate an interrupt on  $\overline{IRQ}$  when a wake-up pulse is detected. WuInt is set and  $\overline{IRQ}$  asserts immediately after DIO is released when WuIntEn = 1.

### Thermal Protection and Considerations

The internal LDOs and drivers can generate more power than the package for the devices can safely dissipate. Ensure that the driver and LDO loading is less than the package can dissipate. Total power dissipation for the device is calculated using the following equation:

$$P_{TOTAL} = P_{DIO} + P_{DO} + P_5 + P_{LDO33} + P_Q$$

where  $P_{DIO}$  is the power generated in the DIO driver,  $P_{DO}$  is the power dissipated by the DO driver,  $P_5$  and  $P_{LDO33}$  are the power generated by the LDOs,  $P_Q$  is the quiescent power generated by the MAX14836.

Ensure that the total power dissipation is less than the limits listed in the [Absolute Maximum Ratings](#) section.

Use the following to calculate the power dissipation (in mW) due to the DIO driver:

$$P_{DIO} = [I_{DIO(max)}] \times [V_{O\_}(max)]$$

where  $V_{O\_}$  = the larger of  $V_{OL\_DIO}$  and  $V_{OH\_DIO}$

(See the *Typical Operating Characteristics* on page 11.)

Calculate the internal power dissipation of the DO driver using the following equation:

$$P_{DO} = [I_{DO(max)}] \times [V_{O\_}(max)]$$

Calculate the power dissipation in the 5V LDO (V5) using the following equation:

$$P_5 = (V_{LDOIN} - V_5) \times I_5$$

where  $I_5$   $V_{O\_}$  includes the  $I_{LDO33}$  current sourced from LDO33.

Calculate the power dissipated in the 3.3V LDO (LDO33) using the following equation:

$$P_{LDO33} = 1.7V \times I_{LDO33}$$

Calculate the quiescent power dissipation in the device using the following equation:

$$P_Q = I_{CC(max)} \times V_{CC(max)}$$

### Overtemperature Warning

Bits in the Status and Mode registers are set when the temperature of the device exceeds +125°C (typ). The OTempInt bit in the Status register is set and  $\overline{IRQ}$  asserts when the OTemp bit in the Mode register is set. Read the Status register to clear the OTempInt bit and  $\overline{IRQ}$ .

The OTemp bit is cleared when the die temperature falls to +102°C.

The device continues to operate normally unless the die temperature reaches the +165°C thermal-shutdown threshold, when the device enters thermal shutdown.

### Thermal Shutdown

All regulators and the DIO and DO output drivers are automatically switched off when the internal die temperature exceeds the +165°C (typ) thermal-shutdown threshold. SPI communication is available, and register content is maintained, during a thermal shutdown event.

## Register Functionality

The devices have four 8-bit-wide registers for configuration and monitoring (Table 1).

**Table 1. Register Summary**

REGISTER	R1	R0	D7	D6	D5	D4	D3	D2	D1	D0	READ/ WRITE
Status	0	0	Wulnt	DoFaultInt	—	$\overline{Q}Lvi$	DIOFaultInt	UV33Int	UV24Int	OTempInt	Read only
DIOConfig	0	1	RxFILTER	—	DIO_N/P	DIO_PP	DIODEn	Q	RxDis	—	R/W
DOConfig	1	0	DoInV	DoAv	DoN/P	DoPP	DoEn	DoBit	—	—	R/W
Mode	1	1	RST	WulntEn	DoFault	DIOFault	UV24	OTemp	UV33En	LDO33Dis	R/W

R1/R0 = Register address.

— Writing to registers has no effect.

### Status Register [R1, R0] = [0,0]

BIT	D7	D6	D5	D4	D3	D2	D1	D0
<b>BIT NAME</b>	Wulnt	DoFaultInt	ResVD	$\overline{Q}Lvi$	DIOFaultInt	UV33Int	UV24Int	OTempInt
<b>READ/WRITE</b>	R	R	R	R	R	R	R	R
<b>POR STATE</b>	0	0	X	X	0	0	0	0
<b>RESET UPON READ</b>	Yes	Yes	No	No	Yes	Yes	Yes	Yes

X = Unknown. These bits are dependent on the DIO input.

