|----------------|-------|------|

## Chapter 1 About This Document

|       |                           |    |
|-------|---------------------------|----|
| 1.1   | Overview.....             | 65 |
| 1.1.1 | Purpose.....              | 65 |
| 1.1.2 | Audience.....             | 65 |
| 1.2   | Conventions.....          | 65 |
| 1.2.1 | Numbering systems.....    | 65 |
| 1.2.2 | Typographic notation..... | 66 |
| 1.2.3 | Special terms.....        | 66 |

## Chapter 2 Introduction

|       |                                     |    |
|-------|-------------------------------------|----|
| 2.1   | Overview.....                       | 67 |
| 2.2   | Block diagram.....                  | 67 |
| 2.3   | Module Functional Categories.....   | 68 |
| 2.3.1 | ARM® Cortex®-M7 Core Modules.....   | 70 |
| 2.3.2 | System Modules.....                 | 70 |
| 2.3.3 | Memories and Memory Interfaces..... | 71 |
| 2.3.4 | Clocks.....                         | 72 |
| 2.3.5 | Security and Integrity modules..... | 72 |
| 2.3.6 | Analog modules.....                 | 73 |
| 2.3.7 | Timer modules.....                  | 73 |
| 2.3.8 | Communication interfaces.....       | 75 |
| 2.3.9 | Human-machine interfaces.....       | 75 |
| 2.4   | Orderable part numbers.....         | 76 |

## Chapter 3 Core Overview

|       |                                           |    |
|-------|-------------------------------------------|----|
| 3.1   | Cortex CM7 Core Introduction.....         | 77 |
| 3.1.1 | Buses, interconnects, and interfaces..... | 79 |

| Section number | Title                                                               | Page |
|----------------|---------------------------------------------------------------------|------|
| 3.1.2          | System Tick Timer.....                                              | 79   |
| 3.1.3          | Debug facilities.....                                               | 79   |
| 3.1.4          | Core privilege levels.....                                          | 79   |
| 3.2            | Nested Vector Interrupt Controller (NVIC) configuration.....        | 80   |
| 3.2.1          | Interrupt priority levels.....                                      | 80   |
| 3.2.2          | Non-maskable interrupt.....                                         | 80   |
| 3.2.3          | Interrupt Vector Assignments.....                                   | 80   |
| 3.3            | Asynchronous Wake-up Interrupt Controller (AWIC) configuration..... | 84   |
| 3.3.1          | Wake-up sources.....                                                | 84   |
| 3.4            | Floating Point Unit (FPU) configuration.....                        | 85   |

## Chapter 4 Memories and Memory Interfaces

|      |                                        |    |
|------|----------------------------------------|----|
| 4.1  | Flash memory types.....                | 87 |
| 4.2  | Flash Memory Sizes.....                | 87 |
| 4.3  | Flash Security.....                    | 87 |
| 4.4  | Flash Modes.....                       | 88 |
| 4.5  | Erase All Flash Contents.....          | 88 |
| 4.6  | FTFE_FOPT Register.....                | 88 |
| 4.7  | RAM Memory Sizes.....                  | 88 |
| 4.8  | Other SRAM arrays.....                 | 89 |
| 4.9  | SRAM accesses.....                     | 89 |
| 4.10 | SRAM retention in low power modes..... | 89 |
| 4.11 | System Register file.....              | 90 |

## Chapter 5 Memory Map

|     |                            |    |
|-----|----------------------------|----|
| 5.1 | Introduction.....          | 91 |
| 5.2 | System Memory Map.....     | 91 |
| 5.3 | AIPS slot assignments..... | 92 |

## Chapter 6 Clock Distribution

| Section number | Title                                   | Page |
|----------------|-----------------------------------------|------|
| 6.1            | Introduction.....                       | 101  |
| 6.2            | High-level device clocking diagram..... | 101  |
| 6.2.1          | Clock definitions.....                  | 102  |
| 6.3            | Internal clocking requirements.....     | 103  |
| 6.3.1          | Clock divider values after reset.....   | 105  |
| 6.3.2          | VLPR mode clocking.....                 | 105  |
| 6.4            | Clock Gating.....                       | 106  |
| 6.5            | Module clocks.....                      | 106  |
| 6.5.1          | Nano-edge clocking.....                 | 108  |
| 6.5.2          | WDOG clocking.....                      | 108  |
| 6.5.3          | Debug trace clock.....                  | 108  |
| 6.5.4          | PMC 1-kHz LPO clock.....                | 109  |
| 6.5.5          | PORT digital filter clocking.....       | 109  |
| 6.5.6          | LPTMR clocking.....                     | 110  |
| 6.5.7          | FlexCAN clocking.....                   | 110  |
| 6.5.8          | UART clocking.....                      | 111  |
| 6.5.9          | Ethernet Clocking.....                  | 111  |
| 6.5.10         | Flexbus Clocking.....                   | 112  |
| 6.6            | External clocks .....                   | 112  |

## Chapter 7 Reset and Boot

|       |                           |     |
|-------|---------------------------|-----|
| 7.1   | Introduction.....         | 113 |
| 7.2   | Cortex CM7 platform.....  | 113 |
| 7.3   | Reset.....                | 114 |
| 7.3.1 | Power-on reset (POR)..... | 114 |
| 7.3.2 | System resets.....        | 114 |
| 7.3.3 | Debug resets.....         | 117 |
| 7.4   | Boot.....                 | 119 |
| 7.4.1 | Boot sources.....         | 119 |

| Section number | Title                  | Page |
|----------------|------------------------|------|
| 7.4.2          | FOPT boot options..... | 119  |
| 7.4.3          | Boot sequence.....     | 120  |

## Chapter 8 Power Management

|       |                                          |     |
|-------|------------------------------------------|-----|
| 8.1   | Introduction.....                        | 123 |
| 8.2   | Clocking Modes.....                      | 123 |
| 8.2.1 | Partial Stop.....                        | 123 |
| 8.2.2 | DMA Wakeup.....                          | 124 |
| 8.2.3 | Compute Operation.....                   | 125 |
| 8.2.4 | Peripheral Doze.....                     | 126 |
| 8.3   | Power modes.....                         | 127 |
| 8.4   | Module Operation in Low Power Modes..... | 128 |
| 8.5   | Power modes shutdown sequencing.....     | 131 |
| 8.6   | Clock Gating.....                        | 132 |
| 8.7   | Flash program restrictions.....          | 132 |

## Chapter 9 Security

|       |                                               |     |
|-------|-----------------------------------------------|-----|
| 9.1   | Introduction.....                             | 133 |
| 9.2   | Flash Security.....                           | 133 |
| 9.3   | Security Interactions with other Modules..... | 134 |
| 9.3.1 | Security Interactions with Debug.....         | 134 |

## Chapter 10 Debug

|        |                                        |     |
|--------|----------------------------------------|-----|
| 10.1   | Introduction.....                      | 135 |
| 10.1.1 | References.....                        | 137 |
| 10.2   | The Debug Port.....                    | 137 |
| 10.2.1 | JTAG-to-SWD change sequence.....       | 138 |
| 10.2.2 | JTAG-to-cJTAG change sequence.....     | 138 |
| 10.3   | Debug Port Pin Descriptions.....       | 139 |
| 10.4   | JTAG status and control registers..... | 139 |

| Section number | Title                                      | Page |
|----------------|--------------------------------------------|------|
| 10.4.1         | MDM-AP Control Register.....               | 140  |
| 10.4.2         | MDM-AP Status Register.....                | 142  |
| 10.5           | Debug Resets.....                          | 143  |
| 10.6           | AHB-AP.....                                | 143  |
| 10.7           | Instrumentation Trace Macrocell (ITM)..... | 144  |
| 10.8           | Core Trace Connectivity with ETM.....      | 145  |
| 10.9           | Embedded Trace Macrocell v4 (ETM).....     | 145  |
| 10.10          | TPIU.....                                  | 146  |
| 10.11          | DWT.....                                   | 146  |
| 10.12          | Debug in Low Power Modes.....              | 147  |
| 10.12.1        | Debug Module State in Low Power Modes..... | 147  |
| 10.13          | Debug and security.....                    | 148  |

## Chapter 11

### Signal Multiplexing and Signal Descriptions

|        |                                                   |     |
|--------|---------------------------------------------------|-----|
| 11.1   | Signal Multiplexing Introduction.....             | 149 |
| 11.2   | Signal Multiplexing Integration.....              | 149 |
| 11.2.1 | Port control and interrupt module features.....   | 150 |
| 11.2.2 | Clock gating.....                                 | 151 |
| 11.2.3 | Signal multiplexing constraints.....              | 151 |
| 11.3   | Pinout.....                                       | 151 |
| 11.3.1 | KV5x Signal Multiplexing and Pin Assignments..... | 151 |
| 11.3.2 | KV5x Pinouts.....                                 | 159 |
| 11.4   | Module Signal Description Tables.....             | 162 |
| 11.4.1 | Core Modules.....                                 | 163 |
| 11.4.2 | System Modules.....                               | 163 |
| 11.4.3 | Clock Modules.....                                | 164 |
| 11.4.4 | Memories and Memory Interfaces.....               | 164 |
| 11.4.5 | Analog.....                                       | 166 |
| 11.4.6 | Timer Modules.....                                | 167 |

| Section number | Title                               | Page |
|----------------|-------------------------------------|------|
| 11.4.7         | Communication Interfaces.....       | 170  |
| 11.4.8         | Human-Machine Interfaces (HMI)..... | 175  |

## Chapter 12

### Port Control and Interrupts (PORT)

|        |                                                     |     |
|--------|-----------------------------------------------------|-----|
| 12.1   | Chip-specific PORT information.....                 | 177 |
| 12.1.1 | Digital filter registers.....                       | 177 |
| 12.2   | Introduction.....                                   | 177 |
| 12.3   | Overview.....                                       | 177 |
| 12.3.1 | Features.....                                       | 177 |
| 12.3.2 | Modes of operation.....                             | 178 |
| 12.4   | External signal description.....                    | 179 |
| 12.5   | Detailed signal description.....                    | 179 |
| 12.6   | Memory map and register definition.....             | 179 |
| 12.6.1 | Pin Control Register n (PORTx_PCRn).....            | 186 |
| 12.6.2 | Global Pin Control Low Register (PORTx_GPCLR).....  | 189 |
| 12.6.3 | Global Pin Control High Register (PORTx_GPCHR)..... | 189 |
| 12.6.4 | Interrupt Status Flag Register (PORTx_ISFR).....    | 190 |
| 12.6.5 | Digital Filter Enable Register (PORTx_DFER).....    | 190 |
| 12.6.6 | Digital Filter Clock Register (PORTx_DFCR).....     | 191 |
| 12.6.7 | Digital Filter Width Register (PORTx_DFWR).....     | 191 |
| 12.7   | Functional description.....                         | 192 |
| 12.7.1 | Pin control.....                                    | 192 |
| 12.7.2 | Global pin control.....                             | 193 |
| 12.7.3 | External interrupts.....                            | 193 |
| 12.7.4 | Digital filter.....                                 | 194 |

## Chapter 13

### System Integration Module (SIM)

|        |                   |     |
|--------|-------------------|-----|
| 13.1   | Introduction..... | 197 |
| 13.1.1 | Features.....     | 197 |

| Section number | Title                                                    | Page |
|----------------|----------------------------------------------------------|------|
| 13.2           | Memory map and register definition.....                  | 198  |
| 13.2.1         | System Options Register 1 (SIM_SOPT1).....               | 199  |
| 13.2.2         | System Options Register 2 (SIM_SOPT2).....               | 200  |
| 13.2.3         | System Options Register 4 (SIM_SOPT4).....               | 202  |
| 13.2.4         | System Options Register 5 (SIM_SOPT5).....               | 205  |
| 13.2.5         | System Options Register 7 (SIM_SOPT7).....               | 206  |
| 13.2.6         | System Options Register 8 (SIM_SOPT8).....               | 209  |
| 13.2.7         | System Options Register 9 (SIM_SOPT9).....               | 212  |
| 13.2.8         | System Device Identification Register (SIM_SDID).....    | 214  |
| 13.2.9         | System Clock Gating Control Register 1 (SIM_SCGC1).....  | 216  |
| 13.2.10        | System Clock Gating Control Register 2 (SIM_SCGC2).....  | 217  |
| 13.2.11        | System Clock Gating Control Register 3 (SIM_SCGC3).....  | 218  |
| 13.2.12        | System Clock Gating Control Register 4 (SIM_SCGC4).....  | 219  |
| 13.2.13        | System Clock Gating Control Register 5 (SIM_SCGC5).....  | 221  |
| 13.2.14        | System Clock Gating Control Register 6 (SIM_SCGC6).....  | 223  |
| 13.2.15        | System Clock Gating Control Register 7 (SIM_SCGC7).....  | 226  |
| 13.2.16        | System Clock Divider Register 1 (SIM_CLKDIV1).....       | 227  |
| 13.2.17        | Flash Configuration Register 1 (SIM_FCFG1).....          | 230  |
| 13.2.18        | Flash Configuration Register 2 (SIM_FCFG2).....          | 231  |
| 13.2.19        | Unique Identification Register High (SIM_UIDH).....      | 232  |
| 13.2.20        | Unique Identification Register Mid-High (SIM_UIDMH)..... | 232  |
| 13.2.21        | Unique Identification Register Mid Low (SIM_UIDML).....  | 233  |
| 13.2.22        | Unique Identification Register Low (SIM_UIDL).....       | 233  |
| 13.2.23        | System Clock Divider Register 4 (SIM_CLKDIV4).....       | 234  |

| 14.3.4 | Flashloader Protocol.....                          | 248 |
| 14.3.5 | Flashloader Packet Types.....                      | 253 |
| 14.3.6 | Flashloader Command API.....                       | 260 |
| 14.4   | Peripherals Supported.....                         | 282 |
| 14.4.1 | I2C Peripheral.....                                | 282 |
| 14.4.2 | SPI Peripheral.....                                | 283 |
| 14.4.3 | UART Peripheral.....                               | 285 |
| 14.4.4 | CAN (or FlexCAN) Peripheral.....                   | 288 |
| 14.5   | Get/SetProperty Command Properties.....            | 290 |
| 14.5.1 | Property Definitions.....                          | 291 |
| 14.6   | Kinetis Flashloader Status Error Codes.....        | 293 |

## Chapter 15 Reset Control Module (RCM)

|        |                                                   |     |
|--------|---------------------------------------------------|-----|
| 15.1   | Introduction.....                                 | 295 |
| 15.2   | Reset memory map and register descriptions.....   | 295 |
| 15.2.1 | System Reset Status Register 0 (RCM_SRS0).....    | 296 |
| 15.2.2 | System Reset Status Register 1 (RCM_SRS1).....    | 297 |
| 15.2.3 | Reset Pin Filter Control register (RCM_RPFC)..... | 299 |
| 15.2.4 | Reset Pin Filter Width register (RCM_RPFW).....   | 300 |

| Section number | Title                                                  | Page |
|----------------|--------------------------------------------------------|------|
| 15.2.5         | Sticky System Reset Status Register 0 (RCM_SSRS0)..... | 301  |
| 15.2.6         | Sticky System Reset Status Register 1 (RCM_SSRS1)..... | 302  |

## Chapter 16 System Mode Controller (SMC)

|        |                                                  |     |
|--------|--------------------------------------------------|-----|
| 16.1   | Introduction.....                                | 305 |
| 16.2   | Modes of operation.....                          | 305 |
| 16.3   | Memory map and register descriptions.....        | 307 |
| 16.3.1 | Power Mode Protection register (SMC_PMPROT)..... | 308 |
| 16.3.2 | Power Mode Control register (SMC_PMCTRL).....    | 309 |
| 16.3.3 | Stop Control Register (SMC_STOPCTRL).....        | 311 |
| 16.3.4 | Power Mode Status register (SMC_PMSTAT).....     | 312 |
| 16.4   | Functional description.....                      | 313 |
| 16.4.1 | Power mode transitions.....                      | 313 |
| 16.4.2 | Power mode entry/exit sequencing.....            | 316 |
| 16.4.3 | Run modes.....                                   | 318 |
| 16.4.4 | Wait modes.....                                  | 320 |
| 16.4.5 | Stop modes.....                                  | 321 |
| 16.4.6 | Debug in low power modes.....                    | 324 |

## Chapter 17 Miscellaneous Control Module (MCM)

|        |                                                                        |     |
|--------|------------------------------------------------------------------------|-----|
| 17.1   | Introduction.....                                                      | 325 |
| 17.1.1 | Features.....                                                          | 325 |
| 17.2   | Memory map/register descriptions.....                                  | 325 |
| 17.2.1 | Processor core type (MCM_PCT).....                                     | 326 |
| 17.2.2 | Control Register (MCM_CR).....                                         | 327 |
| 17.2.3 | Interrupt Status and Control Register (MCM_ISCR).....                  | 328 |
| 17.2.4 | Compute Only Operation Control Register (MCM_CPO).....                 | 330 |
| 17.2.5 | Local Memory General Descriptor Register (MCM_LMEM <sub>n</sub> )..... | 332 |
| 17.3   | Functional description.....                                            | 334 |

| Section number | Title           | Page |
|----------------|-----------------|------|
| 17.3.1         | Interrupts..... | 334  |

## Chapter 18

### Miscellaneous System Control Module (MSCM)

|         |                                                                    |     |
|---------|--------------------------------------------------------------------|-----|
| 18.1    | Overview.....                                                      | 335 |
| 18.2    | Chip Configuration and Boot.....                                   | 335 |
| 18.3    | MSCM Memory Map/Register Definition.....                           | 336 |
| 18.3.1  | CPU Configuration Memory Map and Registers.....                    | 336 |
| 18.3.2  | Processor X Type Register (MSCM_CPxTYPE).....                      | 337 |
| 18.3.3  | Processor X Number Register (MSCM_CPxNUM).....                     | 338 |
| 18.3.4  | Processor X Master Register (MSCM_CPxMASTER).....                  | 339 |
| 18.3.5  | Processor X Count Register (MSCM_CPxCOUNT).....                    | 340 |
| 18.3.6  | Processor X Configuration 1 Register (MSCM_CPxCFG1).....           | 340 |
| 18.3.7  | Processor X Configuration 3 Register (MSCM_CPxCFG3).....           | 341 |
| 18.3.8  | Processor 0 Type Register (MSCM_CP0TYPE).....                      | 343 |
| 18.3.9  | Processor 0 Number Register (MSCM_CP0NUM).....                     | 344 |
| 18.3.10 | Processor 0 Master Register (MSCM_CP0MASTER).....                  | 344 |
| 18.3.11 | Processor 0 Count Register (MSCM_CP0COUNT).....                    | 345 |
| 18.3.12 | Processor 0 Configuration 1 Register (MSCM_CP0CFG1).....           | 346 |
| 18.3.13 | Processor 0 Configuration 3 Register (MSCM_CP0CFG3).....           | 347 |
| 18.3.14 | Processor 1 Type Register (MSCM_CP1TYPE).....                      | 348 |
| 18.3.15 | Processor 1 Number Register (MSCM_CP1NUM).....                     | 349 |
| 18.3.16 | Processor 1 Master Register (MSCM_CP1MASTER).....                  | 350 |
| 18.3.17 | Processor 1 Count Register (MSCM_CP1COUNT).....                    | 351 |
| 18.3.18 | Processor 1 Configuration 1 Register (MSCM_CP1CFG1).....           | 351 |
| 18.3.19 | Processor 1 Configuration 3 Register (MSCM_CP1CFG3).....           | 352 |
| 18.3.20 | On-Chip Memory Descriptor Register (MSCM_OCMDR <sub>n</sub> )..... | 354 |

## Chapter 19

### Power Management Controller (PMC)

|      |                   |     |
|------|-------------------|-----|
| 19.1 | Introduction..... | 359 |
|------|-------------------|-----|

| Section number | Title                                                               | Page |
|----------------|---------------------------------------------------------------------|------|
| 19.2           | Features.....                                                       | 359  |
| 19.3           | Low-voltage detect (LVD) system.....                                | 359  |
| 19.3.1         | LVD reset operation.....                                            | 360  |
| 19.3.2         | LVD interrupt operation.....                                        | 360  |
| 19.3.3         | Low-voltage warning (LVW) interrupt operation.....                  | 360  |
| 19.4           | High-voltage detect (HVD) system.....                               | 361  |
| 19.4.1         | HVD reset operation.....                                            | 361  |
| 19.4.2         | HVD interrupt operation.....                                        | 361  |
| 19.5           | I/O retention.....                                                  | 362  |
| 19.6           | Memory map and register descriptions.....                           | 362  |
| 19.6.1         | Low Voltage Detect Status And Control 1 register (PMC_LVDSC1).....  | 362  |
| 19.6.2         | Low Voltage Detect Status And Control 2 register (PMC_LVDSC2).....  | 364  |
| 19.6.3         | Regulator Status And Control register (PMC_REGSC).....              | 365  |
| 19.6.4         | High Voltage Detect Status And Control 1 register (PMC_HVDSC1)..... | 366  |

## Chapter 20

### Low-Leakage Wakeup Unit (LLWU)

|        |                                            |     |
|--------|--------------------------------------------|-----|
| 20.1   | Chip-specific LLWU information.....        | 369 |
| 20.2   | Introduction.....                          | 370 |
| 20.2.1 | Features.....                              | 370 |
| 20.2.2 | Modes of operation.....                    | 371 |
| 20.2.3 | Block diagram.....                         | 371 |
| 20.3   | LLWU signal descriptions.....              | 372 |
| 20.4   | Memory map/register definition.....        | 373 |
| 20.4.1 | LLWU Pin Enable 1 register (LLWU_PE1)..... | 374 |
| 20.4.2 | LLWU Pin Enable 2 register (LLWU_PE2)..... | 375 |
| 20.4.3 | LLWU Pin Enable 3 register (LLWU_PE3)..... | 376 |
| 20.4.4 | LLWU Pin Enable 4 register (LLWU_PE4)..... | 377 |
| 20.4.5 | LLWU Pin Enable 5 register (LLWU_PE5)..... | 378 |
| 20.4.6 | LLWU Pin Enable 6 register (LLWU_PE6)..... | 379 |

| Section number | Title                                        | Page |
|----------------|----------------------------------------------|------|
| 20.4.7         | LLWU Pin Enable 7 register (LLWU_PE7).....   | 381  |
| 20.4.8         | LLWU Pin Enable 8 register (LLWU_PE8).....   | 382  |
| 20.4.9         | LLWU Module Enable register (LLWU_ME).....   | 383  |
| 20.4.10        | LLWU Pin Flag 1 register (LLWU_PF1).....     | 384  |
| 20.4.11        | LLWU Pin Flag 2 register (LLWU_PF2).....     | 386  |
| 20.4.12        | LLWU Pin Flag 3 register (LLWU_PF3).....     | 388  |
| 20.4.13        | LLWU Pin Flag 4 register (LLWU_PF4).....     | 389  |
| 20.4.14        | LLWU Module Flag 5 register (LLWU_MF5).....  | 391  |
| 20.4.15        | LLWU Pin Filter 1 register (LLWU_FILT1)..... | 393  |
| 20.4.16        | LLWU Pin Filter 2 register (LLWU_FILT2)..... | 394  |
| 20.5           | Functional description.....                  | 395  |
| 20.5.1         | VLLS modes.....                              | 395  |
| 20.5.2         | Initialization.....                          | 395  |

## Chapter 21 Crossbar Switch (AXBS)

|        |                                                            |     |
|--------|------------------------------------------------------------|-----|
| 21.1   | Chip-specific AXBS information.....                        | 397 |
| 21.1.1 | Crossbar Switch Master Assignments - with System MPU.....  | 397 |
| 21.1.2 | Crossbar Switch Slave Assignments - with System MPU.....   | 397 |
| 21.1.3 | PRS register reset values.....                             | 398 |
| 21.2   | Introduction.....                                          | 398 |
| 21.2.1 | Features.....                                              | 398 |
| 21.3   | Memory Map / Register Definition.....                      | 399 |
| 21.3.1 | Priority Registers Slave (AXBS_PRSn).....                  | 400 |
| 21.3.2 | Control Register (AXBS_CRSn).....                          | 402 |
| 21.3.3 | Master General Purpose Control Register (AXBS_MGPCRn)..... | 404 |
| 21.4   | Functional Description.....                                | 405 |
| 21.4.1 | General operation.....                                     | 405 |
| 21.4.2 | Register coherency.....                                    | 406 |
| 21.4.3 | Arbitration.....                                           | 406 |

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 21.5           | Initialization/application information..... | 409  |

