MCP2021A/2A

## LIN Transceiver with Voltage Regulator

Features:

- The MCP2021A/2A is compliant with:
  - LIN Bus Specifications Version 1.3, and 2.x.
  - SAE J2602-2
- Support Baud Rates up to 20 kBaud
- 43V Load Dump Protected
- Maximum Continuous Input Voltage of 30V
- Wide LIN Compliant Supply Voltage, 6.0 - 18.0V
- Extended Temperature Range: -40 to +125°C
- Interface to PIC® EUSART and Standard USARTs
- Wake-up on LIN Bus Activity or Local Wake Input
- LIN Bus Pin
  - Internal Pull-up Termination Resistor and Diode for Slave Node
  - Protected Against V_{BAT} Shorts
  - Protected Against Loss of Ground
  - High-Current Drive
- TXD and LIN Bus Dominant Time-out Function
- Two Low-Power Modes
  - TRANSMITTER OFF Mode: 90 µA (typical)
  - POWER DOWN Mode: 4.5 µA (typical)
- Output Indicating Internal RESET State (POR or SLEEP Wake)
- MCP2021A/2A On-chip Voltage Regulator
  - Output Voltage of 5.0V or 3.3V 70 mA Capability with Tolerances of ±3% Over Temperature Range
  - Internal Short Circuit Current Limit
  - Only External Filter and Load Capacitors Needed
- Automatic Thermal Shutdown
- High Electromagnetic Immunity (EMI), Low Electromagnetic Emission (EME)
- Robust ESD Performance: ±15 kV for LBUS and VBB pin (IEC61000-4-2)
- Transient Protection for LBUS and VBB Pins in Automotive Environment (ISO7637)
- Meets Stringent Automotive Design Requirements Including "OEM Hardware Requirements for LIN, CAN and FlexRay Interfaces in Automotive Applications", Version 1.2, March 2011
- Multiple Package Options Including Small 4x4 mm DFN

Description

The MCP2021A/2A provides a bidirectional, half-duplex communication physical interface to meet the LIN bus specification Revision 2.1 and SAE J2602-2. The device incorporates a voltage regulator with 5V or 3.3V 70 mA regulated power supply output. The device has been designed to meet the stringent quiescent current requirements of the automotive industry and will survive +43V load dump transients, and double battery jumps.

1.0   FUNCTION DESCRIPTION

The MCP2021A/2A provides a physical interface between a microcontroller and a LIN half-duplex bus. It is intended for automotive and industrial applications with serial bus baud rates up to 20 k Baud. This device will translate the CMOS/TTL logic levels to LIN logic levels, and vice versa. The device offers optimum EMI and ESD performance; it can withstand high voltage on the LIN bus. The device supports two low-power modes to meet automotive industry power consumption requirements. The MCP2021A/2A also provides a +5V or 3.3V 70 mA regulated power output.

1.1   Modes of Operation

The MCP2021A/2A works in five modes: POWER-ON-RESET mode, POWER-DOWN mode, READY mode, OPERATION mode, and TRANSMITTER OFF mode. For an overview of all operational modes, please refer to Table 1-1. For the operational mode transition, please refer to Figure 1-1.

FIGURE 1-1:   **STATE DIAGRAM**

Note 1:   VREG_OK : Regulator Output Voltage > $0.8V_{REG\_NOM}$.

   2:   If the voltage on pin VBB falls below V_{OFF}, the device will enter POWER-ON-RESET mode from all other modes, which is not shown in the figure.

   3: $\overline{FAULT}$/TXE = 1 represents input high and no fault conditions. $\overline{FAULT}$/TXE = 0 represents input low or a fault condition, refer to Table 1-3.

1.1.1   POWER-ON-RESET MODE

Upon application of VBB, or whenever the voltage on VBB is below the threshold of regulator turn off voltage V_{OFF} (typically 4.50V), the device enters POWER-ON-RESET mode (POR). During this mode, the device maintains the digital section in a reset mode and waits until the voltage on VBB pin rises above the threshold of regulator turn on voltage V_{ON} (typically 5.75V) to enter to READY mode. In POWER-ON-RESET mode, the LIN physical layer and voltage regulator are disabled, and $\overline{RESET}$ output (MCP2022A only) is forced to LOW.