ResVD = reserved

The Status register reflects the logic levels of DIO and shows the source of interrupts that DIOFault cause an  $\overline{IRQ}$  hardware interrupt. The  $\overline{IRQ}$  interrupt is asserted when an alarm condition (OTemp, UV33, UV24, DIOFault, DoFault, Wul) is detected. All bits in the Status register are read-only. The interrupt bits return to the default state after the Status register is read. If a DIO or DO fault condition persists, the associated interrupt bits are immediately set after the Status register is read.

BIT	NAME	DESCRIPTION
D7	Wulnt	<b>Wake-Up Interrupt Request.</b> Wulnt is set when a wake-up request pulse is detected on DIO and the WulntEn bit in the Mode register is set. $\overline{IRQ}$ asserts when Wulnt is set to 1. Read the Status register to clear the Wulnt bit and deassert $\overline{IRQ}$ .
D6	DoFaultInt	<b>DO Fault Interrupt.</b> DoFaultInt interrupt bit and DoFault bit (in the Mode register) are set when a fault condition occurs on the DO driver output. The device registers a fault condition when a short-circuit or voltage fault is detected on DO (see the <i>DO Fault Detection</i> section for more information). $\overline{IRQ}$ asserts when DoFaultInt is 1. Read the Status register to clear the DoFaultInt bit and deassert $\overline{IRQ}$ . If the DoFault is still present during the next autoretry cycle, the DoFaultInt bit and $\overline{IRQ}$ is set again.
D5	ResVD	Reserved

BIT	NAME	DESCRIPTION
D4	$\overline{QLvl}$	<b>DIO Logic Level.</b> The $\overline{QLvl}$ bit is the inverse of the logic level at DIO. $\overline{QLvl}$ is 1 when the DIO input level is low (< 5.2V) and is 0 when the DIO logic level is high (> 8V) (Table 3). $\overline{QLvl}$ remains active when the DIO receiver is disabled (RxDis = 1). $\overline{QLvl}$ does not affect $\overline{IRQ}$ . $\overline{QLvl}$ is not changed when the Status register is read.
D3	DIOFaultInt	<b>DIO Fault Interrupt.</b> The DIOFaultInt interrupt bit and DIOFault bit (in the Mode register) are set when a short circuit or voltage fault occurs on the DIO driver output (see the <i>DIO Fault Detection</i> section for more information). $\overline{IRQ}$ asserts when DIOFault is 1. Read the Status register to clear the DIOFaultInt bit and deassert $\overline{IRQ}$ . If DIO fault is still present during the next autoretry cycle, the DIOFault bit and $\overline{IRQ}$ is set again.
D2	UV33Int	<b>Internal 3.3V LDO (LDO33) Undervoltage Warning.</b> Both the UV33Int interrupt bit and the UV33En bit (in the Mode register) are set when $V_{LDO33}$ falls below the 2.4V LDO33 undervoltage threshold. If UV33En is set in the Mode register, $\overline{IRQ}$ asserts low when the UV33Int bit is 1. Read the Status register to clear the UV33Int bit and deassert $\overline{IRQ}$ . Set the UV33En bit to 1 in the Mode register to enable undervoltage monitoring for UV33Int. When enabled, UV asserts high when the UV33Int bit is 1. UV deasserts when $V_{LDO33}$ rises above the LDO33 undervoltage threshold.
D1	UV24Int	<b>V<sub>CC</sub> Undervoltage Interrupt.</b> The UV24Int interrupt bit and the UV24 bit (in the Mode register) are set when the V <sub>CC</sub> voltage falls below the 6V undervoltage threshold. $\overline{IRQ}$ asserts low when the UV24Int bit is 1. Read the Status register to clear the UV24Int bit and deassert $\overline{IRQ}$ . V <sub>CC</sub> undervoltage detection cannot be disabled.
D0	OTemplnt	<b>Overtemperature Warning.</b> The OTemplnt interrupt bit and the OTemp bit (in the Mode register) are set when a high-temperature condition is detected by the devices. OTemp is set when the temperature of the die exceeds +125°C (typ). OTemplnt is set and $\overline{IRQ}$ asserts when the OTemp bit is 1. The OTemplnt bit is cleared and $\overline{IRQ}$ deasserts when the Status register is read. Once cleared, OTemplnt is not reset if the die temperature remains above the thermal-warning threshold and does not fall below +102°C.

