

600mA High Efficiency Low Quiescent Current Synchronous Buck Regulator With Z-mode

The 34727 is a high efficiency, low quiescent current (I_Q), synchronous buck regulator, implementing Freescale's innovative Z-mode architecture. Freescale's Z-mode architecture greatly improves the ripple performance during light load currents, but still maintains a low quiescent current of 65 μ A, at no load in "Sleepy" Z-mode.

The 34727 accepts an input voltage in the range of 2.7 to 5.5V, making it ideally suited for single cell Li-Ion based applications. Factory preset output voltages, ranging from 0.8 to 3.3V, reduce the number of required auxiliary components. The part is able to provide 600mA of continuous load current across the input and the output voltage ranges.

The 34727 switches at 2.0MHz to allow the use of small surface mount inductors and capacitors, to save precious board space.

The 34727 is available in the small, space saving, and low cost, 2x2 UDFN-8 packages. The part is guaranteed for operation over the -25°C to +85°C temperature range.

FUNCTIONAL DESCRIPTION

INTRODUCTION

The 34727 is a high efficiency, synchronous, buck regulator, utilizing a voltage mode control architecture with feed forward. It is capable of providing a 600mA load current for output voltages of 0.8V to 3.3V, from a single input voltage rail between 2.7V and 5.5V.

In a buck converter, most of the losses at high output loads are due to conduction losses in the power train, but at light output loads, the conduction losses are reduced and most of the losses become switching losses. Using Freescale's Z-mode architecture, the 34727, at light output loads, will smoothly transition into a lower switching frequency, thus improving its efficiency.

FUNCTIONAL PIN DESCRIPTION

SUPPLY VOLTAGE INPUT (VIN)

2.7V to 5.5V DC power input. Bypass with a 4.7 μ F ceramic capacitor as close as possible to the VIN and GND pins.

GROUND (GND)

Ground.

ENABLE (EN)

Active high enable input. EN is over-voltage protected to 6.0V, independent of the supply voltage. Drive with a logic high signal (or connect to VIN) for normal operation. Drive with a logic low signal, or connect to GND will disable the 34727.

FEEDBACK INPUT (FB)

Feedback of the output voltage.

SWITCHING NODE (SW)

This terminal connects to the output inductor. The node internally connects the drain of both the high side MOSFET and the low side MOSFET.

NO CONNECTION (NC)

Internally not connected. Connect to GND externally.

FUNCTIONAL INTERNAL BLOCK DESCRIPTION

Figure 14. MC34727 Functional Internal Block Diagram

INTEGRATED SUPPLY

INTERNAL REGULATOR AND REFERENCE

The internal regulator and reference block steps down the high input voltage to lower voltage, to power all the internal blocks, and provides the reference voltage for the other internal blocks.

OSCILLATOR

The oscillator block provides 2.0MHz clock signal to the controller.

CONTROL

THERMAL SHUTDOWN

The thermal shutdown block monitors the die temperature. Once the die temperature reaches its threshold, this block turns off the device to prevent the further die temperature rise.

SOFT-START

The soft-start block controls the output voltage ramp after the device is enabled, to limit the in-rush current. The start-up time is internally set to approximately 2.0ms, and is

independent of input voltage, output voltage, or load current. The soft-start sequence also occurs upon recovery from any fault condition.

UVLO

The UVLO block monitors the input voltage. Once the input voltage is lower than the falling threshold voltage, this block turns off the device, to avoid unpredictable circuit behavior.

CURRENT LIMIT

The current limit block monitors the inductor current. When the peak inductor current reaches its current limit, this block turns off the high side MOSFET, to prevent the device and external components from damage.

POWER MOSFET DRIVER

The power-MOSFET driver block controls the phase of the driver signals, and enhances the drive capability of these signals.

POWER-MOSFET

The power-MOSFET block contains two power MOSFETs. One is a PMOS that passes the current from the input to the output, and the other is an NMOS that provides the inductor current loop when PMOS is turned off.