MCP2021A/2A

1.1.2 READY MODE

The device enters READY mode from POR mode after the voltage on VBB rises above the threshold of regulator turn on voltage V_{ON} or from POWER-DOWN mode when a remote or local wake-up event happens.

Upon entering READY mode, the voltage regulator and receiver section of the transceiver are powered up. The transmitter remains in an off state. The device is ready to receive data but not to transmit. In order to minimize the power consumption, the regulator operates in a reduced-power mode. It has a lower GBW product and thus is slower. However, the 70 mA drive capability is unchanged.

The device stays in READY mode until the output of the voltage regulator has stabilized and the CS/LWAKE pin is HIGH ('1').

1.1.3 OPERATION MODE

If V_{REG} is OK (V_{REG}>0.8V_{REG_NORM}), and the CS/LWAKE pin, FAULT/TXE pin and TXD pin are HIGH, the part enters OPERATION mode from either READY or TRANSMITTER OFF mode.

In this mode, all internal modules are operational. The internal pull-up resistor between LBUS and VBB is connected only in this mode.

The device goes into POWER-DOWN mode at the falling edge on CS/LWAKE; or to the TRANSMITTER OFF mode at the falling on FAULT/TXE while CS/LWAKE stays HIGH.

1.1.4 TRANSMITTER OFF MODE

In TRANSMITTER OFF mode, the receiver is enabled but the L$_{BUS}$ transmitter is off. It is a lower power mode.

In order to minimize power consumption, the regulator operates in a reduced power mode. It has a lower GBW product and thus is slower. However the 70 mA drive capability is unchanged.

The transmitter may be re-enabled whenever the FAULT/TXE signal returns high, by removing the internal fault condition and the CPU returning the FAULT/

TXE high. The transmitter will not be enabled even if the FAULT/TXE pin is brought high externally, when the internal fault is still present. However, externally forcing the FAULT/TXE high while internal fault is still present should be avoided, since this will induce high current and power dissipation in the FAULT/TXE pin.

The transmitter is also turned off whenever the voltage regulator is unstable or recovering from a fault. This prevents unwanted disruption of the bus during times of uncertain operation.

1.1.5 POWER-DOWN MODE

In POWER-DOWN mode, the transceiver and the voltage regulator are both off. Only the Bus Wake-up section and the CS/LWAKE pin wake-up circuits are in operation. This is the lowest power mode.

If any bus activity (e.g. a BREAK character) occurs during POWER-DOWN mode, the device will immediately enter READY mode and enable the voltage regulator. Then, once the regulator output has stabilized (approximately 0.3 ms to 1.2 ms), it goes to OPERATION mode. Refer to **Section 1.1.6 "Remote Wake-up"**.

The part will also enter READY mode from POWER-DOWN mode, followed by the OPERATION mode, if the CS/LWAKE pin becomes active HIGH ('1').

1.1.6 REMOTE WAKE-UP

The remote wake-up sub module observes the L$_{BUS}$ in order to detect bus activity. In POWER DOWN mode, normal LIN recessive/dominant threshold is disabled, and the LIN bus Wake-Up Voltage Threshold $V_{WK(LBUS)}$ is used to detect bus activities. Bus activity is detected when the voltage on the L$_{BUS}$ falls below the LIN bus Wake-Up Voltage Threshold $V_{WK(LBUS)}$ (approximately 3.5V) for at least t_{BDB} (a typical duration of 80 µs) followed by a rising edge. Such a condition causes the device to leave POWER-DOWN mode.

TABLE 1-1: OVERVIEW OF OPERATIONAL MODES

State	Transmitter	Receiver	Internal Wake Module	Voltage Regulator	Operation	Comments
POR	OFF	OFF	OFF	OFF	Transfer to READY mode after VBB>V_{ON}	
READY	OFF	ON	OFF	ON	If CS/LWAKE high, then proceed to OPERATION or TRANSMITTER OFF mode.	Bus Off state
OPERATION	ON	ON	OFF	ON	If CS/LWAKE low level, then Power down If FAULT/TXE low level, then TRANSMITTER-OFF mode	Normal Operation mode

1.2 Pin Descriptions

Please refer to Table 1-2 for the pinout overview.