Table 2. DO Driver Enable, Disable

DODIS Pin	DOEn Bit	DO State
Low	x	Enabled
High	0	Disabled
High	1	Enabled

X = Don't care.

Table 3.  $\overline{QLvl}$  and RX Output

V <sub>DIO</sub> (V)	$\overline{QLvl}$ BIT	RX OUTPUT
< 5.2	1	High
> 8	0	Low

**DIOConfig Register [R1, R0] = [0,1]**

BIT	D7	D6	D5	D4	D3	D2	D1	D0
<b>BIT NAME</b>	RxFilter	—	DIO_N/P	DIO_PP	DIODEn	Q	RxDis	—
<b>READ/WRITE</b>	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
<b>POR STATE</b>	0	0	0	0	0	0	0	0

Use the DIOConfig register to control the DIO driver and receiver parameters. All bits in the DIOConfig register are read-write and are set to 0 at power-up.

BIT	NAME	DESCRIPTION
D7	RxFilter	<b>DIO Receiver Filter Control.</b> The DIO receiver has an all-analog lowpass filter to reduce high-frequency noise on the receiver input. Set the RxFilter bit to 0 to set the filter corner frequency to 500kHz. Set the RxFilter bit to 1 to set the filter corner frequency to 1MHz. Noise filters on C/Q and DI are controlled simultaneously by the RxFilter bit.
D6	—	<b>Writing to register has no effect.</b>
D5	DIO_N/P	<b>DIO Driver npn/pnp Mode.</b> The DIO_N/P bit selects between low-side (nnp) and high-side (pnp) modes when the DIO driver is configured as an open-drain output (DIO_PP = 0). Set DIO_N/P to 1 to configure the driver for low-side (nnp) operation. Set DIO_N/P to 0 for high-side (PNP) operation.
D4	DIO_PP	<b>DIO Driver Push-Pull Operation.</b> Set DIO_PP to 1 to enable push-pull operation on the DIO driver. The DIO output is open-drain when DIO_PP is 0.
D3	DIODEn	<b>DIO Driver Enable/Disable.</b> Set the DIODEn bit to 1 to enable the DIO driver. Set DIODEn to 0 for hardware (DIOEN) control. See Table 4.
D2	Q	<b>DIO Driver Output Logic.</b> The Q bit can be used to program the C/Q output driver through software. The DIO driver must be enabled and LIO must be high to control the DIO driver through the Q bit (Figure 7). DIO has the same logic polarity as the Q bit.  Set the Q bit to 0 to control the DIO driver with LIO.  The DIO driver output state depends on the DIO_PP and DIO_N/P bits as shown in Table 5. Note that Table 5 assumes that the C/Q driver is enabled (DIOEN = V <sub>L</sub> or DIODEn = 1).
D1	RxDis	<b>DIO Receiver Enable/Disable.</b> Set the RxDis bit to 1 to disable the DIO receiver. The RX output is high when RxDis is 1.
D0	—	<b>Writing ro register has no effect.</b>

**Table 4. DIODEn and DIOEN DIO Driver Control**

DIODEn	DIOEN	DIO DRIVER
0	Low	Disabled
X	High	Enabled
1	X	Enabled

X = Don't care.

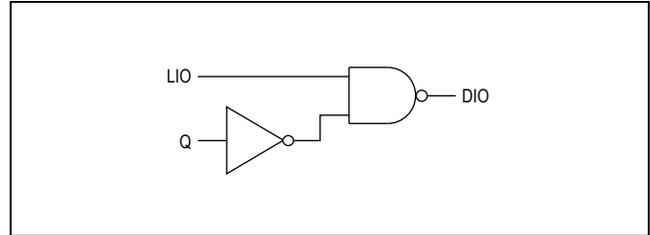

Figure 7. Equivalent DIO Logic

**Table 5. DIO Driver Output State**

LIO (SEE NOTE)	Q	DIO_PP	DIO_N/P	DIO CONFIGURATION	DIO STATE
High	1	0	0	pnp, open-drain	On, DIO is high
High	0	0	0	pnp, open-drain	Off, DIO is high-impedance
High	1	0	1	nnp, open-drain	Off, DIO is high-impedance
High	0	0	1	nnp, open-drain	On, DIO is low
High	1	1	X	Push-pull	High
High	0	1	X	Push-pull	Low

Note: LIO = VL.