## Chapter 22 Peripheral Bridge (AIPS-Lite)

|        |                                                           |     |
|--------|-----------------------------------------------------------|-----|
| 22.1   | Chip-specific AIPS-Lite information.....                  | 411 |
| 22.1.1 | Master Privilege Register A (AIPSx_MPRA) reset value..... | 411 |
| 22.2   | Introduction.....                                         | 411 |
| 22.2.1 | Features.....                                             | 411 |
| 22.2.2 | General operation.....                                    | 411 |
| 22.3   | Memory map/register definition.....                       | 412 |
| 22.3.1 | Master Privilege Register A (AIPSx_MPRA).....             | 413 |
| 22.3.2 | Peripheral Access Control Register (AIPSx_PACRn).....     | 416 |
| 22.3.3 | Peripheral Access Control Register (AIPSx_PACRn).....     | 421 |
| 22.4   | Functional description.....                               | 425 |
| 22.4.1 | Access support.....                                       | 426 |

## Chapter 23 System Memory Protection Unit (MPU)

|        |                                                      |     |
|--------|------------------------------------------------------|-----|
| 23.1   | Chip-specific MPU information.....                   | 427 |
| 23.1.1 | MPU Slave Port Assignments.....                      | 427 |
| 23.1.2 | MPU Logical Bus Master Assignments.....              | 427 |
| 23.1.3 | MPU access violation indications.....                | 428 |
| 23.1.4 | Reset values for RGD0 registers.....                 | 428 |
| 23.1.5 | Write access restrictions for RGD0 registers.....    | 428 |
| 23.2   | Introduction.....                                    | 429 |
| 23.3   | Overview.....                                        | 429 |
| 23.3.1 | Block diagram.....                                   | 429 |
| 23.3.2 | Features.....                                        | 430 |
| 23.4   | Memory map/register definition.....                  | 431 |
| 23.4.1 | Control/Error Status Register (MPU_CESR).....        | 434 |
| 23.4.2 | Error Address Register, slave port n (MPU_EARn)..... | 435 |

| Section number | Title                                                           | Page |
|----------------|-----------------------------------------------------------------|------|
| 23.4.3         | Error Detail Register, slave port n (MPU_EDRn).....             | 436  |
| 23.4.4         | Region Descriptor n, Word 0 (MPU_RGDn_WORD0).....               | 437  |
| 23.4.5         | Region Descriptor n, Word 1 (MPU_RGDn_WORD1).....               | 438  |
| 23.4.6         | Region Descriptor n, Word 2 (MPU_RGDn_WORD2).....               | 438  |
| 23.4.7         | Region Descriptor n, Word 3 (MPU_RGDn_WORD3).....               | 441  |
| 23.4.8         | Region Descriptor Alternate Access Control n (MPU_RGDAACn)..... | 442  |
| 23.5           | Functional description.....                                     | 444  |
| 23.5.1         | Access evaluation macro.....                                    | 444  |
| 23.5.2         | Putting it all together and error terminations.....             | 446  |
| 23.5.3         | Power management.....                                           | 447  |
| 23.6           | Initialization information.....                                 | 447  |
| 23.7           | Application information.....                                    | 447  |

## Chapter 24 Bit Manipulation Engine2 (BME2)

|        |                                         |     |
|--------|-----------------------------------------|-----|
| 24.1   | Introduction.....                       | 451 |
| 24.1.1 | Features.....                           | 452 |
| 24.1.2 | Modes of operation.....                 | 452 |
| 24.2   | Memory map and register definition..... | 452 |
| 24.3   | Functional description.....             | 453 |
| 24.3.1 | BME decorated stores.....               | 453 |
| 24.3.2 | BME decorated loads.....                | 460 |
| 24.4   | Application information.....            | 466 |

## Chapter 25 Direct Memory Access Multiplexer (DMAMUX)

|        |                                       |     |
|--------|---------------------------------------|-----|
| 25.1   | Chip-specific DMAMUX information..... | 469 |
| 25.1.1 | DMA MUX request sources.....          | 469 |
| 25.1.2 | DMA transfers via PIT trigger.....    | 473 |
| 25.2   | Introduction.....                     | 473 |
| 25.2.1 | Overview.....                         | 473 |

| Section number | Title                                                 | Page |
|----------------|-------------------------------------------------------|------|
| 25.2.2         | Features.....                                         | 474  |
| 25.2.3         | Modes of operation.....                               | 474  |
| 25.3           | External signal description.....                      | 475  |
| 25.4           | Memory map/register definition.....                   | 475  |
| 25.4.1         | Channel Configuration register (DMAMUX_CHCFGn).....   | 476  |
| 25.5           | Functional description.....                           | 477  |
| 25.5.1         | DMA channels with periodic triggering capability..... | 477  |
| 25.5.2         | DMA channels with no triggering capability.....       | 480  |
| 25.5.3         | Always-enabled DMA sources.....                       | 480  |
| 25.6           | Initialization/application information.....           | 481  |
| 25.6.1         | Reset.....                                            | 481  |
| 25.6.2         | Enabling and configuring sources.....                 | 481  |

## Chapter 26

### Enhanced Direct Memory Access (eDMA)

|        |                                                       |     |
|--------|-------------------------------------------------------|-----|
| 26.1   | Introduction.....                                     | 485 |
| 26.1.1 | eDMA system block diagram.....                        | 485 |
| 26.1.2 | Block parts.....                                      | 486 |
| 26.1.3 | Features.....                                         | 487 |
| 26.2   | Modes of operation.....                               | 488 |
| 26.3   | Memory map/register definition.....                   | 489 |
| 26.3.1 | TCD memory.....                                       | 489 |
| 26.3.2 | TCD initialization.....                               | 489 |
| 26.3.3 | TCD structure.....                                    | 489 |
| 26.3.4 | Reserved memory and bit fields.....                   | 490 |
| 26.3.5 | Control Register (DMA_CR).....                        | 514 |
| 26.3.6 | Error Status Register (DMA_ES).....                   | 517 |
| 26.3.7 | Enable Request Register (DMA_ERQ).....                | 519 |
| 26.3.8 | Enable Error Interrupt Register (DMA_EEI).....        | 523 |
| 26.3.9 | Clear Enable Error Interrupt Register (DMA_CEEI)..... | 526 |

| Section number | Title                                                                                                           | Page |
|----------------|-----------------------------------------------------------------------------------------------------------------|------|
| 26.3.10        | Set Enable Error Interrupt Register (DMA_SEEI).....                                                             | 527  |
| 26.3.11        | Clear Enable Request Register (DMA_CERQ).....                                                                   | 528  |
| 26.3.12        | Set Enable Request Register (DMA_SERQ).....                                                                     | 529  |
| 26.3.13        | Clear DONE Status Bit Register (DMA_CDNE).....                                                                  | 530  |
| 26.3.14        | Set START Bit Register (DMA_SSRT).....                                                                          | 531  |
| 26.3.15        | Clear Error Register (DMA_CERR).....                                                                            | 532  |
| 26.3.16        | Clear Interrupt Request Register (DMA_CINT).....                                                                | 533  |
| 26.3.17        | Interrupt Request Register (DMA_INT).....                                                                       | 534  |
| 26.3.18        | Error Register (DMA_ERR).....                                                                                   | 537  |
| 26.3.19        | Hardware Request Status Register (DMA_HRS).....                                                                 | 541  |
| 26.3.20        | Enable Asynchronous Request in Stop Register (DMA_EARS).....                                                    | 547  |
| 26.3.21        | Channel n Priority Register (DMA_DCHPRIn).....                                                                  | 550  |
| 26.3.22        | TCD Source Address (DMA_TCDn_SADDR).....                                                                        | 551  |
| 26.3.23        | TCD Signed Source Address Offset (DMA_TCDn_SOFF).....                                                           | 552  |
| 26.3.24        | TCD Transfer Attributes (DMA_TCDn_ATTR).....                                                                    | 552  |
| 26.3.25        | TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCDn_NBYTES_MLNO).....                                  | 553  |
| 26.3.26        | TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled)<br>(DMA_TCDn_NBYTES_MLOFFNO)..... | 554  |
| 26.3.27        | TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled)<br>(DMA_TCDn_NBYTES_MLOFFYES).....         | 555  |
| 26.3.28        | TCD Last Source Address Adjustment (DMA_TCDn_SLAST).....                                                        | 557  |
| 26.3.29        | TCD Destination Address (DMA_TCDn_DADDR).....                                                                   | 557  |
| 26.3.30        | TCD Signed Destination Address Offset (DMA_TCDn_DOFF).....                                                      | 558  |
| 26.3.31        | TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled)<br>(DMA_TCDn_CITER_ELINKYES).....       | 558  |
| 26.3.32        | TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled)<br>(DMA_TCDn_CITER_ELINKNO).....       | 559  |
| 26.3.33        | TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCDn_DLASTSGA).....                         | 560  |
| 26.3.34        | TCD Control and Status (DMA_TCDn_CSR).....                                                                      | 561  |

| Section number | Title                                                                                                       | Page |
|----------------|-------------------------------------------------------------------------------------------------------------|------|
| 26.3.35        | TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled)<br>(DMA_TCDn_BITER_ELINKYES)..... | 563  |
| 26.3.36        | TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled)<br>(DMA_TCDn_BITER_ELINKNO)..... | 564  |
| 26.4           | Functional description.....                                                                                 | 565  |
| 26.4.1         | eDMA basic data flow.....                                                                                   | 565  |
| 26.4.2         | Fault reporting and handling.....                                                                           | 568  |
| 26.4.3         | Channel preemption.....                                                                                     | 571  |
| 26.4.4         | Performance.....                                                                                            | 571  |
| 26.5           | Initialization/application information.....                                                                 | 575  |
| 26.5.1         | eDMA initialization.....                                                                                    | 575  |
| 26.5.2         | Programming errors.....                                                                                     | 577  |
| 26.5.3         | Arbitration mode considerations.....                                                                        | 578  |
| 26.5.4         | Performing DMA transfers.....                                                                               | 579  |
| 26.5.5         | Monitoring transfer descriptor status.....                                                                  | 583  |
| 26.5.6         | Channel Linking.....                                                                                        | 585  |
| 26.5.7         | Dynamic programming.....                                                                                    | 586  |
| 26.5.8         | Lockstep.....                                                                                               | 590  |

## Chapter 27 External Watchdog Monitor (EWM)

|        |                                           |     |
|--------|-------------------------------------------|-----|
| 27.1   | Chip-specific EWM information.....        | 593 |
| 27.1.1 | EWM clocks.....                           | 593 |
| 27.1.2 | EWM low-power modes.....                  | 593 |
| 27.1.3 | EWM_OUT pin state in low power modes..... | 593 |
| 27.2   | Introduction.....                         | 594 |
| 27.2.1 | Features.....                             | 594 |
| 27.2.2 | Modes of Operation.....                   | 595 |

| 27.5.2         | The EWM_in Signal.....                           | 602  |
| 27.5.3         | EWM Counter.....                                 | 602  |
| 27.5.4         | EWM Compare Registers.....                       | 603  |
| 27.5.5         | EWM Refresh Mechanism.....                       | 603  |
| 27.5.6         | EWM Interrupt.....                               | 603  |
| 27.5.7         | Selecting the EWM counter clock.....             | 604  |
| 27.5.8         | Counter clock prescaler.....                     | 604  |

## Chapter 28 Watchdog Timer (WDOG)

|        |                                          |     |
|--------|------------------------------------------|-----|
| 28.1   | Chip-specific WDOG information.....      | 605 |
| 28.1.1 | WDOG clocks.....                         | 605 |
| 28.1.2 | WDOG low-power modes.....                | 605 |
| 28.2   | Introduction.....                        | 606 |
| 28.3   | Features.....                            | 606 |
| 28.4   | Functional overview.....                 | 607 |
| 28.4.1 | Unlocking and updating the watchdog..... | 609 |
| 28.4.2 | Watchdog configuration time (WCT).....   | 610 |
| 28.4.3 | Refreshing the watchdog.....             | 611 |
| 28.4.4 | Windowed mode of operation.....          | 611 |
| 28.4.5 | Watchdog disabled mode of operation..... | 611 |
| 28.4.6 | Low-power modes of operation.....        | 611 |

| Section number | Title                                                         | Page |
|----------------|---------------------------------------------------------------|------|
| 28.4.7         | Debug modes of operation.....                                 | 612  |
| 28.5           | Testing the watchdog.....                                     | 612  |
| 28.5.1         | Quick test.....                                               | 613  |
| 28.5.2         | Byte test.....                                                | 613  |
| 28.6           | Backup reset generator.....                                   | 615  |
| 28.7           | Generated resets and interrupts.....                          | 615  |
| 28.8           | Memory map and register definition.....                       | 616  |
| 28.8.1         | Watchdog Status and Control Register High (WDOG_STCTRLH)..... | 617  |
| 28.8.2         | Watchdog Status and Control Register Low (WDOG_STCTRL).....   | 618  |
| 28.8.3         | Watchdog Time-out Value Register High (WDOG_TOVALH).....      | 619  |
| 28.8.4         | Watchdog Time-out Value Register Low (WDOG_TOVAL).....        | 619  |
| 28.8.5         | Watchdog Window Register High (WDOG_WINH).....                | 620  |
| 28.8.6         | Watchdog Window Register Low (WDOG_WINL).....                 | 620  |
| 28.8.7         | Watchdog Refresh register (WDOG_REFRESH).....                 | 621  |
| 28.8.8         | Watchdog Unlock register (WDOG_UNLOCK).....                   | 621  |
| 28.8.9         | Watchdog Timer Output Register High (WDOG_TMROUTH).....       | 621  |
| 28.8.10        | Watchdog Timer Output Register Low (WDOG_TMROUTL).....        | 622  |
| 28.8.11        | Watchdog Reset Count register (WDOG_RSTCNT).....              | 622  |
| 28.8.12        | Watchdog Prescaler register (WDOG_PRESC).....                 | 622  |
| 28.9           | Watchdog operation with 8-bit access.....                     | 623  |
| 28.9.1         | General guideline.....                                        | 623  |
| 28.9.2         | Refresh and unlock operations with 8-bit access.....          | 623  |
| 28.10          | Restrictions on watchdog operation.....                       | 624  |

## Chapter 29

### Crossbar AND/OR/INVERT (AOI) Module

|        |                                    |     |
|--------|------------------------------------|-----|
| 29.1   | Chip-specific AOI information..... | 627 |
| 29.1.1 | AOI signal assignment.....         | 627 |
| 29.2   | Introduction.....                  | 628 |
| 29.2.1 | Overview.....                      | 628 |

| Section number | Title                                                                                | Page |
|----------------|--------------------------------------------------------------------------------------|------|
| 29.2.2         | Features.....                                                                        | 629  |
| 29.2.3         | Modes of Operation.....                                                              | 630  |
| 29.3           | External Signal Description.....                                                     | 630  |
| 29.4           | Memory Map and Register Descriptions.....                                            | 630  |
| 29.4.1         | Boolean Function Term 0 and 1 Configuration Register for EVENTn (AOLx_BFCRT01n)..... | 632  |
| 29.4.2         | Boolean Function Term 2 and 3 Configuration Register for EVENTn (AOLx_BFCRT23n)..... | 633  |
| 29.5           | Functional Description.....                                                          | 635  |
| 29.5.1         | Configuration Examples for the Boolean Function Evaluation.....                      | 636  |
| 29.5.2         | AOI Timing Between Inputs and Outputs.....                                           | 637  |

## Chapter 30 Inter-Peripheral Crossbar Switch A (XBARA)

|        |                                                |     |
|--------|------------------------------------------------|-----|
| 30.1   | Chip-specific XBARA information.....           | 639 |
| 30.1.1 | XBARA input signal assignment.....             | 639 |
| 30.1.2 | XBARA signal output assignment.....            | 641 |
| 30.2   | Introduction.....                              | 642 |
| 30.2.1 | Overview.....                                  | 642 |
| 30.2.2 | Features.....                                  | 643 |
| 30.2.3 | Modes of Operation.....                        | 643 |
| 30.2.4 | Block Diagram.....                             | 643 |
| 30.3   | Signal Descriptions.....                       | 644 |
| 30.3.1 | XBAR_OUT[0:NUM_OUT-1] - MUX Outputs.....       | 645 |
| 30.3.2 | XBAR_IN[0:NUM_IN-1] - MUX Inputs.....          | 645 |
| 30.3.3 | DMA_REQ[n] - DMA Request Output(s).....        | 645 |
| 30.3.4 | DMA_ACK[n] - DMA Acknowledge Input(s).....     | 645 |
| 30.3.5 | INT_REQ[n] - Interrupt Request Output(s).....  | 645 |
| 30.4   | Memory Map and Register Descriptions.....      | 645 |
| 30.4.1 | Crossbar A Select Register 0 (XBARA_SEL0)..... | 647 |
| 30.4.2 | Crossbar A Select Register 1 (XBARA_SEL1)..... | 648 |
| 30.4.3 | Crossbar A Select Register 2 (XBARA_SEL2)..... | 648 |

| Section number | Title                                            | Page |
|----------------|--------------------------------------------------|------|
| 30.4.4         | Crossbar A Select Register 3 (XBARA_SEL3).....   | 649  |
| 30.4.5         | Crossbar A Select Register 4 (XBARA_SEL4).....   | 649  |
| 30.4.6         | Crossbar A Select Register 5 (XBARA_SEL5).....   | 650  |
| 30.4.7         | Crossbar A Select Register 6 (XBARA_SEL6).....   | 650  |
| 30.4.8         | Crossbar A Select Register 7 (XBARA_SEL7).....   | 651  |
| 30.4.9         | Crossbar A Select Register 8 (XBARA_SEL8).....   | 651  |
| 30.4.10        | Crossbar A Select Register 9 (XBARA_SEL9).....   | 652  |
| 30.4.11        | Crossbar A Select Register 10 (XBARA_SEL10)..... | 652  |
| 30.4.12        | Crossbar A Select Register 11 (XBARA_SEL11)..... | 653  |
| 30.4.13        | Crossbar A Select Register 12 (XBARA_SEL12)..... | 653  |
| 30.4.14        | Crossbar A Select Register 13 (XBARA_SEL13)..... | 654  |
| 30.4.15        | Crossbar A Select Register 14 (XBARA_SEL14)..... | 654  |
| 30.4.16        | Crossbar A Select Register 15 (XBARA_SEL15)..... | 655  |
| 30.4.17        | Crossbar A Select Register 16 (XBARA_SEL16)..... | 655  |
| 30.4.18        | Crossbar A Select Register 17 (XBARA_SEL17)..... | 656  |
| 30.4.19        | Crossbar A Select Register 18 (XBARA_SEL18)..... | 656  |
| 30.4.20        | Crossbar A Select Register 19 (XBARA_SEL19)..... | 657  |
| 30.4.21        | Crossbar A Select Register 20 (XBARA_SEL20)..... | 657  |
| 30.4.22        | Crossbar A Select Register 21 (XBARA_SEL21)..... | 658  |
| 30.4.23        | Crossbar A Select Register 22 (XBARA_SEL22)..... | 658  |
| 30.4.24        | Crossbar A Select Register 23 (XBARA_SEL23)..... | 659  |
| 30.4.25        | Crossbar A Select Register 24 (XBARA_SEL24)..... | 659  |
| 30.4.26        | Crossbar A Select Register 25 (XBARA_SEL25)..... | 660  |
| 30.4.27        | Crossbar A Select Register 26 (XBARA_SEL26)..... | 660  |
| 30.4.28        | Crossbar A Select Register 27 (XBARA_SEL27)..... | 661  |
| 30.4.29        | Crossbar A Select Register 28 (XBARA_SEL28)..... | 661  |
| 30.4.30        | Crossbar A Select Register 29 (XBARA_SEL29)..... | 662  |
| 30.4.31        | Crossbar A Control Register 0 (XBARA_CTRL0)..... | 662  |
| 30.4.32        | Crossbar A Control Register 1 (XBARA_CTRL1)..... | 664  |

| Section number | Title                            | Page |
|----------------|----------------------------------|------|
| 30.5           | Functional Description.....      | 666  |
| 30.5.1         | General.....                     | 666  |
| 30.5.2         | Functional Mode.....             | 667  |
| 30.6           | Resets.....                      | 667  |
| 30.7           | Clocks.....                      | 667  |
| 30.8           | Interrupts and DMA Requests..... | 667  |

## Chapter 31 Inter-Peripheral Crossbar Switch B (XBARB)

|        |                                                |     |
|--------|------------------------------------------------|-----|
| 31.1   | Chip-specific XBARB information.....           | 669 |
| 31.1.1 | XBARB signal input assignment.....             | 669 |
| 31.1.2 | XBARB signal output assignment.....            | 670 |
| 31.2   | Introduction.....                              | 671 |
| 31.3   | Memory Map and Register Descriptions.....      | 671 |
| 31.3.1 | Crossbar B Select Register 0 (XBARB_SEL0)..... | 672 |
| 31.3.2 | Crossbar B Select Register 1 (XBARB_SEL1)..... | 672 |
| 31.3.3 | Crossbar B Select Register 2 (XBARB_SEL2)..... | 673 |
| 31.3.4 | Crossbar B Select Register 3 (XBARB_SEL3)..... | 673 |
| 31.3.5 | Crossbar B Select Register 4 (XBARB_SEL4)..... | 674 |
| 31.3.6 | Crossbar B Select Register 5 (XBARB_SEL5)..... | 674 |
| 31.3.7 | Crossbar B Select Register 6 (XBARB_SEL6)..... | 675 |
| 31.3.8 | Crossbar B Select Register 7 (XBARB_SEL7)..... | 675 |

## Chapter 32 Multipurpose Clock Generator (MCG)

|        |                                         |     |
|--------|-----------------------------------------|-----|
| 32.1   | Chip-specific MCG information.....      | 677 |
| 32.1.1 | MCG oscillator clock input options..... | 677 |
| 32.2   | Introduction.....                       | 677 |
| 32.2.1 | Features.....                           | 678 |
| 32.2.2 | Modes of Operation.....                 | 680 |
| 32.3   | External Signal Description.....        | 681 |

| Section number | Title                                                      | Page |
|----------------|------------------------------------------------------------|------|
| 32.4           | Memory Map/Register Definition.....                        | 681  |
| 32.4.1         | MCG Control 1 Register (MCG_C1).....                       | 681  |
| 32.4.2         | MCG Control 2 Register (MCG_C2).....                       | 682  |
| 32.4.3         | MCG Control 3 Register (MCG_C3).....                       | 684  |
| 32.4.4         | MCG Control 4 Register (MCG_C4).....                       | 684  |
| 32.4.5         | MCG Control 5 Register (MCG_C5).....                       | 685  |
| 32.4.6         | MCG Control 6 Register (MCG_C6).....                       | 687  |
| 32.4.7         | MCG Status Register (MCG_S).....                           | 688  |
| 32.4.8         | MCG Status and Control Register (MCG_SC).....              | 689  |
| 32.4.9         | MCG Auto Trim Compare Value High Register (MCG_ATCVH)..... | 691  |
| 32.4.10        | MCG Auto Trim Compare Value Low Register (MCG_ATCVL).....  | 691  |
| 32.4.11        | MCG Control 8 Register (MCG_C8).....                       | 691  |
| 32.5           | Functional description.....                                | 692  |
| 32.5.1         | MCG mode state diagram.....                                | 692  |
| 32.5.2         | Low-power bit usage.....                                   | 697  |
| 32.5.3         | MCG Internal Reference Clocks.....                         | 697  |
| 32.5.4         | External Reference Clock.....                              | 697  |
| 32.5.5         | MCG Fixed Frequency Clock .....                            | 698  |
| 32.5.6         | MCG PLL clock .....                                        | 698  |
| 32.5.7         | MCG Auto TRIM (ATM).....                                   | 699  |
| 32.6           | Initialization / Application information.....              | 700  |
| 32.6.1         | MCG module initialization sequence.....                    | 700  |
| 32.6.2         | Using a 32.768 kHz reference.....                          | 702  |
| 32.6.3         | MCG mode switching.....                                    | 703  |

## Chapter 33 Oscillator (OSC)

|        |                                      |     |
|--------|--------------------------------------|-----|
| 33.1   | Chip-specific OSC information.....   | 707 |
| 33.1.1 | OSC modes of operation with MCG..... | 707 |
| 33.2   | Introduction.....                    | 707 |

| Section number | Title                                         | Page |
|----------------|-----------------------------------------------|------|
| 33.3           | Features and Modes.....                       | 707  |
| 33.4           | Block Diagram.....                            | 708  |
| 33.5           | OSC Signal Descriptions.....                  | 709  |
| 33.6           | External Crystal / Resonator Connections..... | 709  |
| 33.7           | External Clock Connections.....               | 710  |
| 33.8           | Memory Map/Register Definitions.....          | 711  |
| 33.8.1         | OSC Memory Map/Register Definition.....       | 711  |
| 33.9           | Functional Description.....                   | 713  |
| 33.9.1         | OSC module states.....                        | 713  |
| 33.9.2         | OSC module modes.....                         | 715  |
| 33.9.3         | Counter.....                                  | 717  |
| 33.9.4         | Reference clock pin requirements.....         | 717  |
| 33.10          | Reset.....                                    | 717  |
| 33.11          | Low power modes operation.....                | 718  |
| 33.12          | Interrupts.....                               | 718  |