1.2.1 VBB

Battery Positive Supply Voltage pin. An external diode is connected in series to prevent the device from being reversely powered (refer to **FIGURE 1-9: "Typical Application Circuit"**).

1.2.2 VREG

Positive Supply Voltage Regulator Output pin. An on-chip LDO gives +5.0 or +3.3V 70 mA regulated voltage on this pin.

1.2.3 VSS

Ground pin.

1.2.4 TXD

Transmit data input pin (TTL level, HV compliant, adaptive pull-up). The transmitter reads the data stream on TXD pin and sends it to LIN bus. The LBUS pin is low (dominant) when TXD is low, and high (recessive) when TXD is high.

The Transmit Data Input pin has an internal adaptive pull-up to an internally-generated 4.2V (approximately). When TXD is '0', a weak pull-up (~900 kΩ) is used to reduce current. When TXD is '1', a stronger pull-up (~300 kΩ) is used to maintain the logic level. A series reverse-blocking diode allows applying TXD input voltages greater than the internally generated 4.2V and renders TXD pin HV compliant up to 30V (see block diagram).

1.2.5 RXD

Receive Data Output pin. The RXD pin is a standard CMOS output pin and it follows the state of the LBUS pin.

1.2.6 LBUS

LIN Bus pin. LBUS is a bidirectional LIN bus Interface pin and is controlled by the signal TXD. It has an open collector output with a current limitation. To reduce electromagnetic emission, the slopes during signal changes are controlled, and the LBUS pin has corner-rounding control for both falling and rising edges.

The internal LIN receiver observes the activities on the LIN bus, and generates the output signal RXD that follows the state of the LBUS. A 1st degree 160 kHz, low-pass input filter optimizes electromagnetic immunity.

1.2.7 CS/LWAKE

Chip Select and Local Wake-up Input pin (TTL level, high voltage tolerant). This pin controls the device state transition. Refer to **FIGURE 1-1: "State Diagram"**.

If CS/LWAKE = 1, the device can work in OPERATION mode ($\overline{FAULT}$/TXE = 1) or TRANSMITTER OFF mode ($\overline{FAULT}$/TXE = 0).

If CS/LWAKE = 0, the device can work in POWER-DOWN mode or READY mode.

An internal pull-down resistor will keep the CS/LWAKE pin low to ensure that no disruptive data will be present on the bus while the microcontroller is executing a Power-on Reset and I/O initialization sequence. When CS/LWAKE is '1', a weak pull-down (~600 kΩ) is used to reduce current. When CS/LWAKE is '0' a stronger pull-down (~300 kΩ) is used to maintain the logic level.

This pin may also be used as a local wake-up input (see **FIGURE 1-9: "Typical Application Circuit"**). The microcontroller will set the I/O pin to control the CS/LWAKE. An external switch, or other source, can then wake-up both the transceiver and the microcontroller.

Note:	CS/LWAKE should NOT be tied directly to the VREG pin as this could force the MCP2021A/2A into Operation mode before the microcontroller is initialized.

1.2.8 $\overline{FAULT}$/TXE

Fault Detect Output/Transmitter Enable Input pin. The output section is HV tolerant open drain (up to 30V). The input section is identical with the TXD section (TTL level, HV compliant, adaptive pull-up). The internal pull-up resistor may be too weak for some applications. We recommend to add a 10 k ohm external pull-up resistor to ensure a logic high level. Its state is defined as shown in **TABLE 1-3: "FAULT/TXE Truth Table"**. The device is placed in TRANSMITTER OFF mode whenever this pin is LOW ('0'), either from an internal fault condition or by external drive.

If CS/LWAKE is HIGH ('1'), the $\overline{FAULT}$/TXE signals a mismatch between the TXD input and the LBUS level. This can be used to detect a bus contention. Since the bus exhibits a propagation delay, the sampling of the internal compare is debounced to eliminate false faults.