X = Don't care.

**DOConfig Register [R1, R0] = [1,0]**

BIT	D7	D6	D5	D4	D3	D2	D1	D0
<b>BIT NAME</b>	DoInv	DoAv	DoN/P	DoPP	DoEn	DoBit	—	—
<b>READ/WRITE</b>	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
<b>POR STATE</b>	0	0	0	0	0	0	0	0

Use the DOConfig register to control DO interface. All bits in the DOConfig register are read-write and are set to 0 at power-up.

BIT	NAME	DESCRIPTION
D7	DoInv	<b>DO Output Polarity.</b> Set the DoInv bit to 1 to invert the logic of the DO output. This bit also works in conjunction with the DoAv (Table 6). DO tracks the LIO input with the opposite polarity when both the DoAv and DoInv bits are set.
D6	DoAv	<b>DO Antivalent Operation.</b> Set the DoAv bit to 1 to enable antivalent output operation on DO. DO tracks the LIO and input (and the Q bit) when DoAv is 1 (Table 6). The LO input and the DoBit are ignored when the DoAv bit is 1.
D5	DoN/P	<b>DO Driver npn/pnp Operation.</b> The DoN/P bit selects between low-side (nnp) and high-side (pnp) modes when the DO driver is configured as an open-drain output (DoPP = 0). Set DoN/P to 1 to configure the driver for low-side (nnp) operation. Set DoN/P to 0 for high-side (pnp) operation.
D4	DoPP	<b>DO Driver Push-Pull Operation.</b> Set the DoPP bit to 1 to configure the DO driver output for push-pull operation. DO is an open-drain output when DoPP is 0.
D3	DoEn	<b>DO Driver Enable/Disable.</b> Set the DoEn bit to 1 to enable the DO driver. The DO driver is high-impedance when DoEn is 0.
D2	DoBit	<b>DO Driver Output Logic.</b> The DoBit bit can be used to program the DO output driver through software. Drive LO high to activate DoBit programming (Figure 8). The DO output state is given in Table 7. Note that Table 7 assumes that the DoInv bit is 0.
D1	—	<b>Writing to register has no effect.</b>
D0	—	<b>Writing to register has no effect.</b>

**Table 6. DoAv and DoInv Operation**

DoAv	DoInv	LIO (Note 1)	LO (Note 1)	DO (Note 2)	DIO (Note 2)
0	0	Low	Low	High	High
0	0	Low	High	Low	High
0	0	High	Low	High	Low
0	0	High	High	Low	Low
0	1	Low	Low	Low	High
0	1	Low	High	High	High
0	1	High	Low	Low	Low
0	1	High	High	High	Low
1	0	Low	Low	Low	High
1	0	Low	High	Low	High
1	0	High	Low	High	Low
1	0	High	High	High	Low
1	1	Low	Low	High	High
1	1	Low	High	High	High
1	1	High	Low	Low	Low
1	1	High	High	Low	Low

**Note 1:** Low is when  $V_{LIO}$ , OR  $V_{LO} = 0V$ ; high is when  $V_{LIO}$ ,  $V_{TXQ}$ , or  $V_{LO} = V_L$ .

**Note 2:** Low is when DIO or DO < 5.2V; high is when DIO or DO > 8V.

**Table 7. DO Output Programmed by DoBit**

LO	DoBit	DoPP	DoN/P	DO CONFIGURATION	DO STATE
High	0	1	X	Push-pull	Low
High	1	1	X	Push-pull	High
High	0	0	0	npn	Off, DO is high-impedance
High	1	0	0	npn	On, DO is high
High	0	0	1	nnp	On, DO is low
High	1	0	1	nnp	Off, DO is high-impedance
Low	X	X	X	See Table 6	See Table 6

X = Don't care.