## Chapter 34 Flash Memory Controller (FMC)

|        |                                                   |     |
|--------|---------------------------------------------------|-----|
| 34.1   | Chip-specific FMC information.....                | 719 |
| 34.1.1 | Number of masters.....                            | 719 |
| 34.1.2 | PFB1CR register.....                              | 719 |
| 34.2   | Introduction.....                                 | 719 |
| 34.2.1 | Overview.....                                     | 719 |
| 34.2.2 | Features.....                                     | 720 |
| 34.3   | Modes of operation.....                           | 720 |
| 34.4   | External signal description.....                  | 720 |
| 34.5   | Memory map and register descriptions.....         | 720 |
| 34.5.1 | Flash Access Protection Register (FMC_PFAPR)..... | 722 |
| 34.5.2 | Flash Bank 0 Control Register (FMC_PFB0CR).....   | 724 |
| 34.5.3 | FMC_Reserved.....                                 | 725 |

| Section number | Title                                           | Page |
|----------------|-------------------------------------------------|------|
| 34.6           | Functional description.....                     | 726  |
| 34.6.1         | Default configuration.....                      | 726  |
| 34.6.2         | Configuration options.....                      | 726  |
| 34.6.3         | Speculative reads.....                          | 726  |
| 34.7           | Initialization and application information..... | 727  |

## Chapter 35 Flash Memory Module (FTFE)

|         |                                            |     |
|---------|--------------------------------------------|-----|
| 35.1    | Introduction.....                          | 729 |
| 35.1.1  | Features.....                              | 729 |
| 35.1.2  | Block diagram.....                         | 730 |
| 35.1.3  | Glossary.....                              | 731 |
| 35.2    | External signal description.....           | 732 |
| 35.3    | Memory map and registers.....              | 733 |
| 35.3.1  | Flash configuration field description..... | 733 |
| 35.3.2  | Program flash 0 IFR map.....               | 733 |
| 35.3.3  | Register descriptions.....                 | 734 |
| 35.4    | Functional Description.....                | 743 |
| 35.4.1  | Flash Protection.....                      | 743 |
| 35.4.2  | Interrupts.....                            | 744 |
| 35.4.3  | Flash Operation in Low-Power Modes.....    | 744 |
| 35.4.4  | Functional modes of operation.....         | 745 |
| 35.4.5  | Flash memory reads and ignored writes..... | 745 |
| 35.4.6  | Flash Program and Erase.....               | 745 |
| 35.4.7  | FTFE Command Operations.....               | 745 |
| 35.4.8  | Margin Read Commands.....                  | 750 |
| 35.4.9  | Flash command descriptions.....            | 751 |
| 35.4.10 | Security.....                              | 767 |
| 35.5    | Reset Sequence.....                        | 770 |

## Chapter 36

| Section number | Title                                                           | Page |
|----------------|-----------------------------------------------------------------|------|
|                | <b>External Bus Interface (FlexBus)</b>                         |      |
| 36.1           | Chip-specific Flexbus information.....                          | 773  |
| 36.1.1         | FlexBus clocking.....                                           | 773  |
| 36.1.2         | FlexBus signal multiplexing.....                                | 773  |
| 36.1.3         | FlexBus CSCR0 reset value.....                                  | 775  |
| 36.1.4         | FlexBus Security.....                                           | 775  |
| 36.1.5         | FlexBus line transfers.....                                     | 775  |
| 36.2           | Introduction.....                                               | 775  |
| 36.2.1         | Definition.....                                                 | 775  |
| 36.2.2         | Features.....                                                   | 776  |
| 36.3           | Signal descriptions.....                                        | 776  |
| 36.4           | Memory Map/Register Definition.....                             | 778  |
| 36.4.1         | Chip Select Address Register (FB_CSAR <sub>n</sub> ).....       | 779  |
| 36.4.2         | Chip Select Mask Register (FB_CSMR <sub>n</sub> ).....          | 780  |
| 36.4.3         | Chip Select Control Register (FB_CSCR <sub>n</sub> ).....       | 781  |
| 36.4.4         | Chip Select port Multiplexing Control Register (FB_CSPMCR)..... | 784  |
| 36.5           | Functional description.....                                     | 785  |
| 36.5.1         | Use cases.....                                                  | 785  |
| 36.5.2         | Address comparison.....                                         | 785  |
| 36.5.3         | Address driven on address bus.....                              | 786  |
| 36.5.4         | Connecting address/data lines.....                              | 786  |
| 36.5.5         | Bit ordering.....                                               | 786  |
| 36.5.6         | Data transfer signals.....                                      | 787  |
| 36.5.7         | Signal transitions.....                                         | 787  |
| 36.5.8         | Data-byte alignment and physical connections.....               | 787  |
| 36.5.9         | Address/data bus multiplexing.....                              | 789  |
| 36.5.10        | Data transfer states.....                                       | 790  |
| 36.5.11        | FlexBus Timing Examples.....                                    | 791  |
| 36.5.12        | Burst cycles.....                                               | 809  |

| Section number | Title                                             | Page |
|----------------|---------------------------------------------------|------|
| 36.5.13        | Extended Transfer Start/Address Latch Enable..... | 818  |
| 36.5.14        | Bus errors.....                                   | 819  |
| 36.6           | Initialization/Application Information.....       | 820  |
| 36.6.1         | Initializing a chip-select.....                   | 820  |
| 36.6.2         | Reconfiguring a chip-select.....                  | 820  |

## Chapter 37 Cyclic Redundancy Check (CRC)

|        |                                           |     |
|--------|-------------------------------------------|-----|
| 37.1   | Introduction.....                         | 823 |
| 37.1.1 | Features.....                             | 823 |
| 37.1.2 | Block diagram.....                        | 823 |
| 37.1.3 | Modes of operation.....                   | 824 |
| 37.2   | Memory map and register descriptions..... | 824 |
| 37.2.1 | CRC Data register (CRC_DATA).....         | 825 |
| 37.2.2 | CRC Polynomial register (CRC_GPOLY).....  | 826 |
| 37.2.3 | CRC Control register (CRC_CTRL).....      | 826 |
| 37.3   | Functional description.....               | 827 |
| 37.3.1 | CRC initialization/reinitialization.....  | 827 |
| 37.3.2 | CRC calculations.....                     | 828 |
| 37.3.3 | Transpose feature.....                    | 829 |
| 37.3.4 | CRC result complement.....                | 831 |

## Chapter 38 Memory-Mapped Cryptographic Acceleration Unit (MMCAU)

|        |                                     |     |
|--------|-------------------------------------|-----|
| 38.1   | Introduction.....                   | 833 |
| 38.2   | CAU Block Diagram.....              | 833 |
| 38.3   | Overview.....                       | 835 |
| 38.4   | Features.....                       | 836 |
| 38.5   | Memory map/Register definition..... | 836 |
| 38.5.1 | Status Register (CAU_CASR).....     | 838 |
| 38.5.2 | Accumulator (CAU_CAA).....          | 839 |

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 38.5.3         | General Purpose Register (CAU_CAn).....     | 839  |
| 38.6           | Functional description.....                 | 840  |
| 38.6.1         | CAU programming model.....                  | 840  |
| 38.6.2         | CAU integrity checks.....                   | 842  |
| 38.6.3         | CAU commands.....                           | 844  |
| 38.7           | Application/initialization information..... | 851  |
| 38.7.1         | Code example.....                           | 851  |
| 38.7.2         | Assembler equate values.....                | 852  |

## Chapter 39 True Random Number Generator

|        |                                                            |     |
|--------|------------------------------------------------------------|-----|
| 39.1   | Standalone True Random Number Generator (SA-TRNG).....     | 855 |
| 39.1.1 | Standalone True Random Number Generator Block Diagram..... | 855 |
| 39.1.2 | TRNG Functional Description.....                           | 856 |
| 39.1.3 | SA-TRNG hardware functional description.....               | 857 |
| 39.1.4 | Another TRNG usage example.....                            | 908 |

## Chapter 40 16-bit SAR Analog-to-Digital Converter (ADC)

|        |                                          |     |
|--------|------------------------------------------|-----|
| 40.1   | Chip-specific ADC information.....       | 909 |
| 40.1.1 | ADC instantiation information.....       | 909 |
| 40.1.2 | DMA Support on ADC.....                  | 909 |
| 40.1.3 | ADC0 Connections/Channel Assignment..... | 909 |
| 40.1.4 | ADC Channels MUX Selection.....          | 912 |
| 40.1.5 | ADC Reference Options.....               | 912 |
| 40.1.6 | ADC triggers.....                        | 913 |
| 40.1.7 | Alternate clock.....                     | 913 |
| 40.1.8 | ADC low-power modes.....                 | 913 |
| 40.2   | Introduction.....                        | 914 |
| 40.2.1 | Features.....                            | 914 |
| 40.2.2 | Block diagram.....                       | 915 |

| Section number | Title                                                              | Page |
|----------------|--------------------------------------------------------------------|------|
| 40.3           | ADC signal descriptions.....                                       | 916  |
| 40.3.1         | Analog Power (VDDA).....                                           | 917  |
| 40.3.2         | Analog Ground (VSSA).....                                          | 917  |
| 40.3.3         | Voltage Reference Select.....                                      | 917  |
| 40.3.4         | Analog Channel Inputs (ADx).....                                   | 918  |
| 40.3.5         | Differential Analog Channel Inputs (DADx).....                     | 918  |
| 40.4           | Memory map and register definitions.....                           | 918  |

| 40.6           | Initialization information.....                                    | 957  |
| 40.6.1         | ADC module initialization example.....                             | 958  |
| 40.7           | Application information.....                                       | 960  |
| 40.7.1         | External pins and routing.....                                     | 960  |
| 40.7.2         | Sources of error.....                                              | 962  |

## Chapter 41

### 12-bit 5MSPS Analog-to-Digital Converter (HSADC)

|        |                                                 |     |
|--------|-------------------------------------------------|-----|
| 41.1   | Chip-specific 12-bit SAR HSADC information..... | 967 |
| 41.1.1 | HSADC instantiation.....                        | 967 |
| 41.1.2 | HSADC interconnect assignments.....             | 967 |
| 41.1.3 | HSADC clock sources.....                        | 973 |
| 41.1.4 | Input triggering via PDB.....                   | 973 |
| 41.2   | Introduction.....                               | 974 |
| 41.2.1 | Overview.....                                   | 974 |
| 41.2.2 | Features.....                                   | 974 |
| 41.2.3 | Modes of Operation.....                         | 976 |

| Section number | Title                                                            | Page |
|----------------|------------------------------------------------------------------|------|
| 41.2.4         | Block Diagram.....                                               | 976  |
| 41.3           | Memory Map and Registers.....                                    | 977  |
| 41.3.1         | HSADC Control Register 1 (HSADCx_CTRL1).....                     | 985  |
| 41.3.2         | HSADC Control Register 2 (HSADCx_CTRL2).....                     | 988  |
| 41.3.3         | HSADC Zero Crossing Control 1 Register (HSADCx_ZXCTRL1).....     | 991  |
| 41.3.4         | HSADC Zero Crossing Control 2 Register (HSADCx_ZXCTRL2).....     | 993  |
| 41.3.5         | HSADC Channel List Register 1 (HSADCx_CLIST1).....               | 994  |
| 41.3.6         | HSADC Channel List Register 2 (HSADCx_CLIST2).....               | 996  |
| 41.3.7         | HSADC Channel List Register 3 (HSADCx_CLIST3).....               | 998  |
| 41.3.8         | HSADC Channel List Register 4 (HSADCx_CLIST4).....               | 1000 |
| 41.3.9         | HSADC Sample Disable Register (HSADCx_SDIS).....                 | 1002 |
| 41.3.10        | HSADC Status Register (HSADCx_STAT).....                         | 1003 |
| 41.3.11        | HSADC Ready Register (HSADCx_RDY).....                           | 1006 |
| 41.3.12        | HSADC Low Limit Status Register (HSADCx_LOLIMSTAT).....          | 1006 |
| 41.3.13        | HSADC High Limit Status Register (HSADCx_HILIMSTAT).....         | 1007 |
| 41.3.14        | HSADC Zero Crossing Status Register (HSADCx_ZXSTAT).....         | 1007 |
| 41.3.15        | HSADC Result Registers with sign extension (HSADCx_RSLTn).....   | 1008 |
| 41.3.16        | HSADC Low Limit Registers (HSADCx_LOLIMn).....                   | 1009 |
| 41.3.17        | HSADC High Limit Registers (HSADCx_HILIMn).....                  | 1010 |
| 41.3.18        | HSADC Offset Register (HSADCx_OFFSTn).....                       | 1010 |
| 41.3.19        | HSADC Power Control Register (HSADCx_PWR).....                   | 1011 |
| 41.3.20        | HSADC Scan Control Register (HSADCx_SCTRL).....                  | 1014 |
| 41.3.21        | HSADC Power Control Register 2 (HSADCx_PWR2).....                | 1015 |
| 41.3.22        | HSADC Control Register 3 (HSADCx_CTRL3).....                     | 1015 |
| 41.3.23        | HSADC Scan Interrupt Enable Register (HSADCx_SCINTEN).....       | 1016 |
| 41.3.24        | HSADC Sampling Time Configuration Register (HSADCx_SAMPTIM)..... | 1017 |
| 41.3.25        | HSADCs Calibration Configuration (HSADCx_CALIB).....             | 1017 |
| 41.3.26        | Calibration Values for ADCA Register (HSADCx_CALVAL_A).....      | 1019 |
| 41.3.27        | Calibration Values for ADCB Register (HSADCx_CALVAL_B).....      | 1020 |

| Section number | Title                                                      | Page |
|----------------|------------------------------------------------------------|------|
| 41.3.28        | MUX6_7 Selection Controls Register (HSADCx_MUX67_SEL)..... | 1021 |
| 41.4           | Functional Description.....                                | 1022 |
| 41.4.1         | HSADC Sample Conversion Operating Modes.....               | 1025 |
| 41.4.2         | HSADC Calibration.....                                     | 1030 |
| 41.4.3         | HSADC Data Processing.....                                 | 1030 |
| 41.4.4         | Sequential versus parallel sampling.....                   | 1032 |
| 41.4.5         | Scan Sequencing.....                                       | 1033 |
| 41.4.6         | Power Management.....                                      | 1034 |
| 41.5           | Clocks.....                                                | 1037 |
| 41.6           | Interrupts.....                                            | 1038 |
| 41.7           | Timing Specifications.....                                 | 1040 |

## Chapter 42 Comparator (CMP)

|        |                                            |      |
|--------|--------------------------------------------|------|
| 42.1   | Chip-specific CMP information.....         | 1041 |
| 42.1.1 | CMP instantiation information.....         | 1041 |
| 42.1.2 | CMP Signal Assignments.....                | 1041 |
| 42.1.3 | CMP voltage references.....                | 1044 |
| 42.1.4 | CMP external references.....               | 1044 |
| 42.1.5 | External window/sample input.....          | 1044 |
| 42.2   | Introduction.....                          | 1045 |
| 42.2.1 | CMP features.....                          | 1045 |
| 42.2.2 | 6-bit DAC key features.....                | 1046 |
| 42.2.3 | ANMUX key features.....                    | 1046 |
| 42.2.4 | CMP, DAC and ANMUX diagram.....            | 1046 |
| 42.2.5 | CMP block diagram.....                     | 1047 |
| 42.3   | Memory map/register definitions.....       | 1049 |
| 42.3.1 | CMP Control Register 0 (CMPx_CR0).....     | 1050 |
| 42.3.2 | CMP Control Register 1 (CMPx_CR1).....     | 1050 |
| 42.3.3 | CMP Filter Period Register (CMPx_FPR)..... | 1052 |

| Section number | Title                                           | Page |
|----------------|-------------------------------------------------|------|
| 42.3.4         | CMP Status and Control Register (CMPx_SCR)..... | 1052 |
| 42.3.5         | DAC Control Register (CMPx_DACCR).....          | 1053 |
| 42.3.6         | MUX Control Register (CMPx_MUXCR).....          | 1054 |
| 42.4           | Functional description.....                     | 1055 |
| 42.4.1         | CMP functional modes.....                       | 1055 |
| 42.4.2         | Power modes.....                                | 1065 |
| 42.4.3         | Startup and operation.....                      | 1066 |
| 42.4.4         | Low-pass filter.....                            | 1066 |
| 42.5           | CMP interrupts.....                             | 1069 |
| 42.6           | DMA support.....                                | 1069 |
| 42.7           | CMP Asynchronous DMA support.....               | 1069 |
| 42.8           | Digital-to-analog converter.....                | 1070 |
| 42.9           | DAC functional description.....                 | 1070 |
| 42.9.1         | Voltage reference source select.....            | 1070 |
| 42.10          | DAC resets.....                                 | 1071 |
| 42.11          | DAC clocks.....                                 | 1071 |
| 42.12          | DAC interrupts.....                             | 1071 |
| 42.13          | CMP Trigger Mode.....                           | 1071 |

## Chapter 43 12-bit Digital-to-Analog Converter (DAC)

|        |                                           |      |
|--------|-------------------------------------------|------|
| 43.1   | Chip-specific DAC information.....        | 1073 |
| 43.1.1 | 12-bit DAC Instantiation Information..... | 1073 |
| 43.1.2 | 12-bit DAC Output.....                    | 1073 |
| 43.1.3 | 12-bit DAC Reference.....                 | 1073 |
| 43.2   | Introduction.....                         | 1074 |
| 43.3   | Features.....                             | 1074 |
| 43.4   | Block diagram.....                        | 1074 |
| 43.5   | Memory map/register definition.....       | 1075 |
| 43.5.1 | DAC Data Low Register (DACx_DATnL).....   | 1077 |

| Section number | Title                                                              | Page |
|----------------|--------------------------------------------------------------------|------|
| 43.5.2         | DAC Data High Register (DAC <sub>x</sub> _DAT <sub>n</sub> H)..... | 1077 |
| 43.5.3         | DAC Status Register (DAC <sub>x</sub> _SR).....                    | 1078 |
| 43.5.4         | DAC Control Register (DAC <sub>x</sub> _C0).....                   | 1079 |
| 43.5.5         | DAC Control Register 1 (DAC <sub>x</sub> _C1).....                 | 1080 |
| 43.5.6         | DAC Control Register 2 (DAC <sub>x</sub> _C2).....                 | 1081 |
| 43.6           | Functional description.....                                        | 1081 |
| 43.6.1         | DAC data buffer operation.....                                     | 1081 |
| 43.6.2         | DMA operation.....                                                 | 1083 |
| 43.6.3         | Resets.....                                                        | 1083 |
| 43.6.4         | Low-Power mode operation.....                                      | 1083 |

## Chapter 44 FlexTimer Module (FTM)

|         |                                                     |      |
|---------|-----------------------------------------------------|------|
| 44.1    | Chip-specific FTM information.....                  | 1085 |
| 44.1.1  | Instantiation Information.....                      | 1085 |
| 44.1.2  | External Clock Options.....                         | 1085 |
| 44.1.3  | Fixed frequency clock.....                          | 1086 |
| 44.1.4  | FTM Interrupts.....                                 | 1086 |
| 44.1.5  | FTM Fault Detection Inputs KV5x.....                | 1086 |
| 44.1.6  | FTM Hardware Triggers KV5x.....                     | 1086 |
| 44.1.7  | Input capture options for FTM module instances..... | 1087 |
| 44.1.8  | FTM Hall sensor support.....                        | 1087 |
| 44.1.9  | FTM modulation implementation.....                  | 1088 |
| 44.1.10 | FTM output triggers for other modules.....          | 1089 |
| 44.1.11 | FTM Global Time Base.....                           | 1091 |
| 44.1.12 | FTM BDM and debug halt mode.....                    | 1091 |
| 44.2    | Introduction.....                                   | 1092 |
| 44.2.1  | FlexTimer philosophy.....                           | 1092 |
| 44.2.2  | Features.....                                       | 1093 |
| 44.2.3  | Modes of operation.....                             | 1094 |

| Section number | Title                                                                 | Page |
|----------------|-----------------------------------------------------------------------|------|
| 44.2.4         | Block diagram.....                                                    | 1095 |
| 44.3           | FTM signal descriptions.....                                          | 1097 |
| 44.4           | Memory map and register definition.....                               | 1097 |
| 44.4.1         | Memory map.....                                                       | 1097 |
| 44.4.2         | Register descriptions.....                                            | 1098 |
| 44.4.3         | Status And Control (FTM <sub>x</sub> _SC).....                        | 1104 |
| 44.4.4         | Counter (FTM <sub>x</sub> _CNT).....                                  | 1105 |
| 44.4.5         | Modulo (FTM <sub>x</sub> _MOD).....                                   | 1106 |
| 44.4.6         | Channel (n) Status And Control (FTM <sub>x</sub> _CnSC).....          | 1107 |
| 44.4.7         | Channel (n) Value (FTM <sub>x</sub> _CnV).....                        | 1110 |
| 44.4.8         | Counter Initial Value (FTM <sub>x</sub> _CNTIN).....                  | 1110 |
| 44.4.9         | Capture And Compare Status (FTM <sub>x</sub> _STATUS).....            | 1111 |
| 44.4.10        | Features Mode Selection (FTM <sub>x</sub> _MODE).....                 | 1113 |
| 44.4.11        | Synchronization (FTM <sub>x</sub> _SYNC).....                         | 1115 |
| 44.4.12        | Initial State For Channels Output (FTM <sub>x</sub> _OUTINIT).....    | 1117 |
| 44.4.13        | Output Mask (FTM <sub>x</sub> _OUTMASK).....                          | 1118 |
| 44.4.14        | Function For Linked Channels (FTM <sub>x</sub> _COMBINE).....         | 1120 |
| 44.4.15        | Deadtime Insertion Control (FTM <sub>x</sub> _DEADTIME).....          | 1125 |
| 44.4.16        | FTM External Trigger (FTM <sub>x</sub> _EXTTRIG).....                 | 1126 |
| 44.4.17        | Channels Polarity (FTM <sub>x</sub> _POL).....                        | 1128 |
| 44.4.18        | Fault Mode Status (FTM <sub>x</sub> _FMS).....                        | 1130 |
| 44.4.19        | Input Capture Filter Control (FTM <sub>x</sub> _FILTER).....          | 1132 |
| 44.4.20        | Fault Control (FTM <sub>x</sub> _FLTCTRL).....                        | 1133 |
| 44.4.21        | Quadrature Decoder Control And Status (FTM <sub>x</sub> _QDCTRL)..... | 1136 |
| 44.4.22        | Configuration (FTM <sub>x</sub> _CONF).....                           | 1138 |
| 44.4.23        | FTM Fault Input Polarity (FTM <sub>x</sub> _FLTPOL).....              | 1139 |
| 44.4.24        | Synchronization Configuration (FTM <sub>x</sub> _SYNCONF).....        | 1140 |
| 44.4.25        | FTM Inverting Control (FTM <sub>x</sub> _INVCTRL).....                | 1142 |
| 44.4.26        | FTM Software Output Control (FTM <sub>x</sub> _SWOCTRL).....          | 1143 |

| Section number | Title                                         | Page |
|----------------|-----------------------------------------------|------|
| 44.4.27        | FTM PWM Load (FTM <sub>x</sub> _PWMLOAD)..... | 1146 |
| 44.5           | Functional description.....                   | 1147 |
| 44.5.1         | Clock source.....                             | 1148 |
| 44.5.2         | Prescaler.....                                | 1149 |
| 44.5.3         | Counter.....                                  | 1149 |
| 44.5.4         | Input Capture mode.....                       | 1155 |
| 44.5.5         | Output Compare mode.....                      | 1159 |
| 44.5.6         | Edge-Aligned PWM (EPWM) mode.....             | 1160 |
| 44.5.7         | Center-Aligned PWM (CPWM) mode.....           | 1162 |
| 44.5.8         | Combine mode.....                             | 1164 |
| 44.5.9         | Complementary mode.....                       | 1171 |
| 44.5.10        | Registers updated from write buffers.....     | 1172 |
| 44.5.11        | PWM synchronization.....                      | 1174 |
| 44.5.12        | Inverting.....                                | 1190 |
| 44.5.13        | Software output control.....                  | 1191 |
| 44.5.14        | Deadtime insertion.....                       | 1193 |
| 44.5.15        | Output mask.....                              | 1196 |
| 44.5.16        | Fault control.....                            | 1196 |
| 44.5.17        | Polarity control.....                         | 1200 |
| 44.5.18        | Initialization.....                           | 1201 |
| 44.5.19        | Features priority.....                        | 1201 |
| 44.5.20        | Channel trigger output.....                   | 1202 |
| 44.5.21        | Initialization trigger.....                   | 1203 |
| 44.5.22        | Capture Test mode.....                        | 1206 |
| 44.5.23        | DMA.....                                      | 1206 |
| 44.5.24        | Dual Edge Capture mode.....                   | 1207 |
| 44.5.25        | Quadrature Decoder mode.....                  | 1215 |
| 44.5.26        | BDM mode.....                                 | 1220 |
| 44.5.27        | Intermediate load.....                        | 1221 |

| Section number | Title                         | Page |
|----------------|-------------------------------|------|
| 44.5.28        | Global time base (GTB).....   | 1223 |
| 44.6           | Reset overview.....           | 1225 |
| 44.7           | FTM Interrupts.....           | 1226 |
| 44.7.1         | Timer Overflow Interrupt..... | 1227 |
| 44.7.2         | Channel (n) Interrupt.....    | 1227 |
| 44.7.3         | Fault Interrupt.....          | 1227 |
| 44.8           | Initialization Procedure..... | 1227 |