After the device wakes up, the $\overline{FAULT}$/TXE indicates what wakes the device if CS/LWAKE remains LOW ('0') (refer Table 1-3).

The $\overline{FAULT}$/TXE pin sampled at a rate faster than every 10 µs.

1.2.9 $\overline{RESET}$ (MCP2022A ONLY)

RESET OUTPUT pin. This pin is open drain with ~90 kΩ pull-up to VREG. It indicates the internal voltage has reached a valid, stable level. As long as the internal voltage is valid (above 0.8 VREG), this pin will remain HIGH ('1'); otherwise the $\overline{RESET}$ pin switches to LOW ('0').

1.3   Fail-Safe Features

1.3.1   GENERAL FAIL-SAFE FEATURES

- An internal pull-down resistor on CS/LWAKE pin disables the transmitter if the pin is floating.
- An internal pull-up resistor on the TXD pin places TXD in HIGH thus the LBUS in recessive if TXD pin is floating.
- High-impedance and low-leakage current on LBUS during loss of power or ground.
- The current limit on LBUS protects the transceiver from being damaged if the pin is shorted to VBB.

1.3.2   THERMAL PROTECTION

The thermal protection circuit monitors the die temperature and is able to shut down the LIN transmitter and voltage regulator.
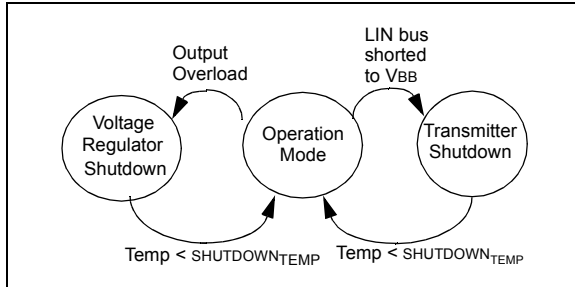

There are three causes for a thermal overload. A thermal shut down can be triggered by any one, or a combination of, the following thermal overload conditions.

- Voltage regulator overload
- LIN bus output overload
- Increase in die temperature due to increase in environment temperature

The recovery time from the thermal shutdown is equal to adequate cooling time.

Driving the TXD and checking the RXD pin make it possible to determine whether there is a bus contention (TXD = high, RXD = low) or a thermal overload condition (TXD = low, RXD = high).

FIGURE 1-2: **THERMAL SHUTDOWN STATE DIAGRAMS**

1.3.3 TXD/LBUS TIME-OUT TIMER

The LIN bus can be driven to a dominant level either from the TXD pin or externally. An internal timer deactivates the LBUS transmitter if a dominant status (LOW) on the LIN bus lasts longer than Bus Dominant Time-out Time $t_{TO(LIN)}$ (approximately 20 milliseconds). At the same time, RXD output is put in recessive (HIGH), FAULT/TXE is also driven to LOW, and the internal LIN pull-up resistor is disconnected. The timer is reset on any recessive LBUS status or POR mode. The recessive status on LBUS can be caused either by the bus being externally pulled up or by the TXD pin being returned high.

1.4 Internal Voltage Regulator

The MCP2021A/2A has a positive regulator capable of supplying +5.00 or +3.30 VDC ±3% at up to 70 mA of load current over the entire operating temperature range of -40°C to +125°C. The regulator uses a LDO design, is short-circuit-protected and will turn the regulator output off if its output falls below the Shutdown Voltage Threshold V_{SD}.

With a load current of 70 mA, the minimum input to output voltage differential required for the output to remain in regulation is typically +0.5V (+1V maximum over the full operating temperature range). Quiescent current is less than 100 μA with a full 70 mA load current when the input to output voltage differential is greater than +3.00V.

Regarding the correlation between VBB, VREG and IDD, please refer to Figure 1-6 and Figure 1-7. When the input voltage (VBB) drops below the differential needed to provide stable regulation, the voltage regulator output VREG will track the input down to approximately VOFF. The regulator will turn off the output at this point. This will allow PIC® microcontrollers, with internal POR circuits, to generate a clean arming of the Power-on

Reset trip point. The MCP2021A/2A will then monitor VBB and turn on the regulator when VBB is above the threshold of regulator turn on voltage V_{ON}.