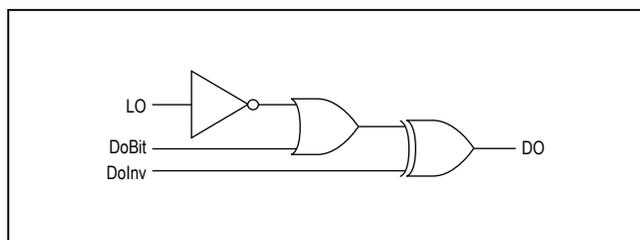

Figure 8. Equivalent DO Logic

**Mode Register [R1, R0] = [1,1]**

BIT	D7	D6	D5	D4	D3	D2	D1	D0
<b>BIT NAME</b>	RST	WulntEn	DoFault	DIOFault	UV24	OTemp	UV33En	LDO33Dis
<b>READ/WRITE</b>	R/W	R/W	R	R	R	R	R	R/W
<b>POR STATE</b>	0	0	0	0	0	0	0	0

Use the Mode register to reset the MAX14836 and manage the 3.3V LDO. The Mode register has bits that represent the current status of fault conditions. When writing to the Mode register, the contents of the fault indication bits (bits 2 to 5) do not change.

BIT	NAME	DESCRIPTION
D7	RST	<b>Register Reset.</b> Set RST to 1 to reset all registers to their default power-up state. Then set RST to 0 for normal operation. The Status register is cleared and $\overline{\text{IRQ}}$ deasserts (if asserted) when RST = 1. Interrupts are not generated while RST = 1.
D6	WulntEn	<b>Wake-Up Interrupt Enable.</b> Set WulntEn to 1 to enable wake-up interrupt generation. When WulntEn is set, the Wulnt bit in the Status register is set and $\overline{\text{IRQ}}$ asserts when a valid wake-up condition is detected. The DIO driver must be enabled for wake-up detection. The state of WulntEn does not affect the WU output. See the <i>Wake-Up Detection</i> section for more information.
D5	DoFault	<b>DO Fault Status.</b> The DoFault bit is set when a short-circuit or voltage fault occurs at the DO driver output (see the <i>DO Fault Detection</i> section for more information). The DoFault and DoFaultInt bits are both set when a fault occurs on DO. In every autoretry fault-detect cycle, the DoFault bit is 0 during the blanking time. DoFault is cleared when the fault is removed.
D4	DIOFault	<b>DIO Fault Status.</b> The DIOFault bit is set when a short-circuit or voltage fault occurs at the C/Q driver output (see the <i>DIO Fault Detection</i> section for more information). The DIOFault and DIOFaultInt bits are both set when a fault occurs on DIO. In every autoretry fault-detect cycle, the DoFault bit is 0 during the blanking time. In every autoretry fault-detect cycle, the DIOFault bit is 0 during the blanking time. DIOFault is cleared when the fault is removed.
D3	UV24	<b>V<sub>CC</sub> Undervoltage Condition.</b> Both the UV24 and the UV24Int bits are set when V <sub>CC</sub> falls below V <sub>CCUVLO</sub> . UV24 is cleared when V <sub>CC</sub> rises above the V <sub>CC</sub> threshold. V <sub>5</sub> must be present for V <sub>CC</sub> undervoltage monitoring
D2	OTemp	<b>Temperature Warning.</b> The OTemp bit is set when a high-temperature condition occurs on the devices. Both the OTempInt interrupt in the Status register and the OTemp bit are set when the junction temperature of the die rises to above +125°C (typ). The OTemp bit is cleared when the junction temperature falls below +102°C (typ).
D1	UV33En	<b>LDO33 UV Enable.</b> Set the UV33En bit to 1 to assert the UV output when LDO33 voltage falls below the 2.4V (typ) undervoltage lockout threshold. The UV33En bit does not affect the UV33Int bit in the Status register; $\overline{\text{IRQ}}$ asserts when V <sub>LDO33</sub> falls below V <sub>LDO33UVLO</sub> regardless of the state of UV33En.
D0	LDO33Dis	<b>LDO33 Enable/Disable.</b> Set LDO33Dis to 1 to disable the 3.3V linear regulator (LDO33).