## Chapter 45

### Low-Power Timer (LPTMR)

|        |                                                                        |      |
|--------|------------------------------------------------------------------------|------|
| 45.1   | Chip-specific LPTMR information.....                                   | 1229 |
| 45.1.1 | Low power timer instantiations.....                                    | 1229 |
| 45.1.2 | LPTMR prescaler/glitch filter clocking options.....                    | 1229 |
| 45.1.3 | LPTMR pulse counter input options.....                                 | 1230 |
| 45.2   | Introduction.....                                                      | 1230 |
| 45.2.1 | Features.....                                                          | 1230 |
| 45.2.2 | Modes of operation.....                                                | 1231 |
| 45.3   | LPTMR signal descriptions.....                                         | 1231 |
| 45.3.1 | Detailed signal descriptions.....                                      | 1231 |
| 45.4   | Memory map and register definition.....                                | 1232 |
| 45.4.1 | Low Power Timer Control Status Register (LPTMR <sub>x</sub> _CSR)..... | 1232 |
| 45.4.2 | Low Power Timer Prescale Register (LPTMR <sub>x</sub> _PSR).....       | 1233 |
| 45.4.3 | Low Power Timer Compare Register (LPTMR <sub>x</sub> _CMR).....        | 1235 |
| 45.4.4 | Low Power Timer Counter Register (LPTMR <sub>x</sub> _CNR).....        | 1235 |
| 45.5   | Functional description.....                                            | 1236 |
| 45.5.1 | LPTMR power and reset.....                                             | 1236 |
| 45.5.2 | LPTMR clocking.....                                                    | 1236 |
| 45.5.3 | LPTMR prescaler/glitch filter.....                                     | 1236 |
| 45.5.4 | LPTMR compare.....                                                     | 1238 |
| 45.5.5 | LPTMR counter.....                                                     | 1238 |

| Section number | Title                       | Page |
|----------------|-----------------------------|------|
| 45.5.6         | LPTMR hardware trigger..... | 1239 |
| 45.5.7         | LPTMR interrupt.....        | 1239 |

## Chapter 46 Programmable Delay Block (PDB)

|         |                                                              |      |
|---------|--------------------------------------------------------------|------|
| 46.1    | Chip-specific PDB information.....                           | 1241 |
| 46.1.1  | PDB Instantiation.....                                       | 1241 |
| 46.1.2  | PDB's DAC External Trigger Input Connections.....            | 1244 |
| 46.1.3  | Pulse-Out Connection.....                                    | 1244 |
| 46.1.4  | Pulse-Out Enable Register Implementation.....                | 1244 |
| 46.2    | Introduction.....                                            | 1244 |
| 46.2.1  | Features.....                                                | 1244 |
| 46.2.2  | Implementation.....                                          | 1245 |
| 46.2.3  | Back-to-back acknowledgment connections.....                 | 1246 |
| 46.2.4  | DAC External Trigger Input Connections.....                  | 1246 |
| 46.2.5  | Block diagram.....                                           | 1246 |
| 46.2.6  | Modes of operation.....                                      | 1248 |
| 46.3    | PDB signal descriptions.....                                 | 1248 |
| 46.4    | Memory map and register definition.....                      | 1248 |
| 46.4.1  | Status and Control register (PDBx_SC).....                   | 1250 |
| 46.4.2  | Modulus register (PDBx_MOD).....                             | 1253 |
| 46.4.3  | Counter register (PDBx_CNT).....                             | 1253 |
| 46.4.4  | Interrupt Delay register (PDBx_IDLY).....                    | 1254 |
| 46.4.5  | Channel n Control register 1 (PDBx_CHnC1).....               | 1254 |
| 46.4.6  | Channel n Status register (PDBx_CHnS).....                   | 1255 |
| 46.4.7  | Channel n Delay 0 register (PDBx_CHnDLY0).....               | 1256 |
| 46.4.8  | Channel n Delay 1 register (PDBx_CHnDLY1).....               | 1257 |
| 46.4.9  | DAC Interval Trigger n Control register (PDBx_DACINTCn)..... | 1257 |
| 46.4.10 | DAC Interval n register (PDBx_DACINTn).....                  | 1258 |
| 46.4.11 | Pulse-Out n Enable register (PDBx_POEN).....                 | 1259 |

| Section number | Title                                                                             | Page |
|----------------|-----------------------------------------------------------------------------------|------|
| 46.4.12        | Pulse-Out n Delay register (PDBx_PO $n$ DLY).....                                 | 1259 |
| 46.5           | Functional description.....                                                       | 1260 |
| 46.5.1         | PDB pre-trigger and trigger outputs.....                                          | 1260 |
| 46.5.2         | PDB trigger input source selection.....                                           | 1262 |
| 46.5.3         | DAC interval trigger outputs.....                                                 | 1262 |
| 46.5.4         | Pulse-Out's.....                                                                  | 1263 |
| 46.5.5         | Updating the delay registers.....                                                 | 1264 |
| 46.5.6         | Interrupts.....                                                                   | 1266 |
| 46.5.7         | DMA.....                                                                          | 1266 |
| 46.6           | Application information.....                                                      | 1266 |
| 46.6.1         | Impact of using the prescaler and multiplication factor on timing resolution..... | 1266 |

## Chapter 47

### Quadrature Encoder/Decoder (ENC)

|         |                                       |      |
|---------|---------------------------------------|------|
| 47.1    | Chip-specific ENC information.....    | 1269 |
| 47.1.1  | ENC signal assignment.....            | 1269 |
| 47.1.2  | Clocks.....                           | 1269 |
| 47.2    | Introduction.....                     | 1270 |
| 47.2.1  | Features.....                         | 1270 |
| 47.2.2  | Decoder Block Diagram.....            | 1270 |
| 47.2.3  | System Block Diagram.....             | 1271 |
| 47.2.4  | Glitch Filter.....                    | 1271 |
| 47.2.5  | Edge Detect State Machine.....        | 1272 |
| 47.2.6  | Position Counter.....                 | 1272 |
| 47.2.7  | Position Difference Counter.....      | 1273 |
| 47.2.8  | Position Difference Counter Hold..... | 1273 |
| 47.2.9  | Revolution Counter.....               | 1273 |
| 47.2.10 | Pulse Accumulator Functionality.....  | 1273 |
| 47.2.11 | Watchdog Timer.....                   | 1273 |
| 47.3    | Signal Descriptions.....              | 1274 |

| Section number | Title                                                | Page |
|----------------|------------------------------------------------------|------|
| 47.3.1         | Phase A Input (PHASEA).....                          | 1274 |
| 47.3.2         | Phase B Input (PHASEB).....                          | 1274 |
| 47.3.3         | Index Input (INDEX).....                             | 1274 |
| 47.3.4         | Home Switch Input (HOME).....                        | 1275 |
| 47.3.5         | Trigger Input (TRIGGER).....                         | 1275 |
| 47.3.6         | Position Match Output (POSMATCH).....                | 1275 |
| 47.4           | Memory Map and Registers.....                        | 1276 |
| 47.4.1         | Control Register (ENC_CTRL).....                     | 1277 |
| 47.4.2         | Input Filter Register (ENC_FILT).....                | 1279 |
| 47.4.3         | Watchdog Timeout Register (ENC_WTR).....             | 1280 |
| 47.4.4         | Position Difference Counter Register (ENC_POSD)..... | 1281 |
| 47.4.5         | Position Difference Hold Register (ENC_POSDH).....   | 1281 |
| 47.4.6         | Revolution Counter Register (ENC_REV).....           | 1282 |
| 47.4.7         | Revolution Hold Register (ENC_REVH).....             | 1282 |
| 47.4.8         | Upper Position Counter Register (ENC_UPOS).....      | 1282 |
| 47.4.9         | Lower Position Counter Register (ENC_LPOS).....      | 1283 |
| 47.4.10        | Upper Position Hold Register (ENC_UPOSH).....        | 1283 |
| 47.4.11        | Lower Position Hold Register (ENC_LPOSH).....        | 1283 |
| 47.4.12        | Upper Initialization Register (ENC_UINIT).....       | 1284 |
| 47.4.13        | Lower Initialization Register (ENC_LINIT).....       | 1284 |
| 47.4.14        | Input Monitor Register (ENC_IMR).....                | 1285 |
| 47.4.15        | Test Register (ENC_TST).....                         | 1286 |
| 47.4.16        | Control 2 Register (ENC_CTRL2).....                  | 1287 |
| 47.4.17        | Upper Modulus Register (ENC_UMOD).....               | 1289 |
| 47.4.18        | Lower Modulus Register (ENC_LMOD).....               | 1289 |
| 47.4.19        | Upper Position Compare Register (ENC_UCOMP).....     | 1290 |
| 47.4.20        | Lower Position Compare Register (ENC_LCOMP).....     | 1290 |
| 47.5           | Functional Description.....                          | 1290 |
| 47.5.1         | Positive versus Negative Direction.....              | 1291 |

| Section number | Title                                             | Page |
|----------------|---------------------------------------------------|------|
| 47.5.2         | Prescaler for Slow or Fast Speed Measurement..... | 1291 |
| 47.5.3         | Holding Registers and Initializing Registers..... | 1291 |
| 47.6           | Resets.....                                       | 1292 |
| 47.7           | Clocks.....                                       | 1292 |
| 47.8           | Interrupts.....                                   | 1292 |

## Chapter 48

### Enhanced Flex Pulse Width Modulator (eFlexPWM)

|        |                                                                      |      |
|--------|----------------------------------------------------------------------|------|
| 48.1   | Chip-specific eFlexPWM information.....                              | 1293 |
| 48.1.1 | PWM0 with nano-edge placement.....                                   | 1293 |
| 48.1.2 | PWM1 without nano-edge placement.....                                | 1295 |
| 48.2   | Introduction.....                                                    | 1296 |
| 48.2.1 | Features.....                                                        | 1296 |
| 48.2.2 | Modes of Operation.....                                              | 1297 |
| 48.2.3 | Block Diagram.....                                                   | 1298 |
| 48.3   | Signal Descriptions.....                                             | 1300 |
| 48.3.1 | PWMx_A[n] and PWMx_B[n] - External PWM Output Pair.....              | 1300 |
| 48.3.2 | PWMx_X[n] - Auxiliary PWM Output signal.....                         | 1300 |
| 48.3.3 | FAULT[n] - Fault Inputs.....                                         | 1301 |
| 48.3.4 | PWMx_EXT_SYNC[n] - External Synchronization Signal.....              | 1301 |
| 48.3.5 | EXT_FORCE - External Output Force Signal.....                        | 1301 |
| 48.3.6 | PWMx_EXT_A[n] and PWMx_EXT_B[n] - Alternate PWM Control Signals..... | 1301 |
| 48.3.7 | PWMx_OUT_TRIG0 and PWMx_OUT_TRIG1 - Output Triggers.....             | 1301 |
| 48.3.8 | EXT_CLK - External Clock Signal.....                                 | 1302 |
| 48.4   | Memory Map and Registers.....                                        | 1302 |
| 48.4.1 | Counter Register (PWMx_SMnCNT).....                                  | 1318 |
| 48.4.2 | Initial Count Register (PWMx_SMnINIT).....                           | 1318 |
| 48.4.3 | Control 2 Register (PWMx_SMnCTRL2).....                              | 1319 |
| 48.4.4 | Control Register (PWMx_SMnCTRL).....                                 | 1321 |
| 48.4.5 | Value Register 0 (PWMx_SMnVAL0).....                                 | 1323 |

| Section number | Title                                                   | Page |
|----------------|---------------------------------------------------------|------|
| 48.4.6         | Fractional Value Register 1 (PWMx_SMnFRACVAL1).....     | 1324 |
| 48.4.7         | Value Register 1 (PWMx_SMnVAL1).....                    | 1325 |
| 48.4.8         | Fractional Value Register 2 (PWMx_SMnFRACVAL2).....     | 1325 |
| 48.4.9         | Value Register 2 (PWMx_SMnVAL2).....                    | 1326 |
| 48.4.10        | Fractional Value Register 3 (PWMx_SMnFRACVAL3).....     | 1326 |
| 48.4.11        | Value Register 3 (PWMx_SMnVAL3).....                    | 1327 |
| 48.4.12        | Fractional Value Register 4 (PWMx_SMnFRACVAL4).....     | 1327 |
| 48.4.13        | Value Register 4 (PWMx_SMnVAL4).....                    | 1328 |
| 48.4.14        | Fractional Value Register 5 (PWMx_SMnFRACVAL5).....     | 1328 |
| 48.4.15        | Value Register 5 (PWMx_SMnVAL5).....                    | 1329 |
| 48.4.16        | Fractional Control Register (PWMx_SMnFRCTRL).....       | 1329 |
| 48.4.17        | Output Control Register (PWMx_SMnOCTRL).....            | 1331 |
| 48.4.18        | Status Register (PWMx_SMnSTS).....                      | 1333 |
| 48.4.19        | Interrupt Enable Register (PWMx_SMnINTEN).....          | 1334 |
| 48.4.20        | DMA Enable Register (PWMx_SMnDMAEN).....                | 1336 |
| 48.4.21        | Output Trigger Control Register (PWMx_SMnTCTRL).....    | 1337 |
| 48.4.22        | Fault Disable Mapping Register 0 (PWMx_SMnDISMAP0)..... | 1339 |
| 48.4.23        | Deadtime Count Register 0 (PWMx_SMnDTCNT0).....         | 1340 |
| 48.4.24        | Deadtime Count Register 1 (PWMx_SMnDTCNT1).....         | 1340 |
| 48.4.25        | Capture Control A Register (PWMx_SMnCPTCTRLA).....      | 1341 |
| 48.4.26        | Capture Compare A Register (PWMx_SMnCPTCOMPA).....      | 1343 |
| 48.4.27        | Capture Control B Register (PWMx_SMnCPTCTRLB).....      | 1343 |
| 48.4.28        | Capture Compare B Register (PWMx_SMnCPTCOMPB).....      | 1345 |
| 48.4.29        | Capture Control X Register (PWMx_SMnCPTCTRLX).....      | 1346 |
| 48.4.30        | Capture Compare X Register (PWMx_SMnCPTCOMPX).....      | 1347 |
| 48.4.31        | Capture Value 0 Register (PWMx_SMnCVAL0).....           | 1348 |
| 48.4.32        | Capture Value 0 Cycle Register (PWMx_SMnCVAL0CYC).....  | 1348 |
| 48.4.33        | Capture Value 1 Register (PWMx_SMnCVAL1).....           | 1349 |
| 48.4.34        | Capture Value 1 Cycle Register (PWMx_SMnCVAL1CYC).....  | 1349 |

| Section number | Title                                                     | Page |
|----------------|-----------------------------------------------------------|------|
| 48.4.35        | Capture Value 2 Register (PWMx_SMnCVAL2).....             | 1349 |
| 48.4.36        | Capture Value 2 Cycle Register (PWMx_SMnCVAL2CYC).....    | 1350 |
| 48.4.37        | Capture Value 3 Register (PWMx_SMnCVAL3).....             | 1350 |
| 48.4.38        | Capture Value 3 Cycle Register (PWMx_SMnCVAL3CYC).....    | 1351 |
| 48.4.39        | Capture Value 4 Register (PWMx_SMnCVAL4).....             | 1351 |
| 48.4.40        | Capture Value 4 Cycle Register (PWMx_SMnCVAL4CYC).....    | 1351 |
| 48.4.41        | Capture Value 5 Register (PWMx_SMnCVAL5).....             | 1352 |
| 48.4.42        | Capture Value 5 Cycle Register (PWMx_SMnCVAL5CYC).....    | 1352 |
| 48.4.43        | Output Enable Register (PWMx_OUTEN).....                  | 1353 |
| 48.4.44        | Mask Register (PWMx_MASK).....                            | 1354 |
| 48.4.45        | Software Controlled Output Register (PWMx_SWCOUT).....    | 1355 |
| 48.4.46        | PWM Source Select Register (PWMx_DTSSRCSEL).....          | 1356 |
| 48.4.47        | Master Control Register 0 (PWMx_MCTRL0).....              | 1358 |
| 48.4.48        | Master Control Register 1 (PWMx_MCTRL1).....              | 1359 |
| 48.4.49        | Fault Control Register (PWMx_FCTRLn).....                 | 1360 |
| 48.4.50        | Fault Status Register (PWMx_FSTS <sub>n</sub> ).....      | 1361 |
| 48.4.51        | Fault Filter Register (PWMx_FFILT <sub>n</sub> ).....     | 1362 |
| 48.4.52        | Fault Test Register (PWMx_FTST <sub>n</sub> ).....        | 1364 |
| 48.4.53        | Fault Control 2 Register (PWMx_FCTRL2 <sub>n</sub> )..... | 1364 |
| 48.5           | Functional Description.....                               | 1365 |
| 48.5.1         | PWM Capabilities.....                                     | 1365 |
| 48.5.2         | Functional Details.....                                   | 1374 |
| 48.5.3         | PWM Generator Loading.....                                | 1394 |
| 48.6           | Resets.....                                               | 1397 |
| 48.7           | Interrupts.....                                           | 1398 |
| 48.8           | DMA.....                                                  | 1399 |

## Chapter 49

### Periodic Interrupt Timer (PIT)

|      |                                    |      |
|------|------------------------------------|------|
| 49.1 | Chip-specific PIT information..... | 1403 |
|------|------------------------------------|------|

| Section number | Title                                                      | Page |
|----------------|------------------------------------------------------------|------|
| 49.1.1         | PIT Instantiations.....                                    | 1403 |
| 49.1.2         | PIT/DMA Periodic Trigger Assignments .....                 | 1403 |
| 49.1.3         | PIT/ADC Triggers.....                                      | 1403 |
| 49.1.4         | PIT Trigger Output Assignments.....                        | 1403 |
| 49.2           | Introduction.....                                          | 1404 |
| 49.2.1         | Block diagram.....                                         | 1404 |
| 49.2.2         | Features.....                                              | 1405 |
| 49.3           | Signal description.....                                    | 1405 |
| 49.4           | Memory map/register description.....                       | 1406 |
| 49.4.1         | PIT Module Control Register (PIT_MCR).....                 | 1406 |
| 49.4.2         | PIT Upper Lifetime Timer Register (PIT_LTMR64H).....       | 1408 |
| 49.4.3         | PIT Lower Lifetime Timer Register (PIT_LTMR64L).....       | 1408 |
| 49.4.4         | Timer Load Value Register (PIT_LDVAL <sub>n</sub> ).....   | 1409 |
| 49.4.5         | Current Timer Value Register (PIT_CVAL <sub>n</sub> )..... | 1409 |
| 49.4.6         | Timer Control Register (PIT_TCTRL <sub>n</sub> ).....      | 1410 |
| 49.4.7         | Timer Flag Register (PIT_TFLG <sub>n</sub> ).....          | 1410 |
| 49.5           | Functional description.....                                | 1411 |
| 49.5.1         | General operation.....                                     | 1411 |
| 49.5.2         | Interrupts.....                                            | 1413 |
| 49.5.3         | Chained timers.....                                        | 1413 |
| 49.6           | Initialization and application information.....            | 1413 |
| 49.7           | Example configuration for chained timers.....              | 1414 |
| 49.8           | Example configuration for the lifetime timer.....          | 1415 |

## Chapter 50 Serial Peripheral Interface (SPI)

|        |                                    |      |
|--------|------------------------------------|------|
| 50.1   | Chip-specific SPI information..... | 1417 |
| 50.1.1 | SPI instantiation information..... | 1417 |
| 50.1.2 | SPI clocking.....                  | 1417 |
| 50.1.3 | Number of CTARs.....               | 1417 |

| Section number | Title                                                                                       | Page |
|----------------|---------------------------------------------------------------------------------------------|------|
| 50.1.4         | TX FIFO size.....                                                                           | 1417 |
| 50.1.5         | RX FIFO Size.....                                                                           | 1418 |
| 50.1.6         | Number of PCS signals.....                                                                  | 1418 |
| 50.1.7         | SPI Operation in Low Power Modes.....                                                       | 1418 |
| 50.1.8         | SPI Doze Mode.....                                                                          | 1419 |
| 50.1.9         | SPI Interrupts.....                                                                         | 1419 |
| 50.1.10        | SPI clocks.....                                                                             | 1419 |
| 50.1.11        | Writing SPI Transmit FIFO.....                                                              | 1420 |
| 50.2           | Introduction.....                                                                           | 1420 |
| 50.2.1         | Block Diagram.....                                                                          | 1420 |
| 50.2.2         | Features.....                                                                               | 1421 |
| 50.2.3         | Interface configurations.....                                                               | 1422 |
| 50.2.4         | Modes of Operation.....                                                                     | 1423 |
| 50.3           | Module signal descriptions.....                                                             | 1424 |
| 50.3.1         | PCS0/SS—Peripheral Chip Select/Slave Select.....                                            | 1425 |
| 50.3.2         | PCS1—PCS3—Peripheral Chip Selects 1–3.....                                                  | 1425 |
| 50.3.3         | PCS4—Peripheral Chip Select 4.....                                                          | 1425 |
| 50.3.4         | PCS5/PCSS—Peripheral Chip Select 5/Peripheral Chip Select Strobe.....                       | 1425 |
| 50.3.5         | SCK—Serial Clock.....                                                                       | 1426 |
| 50.3.6         | SIN—Serial Input.....                                                                       | 1426 |
| 50.3.7         | SOUT—Serial Output.....                                                                     | 1426 |
| 50.4           | Memory Map/Register Definition.....                                                         | 1426 |
| 50.4.1         | Module Configuration Register (SPIx_MCR).....                                               | 1429 |
| 50.4.2         | Transfer Count Register (SPIx_TCR).....                                                     | 1432 |
| 50.4.3         | Clock and Transfer Attributes Register (In Master Mode) (SPIx_CTAR <sub>n</sub> ).....      | 1433 |
| 50.4.4         | Clock and Transfer Attributes Register (In Slave Mode) (SPIx_CTAR <sub>n</sub> _SLAVE)..... | 1438 |
| 50.4.5         | Status Register (SPIx_SR).....                                                              | 1439 |
| 50.4.6         | DMA/Interrupt Request Select and Enable Register (SPIx_RSER).....                           | 1442 |
| 50.4.7         | PUSH TX FIFO Register In Master Mode (SPIx_PUSHR).....                                      | 1444 |

| Section number | Title                                                       | Page |
|----------------|-------------------------------------------------------------|------|
| 50.4.8         | PUSH TX FIFO Register In Slave Mode (SPLx_PUSHR_SLAVE)..... | 1446 |
| 50.4.9         | POP RX FIFO Register (SPLx_POPR).....                       | 1446 |
| 50.4.10        | Transmit FIFO Registers (SPLx_TXFRn).....                   | 1447 |
| 50.4.11        | Receive FIFO Registers (SPLx_RXFRn).....                    | 1447 |
| 50.5           | Functional description.....                                 | 1448 |
| 50.5.1         | Start and Stop of module transfers.....                     | 1449 |
| 50.5.2         | Serial Peripheral Interface (SPI) configuration.....        | 1449 |
| 50.5.3         | Module baud rate and clock delay generation.....            | 1453 |
| 50.5.4         | Transfer formats.....                                       | 1457 |
| 50.5.5         | Continuous Serial Communications Clock.....                 | 1466 |
| 50.5.6         | Slave Mode Operation Constraints.....                       | 1468 |
| 50.5.7         | Interrupts/DMA requests.....                                | 1468 |
| 50.5.8         | Power saving features.....                                  | 1470 |
| 50.6           | Initialization/application information.....                 | 1471 |
| 50.6.1         | How to manage queues.....                                   | 1472 |
| 50.6.2         | Switching Master and Slave mode.....                        | 1472 |
| 50.6.3         | Initializing Module in Master/Slave Modes.....              | 1473 |
| 50.6.4         | Baud rate settings.....                                     | 1473 |
| 50.6.5         | Delay settings.....                                         | 1474 |
| 50.6.6         | Calculation of FIFO pointer addresses.....                  | 1475 |