In Power-down mode, the VBB monitor is turned off.

Under a specific ambient temperature and battery voltage range, the voltage regulator can output as high as 150mA current. For current load capability of the voltage regulator, refer Figure 1-4 and Figure 1-5.

> **Note:** The regulator overload current limit is approximately 250 mA. The regulator output voltage V_{REG} is monitored. If output voltage V_{REG} is lower than V_{SD}, the voltage regulator will turn off. After a recovery time of about 3mS, the V_{REG} will be checked again. If there is no short circuit ($V_{REG} > V_{SD}$), then the voltage regulator remains on.

The regulator requires an external output bypass capacitor for stability. See Figure 2-1 for correct capacity and ESR for stable operation.

> **Note:** A ceramic capacitor of at least 10 uF, or a tantalum capacitor of at least 2.2 uF is recommended for stability.

> **Warning:** A ceramic capacitor may worst case de-rate 50%, based on tolerance, voltage and temperature. Therefore, in order to ensure stability, ceramic capacitors smaller than 10 uF may require a small series resistance to meet the ESR requirements. We recommend 1 Ohm in series with a 1 uF capacitor, 0.47 Ohm in series with a 2.2 uF capacitor, 0.22 Ohm in series with a 4.7 uF capacitor and 0.1 Ohm in series with a 6.8 uF capacitor.

1.5 Optional External Protection

1.5.1 REVERSE BATTERY PROTECTION

An external reverse-battery-blocking diode should be used to provide polarity protection (see Figure 1-9).

1.5.2 TRANSIENT VOLTAGE PROTECTION (LOAD DUMP)

An external 43V transient suppressor (TVS) diode, between V_{BB} and ground, with a transient protection resistor (R_{TP}) in series with the battery supply and the V_{BB} pin protects the device from power transients and ESD events greater than 43V (see Figure 1-9). The maximum value for the R_{TP} protection resistor depends upon two parameters: the minimum voltage the part will start at, and the impacts of this R_{TP} resistor on the V_{BB} value, thus on the Bus recessive level and slopes.

This leads to a set of three equations to fulfill.

Equation 1-1 provides a max R_{TP} value according to the minimum battery voltage the user wants.

Equation 1-2 provides a max R_{TP} value according to the maximum error on the recessive level, thus V_{BB}, since the part uses V_{BB} as the reference value for the recessive level.

Equation 1-3 provides a max R_{TP} value according to the maximum relative variation the user can accept on the slope when I_{REG} varies.

Since both Equation 1-1 and Equation 1-2 must be fulfilled, the maximum allowed value for RTP is thus the smaller of the two values found when solving Equation 1-1 and Equation 1-2.

Usually Equation 1-1 gives the higher constraint (smaller value) for R_{TP} as shown in the following example where V_{BATmin} is 8V.

However, the user needs to check that the value found with Equation 1-1 fulfills Equation 1-2 and Equation 1-3 as well.

While this protection is optional, it should be considered as good engineering practice.

EQUATION 1-1:

$$R_{TP} \le \frac{V_{BATmin} - 5.5V}{250mA}$$

$$5.5V = V_{OFF} + 1.0V$$

250 mA is the peak current at power-on when VBB =5.5V

Assume V$_{BATMIN}$ = 8V. Equation 1-1 shows 10Ω.

EQUATION 1-2:

$R_{TP} <= \Delta V_{RECESSIVE} / I_{REGMAX}$.
$\Delta V_{RECESSIVE}$ *is the maximum variation tolerated on the recessive level*

Assume ΔV$_{RECESSIVE}$ = 1V and I$_{REGMAX}$ = 50 mA Equation 1-2 shows 20Ω.

EQUATION 1-3:

$$R_{TP} \le \frac{\Delta Slope \times (V_{BATmin} - 1V)}{I_{regmax}}$$

Δ*Slope is the maximum variation tolerated on the slope level and I$_{REGMAX}$ is the maximum current the regulator will provide to the load.*
$V_{BATmin} > V_{OFF} + 1.0V$.