**SPI Interface**

The device communicates through an SPI-compatible 4-wire serial interface. The interface has three inputs—clock (SCLK), chip-select ( $\overline{CS}$ ), and data in (SDI)—and one output, data out (SDO). The maximum SPI clock rate

for the device is 12MHz. The SPI interface complies with clock polarity CPOL = 0 and clock phase CPHA = 0 (see [Figure 9](#) and [Figure 10](#)).

The SPI interface is not available when  $V_5$  or  $V_L$  are not present.

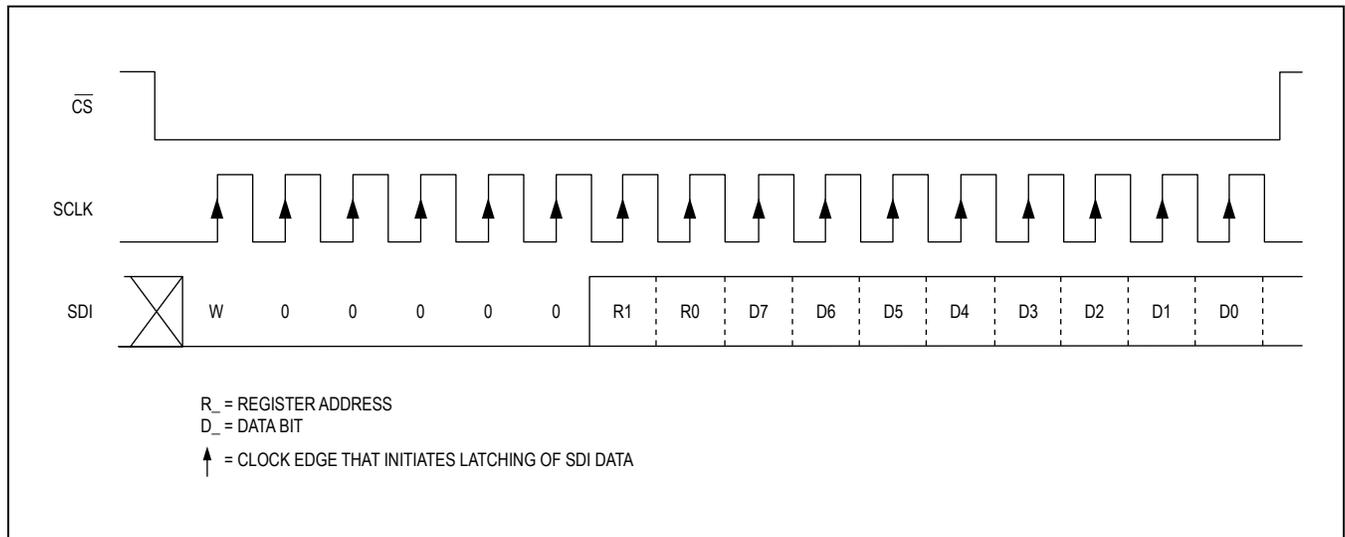

Figure 9. SPI Write Cycle

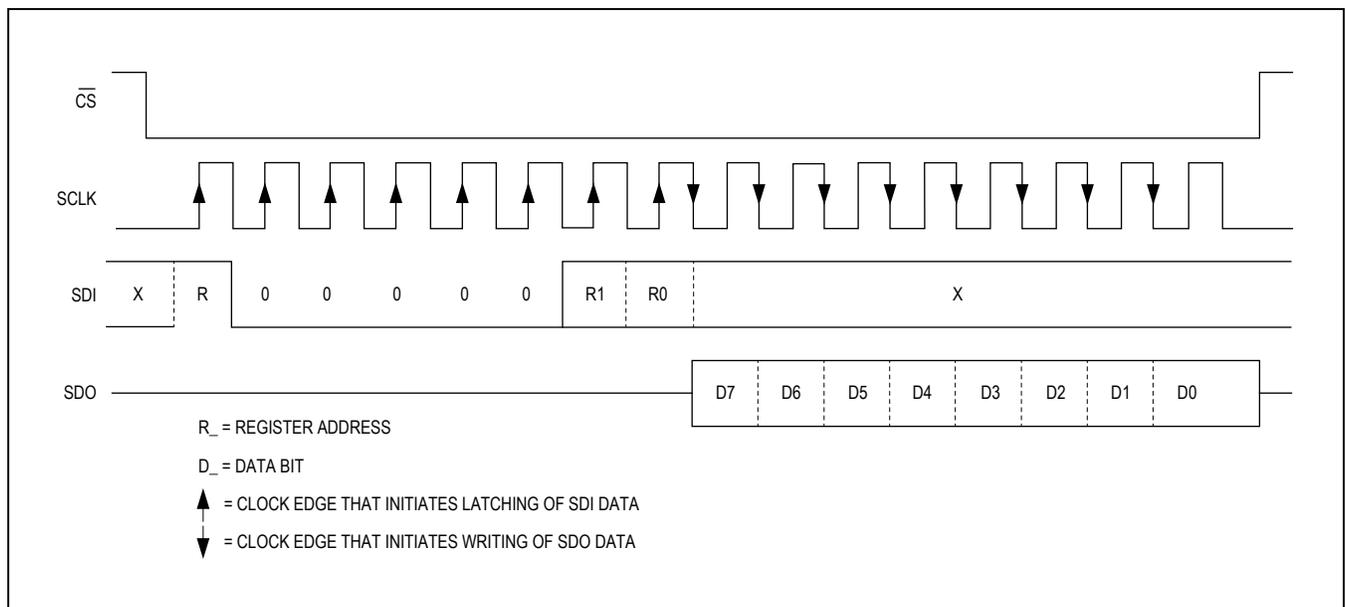

Figure 10. SPI Read Cycle

**Applications Information**

**UART Interfacing**

The logic levels of the microcontroller interface I/Os (LIO, DODIS, DIOEN, and RX) are defined by  $V_L$ .

**Transient Protection**

Inductive load-switching, surges, and bursts create high transient voltages. DIO and DO should be protected against high overvoltage and undervoltage transients. Positive voltage transients on DIO and DO must be limited to +55V relative to GND and negative voltage transients must be limited to -55V (relative to  $V_{CC}$ ) on DO. [Figure 11](#) shows suitable protection using TVS diodes to meet both the IEC 61000-4-2 ESD and IEC 61000-4-5 surge testing. Other protection schemes may also be suitable.

The external TVS diodes can be biased via the internal  $V_P$  diode, or by using an external diode, as shown in [Figure 12](#). The scheme shown in [Figure 12](#) has the benefit of not supplying the sensor power supply when the external 24V L+ supply is not present and an external voltage is applied to DIO or DO.