## Chapter 51

### 10/100-Mbps Ethernet MAC (ENET)

|        |                                            |      |
|--------|--------------------------------------------|------|
| 51.1   | Chip-specific ENET information.....        | 1477 |
| 51.1.1 | Ethernet Clocking Options.....             | 1477 |
| 51.1.2 | RMII Clocking.....                         | 1477 |
| 51.1.3 | IEEE 1588 Timers.....                      | 1477 |
| 51.1.4 | Ethernet Operation in Low Power Modes..... | 1478 |
| 51.1.5 | Ethernet Doze Mode.....                    | 1478 |
| 51.1.6 | Ethernet Interrupts.....                   | 1478 |

| Section number | Title                                                           | Page |
|----------------|-----------------------------------------------------------------|------|
| 51.1.7         | Ethernet event signal.....                                      | 1479 |
| 51.2           | Introduction.....                                               | 1479 |
| 51.3           | Overview.....                                                   | 1479 |
| 51.3.1         | Features.....                                                   | 1480 |
| 51.3.2         | Block diagram.....                                              | 1482 |
| 51.4           | External signal description.....                                | 1483 |
| 51.5           | Memory map/register definition.....                             | 1485 |
| 51.5.1         | Interrupt Event Register (ENET_EIR).....                        | 1490 |
| 51.5.2         | Interrupt Mask Register (ENET_EIMR).....                        | 1493 |
| 51.5.3         | Receive Descriptor Active Register (ENET_RDAR).....             | 1496 |
| 51.5.4         | Transmit Descriptor Active Register (ENET_TDAR).....            | 1496 |
| 51.5.5         | Ethernet Control Register (ENET_ECR).....                       | 1497 |
| 51.5.6         | MII Management Frame Register (ENET_MMFR).....                  | 1499 |
| 51.5.7         | MII Speed Control Register (ENET_MSCR).....                     | 1500 |
| 51.5.8         | MIB Control Register (ENET_MIBC).....                           | 1502 |
| 51.5.9         | Receive Control Register (ENET_RCR).....                        | 1503 |
| 51.5.10        | Transmit Control Register (ENET_TCR).....                       | 1506 |
| 51.5.11        | Physical Address Lower Register (ENET_PALR).....                | 1508 |
| 51.5.12        | Physical Address Upper Register (ENET_PAUR).....                | 1508 |
| 51.5.13        | Opcode/Pause Duration Register (ENET_OPD).....                  | 1509 |
| 51.5.14        | Descriptor Individual Upper Address Register (ENET_IAUR).....   | 1509 |
| 51.5.15        | Descriptor Individual Lower Address Register (ENET_IALR).....   | 1510 |
| 51.5.16        | Descriptor Group Upper Address Register (ENET_GAUR).....        | 1510 |
| 51.5.17        | Descriptor Group Lower Address Register (ENET_GALR).....        | 1511 |
| 51.5.18        | Transmit FIFO Watermark Register (ENET_TFWR).....               | 1511 |
| 51.5.19        | Receive Descriptor Ring Start Register (ENET_RDSR).....         | 1512 |
| 51.5.20        | Transmit Buffer Descriptor Ring Start Register (ENET_TDSR)..... | 1513 |
| 51.5.21        | Maximum Receive Buffer Size Register (ENET_MRBR).....           | 1514 |
| 51.5.22        | Receive FIFO Section Full Threshold (ENET_RSFL).....            | 1515 |

| Section number | Title                                                                                      | Page |
|----------------|--------------------------------------------------------------------------------------------|------|
| 51.5.23        | Receive FIFO Section Empty Threshold (ENET_RSEM).....                                      | 1515 |
| 51.5.24        | Receive FIFO Almost Empty Threshold (ENET_RAEM).....                                       | 1516 |
| 51.5.25        | Receive FIFO Almost Full Threshold (ENET_RAFL).....                                        | 1516 |
| 51.5.26        | Transmit FIFO Section Empty Threshold (ENET_TSEM).....                                     | 1517 |
| 51.5.27        | Transmit FIFO Almost Empty Threshold (ENET_TAEM).....                                      | 1517 |
| 51.5.28        | Transmit FIFO Almost Full Threshold (ENET_TAFL).....                                       | 1518 |
| 51.5.29        | Transmit Inter-Packet Gap (ENET_TIPG).....                                                 | 1518 |
| 51.5.30        | Frame Truncation Length (ENET_FTRL).....                                                   | 1519 |
| 51.5.31        | Transmit Accelerator Function Configuration (ENET_TACC).....                               | 1519 |
| 51.5.32        | Receive Accelerator Function Configuration (ENET_RACC).....                                | 1520 |
| 51.5.33        | Reserved Statistic Register (ENET_RMON_T_DROP).....                                        | 1521 |
| 51.5.34        | Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS).....                              | 1522 |
| 51.5.35        | Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT).....                          | 1522 |
| 51.5.36        | Tx Multicast Packets Statistic Register (ENET_RMON_T_MC_PKT).....                          | 1523 |
| 51.5.37        | Tx Packets with CRC/Align Error Statistic Register (ENET_RMON_T_CRC_ALIGN).....            | 1523 |
| 51.5.38        | Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET_RMON_T_UNDERSIZE).....    | 1523 |
| 51.5.39        | Tx Packets GT MAX_FL bytes and Good CRC Statistic Register (ENET_RMON_T_OVERSIZE).....     | 1524 |
| 51.5.40        | Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_T_FRAG).....       | 1524 |
| 51.5.41        | Tx Packets Greater Than MAX_FL bytes and Bad CRC Statistic Register (ENET_RMON_T_JAB)..... | 1525 |
| 51.5.42        | Tx Collision Count Statistic Register (ENET_RMON_T_COL).....                               | 1525 |
| 51.5.43        | Tx 64-Byte Packets Statistic Register (ENET_RMON_T_P64).....                               | 1525 |
| 51.5.44        | Tx 65- to 127-byte Packets Statistic Register (ENET_RMON_T_P65TO127).....                  | 1526 |
| 51.5.45        | Tx 128- to 255-byte Packets Statistic Register (ENET_RMON_T_P128TO255).....                | 1526 |
| 51.5.46        | Tx 256- to 511-byte Packets Statistic Register (ENET_RMON_T_P256TO511).....                | 1527 |
| 51.5.47        | Tx 512- to 1023-byte Packets Statistic Register (ENET_RMON_T_P512TO1023).....              | 1527 |
| 51.5.48        | Tx 1024- to 2047-byte Packets Statistic Register (ENET_RMON_T_P1024TO2047).....            | 1528 |
| 51.5.49        | Tx Packets Greater Than 2048 Bytes Statistic Register (ENET_RMON_T_P_GTE2048).....         | 1528 |
| 51.5.50        | Tx Octets Statistic Register (ENET_RMON_T_OCTETS).....                                     | 1528 |
| 51.5.51        | Reserved Statistic Register (ENET_IEEE_T_DROP).....                                        | 1529 |

| Section number | Title                                                                                              | Page |
|----------------|----------------------------------------------------------------------------------------------------|------|
| 51.5.52        | Frames Transmitted OK Statistic Register (ENET_IEEE_T_FRAME_OK).....                               | 1529 |
| 51.5.53        | Frames Transmitted with Single Collision Statistic Register (ENET_IEEE_T_1COL).....                | 1530 |
| 51.5.54        | Frames Transmitted with Multiple Collisions Statistic Register (ENET_IEEE_T_MCOL).....             | 1530 |
| 51.5.55        | Frames Transmitted after Deferral Delay Statistic Register (ENET_IEEE_T_DEF).....                  | 1530 |
| 51.5.56        | Frames Transmitted with Late Collision Statistic Register (ENET_IEEE_T_LCOL).....                  | 1531 |
| 51.5.57        | Frames Transmitted with Excessive Collisions Statistic Register (ENET_IEEE_T_EXCOL).....           | 1531 |
| 51.5.58        | Frames Transmitted with Tx FIFO Underrun Statistic Register (ENET_IEEE_T_MACERR).....              | 1532 |
| 51.5.59        | Frames Transmitted with Carrier Sense Error Statistic Register (ENET_IEEE_T_CSERR).....            | 1532 |
| 51.5.60        | Reserved Statistic Register (ENET_IEEE_T_SQE).....                                                 | 1532 |

| 51.5.62        | Octet Count for Frames Transmitted w/o Error Statistic Register (ENET_IEEE_T_OCTETS_OK).....       | 1533 |
| 51.5.63        | Rx Packet Count Statistic Register (ENET_RMON_R_PACKETS).....                                      | 1534 |
| 51.5.64        | Rx Broadcast Packets Statistic Register (ENET_RMON_R_BC_PKT).....                                  | 1534 |
| 51.5.65        | Rx Multicast Packets Statistic Register (ENET_RMON_R_MC_PKT).....                                  | 1534 |
| 51.5.66        | Rx Packets with CRC/Align Error Statistic Register (ENET_RMON_R_CRC_ALIGN).....                    | 1535 |
| 51.5.67        | Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register<br>(ENET_RMON_R_UNDERSIZE)..... | 1535 |
| 51.5.68        | Rx Packets Greater Than MAX_FL and Good CRC Statistic Register (ENET_RMON_R_OVERSIZE).             | 1536 |
| 51.5.69        | Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_R_FRAG).....               | 1536 |
| 51.5.70        | Rx Packets Greater Than MAX_FL Bytes and Bad CRC Statistic Register (ENET_RMON_R_JAB).....         | 1536 |
| 51.5.71        | Reserved Statistic Register (ENET_RMON_R_RESVD_0).....                                             | 1537 |
| 51.5.72        | Rx 64-Byte Packets Statistic Register (ENET_RMON_R_P64).....                                       | 1537 |
| 51.5.73        | Rx 65- to 127-Byte Packets Statistic Register (ENET_RMON_R_P65TO127).....                          | 1538 |
| 51.5.74        | Rx 128- to 255-Byte Packets Statistic Register (ENET_RMON_R_P128TO255).....                        | 1538 |
| 51.5.75        | Rx 256- to 511-Byte Packets Statistic Register (ENET_RMON_R_P256TO511).....                        | 1538 |
| 51.5.76        | Rx 512- to 1023-Byte Packets Statistic Register (ENET_RMON_R_P512TO1023).....                      | 1539 |
| 51.5.77        | Rx 1024- to 2047-Byte Packets Statistic Register (ENET_RMON_R_P1024TO2047).....                    | 1539 |
| 51.5.78        | Rx Packets Greater than 2048 Bytes Statistic Register (ENET_RMON_R_P_GTE2048).....                 | 1540 |
| 51.5.79        | Rx Octets Statistic Register (ENET_RMON_R_OCTETS).....                                             | 1540 |

| Section number | Title                                                                                         | Page |
|----------------|-----------------------------------------------------------------------------------------------|------|
| 51.5.80        | Frames not Counted Correctly Statistic Register (ENET_IEEE_R_DROP).....                       | 1540 |
| 51.5.81        | Frames Received OK Statistic Register (ENET_IEEE_R_FRAME_OK).....                             | 1541 |
| 51.5.82        | Frames Received with CRC Error Statistic Register (ENET_IEEE_R_CRC).....                      | 1541 |
| 51.5.83        | Frames Received with Alignment Error Statistic Register (ENET_IEEE_R_ALIGN).....              | 1542 |
| 51.5.84        | Receive FIFO Overflow Count Statistic Register (ENET_IEEE_R_MACERR).....                      | 1542 |
| 51.5.85        | Flow Control Pause Frames Received Statistic Register (ENET_IEEE_R_FDXFC).....                | 1542 |
| 51.5.86        | Octet Count for Frames Received without Error Statistic Register (ENET_IEEE_R_OCTETS_OK)..... | 1543 |
| 51.5.87        | Adjustable Timer Control Register (ENET_ATCR).....                                            | 1544 |
| 51.5.88        | Timer Value Register (ENET_ATVR).....                                                         | 1546 |
| 51.5.89        | Timer Offset Register (ENET_ATOFF).....                                                       | 1546 |
| 51.5.90        | Timer Period Register (ENET_ATPER).....                                                       | 1546 |
| 51.5.91        | Timer Correction Register (ENET_ATCOR).....                                                   | 1547 |
| 51.5.92        | Time-Stamping Clock Period Register (ENET_ATINC).....                                         | 1547 |
| 51.5.93        | Timestamp of Last Transmitted Frame (ENET_ATSTMP).....                                        | 1548 |
| 51.5.94        | Timer Global Status Register (ENET_TGSR).....                                                 | 1548 |
| 51.5.95        | Timer Control Status Register (ENET_TCSR <sub>n</sub> ).....                                  | 1549 |
| 51.5.96        | Timer Compare Capture Register (ENET_TCCR <sub>n</sub> ).....                                 | 1550 |
| 51.6           | Functional description.....                                                                   | 1551 |
| 51.6.1         | Ethernet MAC frame formats.....                                                               | 1551 |
| 51.6.2         | IP and higher layers frame format.....                                                        | 1554 |
| 51.6.3         | IEEE 1588 message formats.....                                                                | 1558 |
| 51.6.4         | MAC receive.....                                                                              | 1562 |
| 51.6.5         | MAC transmit.....                                                                             | 1568 |
| 51.6.6         | Full-duplex flow control operation.....                                                       | 1572 |
| 51.6.7         | Magic packet detection.....                                                                   | 1574 |
| 51.6.8         | IP accelerator functions.....                                                                 | 1575 |
| 51.6.9         | Resets and stop controls.....                                                                 | 1579 |
| 51.6.10        | IEEE 1588 functions.....                                                                      | 1582 |
| 51.6.11        | FIFO thresholds.....                                                                          | 1586 |

| Section number | Title                                  | Page |
|----------------|----------------------------------------|------|
| 51.6.12        | Loopback options.....                  | 1589 |
| 51.6.13        | Legacy buffer descriptors.....         | 1590 |
| 51.6.14        | Enhanced buffer descriptors.....       | 1591 |
| 51.6.15        | Client FIFO application interface..... | 1597 |
| 51.6.16        | FIFO protection.....                   | 1600 |
| 51.6.17        | Reference clock.....                   | 1603 |
| 51.6.18        | PHY management interface.....          | 1603 |
| 51.6.19        | Ethernet interfaces.....               | 1606 |

## Chapter 52 Inter-Integrated Circuit (I2C)

|         |                                                               |      |
|---------|---------------------------------------------------------------|------|
| 52.1    | Chip-specific I2C information.....                            | 1611 |
| 52.1.1  | Number of I2C modules.....                                    | 1611 |
| 52.2    | Introduction.....                                             | 1611 |
| 52.2.1  | Features.....                                                 | 1611 |
| 52.2.2  | Modes of operation.....                                       | 1612 |
| 52.2.3  | Block diagram.....                                            | 1612 |
| 52.3    | I2C signal descriptions.....                                  | 1613 |
| 52.4    | Memory map/register definition.....                           | 1614 |
| 52.4.1  | I2C Address Register 1 (I2Cx_A1).....                         | 1615 |
| 52.4.2  | I2C Frequency Divider register (I2Cx_F).....                  | 1615 |
| 52.4.3  | I2C Control Register 1 (I2Cx_C1).....                         | 1616 |
| 52.4.4  | I2C Status register (I2Cx_S).....                             | 1618 |
| 52.4.5  | I2C Data I/O register (I2Cx_D).....                           | 1620 |
| 52.4.6  | I2C Control Register 2 (I2Cx_C2).....                         | 1620 |
| 52.4.7  | I2C Programmable Input Glitch Filter Register (I2Cx_FLT)..... | 1621 |
| 52.4.8  | I2C Range Address register (I2Cx_RA).....                     | 1623 |
| 52.4.9  | I2C SMBus Control and Status register (I2Cx_SMB).....         | 1623 |
| 52.4.10 | I2C Address Register 2 (I2Cx_A2).....                         | 1625 |
| 52.4.11 | I2C SCL Low Timeout Register High (I2Cx_SLTH).....            | 1625 |

| Section number | Title                                             | Page |
|----------------|---------------------------------------------------|------|
| 52.4.12        | I2C SCL Low Timeout Register Low (I2Cx_SLTL)..... | 1626 |
| 52.5           | Functional description.....                       | 1626 |
| 52.5.1         | I2C protocol.....                                 | 1626 |
| 52.5.2         | 10-bit address.....                               | 1631 |
| 52.5.3         | Address matching.....                             | 1633 |
| 52.5.4         | System management bus specification.....          | 1634 |
| 52.5.5         | Resets.....                                       | 1636 |
| 52.5.6         | Interrupts.....                                   | 1636 |
| 52.5.7         | Programmable input glitch filter.....             | 1639 |
| 52.5.8         | Address matching wake-up.....                     | 1639 |
| 52.5.9         | DMA support.....                                  | 1640 |
| 52.6           | Initialization/application information.....       | 1640 |

## Chapter 53

### Universal Asynchronous Receiver/Transmitter (UART) / FlexSCI

|        |                                                 |      |
|--------|-------------------------------------------------|------|
| 53.1   | Chip-specific UART information.....             | 1645 |
| 53.1.1 | UART configuration.....                         | 1645 |
| 53.1.2 | UART signals.....                               | 1645 |
| 53.1.3 | UART wakeup.....                                | 1646 |
| 53.1.4 | UART interrupts.....                            | 1646 |
| 53.2   | Introduction.....                               | 1648 |
| 53.2.1 | Features.....                                   | 1648 |
| 53.2.2 | Modes of operation.....                         | 1650 |
| 53.3   | UART signal descriptions.....                   | 1651 |
| 53.3.1 | Detailed signal descriptions.....               | 1651 |
| 53.4   | Memory map and registers.....                   | 1652 |
| 53.4.1 | UART Baud Rate Registers: High (UARTx_BDH)..... | 1662 |
| 53.4.2 | UART Baud Rate Registers: Low (UARTx_BDL).....  | 1663 |
| 53.4.3 | UART Control Register 1 (UARTx_C1).....         | 1663 |
| 53.4.4 | UART Control Register 2 (UARTx_C2).....         | 1665 |

| Section number | Title                                                           | Page |
|----------------|-----------------------------------------------------------------|------|
| 53.4.5         | UART Status Register 1 (UARTx_S1).....                          | 1667 |
| 53.4.6         | UART Status Register 2 (UARTx_S2).....                          | 1670 |
| 53.4.7         | UART Control Register 3 (UARTx_C3).....                         | 1672 |
| 53.4.8         | UART Data Register (UARTx_D).....                               | 1673 |
| 53.4.9         | UART Match Address Registers 1 (UARTx_MA1).....                 | 1674 |
| 53.4.10        | UART Match Address Registers 2 (UARTx_MA2).....                 | 1675 |
| 53.4.11        | UART Control Register 4 (UARTx_C4).....                         | 1675 |
| 53.4.12        | UART Control Register 5 (UARTx_C5).....                         | 1676 |
| 53.4.13        | UART Extended Data Register (UARTx_ED).....                     | 1677 |
| 53.4.14        | UART Modem Register (UARTx_MODEM).....                          | 1678 |
| 53.4.15        | UART Infrared Register (UARTx_IR).....                          | 1679 |
| 53.4.16        | UART FIFO Parameters (UARTx_PFIFO).....                         | 1680 |
| 53.4.17        | UART FIFO Control Register (UARTx_CFIFO).....                   | 1681 |
| 53.4.18        | UART FIFO Status Register (UARTx_SFIFO).....                    | 1682 |
| 53.4.19        | UART FIFO Transmit Watermark (UARTx_TWFIFO).....                | 1684 |
| 53.4.20        | UART FIFO Transmit Count (UARTx_TCFIFO).....                    | 1684 |
| 53.4.21        | UART FIFO Receive Watermark (UARTx_RWFIFO).....                 | 1685 |
| 53.4.22        | UART FIFO Receive Count (UARTx_RCFIFO).....                     | 1685 |
| 53.4.23        | UART 7816 Control Register (UARTx_C7816).....                   | 1686 |
| 53.4.24        | UART 7816 Interrupt Enable Register (UARTx_IE7816).....         | 1687 |
| 53.4.25        | UART 7816 Interrupt Status Register (UARTx_IS7816).....         | 1688 |
| 53.4.26        | UART 7816 Wait Parameter Register (UARTx_WP7816).....           | 1690 |
| 53.4.27        | UART 7816 Wait N Register (UARTx_WN7816).....                   | 1691 |
| 53.4.28        | UART 7816 Wait FD Register (UARTx_WF7816).....                  | 1691 |
| 53.4.29        | UART 7816 Error Threshold Register (UARTx_ET7816).....          | 1692 |
| 53.4.30        | UART 7816 Transmit Length Register (UARTx_TL7816).....          | 1692 |
| 53.4.31        | UART 7816 ATR Duration Timer Register A (UARTx_AP7816A_T0)..... | 1693 |
| 53.4.32        | UART 7816 ATR Duration Timer Register B (UARTx_AP7816B_T0)..... | 1694 |
| 53.4.33        | UART 7816 Wait Parameter Register A (UARTx_WP7816A_T0).....     | 1694 |

| Section number | Title                                                               | Page |
|----------------|---------------------------------------------------------------------|------|
| 53.4.34        | UART 7816 Wait Parameter Register A (UARTx_WP7816A_T1).....         | 1695 |
| 53.4.35        | UART 7816 Wait Parameter Register B (UARTx_WP7816B_T0).....         | 1695 |
| 53.4.36        | UART 7816 Wait Parameter Register B (UARTx_WP7816B_T1).....         | 1696 |
| 53.4.37        | UART 7816 Wait and Guard Parameter Register (UARTx_WGP7816_T1)..... | 1696 |
| 53.4.38        | UART 7816 Wait Parameter Register C (UARTx_WP7816C_T1).....         | 1697 |
| 53.5           | Functional description.....                                         | 1697 |
| 53.5.1         | Transmitter.....                                                    | 1697 |
| 53.5.2         | Receiver.....                                                       | 1703 |
| 53.5.3         | Baud rate generation.....                                           | 1717 |
| 53.5.4         | Data format (non ISO-7816).....                                     | 1719 |
| 53.5.5         | Single-wire operation.....                                          | 1722 |
| 53.5.6         | Loop operation.....                                                 | 1723 |
| 53.5.7         | ISO-7816/smartcard support.....                                     | 1724 |
| 53.5.8         | Infrared interface.....                                             | 1729 |
| 53.6           | Reset.....                                                          | 1730 |
| 53.7           | System level interrupt sources.....                                 | 1730 |
| 53.7.1         | RXEDGIF description.....                                            | 1731 |
| 53.8           | DMA operation.....                                                  | 1732 |
| 53.9           | Application information.....                                        | 1733 |
| 53.9.1         | Transmit/receive data buffer operation.....                         | 1733 |
| 53.9.2         | ISO-7816 initialization sequence.....                               | 1733 |
| 53.9.3         | Initialization sequence (non ISO-7816).....                         | 1735 |
| 53.9.4         | Overrun (OR) flag implications.....                                 | 1736 |
| 53.9.5         | Overrun NACK considerations.....                                    | 1737 |
| 53.9.6         | Match address registers.....                                        | 1738 |
| 53.9.7         | Modem feature.....                                                  | 1738 |
| 53.9.8         | IrDA minimum pulse width.....                                       | 1739 |
| 53.9.9         | Clearing 7816 wait timer (WT, BWT, CWT) interrupts.....             | 1740 |
| 53.9.10        | Legacy and reverse compatibility considerations.....                | 1740 |

| Section number                                | Title                                                  | Page |
|-----------------------------------------------|--------------------------------------------------------|------|
| <b>Chapter 54</b>                             |                                                        |      |
| <b>Flex Controller Area Network (FlexCAN)</b> |                                                        |      |
| 54.1                                          | Chip-specific FlexCAN information.....                 | 1743 |
| 54.1.1                                        | Instantiation information.....                         | 1743 |
| 54.1.2                                        | FlexCAN glitch filter.....                             | 1743 |
| 54.1.3                                        | FlexCAN Supervisor Mode.....                           | 1743 |
| 54.2                                          | Introduction.....                                      | 1744 |
| 54.2.1                                        | Overview.....                                          | 1744 |
| 54.2.2                                        | FlexCAN module features.....                           | 1745 |
| 54.2.3                                        | Modes of operation.....                                | 1747 |
| 54.3                                          | FlexCAN signal descriptions.....                       | 1748 |
| 54.3.1                                        | CAN Rx .....                                           | 1749 |
| 54.3.2                                        | CAN Tx .....                                           | 1749 |
| 54.4                                          | Memory map/register definition.....                    | 1749 |
| 54.4.1                                        | FlexCAN memory mapping.....                            | 1749 |
| 54.4.2                                        | Module Configuration Register (CANx_MCR).....          | 1755 |
| 54.4.3                                        | Control 1 register (CANx_CTRL1).....                   | 1760 |
| 54.4.4                                        | Free Running Timer (CANx_TIMER).....                   | 1764 |
| 54.4.5                                        | Rx Mailboxes Global Mask Register (CANx_RXMGMASK)..... | 1765 |
| 54.4.6                                        | Rx 14 Mask register (CANx_RX14MASK).....               | 1766 |
| 54.4.7                                        | Rx 15 Mask register (CANx_RX15MASK).....               | 1767 |
| 54.4.8                                        | Error Counter (CANx_ECR).....                          | 1767 |
| 54.4.9                                        | Error and Status 1 register (CANx_ESR1).....           | 1769 |
| 54.4.10                                       | Interrupt Masks 1 register (CANx_IMASK1).....          | 1775 |
| 54.4.11                                       | Interrupt Flags 1 register (CANx_IFLAG1).....          | 1775 |
| 54.4.12                                       | Control 2 register (CANx_CTRL2).....                   | 1778 |
| 54.4.13                                       | Error and Status 2 register (CANx_ESR2).....           | 1781 |
| 54.4.14                                       | CRC Register (CANx_CRCCR).....                         | 1783 |
| 54.4.15                                       | Rx FIFO Global Mask register (CANx_RXFGMASK).....      | 1783 |

| Section number | Title                                                        | Page |
|----------------|--------------------------------------------------------------|------|
| 54.4.16        | Rx FIFO Information Register (CANx_RXFIR).....               | 1784 |
| 54.4.17        | CAN Bit Timing Register (CANx_CBT).....                      | 1785 |
| 54.4.18        | Rx Individual Mask Registers (CANx_RXIMR <sub>n</sub> )..... | 1787 |
| 54.4.70        | Message buffer structure.....                                | 1788 |
| 54.4.71        | Rx FIFO structure.....                                       | 1793 |
| 54.5           | Functional description.....                                  | 1796 |
| 54.5.1         | Transmit process.....                                        | 1796 |
| 54.5.2         | Arbitration process.....                                     | 1797 |
| 54.5.3         | Receive process.....                                         | 1801 |
| 54.5.4         | Matching process.....                                        | 1803 |
| 54.5.5         | Move process.....                                            | 1808 |
| 54.5.6         | Data coherence.....                                          | 1809 |
| 54.5.7         | Rx FIFO.....                                                 | 1813 |
| 54.5.8         | CAN protocol related features.....                           | 1816 |
| 54.5.9         | Clock domains and restrictions.....                          | 1824 |
| 54.5.10        | Modes of operation details.....                              | 1825 |
| 54.5.11        | Interrupts.....                                              | 1830 |
| 54.5.12        | Bus interface.....                                           | 1831 |
| 54.6           | Initialization/application information.....                  | 1832 |
| 54.6.1         | FlexCAN initialization sequence.....                         | 1832 |