Assume ΔSlope = 15%, V$_{BATMIN}$ = 8V and I$_{REGMAX}$ = 50 mA. Equation 1-2 shows 20Ω.

1.5.3 CBAT CAP

Selecting C$_{BAT}$ = 10* C$_{REG}$ is recommended, however, this leads to a high value cap. Lower values for C$_{BAT}$ cap can be used with respect to some rules. In any case, the voltage at the V$_{BB}$ pin should remain above V$_{OFF}$ when the device is turned on.

The current peak at start-up (due to the fast charge of the C$_{REG}$ and C$_{BAT}$ capacitors) may induce a significant drop on the VBB pin. This drop is proportional to the impedance of the V$_{BAT}$ connection (see Figure 1-9).

Assume that the V$_{BAT}$ connection is mainly inductive and resistive, and that the customer knows the resistive and inductive values of the connection.

The following formula gives an indication of the minimum value the customer should use for C$_{BAT}$:

EQUATION 1-4:

$$\frac{C_{BAT}}{C_{REG}} = \sqrt{\frac{100L^2 + R_{tot}^2}{1 + L^2 + \frac{R_{tot}^2}{100}}}$$

where L is in mH and R$_{tot}$ in Ω.
R$_{tot}$ = R$_{line}$ + R$_{TP}$.

Equation 1-4 allows lower C$_{BAT}$/C$_{REG}$ values than the 10* ratio we recommend.

Assume that we have a good quality connection with R$_{TOT}$ = 0.1Ω and L = 0.1 mH.

Solving the equation gives C$_{BAT}$/C$_{REG}$ = 1.

If we increase R$_{TOT}$ up to 1Ω, the result becomes C$_{BAT}$/C$_{REG}$ = 1.4.
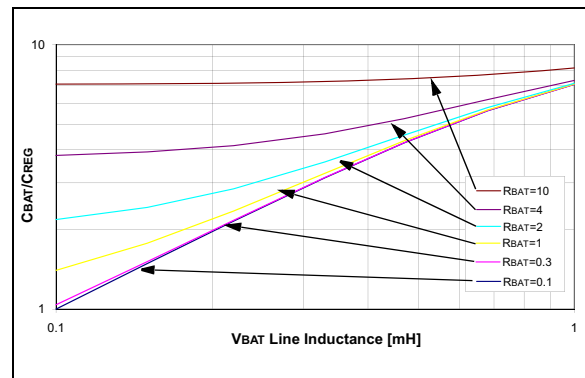

But if the connection is highly resistive or highly inductive (poor connection), the C$_{BAT}$/C$_{REG}$ ratio greatly increases.

Highly inductive connection: R$_{TOT}$ = 0.1Ω and L = 1 mH: the C$_{BAT}$/C$_{REG}$ ratio increases to 7!

Highly resistive connection: R$_{TOT}$ = 10Ω and L = 0.1 mH: again the C$_{BAT}$/C$_{REG}$ ratio increases to 7!

Figure 1-8 shows the minimum recommended C$_{BAT}$/C$_{REG}$ ratio as a function of the impedance of the V$_{BAT}$ connection.

FIGURE 1-8: Minimum Recommended CBAT/CREG Ratio

## 1.6 Typical Applications

FIGURE 1-9: TYPICAL APPLICATION CIRCUIT

Note 1: C$_{REG}$, the load capacitor, should be ceramic or tantalum rated for extended temperatures, 1.0-22 µF. See Figure 2-1 for selecting the correct ESR.

2: C$_{BAT}$ is the filter capacitor for the external voltage supply. Typically 10 * C$_{REG}$, with no ESR restriction. See Figure 1-8 to select the minimum recommended value for C$_{BAT}$. The R$_{TP}$ value is added to the line resistance.

3: This diode is only needed if CS/LWAKE is connected to V$_{BAT}$ supply.

4: Transient suppressor diode. Vclamp L = 43V.

5: This component is for additional load dump protection.

6: An external 10 kΩ resistor is recommended for some applications.