The device has to be protected against transients that occur during hot-plugging of the L+ sensor supply ( $V_{CC}$  input). This is achieved by placing a  $10\Omega$  resistor with  $1\mu F$  capacitor before LDOIN and connecting an RC between the sensor supply input and the  $V_{CC}$  pin, as shown in

[Figure 11](#). The RC time constant of the filter on  $V_{CC}$  should be larger or equal to  $0.8\mu s$ . In case that  $V_L$  is supplied by  $V_5$  and the bypass capacitor on  $V_5$  is  $100nF$ , the  $10\Omega$  resistor in series with LDOIN is not needed.

**Optional External Powering**

The MAX14836 is powered by  $V_{CC}$  and  $V_5$ .  $V_L$  is a reference voltage input to set the logic levels of the microcontroller interface. The logic and SPI interface are operational when  $V_5$  and  $V_L$  are present even if  $V_{CC}$  is not present.

The  $V_P$  output provides a reverse-polarity-protected voltage one diode drop below  $V_{CC}$  and can be used for supplying external circuitry, like power supplies. The current drawn from  $V_P$  cannot exceed 50mA. Be aware that capacitance on  $V_P$  can cause transient currents at power-up equal to  $C \times dV_{CC}/dt$ .

$V_5$  is typically powered by the internal 5V regulator, but can alternatively be powered by an external 5V regulator. When powering  $V_5$  externally, connect LDOIN to  $V_5$  ([Figure 12](#)). This configuration disables operation of the internal 5V regulator and reduces power consumption.

When an external 5V regulator is used to power  $V_5$ , the  $V_5$  bypass capacitance is determined by that regulator, and is not limited to  $100nF$ .