## Chapter 55

### General-Purpose Input/Output (GPIO)

|        |                                     |      |
|--------|-------------------------------------|------|
| 55.1   | Chip-specific GPIO information..... | 1835 |
| 55.1.1 | GPIO access protection.....         | 1835 |
| 55.1.2 | Number of GPIO signals.....         | 1835 |
| 55.2   | Introduction.....                   | 1835 |
| 55.2.1 | Features.....                       | 1836 |
| 55.2.2 | Modes of operation.....             | 1836 |
| 55.2.3 | GPIO signal descriptions.....       | 1836 |

| Section number | Title                                          | Page |
|----------------|------------------------------------------------|------|
| 55.3           | Memory map and register definition.....        | 1837 |
| 55.3.1         | Port Data Output Register (GPIOx_PDOR).....    | 1839 |
| 55.3.2         | Port Set Output Register (GPIOx_PSOR).....     | 1840 |
| 55.3.3         | Port Clear Output Register (GPIOx_PCOR).....   | 1840 |
| 55.3.4         | Port Toggle Output Register (GPIOx_PTOR).....  | 1841 |
| 55.3.5         | Port Data Input Register (GPIOx_PDIR).....     | 1841 |
| 55.3.6         | Port Data Direction Register (GPIOx_PDDR)..... | 1842 |
| 55.4           | Functional description.....                    | 1842 |
| 55.4.1         | General-purpose input.....                     | 1842 |
| 55.4.2         | General-purpose output.....                    | 1842 |

## Chapter 56 JTAG Controller (JTAGC)

|        |                                               |      |
|--------|-----------------------------------------------|------|
| 56.1   | Introduction.....                             | 1845 |
| 56.1.1 | Block diagram.....                            | 1845 |
| 56.1.2 | Features.....                                 | 1846 |
| 56.1.3 | Modes of operation.....                       | 1846 |
| 56.2   | External signal description.....              | 1847 |
| 56.2.1 | TCK—Test clock input.....                     | 1847 |
| 56.2.2 | TDI—Test data input.....                      | 1848 |
| 56.2.3 | TDO—Test data output.....                     | 1848 |
| 56.2.4 | TMS—Test mode select.....                     | 1848 |
| 56.3   | Register description.....                     | 1848 |
| 56.3.1 | Instruction register.....                     | 1848 |
| 56.3.2 | Bypass register.....                          | 1849 |
| 56.3.3 | Device identification register.....           | 1849 |
| 56.3.4 | Boundary scan register.....                   | 1850 |
| 56.4   | Functional description.....                   | 1850 |
| 56.4.1 | JTAGC reset configuration.....                | 1850 |
| 56.4.2 | IEEE 1149.1-2001 (JTAG) Test Access Port..... | 1850 |

| Section number | Title                                       | Page |
|----------------|---------------------------------------------|------|
| 56.4.3         | TAP controller state machine.....           | 1851 |
| 56.4.4         | JTAGC block instructions.....               | 1853 |
| 56.4.5         | Boundary scan.....                          | 1856 |
| 56.5           | Initialization/Application information..... | 1856 |

## Chapter 57

### Release Notes for Revision 4

|         |                                                                  |      |
|---------|------------------------------------------------------------------|------|
| 57.1    | General changes throughout document .....                        | 1857 |
| 57.2    | About This Document chapter changes.....                         | 1857 |
| 57.3    | Introduction chapter changes.....                                | 1857 |
| 57.4    | Core Overview changes .....                                      | 1857 |
| 57.5    | Memories and Memory Interfaces changes.....                      | 1857 |
| 57.6    | Memory Map changes .....                                         | 1858 |
| 57.7    | Clock Distribution changes.....                                  | 1858 |
| 57.8    | Reset and Boot chapter changes.....                              | 1858 |
| 57.9    | Power Management chapter changes.....                            | 1858 |
| 57.10   | Security chapter changes.....                                    | 1858 |
| 57.11   | Debug chapter changes.....                                       | 1858 |
| 57.12   | Signal Multiplexing and Signal Descriptions chapter changes..... | 1858 |
| 57.13   | PORT changes.....                                                | 1859 |
| 57.13.1 | Chip-specific PORT information changes.....                      | 1859 |
| 57.13.2 | PORT changes.....                                                | 1859 |
| 57.14   | SIM changes.....                                                 | 1859 |
| 57.15   | Kinetis Flashloader changes.....                                 | 1859 |
| 57.15.1 | Chip-specific Kinetis Flashloader information changes.....       | 1859 |
| 57.15.2 | Kinetis Flash Bootloader changes .....                           | 1859 |
| 57.16   | RCM changes.....                                                 | 1859 |
| 57.17   | SMC changes.....                                                 | 1860 |
| 57.18   | MCM changes.....                                                 | 1860 |
| 57.19   | MSCM changes.....                                                | 1860 |

| Section number | Title                                            | Page |
|----------------|--------------------------------------------------|------|
| 57.20          | PMC changes.....                                 | 1860 |
| 57.21          | LLWU changes.....                                | 1860 |
| 57.21.1        | Chip-specific LLWU information changes.....      | 1860 |
| 57.21.2        | LLWU changes.....                                | 1860 |
| 57.22          | AXBS changes.....                                | 1861 |
| 57.22.1        | Chip-specific AXBS information changes.....      | 1861 |
| 57.22.2        | Crossbar switch module changes.....              | 1861 |
| 57.23          | AIPS-Lite changes.....                           | 1861 |
| 57.23.1        | Chip-specific AIPS-Lite information changes..... | 1861 |
| 57.23.2        | AIPS module changes.....                         | 1861 |
| 57.24          | MPU changes.....                                 | 1861 |
| 57.24.1        | Chip-specific MPU information changes.....       | 1861 |
| 57.24.2        | MPU module changes.....                          | 1862 |
| 57.25          | BME configuration changes.....                   | 1862 |
| 57.26          | DMAMUX changes.....                              | 1862 |
| 57.26.1        | Chip-specific DMAMUX information changes.....    | 1862 |
| 57.26.2        | DMAMUX module changes.....                       | 1862 |
| 57.27          | eDMA module changes.....                         | 1862 |
| 57.28          | EWM changes.....                                 | 1863 |
| 57.28.1        | Chip-specific EWM information changes.....       | 1863 |
| 57.28.2        | EWM changes.....                                 | 1863 |
| 57.29          | WDOG changes.....                                | 1863 |
| 57.29.1        | Chip-specific WDOG information changes.....      | 1863 |
| 57.29.2        | WDOG changes.....                                | 1863 |
| 57.30          | AOI changes.....                                 | 1863 |
| 57.30.1        | Chip-specific AOI information changes.....       | 1863 |
| 57.30.2        | AOI changes.....                                 | 1864 |
| 57.31          | XBARA changes.....                               | 1864 |
| 57.31.1        | Chip-specific XBARA information changes.....     | 1864 |

| Section number | Title                                          | Page |
|----------------|------------------------------------------------|------|
| 57.31.2        | XBARA changes.....                             | 1864 |
| 57.32          | XBARB changes.....                             | 1864 |
| 57.32.1        | Chip-specific XBARB information changes.....   | 1864 |
| 57.32.2        | XBARB changes.....                             | 1864 |
| 57.33          | MCG changes.....                               | 1864 |
| 57.33.1        | Chip-specific MCG information changes.....     | 1864 |
| 57.33.2        | MCG changes.....                               | 1865 |
| 57.34          | OSC changes.....                               | 1865 |
| 57.34.1        | Chip-specific OSC information changes.....     | 1865 |
| 57.34.2        | OSC changes.....                               | 1865 |
| 57.35          | FMC changes.....                               | 1865 |
| 57.35.1        | Chip-specific FMC information changes.....     | 1865 |
| 57.35.2        | FMC changes.....                               | 1865 |
| 57.36          | FTFE changes.....                              | 1865 |
| 57.37          | FlexBus changes.....                           | 1866 |
| 57.37.1        | Chip-specific FlexBus information changes..... | 1866 |
| 57.37.2        | FlexBus changes.....                           | 1866 |
| 57.38          | CRC changes.....                               | 1866 |
| 57.39          | MMCAU changes.....                             | 1866 |
| 57.40          | 16-bit ADC changes.....                        | 1866 |
| 57.40.1        | Chip-specific ADC information changes.....     | 1866 |
| 57.40.2        | ADC changes.....                               | 1866 |
| 57.41          | HSADC changes.....                             | 1867 |
| 57.41.1        | Chip-specific HSADC information changes.....   | 1867 |
| 57.41.2        | SAR ADC 12b5Msps changes.....                  | 1867 |
| 57.42          | CMP changes.....                               | 1867 |
| 57.42.1        | Chip-specific CMP information changes.....     | 1867 |
| 57.42.2        | CMP changes.....                               | 1867 |
| 57.43          | DAC changes.....                               | 1867 |

| Section number | Title                                            | Page |
|----------------|--------------------------------------------------|------|
| 57.43.1        | Chip-specific DAC information changes.....       | 1867 |
| 57.43.2        | DAC changes.....                                 | 1867 |
| 57.44          | FlexTimer changes.....                           | 1868 |
| 57.44.1        | Chip-specific FlexTimer information changes..... | 1868 |
| 57.44.2        | FTM changes.....                                 | 1868 |
| 57.45          | LPTMR changes.....                               | 1868 |
| 57.45.1        | Chip-specific LPTMR information changes.....     | 1868 |
| 57.45.2        | LPTMR changes.....                               | 1868 |
| 57.46          | PDB changes.....                                 | 1868 |
| 57.46.1        | Chip-specific PDB information changes.....       | 1868 |
| 57.46.2        | PDB changes .....                                | 1868 |
| 57.47          | ENC changes.....                                 | 1869 |
| 57.47.1        | Chip-specific ENC information changes.....       | 1869 |
| 57.47.2        | ENC changes.....                                 | 1869 |
| 57.48          | eFlexPWM changes.....                            | 1869 |
| 57.48.1        | Chip-specific eFlexPWM information changes.....  | 1869 |
| 57.48.2        | eFlexPWM changes.....                            | 1869 |
| 57.49          | PIT changes.....                                 | 1869 |
| 57.49.1        | Chip-specific PIT information changes.....       | 1869 |
| 57.49.2        | PIT module changes .....                         | 1869 |
| 57.50          | SPI changes.....                                 | 1870 |
| 57.50.1        | Chip-specific SPI information changes.....       | 1870 |
| 57.50.2        | SPI module changes .....                         | 1870 |
| 57.51          | ENET changes.....                                | 1870 |

# Chapter 1

## About This Document

### 1.1 Overview

#### 1.1.1 Purpose

This document describes the features, architecture, and programming model of the microcontroller.

#### 1.1.2 Audience

This document is intended for system architects and software application developers who are using (or considering using) the microcontroller in a system.

### 1.2 Conventions

#### 1.2.1 Numbering systems

The following suffixes identify different numbering systems:

| This suffix | Identifies a                                                                                                                                                       |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| b           | Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix 0b.                     |
| d           | Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix. |
| h           | Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix 0x.      |

## 1.2.2 Typographic notation

The following typographic notation is used throughout this document:

| Example               | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>placeholder, x</i> | Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.                                                                                                                                                                              |
| code                  | Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.                                                                                             |
| SR[SCM]               | A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).                                                                                                                                                                                                                                                                      |
| REVNO[6:4], XAD[7:0]  | Numbers in brackets and separated by a colon represent either: <ul style="list-style-type: none"> <li>• A subset of a register's named field<br/>For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register.</li> <li>• A continuous range of individual signals of a bus<br/>For example, XAD[7:0] refers to signals 7–0 of the XAD bus.</li> </ul> |

## 1.2.3 Special terms

The following terms have special meanings:

| Term       | Meaning                                                                                                                                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| asserted   | Refers to the state of a signal as follows: <ul style="list-style-type: none"> <li>• An active-high signal is asserted when high (1).</li> <li>• An active-low signal is asserted when low (0).</li> </ul>                                                                               |
| deasserted | Refers to the state of a signal as follows: <ul style="list-style-type: none"> <li>• An active-high signal is deasserted when low (0).</li> <li>• An active-low signal is deasserted when high (1).</li> </ul> <p>In some cases, deasserted signals are described as <i>negated</i>.</p> |
| reserved   | Refers to a memory space, register, or field that is either reserved for future use or for which, when written to, the module or chip behavior is unpredictable.                                                                                                                         |
| w1c        | Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."                                                                                                                                                                                               |

## **Chapter 2**

# **Introduction**

### **2.1 Overview**

This chapter provides high-level descriptions of the modules available on the devices covered by this document.

### **2.2 Block diagram**

The block diagram shows the features of this chip. Within each category, the diagram shows the superset of modules and number of module instances on the 144-pin member of the family.

Figure 2-1. KV5x series block diagram

2.3 Module Functional Categories

The modules on this device are grouped into functional categories. The following sections describe the modules assigned to each category in more detail.

Table 2-1. Module functional categories

| Module category            | Description                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARM® Cortex®-M7 based core | <ul style="list-style-type: none"><li>The Cortex-M7 is ARM's highest-performing Cortex-M processor. It combines a six-stage, superscalar pipeline with flexible system and memory interfaces including AXI, AHB, caches and tightly-coupled memories, and delivers high integer, floating point, single precision, and DSP performance in an MCU.</li></ul> |

Table continues on the next page...

**Table 2-1. Module functional categories (continued)**

| Module category                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 2.3.1 ARM® Cortex®-M7 Core Modules

The following core modules are available on this device.

**Table 2-2. Core modules**

| Module                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARM Cortex-M7             | The ARM Cortex-M7 is a member of the Cortex M Series of processors targeting microcontroller cores focused on very cost sensitive, deterministic, interrupt driven environments. The Cortex-M7 processor is a highly efficient high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline and supports dual-issue of load/store instruction pairs to multiple memory interfaces.                                                                          |
| Floating point unit (FPU) | A single-precision floating point unit (FPU) that is compliant to the <i>IEEE Standard for Floating-Point Arithmetic</i> (IEEE 754).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| NVIC                      | The ARMv7-M exception model and nested-vector interrupt controller (NVIC) implement a relocatable vector table supporting many external interrupts, a single non-maskable interrupt (NMI), and priority levels.<br><br>The NVIC replaces shadow registers with equivalent system and simplified programmability. The NVIC contains the address of the function to execute for a particular handler. The address is fetched via the instruction port allowing parallel register stacking and look-up. The first sixteen entries are allocated to ARM internal sources with the others mapping to MCU-defined interrupts. |
| AWIC                      | The primary function of the Asynchronous Wake-up Interrupt Controller (AWIC) is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.                                                                                                                                                                                                                                                                                                    |
| Debug interfaces          | Most of this device's debug hardware is based on the ARM CoreSight™ architecture. Four debug interfaces are supported: <ul style="list-style-type: none"> <li>• IEEE 1149.1 JTAG</li> <li>• IEEE 1149.7 JTAG (cJTAG)</li> <li>• Serial Wire Debug (SWD)</li> <li>• ARM Real-Time Trace Interface</li> </ul>                                                                                                                                                                                                                                                                                                             |

## 2.3.2 System Modules

The following system modules are available on this device.

**Table 2-3. System modules**

| Module                          | Description                                                                                                                                                                     |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System integration module (SIM) | The SIM includes integration logic and several module configuration settings.                                                                                                   |
| System mode controller          | The SMC provides control and protection on entry and exit to each power mode, control for the Power management controller (PMC), and reset entry and exit for the complete MCU. |

*Table continues on the next page...*

**Table 2-3. System modules (continued)**

| Module                                     | Description                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power management controller (PMC)          | The PMC provides the user with multiple power options. More than ten different modes are supported that allow the user to optimize power consumption for the level of functionality needed. Includes power-on-reset (POR) and integrated low voltage detect (LVD) with reset (brownout) capability and selectable LVD trip points. |
| Low-leakage wakeup unit (LLWU)             | The LLWU module allows the device to wake from low leakage power modes (VLLS) through various internal peripheral and external pin sources.                                                                                                                                                                                        |
| Miscellaneous control module (MCM)         | The MCM includes miscellaneous control functions and local memory descriptors.                                                                                                                                                                                                                                                     |
| Miscellaneous System Control Module (MSCM) | The MSCM includes CPU configuration information and system memory descriptors.                                                                                                                                                                                                                                                     |
| Crossbar switch (AXBS)                     | The AXBS connects bus masters and bus slaves, allowing all bus masters to access different bus slaves simultaneously and providing arbitration among the bus masters when they access the same slave.                                                                                                                              |
| NIC301 Crossbar                            | Provides interconnections between the CM7's 64-bit AXI bus and the AXBS to the flash memory.                                                                                                                                                                                                                                       |
| System Memory protection unit (MPU)        | The System MPU provides memory protection and task isolation. It concurrently monitors all bus master transactions for the slave connections.                                                                                                                                                                                      |
| Peripheral bridges                         | The peripheral bridge converts the crossbar switch interface to an interface to access a majority of peripherals on the device.                                                                                                                                                                                                    |
| DMA multiplexer (DMAMUX)                   | The DMA multiplexer selects from many DMA requests down to a smaller number for the DMA controller.                                                                                                                                                                                                                                |
| Direct memory access (DMA) controller      | The DMA controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.                                                                                                                                                         |
| External watchdog monitor (EWM)            | The EWM is a redundant mechanism to the software watchdog module that monitors both internal and external system operation for fail conditions.                                                                                                                                                                                    |
| Software watchdog (WDOG)                   | The WDOG monitors internal system operation and forces a reset in case of failure. It can run from an independent 1 KHz low power oscillator with a programmable refresh window to detect deviations in program flow or system frequency.                                                                                          |
| Bit Manipulation Engine2 (BME2)            | The second-generation BME2 provides hardware support for atomic read-modify-write operations to the peripheral address space.                                                                                                                                                                                                      |

### 2.3.3 Memories and Memory Interfaces

The following memories and memory interfaces are available on this device.

**Table 2-4. Memories and memory interfaces**

| Module                  | Description                                                                    |
|-------------------------|--------------------------------------------------------------------------------|
| Flash memory            | Program flash memory — non-volatile flash memory that can execute program code |
| Flash memory controller | Manages the interface between the device and the on-chip flash memory.         |
| SRAM - OCRAM            | Internal system RAM. Partial SRAM kept powered in VLLS2 low leakage mode.      |

*Table continues on the next page...*

**Table 2-4. Memories and memory interfaces (continued)**

| Module                                   | Description                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SRAM - TCM                               | Internal tightly-coupled RAM. Partial SRAM kept powered in VLLS2 low leakage mode.                                                                                                                                                                                                                                                                              |
| Cortex-M7 ITCM, D0TCM, D1TCM controllers | Manage simultaneous accesses to tightly-coupled memory by multiple master peripherals and core.                                                                                                                                                                                                                                                                 |
| System register file                     | 32-byte register file that is accessible during all power modes and is powered by VDD.                                                                                                                                                                                                                                                                          |
| FlexBus                                  | External bus interface with multiple independent, user-programmable chip-select signals that can interface with external SRAM, PROM, EPROM, EEPROM, flash, and other peripherals via 8-, 16- and 32-bit port sizes. Configurations include multiplexed or non-multiplexed address and data buses using 8-bit, 16-bit, 32-bit, and 16-byte line-sized transfers. |

## 2.3.4 Clocks

The following clock modules are available on this device.

**Table 2-5. Clock modules**

| Module                             | Description                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multipurpose clock generator (MCG) | The MCG provides several clock sources for the MCU that include: <ul style="list-style-type: none"> <li>• Phase-locked loop (PLL) — Voltage-controlled oscillator (VCO)</li> <li>• Frequency-locked loop (FLL) — Digitally-controlled oscillator (DCO)</li> <li>• Internal reference clocks — Can be used as a clock source for other on-chip peripherals</li> </ul> |
| System oscillator                  | The system oscillator, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.                                                                                                                                                                                                                                                |

## 2.3.5 Security and Integrity modules

The following security and integrity modules are available on this device:

**Table 2-6. Security and integrity modules**

| Module                                | Description                                                                                                                                                                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cryptographic acceleration unit (CAU) | Supports the following algorithms: <ul style="list-style-type: none"> <li>• DES</li> <li>• 3-DES</li> <li>• AES</li> <li>• SHA-1 and SHA-256</li> <li>• MD5</li> </ul> Via simple C calls to optimized security functions provided by Freescale. |

*Table continues on the next page...*

**Table 2-6. Security and integrity modules (continued)**

| Module                              | Description                                                                                                                                                                                                                                                 |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| True Random number generator (TRNG) | Supports the key generation algorithm defined in the Digital Signature Standard. A hardware entropy source which can be used to seed a software random number generator.                                                                                    |
| Cyclic Redundancy Check (CRC)       | Hardware CRC generator circuit using 16/32-bit shift register. Error detection for all single, double, odd, and most multi-bit errors, programmable initial seed value, and optional feature to transpose input data and CRC result via transpose register. |

## 2.3.6 Analog modules

The following analog modules are available on this device:

**Table 2-7. Analog modules**

| Module                                        | Description                                                                                                                               |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 16-bit analog-to-digital converters (ADC)     | 16-bit successive-approximation ADC                                                                                                       |
| 12-bit High Speed analog-to-digital converter | 12-bit SAR High Speed ADC                                                                                                                 |
| Analog comparators                            | Compares two analog input voltages across the full range of the supply voltage.                                                           |
| 12-bit digital-to-analog converters (DAC)     | Low-power general-purpose DAC, whose output can be placed on an external pin or set as one of the inputs to the analog comparator or ADC. |

## 2.3.7 Timer modules

The following timer modules are available on this device:

**Table 2-8. Timer modules**

| Module                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 2.3.8 Communication interfaces

The following communication interfaces are available on this device:

**Table 2-9. Communication modules**

| Module                                             | Description                                                                                                                            |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Ethernet MAC with IEEE 1588 capability (ENET)      | 10/100 MB/s Ethernet MAC (MII and RMII) with hardware support for IEEE 1588                                                            |
| Controller Area Network (CAN)                      | Supports the full implementation of the CAN Specification Version 2.0, Part B                                                          |
| Serial peripheral interface (SPI)                  | Synchronous serial bus for communication to an external device                                                                         |
| Inter-Integrated Circuit (I <sup>2</sup> C)        | Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.            |
| Universal asynchronous receiver/transmitter (UART) | Asynchronous serial bus communication interface with programmable 8- or 9-bit data format and support of ISO 7816 smart card interface |

## 2.3.9 Human-machine interfaces

The following human-machine interfaces (HMI) are available on this device:

**Table 2-10. HMI modules**

| Module                              | Description                                                                                                                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| General purpose input/output (GPIO) | <p>All general purpose input or output (GPIO) pins are capable of interrupt and DMA request generation.</p> <p>Configurable slew rate on all output pins.</p> <p>High drive configurable option on 8 pins</p> |

**Table 2-10. HMI modules**

| Module | Description                                           |
|--------|-------------------------------------------------------|
|        | (PTB0, PTB1, PTD4, PTD5, PTD6, PTD7, PTC3, and PTC4). |

## 2.4 Orderable part numbers

The following table summarizes the part numbers of the devices covered by this document.