FUNCTIONAL DEVICE OPERATION

OPERATIONAL MODES

Z-MODE OPERATION

The 34727 operates as a typical fixed frequency, PWM regulator, at moderate to heavy load currents. As the load is decreased, such that operation transitions from continuous conduction mode (CCM) to discontinuous conduction mode (DCM), the duty cycle is reduced until it approaches 85% of the full load duty cycle. At this point, the 34727 transitions into Z-mode operation, where the Z-mode Factor is 0.85. In Z-mode, the regulator skips pulses whenever the duty cycle is

below 85% of the CCM duty cycle. As the load decreases, this pulse skipping reduces the switching frequency and the switching losses thus improving efficiency. For example, if a light load demanded a 30% duty cycle at 2.0MHz, with Z-mode, this same load will require only $(0.3/0.85)^2 \times 2.0\text{MHz} = 0.249\text{MHz}$ switching frequency, hence switching losses will be reduced by almost ten fold. [Figure 15](#) illustrates the transition to and the exit from Z-mode.

Figure 15. Z-mode Operation

SLEEPY Z-MODE OPERATION

To improve low current efficiency, the 34727 transitions into the Sleepy Z-mode at load currents of approximately 1.0mA and lower. This is accomplished by powering down

internal circuit blocks to lower the device's quiescent current. Additionally, the oscillator frequency drops to 250kHz and the low side switch is turned off, to emulate the operation of an asynchronous buck converter.

DETAILED FUNCTIONAL DEVICE OPERATION

OVER-CURRENT PROTECTION

The 34727 implements two layers of protection during overload conditions. The first is a current limit feature to prevent the device and external components from damage. When the peak inductor current reaches the over-current limit, nominally 900mA, the high side MOSFET turns off to provide cycle by cycle protection. If the over-current condition persists and the die temperature surpasses the over-temperature protection (OTP) threshold, this second layer of protection shuts down the device.

SHORT-CIRCUIT PROTECTION

When a short-circuit condition occurs on the output, typical regulators will tend to operate at maximum duty cycle. This condition can saturate the inductor and produce severe peak currents, resulting in damage to the device. The 34727 avoids this scenario by detecting output voltages below 0.5V. Upon detection, the part re-starts continuously until the short circuit condition is removed, or the part surpasses its OTP threshold.

OVER-TEMPERATURE PROTECTION

To limit its operating temperature, the 34727 shuts down if the junction temperature of the switching MOSFET surpasses 140°C. If the junction temperature subsequently drops to 130°C, the 34727 re-starts.

SOFT-START OPERATION

To limit the in-rush current, an internal timer controls the output voltage ramp after the part is enabled. The start-up time is internally set to approximately 2.0ms and is independent of input voltage, output voltage, or load current.

The soft-start sequence also occurs upon recovery from any fault condition.

UNDER-VOLTAGE LOCK-OUT

The UVLO threshold is set to 2.7V for rising V_{IN} , and to 2.5V for falling V_{IN} . For a V_{OUT} of 3.3V, the V_{OUT} value will track V_{IN} below 3.6V until the 2.5V falling V_{IN} threshold is reached.

If the UVLO falling threshold is met, the part shuts down and will power up again with soft-start, when the UVLO rising threshold is surpassed.

TYPICAL APPLICATIONS

APPLICATION INFORMATION

INPUT CAPACITOR

The input capacitor is used to minimize the input voltage transient that may cause instability when the load transient current is high. Typically a 4.7µF X5R ceramic capacitor is sufficient for most applications.

OUTPUT CAPACITOR

For stable operation and low output voltage ripple, an X5R ceramic capacitor of 4.7µF minimum value is needed.

Depending on the load transient current, a larger capacitance may be required.

INDUCTOR SELECTION

A 4.7µH low DC resistance inductor is typically used for the 34727 to guarantee the system stable operation.

TYPICAL APPLICATIONS

1.8V OUTPUT DC/DC CONVERTOR

Figure 16 shows a typical application using 34727B. C_{IN} and C_{OUT} are typically 4.7µF/X5R ceramic capacitors. L1 is typically a 4.7µH low DC resistance inductor. The FB

connects to the output directly for monitoring the output voltage. Normally, the EN pin connects to the input supply directly to enable the regulator.