1.7 ICSP™ Considerations

The following should be considered when the MCP2021A/2A is connected to pins supporting in-circuit programming:

• Power used for programming the microcontroller can be supplied from the programmer, or from the MCP2021A/2A.

• The voltage on the pin VREG should not exceed the maximum value of VREG in **Section 2.3 "DC Specifications"**.

† NOTICE: Stresses above those listed under "Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

2.2 Nomenclature Used in This Document

Some terms and names used in this data sheet deviate from those referred to in the LIN specifications. Equivalent values are shown below.

| LIN 2.1 Name	Term used in the following tables	
V_{BAT}	*not used*	ECU operating voltage
V_{SUP}	V_{BB}	Supply voltage at device pin
V_{BUS_LIM}	I_{SC}	Current limit of Driver
V_{BUSREC}	$V_{IH}(LBUS)$	Recessive state
V_{BUSDOM}	$V_{IL}(LBUS)$	Dominant state

2.5 Thermal Specifications

THERMAL CHARACTERISTICS					
Parameter	**Symbol**	**Typ.**	**Max.**	**Units**	**Test Conditions**
Recovery Temperature	$\theta_{RECOVERY}$	+140	—	°C	
Shutdown Temperature	$\theta_{SHUTDOWN}$	+150	—	°C	
Short Circuit Recovery Time	t_{THERM}	1.5	5.0	ms	
Thermal Package Resistances					
Thermal Resistance, 8L-PDIP	θ_{JA}	89.3	—	°C/W	
Thermal Resistance, 8L-SOIC	θ_{JA}	149.5	—	°C/W	
Thermal Resistance, 8L-DFN	θ_{JA}	48	—	°C/W	
Thermal Resistance, 14L-PDIP	θ_{JA}	70	—	°C/W	
Thermal Resistance, 14L-SOIC	θ_{JA}	95.3	—	°C/W	
Thermal Resistance, 14L-TSSOP	θ_{JA}	100	—	°C/W	

Note 1: The maximum power dissipation is a function of T_{JMAX}, Θ_{JA} and ambient temperature T_A. The maximum allowable power dissipation at an ambient temperature is P_D = (T_{JMAX} - T_A) Θ_{JA}. If this dissipation is exceeded, the die temperature will rise above 150°C and the MCP2021A/2A will go into thermal shutdown.

PART NO.	–X	/XX
Device	**Temperature Range**	**Package**

Device:	MCP2021A: LIN Transceiver with Voltage Regulator MCP2021AT: LIN Transceiver with Voltage Regulator (Tape and Reel) (SOIC only)
Temperature Range:	E = -40°C to +125°C
Package:	MD = Plastic Dual Flat DFN, 8-lead SN = Plastic Small Outline SOIC, 8-lead P = Plastic DIP (300 mil Body), 8-lead, 14-lead SL = Plastic SOIC, (150 mil Body), 14-lead ST = Plastic TSSOP, 14-lead

Examples:

a) MCP2021A-330E/SN: 3.3V, 8L-SOIC package
b) MCP2021A-330E/P: 3.3V, 8L-PDIP package
c) MCP2021A-500E/SN: 5.0V, 8L-SOIC package
d) MCP2021A-500E/P: 5.0V, 8L-PDIP package
e) MCP2021AT-330E/SN: Tape and Reel,
                3.3V, 8L-SOIC package
f) MCP2021AT-500E/SN: Tape and Reel,
                5.0V, 8L-SOIC package
g) MCP2022A-330E/SL: 3.3V, 14L-SOIC package

APPENDIX A: REVISION HISTORY

Revision B (December 2013)

The following is the list of modifications:

1. Removed two notes in **Section 2.4 "AC Specification"**.
2. Updated Figure 1-4.
3. Added pull-up to FAULT/TXE pin in the pin description and typical applications.
4. Revised product identification examples for SOIC package.

Revision A (March 2012)

• Original Release of this Document.

NOTES:

Note the following details of the code protection feature on Microchip devices:

• Microchip products meet the specification contained in their particular Microchip Data Sheet.

• Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.

• There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.

• Microchip is willing to work with the customer who is concerned about the integrity of their code.

• Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