**Table 2-11. Orderable part numbers summary**

| NXP part number             | CPU frequency (MHz) | Ambient operating temperature (°C) | Package    | Flash/SRAM    | Ethernet | CAN | GPIO |
|-----------------------------|---------------------|------------------------------------|------------|---------------|----------|-----|------|
| MKV58F1M0VMD24 <sup>1</sup> | 240                 | 105                                | 144 MAPBGA | 1 MB/256 KB   | Yes      | 3   | 111  |
| MKV58F1M0VLQ24              | 240                 | 105                                | 144 LQFP   | 1 MB/256 KB   | Yes      | 3   | 111  |
| MKV58F1M0VLL24              | 240                 | 105                                | 100 LQFP   | 1 MB/256 KB   | Yes      | 3   | 74   |
| MKV56F1M0VMD24 <sup>1</sup> | 240                 | 105                                | 144 MAPBGA | 1 MB/256 KB   | No       | 2   | 111  |
| MKV56F1M0VLQ24              | 240                 | 105                                | 144 LQFP   | 1 MB/256 KB   | No       | 2   | 111  |
| MKV56F1M0VLL24              | 240                 | 105                                | 100 LQFP   | 1 MB/256 KB   | No       | 2   | 74   |
| MKV58F512VMD24 <sup>1</sup> | 240                 | 105                                | 144 MAPBGA | 512 KB/128 KB | Yes      | 3   | 111  |
| MKV58F512VLQ24              | 240                 | 105                                | 144 LQFP   | 512 KB/128 KB | Yes      | 3   | 111  |
| MKV58F512VLL24              | 240                 | 105                                | 100 LQFP   | 512 KB/128 KB | Yes      | 3   | 74   |
| MKV56F512VMD24 <sup>1</sup> | 240                 | 105                                | 144 MAPBGA | 512 KB/128 KB | No       | 2   | 111  |
| MKV56F512VLQ24              | 240                 | 105                                | 144 LQFP   | 512 KB/128 KB | No       | 2   | 111  |
| MKV56F512VLL24              | 240                 | 105                                | 100 LQFP   | 512 KB/128 KB | No       | 2   | 74   |

1. The 144-pin MAPBGA package for this product is not yet available. However, it is included in a Package Your Way program for Kinetis MCUs. Visit [nxp.com/KPYW](http://nxp.com/KPYW) for more details.

## Chapter 3

# Core Overview

### 3.1 Cortex CM7 Core Introduction

The Cortex-M7 processor is a highly efficient high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline and supports dual-issue of load/load and load/store instruction pairs to multiple memory interfaces.

Memory interfaces that the processor supports include:

1. Tightly Coupled Memory (TCM) interface.
2. Harvard instruction and data caches and AXI master (AXIM) interface.
3. Dedicated low-latency AHB-Lite peripheral (AHBP) interface.

The processor has a Memory Protection Unit (MPU) that you can configure to protect regions of memory.

The Cortex-M7 processor includes floating-point arithmetic functionality, with support for single-precision arithmetic.

The CM7 core has several memory interfaces:

1. 64-bit ITCM (Instruction Tightly Coupled Memory) – connected to fast memory, RAM, to provide no wait state instruction execution.
2. 64-bit DTCM (Data Tightly Coupled Memory) – split into two interleaved 32-bit interfaces named D0TCM and D1TCM. RAM is expected to be connected to these interfaces and provide no wait state data fetches.
3. 64-bit AXI AMBA4 memory interface with I-cache and D-cache for efficient access to external resources.
4. 32-bit AHBP Peripheral port for interfacing to low latency on chip peripherals.
5. 32-bit AHBS Slave port for interfacing to slaves such as DMA.

The CM7 core also includes:

- Nested Interrupt Controller
- Asynchronous Wake-up Interrupt Controller (AWIC)
- Debug and Trace Unit (Coresight components)

The CM7 processor is intended for deeply embedded applications that require fast interrupt response features, and a typical system implementation is shown:

This chip has the following system modules:

- Single Precision Floating Point Unit, SPFPU
- Memory Protection Unit MPU, with capability to segment into 16 memory regions
- ITCM Controller connected to 64 KB of RAM
- DTCM Controller connected to 128 KB of RAM ( D0TCM – 64KB, D1TCM – 64KB)
- 16 KB Instruction cache and 8 KB Data cache

This device has two crossbars:

1. Crossbar Switch AXBS with 4 Master Ports and 7 Slave Ports. This provides interfaces for the CM7 to access peripherals, off platform RAM, external memory access, DMA and other Masters
2. The PL301 crossbar provides the 64-bit AHB interface to the embedded flash.

### 3.1.1 Buses, interconnects, and interfaces

The ARM Cortex-M7 core has four buses as described in the following table.

| Bus name                     | Description                                                                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AXI Master (AXIM) bus        | This bus is connected to the PL301 and to a separate master on the crossbar.                                                                                                                                                                                                       |
| AHB Slave (AHBS) bus         | The AHBS (TCM) interface is connected to a separate crossbar slave for system access.                                                                                                                                                                                              |
| AHB Peripheral (AHBP) bus    | The AHBP interface is connected to a separate master on the crossbar. It accesses AIPSO and AIPS1.                                                                                                                                                                                 |
| Private Peripheral bus (PPB) | The PPB provides access to these modules: <ul style="list-style-type: none"> <li>• ARM modules such as the NVIC, ETCM, ITM, DWT, FBP, and ROM tables</li> <li>• NXP Miscellaneous Control Module (MCM)</li> <li>• Memory-Mapped Cryptographic Acceleration Unit (MMCAU)</li> </ul> |

### 3.1.2 System Tick Timer

The System Tick Timer's clock source is always the core clock, FCLK. This results in the following:

- The CLKSOURCE bit in SysTick Control and Status register is always set to select the core clock.
- Because the timing reference (FCLK) is a variable frequency, the TENMS bit in the SysTick Calibration Value Register is always zero.
- The NOREF bit in SysTick Calibration Value Register is always set, implying that FCLK is the only available source of reference timing.

### 3.1.3 Debug facilities

This device has extensive debug capabilities including run control and tracing capabilities. The standard ARM debug port that supports JTAG and SWD interfaces. Also the cJTAG interface is supported on this device.

### 3.1.4 Core privilege levels

The ARM documentation uses different terms than this document to distinguish between privilege levels.

| If you see this term... | it also means this term... |
|-------------------------|----------------------------|
| Privileged              | Supervisor                 |
| Unprivileged            | User                       |

## 3.2 Nested Vector Interrupt Controller (NVIC) configuration

### 3.2.1 Interrupt priority levels

This device supports 16 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 4 bits. For example, IPR0 is shown below:

|   |      |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |
|---|------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|------|----|----|----|----|----|---|---|------|---|---|---|---|---|---|---|
|   | 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15   | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R | IRQ3 |    |    |    | 0  | 0  | 0  | 0  | IRQ2 |    |    |    | 0  | 0  | 0  | 0  | IRQ1 |    |    |    | 0  | 0  | 0 | 0 | IRQ0 |   |   |   | 0 | 0 | 0 | 0 |
| W |      |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |      |   |   |   |   |   |   |   |

### 3.2.2 Non-maskable interrupt

The non-maskable interrupt request to the NVIC is controlled by the external  $\overline{\text{NMI}}$  signal. The pin the  $\overline{\text{NMI}}$  signal is multiplexed on, must be configured for the  $\overline{\text{NMI}}$  function to generate the non-maskable interrupt request.

### 3.2.3 Interrupt Vector Assignments

Table 3-2. Interrupt vector assignments - KV5x

| Address Offset                  | Vector | IRQ | Source Module | Source Description           |
|---------------------------------|--------|-----|---------------|------------------------------|
| ARM Core System Handler Vectors |        |     |               |                              |
| 0x0000_0000                     | 0      | –   | ARM Core      | Initial Stack Pointer        |
| 0x0000_0004                     | 1      | –   | ARM Core      | Initial Program Counter      |
| 0x0000_0008                     | 2      | –   | ARM Core      | Non-Maskable Interrupt (NMI) |
| 0x0000_000C                     | 3      | –   | ARM Core      | Hard Fault                   |

Table continues on the next page...

**Table 3-2. Interrupt vector assignments - KV5x (continued)**

| Address Offset              | Vector | IRQ | Source Module                     | Source Description                                  |
|-----------------------------|--------|-----|-----------------------------------|-----------------------------------------------------|
| 0x0000_0010                 | 4      | –   | ARM Core                          | MemManage Fault                                     |
| 0x0000_0014                 | 5      | –   | ARM Core                          | Bus Fault                                           |
| 0x0000_0018                 | 6      | –   | ARM Core                          | Usage Fault                                         |
| 0x0000_001C                 | 7      | –   | –                                 | –                                                   |
| 0x0000_0020                 | 8      | –   | –                                 | –                                                   |
| 0x0000_0024                 | 9      | –   | –                                 | –                                                   |
| 0x0000_0028                 | 10     | –   | –                                 | –                                                   |

| 0x0000_0210    | 132    | 116 | FlexCAN2            | Bus Off                         |
| 0x0000_0214    | 133    | 117 | FlexCAN2            | Error Sources                   |
| 0x0000_0218    | 134    | 118 | FlexCAN2            | Transmit Warning                |
| 0x0000_021C    | 135    | 119 | FlexCAN2            | Receive Warning                 |
| 0x0000_0220    | 136    | 120 | FlexCAN2            | Wake-Up                         |

### 3.3 Asynchronous Wake-up Interrupt Controller (AWIC) configuration

The primary function of the AWIC block is to detect asynchronous wake-up events in stop modes and signal to clock control logic to resume system clocking. After clock restart, the NVIC observes the pending interrupt and performs the normal interrupt or event processing.

### 3.3.1 Wake-up sources

The device uses the following internal and external inputs to the AWIC module.

**Table 3-3. AWIC Stop and VLPS Wake-up Sources**

| Wake-up source          | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| Available system resets | RESET pin and WDOG when LPO is its clock source, and JTAG                       |
| Low-voltage detect      | Mode Controller                                                                 |
| Low-voltage warning     | Mode Controller                                                                 |
| High-voltage detect     | Power Mode Controller                                                           |
| Pin interrupts          | Port Control Module - Any enabled pin interrupt is capable of waking the system |
| ADC0 (16-bit SAR)       | The ADC0 can be functional in STOP/VLPS mode                                    |
| HSADCx                  | The HSADCx can be functional with MCGIRCLK in the STOP/VLPS mode, if enabled    |
| CMPx                    | Since no system clocks are available, functionality is limited                  |
| I <sup>2</sup> C        | Address match wakeup                                                            |
| UART                    | Active edge on RXD                                                              |
| LPTMR                   | Functional in Stop/VLPS modes                                                   |
| FlexCAN                 | Functional in Stop mode                                                         |
| Ethernet                | Magic Packet Wake-up                                                            |
| NMI                     | Non-maskable interrupt                                                          |

### 3.4 Floating Point Unit (FPU) configuration

This device includes ARM's Single Precision Floating Point Unit (FPv5-SP FPU).

The FPv5-SP FPU supports:

- FP extension registers that the software can view as either 32 single-precision or 16 double-precision registers
- Single-precision floating-point arithmetic
- Conversions between integer, single-precision floating-point, and half-precision floating-point formats
- Data transfers of single-precision and double-precision registers
- Identical load/store instruction support to FPv4 extensions that already includes support for 64-bit data types

## NOTE

FPv5-SP is a single-precision only variant of ARMS's FPv5-D16 module.

## Chapter 4

# Memories and Memory Interfaces

### 4.1 Flash memory types

This chip contains a non-volatile program flash memory that can execute program code.

### 4.2 Flash Memory Sizes

The amounts of flash memory for the devices covered in this document are:

**Table 4-1. Flash memory size**

| Device                      | Flash (Bytes) | Block 0 (flash) address range |
|-----------------------------|---------------|-------------------------------|
| MKV58F1M0VMD24 <sup>1</sup> | 1M            | 1000_0000 - 100F_FFFF         |
| MKV58F1M0VLQ24              |               |                               |
| MKV58F1M0VLL24              |               |                               |
| MKV56F1M0VMD24 <sup>1</sup> |               |                               |
| MKV56F1M0VLQ24              |               |                               |
| MKV56F1M0VLL24              |               |                               |
| MKV58F512VMD24 <sup>1</sup> | 512K          | 1000_0000 - 1007_FFFF         |
| MKV58F512VLQ24              |               |                               |
| MKV58F512VLL24              |               |                               |
| MKV56F512VMD24 <sup>1</sup> |               |                               |
| MKV56F512VLQ24              |               |                               |
| MKV56F512VLL24              |               |                               |

1. The 144-pin MAPBGA package for this product is not yet available. However, it is included in a Package Your Way program for Kinetis MCUs. Visit [nxp.com/KPYW](http://nxp.com/KPYW) for more details.

### 4.3 Flash Security

How flash security is implemented on this device is described in [Chip Security](#).

## 4.4 Flash Modes

The flash memory is always configured in NVM normal. There are no operating conditions in which the flash is configured for NVM special mode.

## 4.5 Erase All Flash Contents

An Erase All Flash Blocks operation can be launched by software through a series of peripheral bus writes to flash registers. In addition the entire flash memory may be erased external to the flash memory from the SWJ-DP debug port by setting DAP\_CONTROL[0]. DAP\_STATUS[0] is set to indicate the mass erase command has been accepted. DAP\_STATUS[0] is cleared when the mass erase completes.

## 4.6 FTFE\_FOPT Register

The flash memory's FTFE\_FOPT register allows the user to customize the operation of the MCU at boot time. See [FOPT boot options](#) for details of its definition.

## 4.7 RAM Memory Sizes

Table 4-2. RAM memory sizes

| Device                       | ITCM (Bytes) | ITCM address range    | D0TCM/D1TCM | DTCM address range    | OCRAM (bytes) | OCRAM address range   |
|------------------------------|--------------|-----------------------|-------------|-----------------------|---------------|-----------------------|
| MKV58F1M0VM D24 <sup>1</sup> | 64K          | 0000_0000 - 0000_FFFF | 64K / 64K   | 2000_0000 - 2001_FFFF | 64K           | 2F00_0000 - 2F00_FFFF |
| MKV58F1M0VL Q24              |              |                       |             |                       |               |                       |
| MKV58F1M0VL L24              |              |                       |             |                       |               |                       |
| MKV56F1M0VM D24 <sup>1</sup> |              |                       |             |                       |               |                       |
| MKV56F1M0VL Q24              |              |                       |             |                       |               |                       |
| MKV56F1M0VL L24              |              |                       |             |                       |               |                       |
| MKV58F512VM D24 <sup>1</sup> | 64K          | 0000_0000 - 0000_FFFF | 32K / 32K   | 2000_0000 - 2000_FFFF | 0K            | —                     |

| MKV56F512VLL 24              |              |                    |             |                    |               |                     |

1. The 144-pin MAPBGA package for this product is not yet available. However, it is included in a Package Your Way program for Kinetis MCUs. Visit [freescale.com/KPYW](http://freescale.com/KPYW) for more details.

## 4.8 Other SRAM arrays

On top of the ITCM, DTCM, and OCRM, there is also a RAM associated with the CM7 internal cache.

This device comes with 16 KB of Instruction cache RAM and 8 KB of Data cache RAM.

Other peripherals that require RAM for FIFOs/buffering are:

- eDMA: 2 sets of 512 bytes for DMA channel descriptors
- FlexCAN: 3 sets of 512 bytes for support of up to 16 mailboxes
- Ethernet: 4 KB of SRAM

## 4.9 SRAM accesses

The ITCM, DTCM, OCRM, I-cache RAM, and D-cache RAM are all accessible by the CM7 CPU. The ITCM RAM and DTCM RAM have backdoor access for other Masters such as the DMA, for example to bootload instructions into ITCM.

Another master that may require access to DTCM RAM is the Ethernet module.

## 4.10 SRAM retention in low power modes

The various SRAM arrays for KV5x will have the following characteristic in low power modes:

- All RAM contents are retained in WAIT, VLPW, STOP, and VLPS modes.
- LLS mode is not supported.
- In VLLS3 mode, I-cache and D-cache RAM are switched off so contents are lost. ITCM, DTCM, and OCRAM contents are retained.
- In VLLS2 mode, I-cache and D-cache, OCRAM, and partial DTCM RAM contents will be lost. ITCM contents are retained if SMC\_STOPCTRL[RAM2PO] is set. DTCM RAM contents in the first half of the DTCM address range (0x2000\_0000 - 0x2000\_ffff) are retained.
- In VLLS1 and VLLS0 modes, I-cache, D-cache, OCRAM, ITCM, and DTCM are powered off. 32-byte register file contents are retained.

## 4.11 System Register file

This device includes a 32-byte register file that is powered in all power modes.

Also, it retains contents during low-voltage detect (LVD) events and is only reset during a power-on reset.

# Chapter 5

## Memory Map

### 5.1 Introduction

This chip contains both Flash and RAM memories and memory-mapped peripherals which are located in one contiguous memory space. The ARM M7 core supports both register access of the various peripherals and also bit-band accesses. Following are the memory sizes present.

- 1 MB Flash memory
- 256 KB RAM partitioned with 64 KB on ITCM, 64 KB on D0TCM, 64 KB on D1TCM, and 64 KB on OCRAM.

### 5.2 System Memory Map

The following table shows the high-level device memory map. This map provides the complete architectural address space definition for the various sections. Based on the physical sizes of the memories and peripherals, the actual address regions used may be smaller.

**Table 5-1. System Memory Map**

| System 32-bit Byte Address Range | Destination Slave                  | Access                                       |
|----------------------------------|------------------------------------|----------------------------------------------|
| 0x0000_0000–0x0000_FFFF          | ITCM RAM - 64K bytes               | M7 mainly, backdoor access for DMA and Enet. |
| 0x0001_0000–0x0FFF_FFFF          | Reserved                           | -                                            |
| 0x1000_0000–0x100F_FFFF          | Code Flash 1M bytes (cache-able)   | All Masters                                  |
| 0x1010_0000–0x17FF_FFFF          | Reserved                           | -                                            |
| 0x1800_0000–0x1800_0FFF          | Programming Acceleration RAM       | Flash Controller access.                     |
| 0x1800_1000–0x1FFF_FFFF          | Reserved                           |                                              |
| 0x2000_0000–0x2001_FFFF          | DTCM - D0TCM - 64K and D1TCM - 64K | M7 mainly, backdoor access for DMA and Enet. |

*Table continues on the next page...*

**Table 5-1. System Memory Map (continued)**

| System 32-bit Byte Address Range | Destination Slave                   | Access      |
|----------------------------------|-------------------------------------|-------------|
| 0x2002_0000–0x2EFF_FFFF          | Reserved                            | -           |
| 0x2F00_0000–0x2F00_FFFF          | OC-RAM 64K ( cache-able)            | All Masters |

## 5.3 AIPS slot assignments

Slots 0-79 are 32-bit data width modules, slots 80-95 are 16-bit data width modules, and slots 96-126 are 8-bit data width modules.

**Table 5-2. AIPS–0**

| System Base Address | Slot Number | Module                            |
|---------------------|-------------|-----------------------------------|
| 0x4000_0000         | 0           | Peripheral Bridge 0 (AIPS–Lite 0) |
| 0x4000_1000         | 1           | MSCM                              |
| 0x4000_2000         | 2           | –                                 |
| 0x4000_3000         | 3           | –                                 |
| 0x4000_4000         | 4           | Crossbar Switch                   |
| 0x4000_5000         | 5           | –                                 |
| 0x4000_6000         | 6           | –                                 |

The following table shows the peripheral assignments for the AIPS1.

## AIPS slot assignments

Slots 0-79 are 32-bit data width modules, slots 80-95 are 16-bit data width modules, and slots 96-126 are 8-bit data width modules.

**Table 5-3. AIPS–1**

| System Base Address | Slot Number | Module                              |
|---------------------|-------------|-------------------------------------|
| 0x4008_0000         | 0           | Peripheral Bridge 1 (AIPS–Lite 1)   |
| 0x4008_1000         | 1           | –                                   |
| 0x4008_2000         | 2           | –                                   |
| 0x4008_3000         | 3           | –                                   |

| 0x400F_F000         | 127         | Not an AIPS-Lite slot. The 32-bit general purpose input/output module that shares the crossbar switch slave port with the AIPS-Lite is accessed at this address. |

# Chapter 6

## Clock Distribution

### 6.1 Introduction

The KV5x family is a Kinetis MCU product line based on the ARM Cortex-M7 core and utilizes the MCG (Multipurpose Clock Generator) module that provides the clocks for the CPU, memories, and peripherals. The MCG accepts input clocks from the OSC module, providing an external feed from a ceramic resonator/crystal/external clock, and internal RC oscillators. The MCG has a PLL that provides a multiplying function on the input clock source to generate clock frequencies from 110 MHz to 240 MHz. The MCG also has an FLL that provides multiplying function to the input clock source to generate frequencies from 20 MHz to 100 MHz.

The primary clocks for the system are generated from the MCGOUTCLK clock. The clock generation circuitry of the SIM module provides several clock dividers. These clock divider configurations, namely:

1. System (CPU) clock,
2. Fast peripheral clock,
3. Flexbus clock, and
4. Flash/Bus clock

allow different portions of the device to be clocked at different frequencies. This allows for trade-offs between performance and power dissipation.

Various modules have alternate clock sources. Clock selection for these modules is controlled by the SOPT registers in the SIM module.

### 6.2 High-level device clocking diagram

The following [system oscillator](#), [MCG](#), and [SIM](#) module registers control the multiplexers, dividers, and clock gates shown in the below figure:

High-level device clocking diagram

|              | OSC    | MCG    | SIM                  |
|--------------|--------|--------|----------------------|
| Multiplexers | MCG_Cx | MCG_Cx | SIM_SOPT1, SIM_SOPT2 |
| Dividers     | —      | MCG_Cx | SIM_CLKDIVx          |
| Clock gates  | OSC_CR | MCG_C1 | SIM_SCGCx            |

CG — Clock gate  
**Note:** See subsequent sections for details on where these clocks are used.

Figure 6-1. Clocking diagram

6.2.1 Clock definitions

The following table describes the clocks in the previous block diagram.

| Clock name         | Description                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| System (CPU) clock | MCGOUTCLK divided by OUTDIV1 clocks the ARM Cortex-M7 core, RAM, DMA, GPIO, FMC module, and crossbar switch bus masters. |

Table continues on the next page...

| Clock name            | Description                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast Peripheral clock | MCGOUTCLK divided by OUTDIV2 clocks the UARTs, SPI, eFlexPWM, FTMs, PDBs, ENC, FlexCAN, XBARA, and ADC modules.                                                                                            |
| Bus /Flash clock      | MCGOUTCLK divided by OUTDIV4 clocks Flash, I2C, WDOG, EWM, PIT, LPTIMER, OSC, MCG, PMC, XBARB/AOI, CMP.                                                                                                    |
| Flexbus clock         | MCGOUTCLK divided by OUTDIV3 clocks the Flexbus module.                                                                                                                                                    |
| nanoedge clock        | The nanoedge clock will be fed with Fast Peripheral Bus clock. In addition the nanoedge module will also be fed with the MCGPLLCLK which needs to be two times the frequency of the Fast Peripheral clock. |
| MCGIRCLK              | MCG output of the slow or fast internal reference clock.                                                                                                                                                   |
| MCGFFCLK              | MCG output of the slow internal reference clock or a divided MCG external reference clock.                                                                                                                 |
| MCGOUTCLK             | MCG output of either IRC, MCGPLLCLK, or MCG's external reference clock that sources the core, Fast Peripheral, FlexBus and flash clocks. It is also an option for the debug trace clock.                   |
| MCGPLLCLK             | MCG output of the PLL.                                                                                                                                                                                     |
| MCGFLLCLK             | MCG output of the FLL.                                                                                                                                                                                     |
| OSCCLK                | System oscillator output of the internal oscillator or sourced directly from EXTAL.                                                                                                                        |
| OSCERCLK              | System oscillator output sourced from OSCCLK that may clock some on-chip modules. Divisible by 1, 2, 4, or 8.                                                                                              |
| OSCERCLK_UNDIV        | System oscillator output sourced directly from OSCCLK.                                                                                                                                                     |
| LPO                   | PMC 1kHz output                                                                                                                                                                                            |

## 6.3 Internal clocking requirements

The clock dividers are programmed via the SIM module's CLKDIV registers. Each divider is programmable from a divide-by-1 through divide-by-16 setting. The following requirements must be met when configuring the clocks for this device:

1. The System (CPU) clock frequency that drives the CPU platform must be in the range of 240 MHz or less in HSRUN mode. In normal RUN mode, it must be in the range of 160 MHz or less. In Very Low Power Run mode, the System (CPU) clock frequency must be less than 4 MHz.
2. The Fast Peripheral clock frequency must be an integer divide or multiple of the System (CPU) clock, that is, x2, x3, x4, or divide by 2/4/8. This allows key peripherals to be clocked at high speed, while System (CPU) clock is running slower to conserve power consumption. The Fast Peripheral clock should not exceed 120 MHz.

3. The FlexBus clock frequency must be an integer divide of the System (CPU) clock. The FlexBus also has pad interface restrictions that limits the maximum frequency. The System (CPU) clock to FlexBus clock ratio is limited to a max value of 8.
4. The Bus/Flash clock must not exceed 27.5 MHz, and be an integer divide of the System (CPU) clock and an integer divide of the Fast Peripheral clock.
5. The nanoedge module requires two clock inputs, where one clock input is 2x the other clock frequency. Thus the fast peripheral bus clock provides the nanoedge clock, and MCGPLLCLK provides the "2x Fast peripheral bus clock". Each of these clocks must be an integer divide or multiple of the System (CPU) clock. The nanoedge module is expected to be programmed to use clock inputs of 80/160 MHz, 100/200 MHz, and possible 120/240 MHz to support sub-nanosecond resolution control of the FlexPWM.

### NOTE

To enable the nanoedge module for nanosecond resolution, the PLL must be enabled to provide high frequencies clock source, MCGPLLCLK. When the nanoedge module is enabled, the System (CPU) clock, the Fast Peripheral clock, and the Bus/Flash clock must be derived from the MCGPLLCLK.

The following are a few of the more common clock configurations for this device:

| High Speed Run Mode   | Frequency    |
|-----------------------|--------------|
| System (CPU) clock    | 240 MHz max. |
| Fast Peripheral clock | 120 MHz max. |
| Bus / Flash clock     | 24 MHz max   |
| Flexbus clock         | 60 MHZ       |

| High speed Run mode   | Frequency |
|-----------------------|-----------|
| System (CPU) clock    | 180 MHz   |
| Fast Peripheral clock | 90 MHz    |
| Bus / Flash clock     | 22.5 MHz  |
| Flexbus clock         | 60 MHz    |

| RUN mode              | Frequency |
|-----------------------|-----------|
| System (CPU) clock    | 100 MHz   |
| Fast Peripheral clock | 100 MHZ   |
| Bus / Flash clock     | 25 MHz    |
| Flexbus clock         | 50 MHZ    |

| RUN mode              | Frequency |
|-----------------------|-----------|
| System (CPU) clock    | 50 MHz    |
| Fast Peripheral clock | 100 MHz   |
| Bus / Flash clock     | 25 MHz    |
| Flexbus clock         | 50 MHz    |

### 6.3.1 Clock divider values after reset

Each clock divider is programmed via the SIM module's CLKDIV $n$  registers. The flash memory's FTFA\_FOPT[LPBOOT] bit controls the reset value of the core clock, System (CPU) clock, bus clock, and flash clock dividers as shown below:

| FTFA_FOPT [LPBOOT] | System (CPU) clock | Fast Peripheral clock | Bus / Flash clock  | Description     |
|--------------------|--------------------|-----------------------|--------------------|-----------------|
| 0                  | 0x7 (divide by 8)  | 0x7 (divide by 8)     | 0xF (divide by 16) | Low power boot  |
| 1                  | 0x0 (divide by 1)  | 0x0 (divide by 1)     | 0x1 (divide by 2)  | Fast clock boot |

This gives the user flexibility for a lower frequency, low-power boot option. The flash erased state defaults to fast clocking mode, since where the low power boot (FTFA\_FOPT[LPBOOT]) bit resides in flash is logic 1 in the flash erased state.

To enable the low power boot option program FTFA\_FOPT[LPBOOT] to zero. During the reset sequence, if LPBOOT is cleared, the system is in a slow clock configuration. Upon any system reset, the clock dividers return to this configurable reset state.

### 6.3.2 VLPR mode clocking

The clock dividers cannot be changed while in VLPR mode. They must be programmed prior to entering VLPR mode to ensure that:

- the System (CPU) and Fast Peripheral clocks are less than or equal to 4 MHz
- the Bus/Flash clock is less than or equal to 500 kHz
- the nano-edge module is disabled

## 6.4 Clock Gating

The clock to each module can be individually gated on and off using the SIM module's SCGCx registers. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing a module, set the corresponding bit in SCGCx register to enable the clock. Before turning off the clock, make sure to disable the module.

Any bus access to a peripheral that has its clock disabled generates an error termination.

## 6.5 Module clocks

The following table summarizes the clocks associated with each module.

**Table 6-1. Module clocks**

| Module                | Bus interface clock   | Internal clocks    | I/O interface clocks |
|-----------------------|-----------------------|--------------------|----------------------|
| <b>Core modules</b>   |                       |                    |                      |
| ARM Cortex-CM7core    | System (CPU) clock    | System (CPU) clock | —                    |
| NVIC                  | System (CPU) clock    | —                  | —                    |
| DAP                   | System (CPU) clock    | —                  | —                    |
| ITM                   | System (CPU) clock    | —                  | —                    |
| JTAGC/SWD             | —                     | —                  | JTAG_CLK             |
| <b>System modules</b> |                       |                    |                      |
| DMA                   | System (CPU) clock    | —                  | —                    |
| DMA Mux               | Bus / Flash clock     | —                  | —                    |
| Port control          | Bus / Flash clock     | LPO                | —                    |
| AXBS Crossbar Switch  | System (CPU) clock    | —                  | —                    |
| PL301 crossbar switch | System (CPU) clock    | —                  | —                    |
| Peripheral bridges    | System (CPU) clock    | Bus / Flash clock  | —                    |
| XBARA                 | Fast peripheral clock | —                  | —                    |
| XBARB,AOI             | Bus/Flash clock       | —                  | —                    |
| LLWU, PMC, SIM, RCM   | Bus/ Flash clock      | LPO                | —                    |
| Mode controller       | Bus / Flash clock     | —                  | —                    |
| MCM                   | System (CPU) clock    | —                  | —                    |
| MSCM                  | System (CPU) clock    | —                  | —                    |
| EWM                   | Bus / Flash clock     | LPO                | —                    |
| Watchdog timer        | Bus / Flash clock     | LPO                | —                    |
| <b>Clocks</b>         |                       |                    |                      |

### 6.5.1 Nano-edge clocking

The clocking options for the PWM0 module with nano-edge functionality are shown in the following figure.

**Figure 6-2. Nano-Edge module Clock inputs**

### 6.5.2 WDOG clocking

The WDOG may be clocked from two clock sources as shown in the following figure.

**Figure 6-3. WDOG clock generation**

### 6.5.3 Debug trace clock

The debug trace clock source can be clocked as shown in the following figure.

**Figure 6-4. Trace clock generation**

### NOTE

The trace clock frequency observed at the TRACE\_CLKOUT pin will be half that of the selected clock source.

## 6.5.4 PMC 1-kHz LPO clock

The Power Management Controller (PMC) generates a 1-kHz clock that is enabled in all modes of operation, including all low power modes, provided that SMC\_STOPCTRL[LPOPO] is not set and the low power mode being entered is not VLLS0. This 1-kHz source is commonly referred to as LPO clock or 1-kHz LPO clock.

## 6.5.5 PORT digital filter clocking

The digital filters can be clocked as shown in the following figure.

### NOTE

In stop mode, the digital input filters are bypassed unless they are configured to run from the 1 kHz LPO clock source.

**Figure 6-5. PORTx digital input filter clock generation**

### 6.5.6 LPTMR clocking

The prescaler and glitch filters in each of the LPTMR<sub>x</sub> modules can be clocked as shown in the following figure.

#### NOTE

The chosen clock must remain enabled if the LPTMR<sub>x</sub> is to continue operating in all required low-power modes.

**Figure 6-6. LPTMRx prescaler/glitch filter clock generation**

### 6.5.7 FlexCAN clocking

The clock for the FlexCAN's protocol engine can be selected as shown in the following figure.

**Figure 6-7. FlexCAN clock generation**

### 6.5.8 UART clocking

UART0 to UART5 modules operate from the Fast Peripheral clock, which provides higher performance level for these modules.

### 6.5.9 Ethernet Clocking

- The RMII clock source can be EXTAL clock or ENET\_1588\_CLKIN selected via SIM\_SOPT2[RMIISRC]
- The MII clocks, MII0\_RXCLK and MII0\_TXCLK, are supplied from pins and must be 25 MHz
- The IEEE 1588 timestamp clock can run up to 180 MHz, if generated from internal clock sources. Its period must be an integer number of nanoseconds (eg: 10ns = 100 MHz, 15ns = 66.67 MHz, 20ns = 50 MHz). Its clock source is chosen as shown in the following figure.

**Figure 6-8. Ethernet IEEE1588 timestamp clock generation**

### 6.5.10 Flexbus Clocking

The Flexbus requires the System (CPU) clock to be on to operate.

## 6.6 External clocks

The input clocks to the SoC are described in detail in the MCG chapter.

- FlexTimers
  - The FlexTimers have an external clock input, FTM\_XCLK, which must be no faster than 1/4 of the Fast Peripheral clock
- ARM Trace
  - TRACE\_CLK generated by simple div-by-2 within ARM core and driven out to pad
  - ARM Trace port outputs are synchronous to this clock

# Chapter 7

## Reset and Boot

### 7.1 Introduction

The following reset sources are supported in this MCU:

**Table 7-1. Reset sources**

| Reset sources | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Each of the system reset sources has an associated bit in the system reset status (SRS) registers. See the [Reset Control Module](#) for register details.

The MCU can exit and reset in functional mode where the CPU is executing code (default) or the CPU is in a debug halted state. There are several boot options that can be configured. See [Boot information](#) for more details.

### 7.2 Cortex CM7 platform

The Cortex CM7 platform provides the capability to offset the base address of vectors. In this device, the default base address for the vectors is 0x1000\_0000.

## 7.3 Reset

This section discusses basic reset mechanisms and sources. Some modules that cause resets can be configured to cause interrupts instead. Consult the individual peripheral chapters for more information.

### 7.3.1 Power-on reset (POR)

When power is initially applied to the MCU or when the supply voltage drops below the power-on reset re-arm voltage level ( $V_{POR}$ ), the POR circuit causes a POR reset condition.

As the supply voltage rises, the LVD circuit holds the MCU in reset until the supply has risen above the LVD low threshold ( $V_{LVDL}$ ). The POR and LVD bits in SRSL register are set following a POR.

### 7.3.2 System resets

Resetting the MCU provides a way to start processing from a known set of initial conditions. System reset begins with the on-chip regulator in full regulation and system clocking generation from an internal reference. When the processor exits reset, it performs the following:

- Reads the start SP (SP\_main) from vector-table offset 0
- Reads the start PC from vector-table offset 4
- LR is set to 0xFFFF\_FFFF

The on-chip peripheral modules are disabled and the non-analog I/O pins are initially configured as disabled. The pins with analog functions assigned to them default to their analog function after reset.

During and following a reset, the JTAG pins have their associated input pins configured as:

- TDI in pull-up (PU)
- TCK in pull-down (PD)
- TMS in PU

and associated output pin configured as:

- TDO with no pull-down or pull-up

Note that the nTRST (Debug Tap Reset) signal is initially configured as disabled, however once configured to its JTAG functionality its associated input pin is configured as:

- nTRST in pull-up (PU)

### 7.3.2.1 External pin reset (PIN)

On this device,  $\overline{\text{RESET}}$  is a dedicated pin. This pin is open drain and has an internal pullup device. Asserting  $\overline{\text{RESET}}$  wakes the device from any mode. During a pin reset, the SRSI[PIN] bit is set.

#### 7.3.2.1.1 Reset pin filter

The  $\overline{\text{RESET}}$  pin supports digital filtering in all modes of operation. For VLLSx modes, the LLWU provides an optional fixed digital filter running off the 1 kHz LPO clock. See the LLWU chapter for operation of this filter. During non-low leakage operation, there are two clock options for the  $\overline{\text{RESET}}$  pin filter – the 1kHz LPO clock and the bus clock.

This  $\overline{\text{RESET}}$  pin filter implemented in SIM logic includes a separate filter for each clock source. In Stop and VLPS operation this logic either switches to bypass operation or has continued filtering operation depending on the filtering mode selected.

There are several modes defined – See the SOPT6 register description in module for more details. SOPT6[RSTFLTEN[2:0]] and SOPT6[RSTFLTSEL[4:0]] fields control the desired functionality. Both filters are reset on POR, LVD, and wakeup from VLLS. The reset value for each filter defaults to off (non-detect).

The LPO filter is simple with a fixed filter value count of 3. There is also a synchronizer on the input signal that results in an associated latency (2 cycles). As such, it takes 5 cycles to complete a transition from low-to-high or high-to-low. The LPO Filter initializes to off (logic 1) when the LPO filter is not enabled.

The Bus Filter initializes to off (logic 1) when the Bus Filter not enabled. When the Bus Filter is enabled, the number of counts is controlled by SOPT6[RSTFLTSEL[4:0]].

### 7.3.2.2 Low-voltage detect (LVD) reset

This device includes a system to protect against low voltage conditions to protect memory contents and control MCU system states during supply voltage variations. The system is comprised of a power-on reset (POR) circuit and a low-voltage detect (LVD) circuit with a user-selectable trip voltage, either high ( $V_{\text{LVDH}}$ ) or low ( $V_{\text{LVDL}}$ ). The trip

voltage is selected by the PMC\_LVDSC1[LVDV] bits. The LVD system is always enabled in normal run, wait, and stop modes. The LVD system is disabled in VLPx, and VLLSx modes. Refer to Power Management Controller (PMC) chapter for more details.

The LVD can be configured to generate a reset upon detection of a low voltage condition by setting PMC\_LVDSC1[LVDRE]. After an LVD reset has occurred, the LVD system holds the MCU in reset until the supply voltage rises above the low voltage detection threshold.

RCM\_SRS0[LVD] is set following an LVD reset or POR.

### 7.3.2.3 Computer operating properly (COP) watchdog reset

The computer operating properly (COP) watchdog timer (WDOG) monitors the operation of the system by expecting periodic communication from the software. This communication is generally known as servicing (or refreshing) the COP watchdog. If this periodic refreshing does not occur, the watchdog issues a system reset. The COP reset causes RCM\_SRS0[WDOG] to set.

### 7.3.2.4 Low leakage wakeup (LLWU) reset

The LLWU allows up to 16 external pins, the  $\overline{\text{RESET}}$  pin, and up to seven internal peripherals to wake the MCU from VLLSx power modes. The LLWU module is only functional in VLLSx power modes. Any VLLS mode exits via a wakeup or reset event, RCM\_SRS0[WAKEUP] is set indicating the low leakage mode was active prior to the last system reset flow. Using the  $\overline{\text{RESET}}$  pin to trigger an exit from VLLS results in RCM\_SRS0[PIN] being set as well. See the mode controller chapter for more details.

After a system reset, the LLWU retains the flags to indicate the source of the last wakeup until the user clears them.

#### NOTE

Pin wakeup and error condition flags are cleared in the LLWU and module wakeup flags are required to be cleared in the peripheral module. Refer to the individual peripheral specifications for more information.

### 7.3.2.5 Multipurpose clock generator loss-of-clock (LOC) reset

The MCG includes a clock monitor. The clock monitor resets the device when the following conditions are met:

- The clock monitor is enabled (MCG\_C6[CME] = 1)
- The MCG's external reference clock falls outside of the expected frequency range, depending on the MCG\_C2[RANGE] bit
- MCG\_C2[LOCRE0] = 1

RCM\_SRS0[LOC] is set to indicate the error.

### 7.3.2.6 Software reset (SW)

The SYSRESETREQ bit in the NVIC application interrupt and reset control register can be set to force a software reset on the device. (See ARM's NVIC documentation for the full description of the register fields, especially the VECTKEY field requirements.) Setting SYSRESETREQ generates a software reset request. This reset forces a system reset of all major components except for the debug module. A software reset causes RCM\_SRS1[SW] to set.

### 7.3.2.7 Lockup reset (LOCKUP)

The LOCKUP gives immediate indication of seriously errant kernel software. This is the result of the core being locked because of an unrecoverable exception following the activation of the processor's built in system state protection hardware.

The LOCKUP condition causes a system reset and also causes RCM\_SRS1[LOCKUP] to set.

### 7.3.2.8 MDM-AP system reset request

Set the system reset request bit in the MDM-AP control register to initiate a system reset. This is the primary method for resets via the JTAG interface. The system reset is held until this bit is cleared.

Set the core hold reset bit in the MDM-AP control register to hold the core in reset as the rest of the chip comes out of system reset.

## 7.3.3 Debug resets

The following sections detail the debug resets available on the device.

### 7.3.3.1 JTAG reset

The JTAG module generate a system reset when certain IR codes are selected. This functional reset is asserted when EXTEST, HIGHZ and CLAMP instructions are active. The reset source from the JTAG module is released when any other IR code is selected. A JTAG reset causes the JTAG field in the Reset Module Controller's System Reset Status register (RCM\_SRS1[JTAG]) to be set.

### 7.3.3.2 nTRST (Debug TAP Reset)

The nTRST pin causes a reset of the JTAG logic when asserted. Asserting the nTRST pin allows the debugger to gain control of the Test Access Port (TAP) controller state machine (after exiting VLLSx) without resetting the state of the debug modules.

The nTRST pin does not cause a system reset.

### 7.3.3.3 Resetting the Debug subsystem

Use the CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register to reset the debug modules. However, as explained below, using the CDBGRSTREQ bit does not reset all debug-related registers.

CDBGRSTREQ resets the debug-related registers within the following modules:

- SWJ-DP
- AHB-AP
- TPIU
- MDM-AP (MDM control and status registers)
- MCM

CDBGRSTREQ does not reset the debug-related registers within the following modules:

- CM7 core (core debug registers: DHCSR, DCRSR, DCRDR, DEMCR)
- FPB
- DWT
- ITM
- NVIC
- Crossbar bus switch
- AHB-AP
- Private peripheral bus

**NOTE**

CDBGIRSTREQ does not affect AHB resources so that debug resources on the private peripheral bus are available during System Reset.

## 7.4 Boot

This section describes the boot sequence, including sources and options.

### 7.4.1 Boot sources

This device only supports booting from internal flash. Any secondary boot must go through an initialization sequence in flash.

### 7.4.2 FOPT boot options

The flash option register (FOPT) in the flash memory module allows the user to customize the operation of the MCU at boot time. The register contains read-only bits that are loaded from the NVM's option byte in the flash configuration field. The user can reprogram the option byte in flash to change the FOPT values that are used for subsequent resets. For more details on programming the option byte, refer to the flash memory chapter.

The MCU uses the FOPT register bits to configure the device at reset as shown in the following table.

**Table 7-2. Flash Option Register Bit Definitions**

| Bit Num | Field     | Value | Definition                                                                                                                                                                                                                                    |
|---------|-----------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7-6     | Reserved  |       | Reserved for future expansion.                                                                                                                                                                                                                |
| 5       | FAST_INIT |       | Select initialization speed on POR, VLLSx, and any system reset.                                                                                                                                                                              |
|         |           | 0     | Slower initialization. The Flash initialization will be slower with the benefit of reduced average current during this time. The duration of the recovery will be controlled by the clock divider selection determined by the LPBOOT setting. |
|         |           | 1     | Fast Initialization. The Flash has faster recoveries at the expense of higher current during these times.                                                                                                                                     |
| 4-3     | Reserved  |       | Reserved for future expansion.                                                                                                                                                                                                                |
| 2       | NMI_DIS   |       | Enable/disable control for the NMI function.                                                                                                                                                                                                  |

*Table continues on the next page...*

**Table 7-2. Flash Option Register Bit Definitions (continued)**

| Bit Num | Field    | Value                                                                                                                                                                                                             | Definition                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         |          | 0                                                                                                                                                                                                                 | NMI interrupts are always blocked. The associated pin continues to default to NMI pin controls with internal pullup enabled.                                                                                                                                                                                                                                                                            |
|         |          | 1                                                                                                                                                                                                                 | NMI pin/interrupts reset default to enabled.                                                                                                                                                                                                                                                                                                                                                            |
| 1       | Reserved | Reserved for future expansion.                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                         |
| 0       | LPBOOT   | Control the reset value of OUTDIVx values in SIM_CLKDIV1 register. Larger divide value selections produce lower average power consumption during POR, VLLSx recoveries and reset sequencing and after reset exit. |                                                                                                                                                                                                                                                                                                                                                                                                         |
|         |          | 0                                                                                                                                                                                                                 | Low-power boot: OUTDIVx values in SIM_CLKDIV1 register are auto-configured at reset exit for higher divide values that produce lower power consumption at reset exit. <ul style="list-style-type: none"> <li>Core and system clock divider (OUTDIV1) and fast peripheral clock divider (OUTDIV2) are 0x7 (divide by 8)</li> <li>Flash/Bus clock divider (OUTDIV4) are 0xF (divide by 16)</li> </ul>     |

### 7.4.3 Boot sequence

At power up, the on-chip regulator holds the system in a POR state until the input supply is above the POR threshold. The system continues to be held in this static state until the internally regulated supplies have reached a safe operating voltage as determined by the LVD. The Mode Controller reset logic then controls a sequence to exit reset.

1. A system reset is held on internal logic, the  $\overline{\text{RESET}}$  pin is driven out low, and the MCG is enabled in its default clocking mode.
2. Required clocks are enabled (Core Clock, System Clock, Flash Clock, and any Bus Clocks that do not have clock gate control).
3. The system reset on internal logic continues to be held, but the Flash Controller is released from reset and begins initialization operation while the Mode Control logic continues to drive the  $\overline{\text{RESET}}$  pin out low for a count of ~128 Bus Clock cycles.
4. The  $\overline{\text{RESET}}$  pin is released, but the system reset of internal logic continues to be held until the Flash Controller finishes initialization. .
5. When Flash Initialization completes, the  $\overline{\text{RESET}}$  pin is observed. If  $\overline{\text{RESET}}$  continues to be asserted (an indication of a slow rise time on the  $\overline{\text{RESET}}$  pin or external drive in low), the system continues to be held in reset. Once the  $\overline{\text{RESET}}$  pin is detected high, the system is released from reset.

6. At release of system reset, clocking is switched to a slow clock if the FOPT[LPBOOT] field in the Flash Memory module is configured for Low Power Boot
7. When the system exits reset, the processor sets up the stack, program counter (PC), and link register (LR). The cortex M7 CPU on reset access addresses 0x1000\_0000 to 0x1000\_01FF as the default vector table. The processor reads the start SP (SP\_main) from vector-table offset 0. The core reads the start PC from vector-table offset 4. LR is set to 0xFFFF\_FFFF. What happens next depends on the NMI input and the FOPT[NMI\_DIS] field in the Flash Memory module:
  - If the NMI input is high or the NMI function is disabled in the NMI\_DIS field, the CPU begins execution at the PC location.
  - If the NMI input is low and the NMI function is enabled in the NMI\_DIS field, this results in an NMI interrupt. The processor executes an Exception Entry and reads the NMI interrupt handler address from vector-table offset 8. The CPU begins execution at the NMI interrupt handler.

Subsequent system resets follow this reset flow beginning with the step where system clocks are enabled.

# Chapter 8

## Power Management

### 8.1 Introduction

This chapter describes the various chip power modes and functionality of the individual modules in these modes.

### 8.2 Clocking Modes

This section describes the various clocking modes supported on this device.

#### 8.2.1 Partial Stop

Partial Stop is a clocking option that can be taken instead of entering Stop mode and is configured in the SMC Stop Control Register (SMC\_STOPCTRL). The Stop mode is only partially entered, which leaves some additional functionality alive at the expense of higher power consumption. Partial Stop can be entered from either Run mode or VLP Run mode.

When configured for PSTOP2, only the core and system clocks are gated and the bus clock remains active. The bus masters and bus slaves clocked by the system clock enter Stop mode, but the bus slaves clocked by the bus clock remain in Run (or VLP Run) mode. The clock generators in the MCG and the on-chip regulator in the PMC also remain in Run (or VLP Run) mode. Exit from PSTOP2 can be initiated by a reset, an asynchronous interrupt from a bus master or bus slave clocked by the system clock, or a synchronous interrupt from a bus slave clocked by the bus clock. If configured, a DMA request (using the asynchronous DMA wakeup) can also be used to exit Partial Stop for the duration of a DMA transfer before the device is transitioned back into PSTOP2.

When configured for PSTOP1, both the system clock and the bus clock are gated. All bus masters and bus slaves enter Stop mode, but the clock generators in the MCG and the on-chip regulator in the PMC remain in Run (or VLP Run) mode. Exit from PSTOP1 can be initiated by a reset or an asynchronous interrupt from a bus master or bus slave. If configured, an asynchronous DMA request can also be used to exit Partial Stop for the duration of a DMA transfer before the device is transitioned back into PSTOP1.

PSTOP1 is functionally similar to STOP mode, but offers faster wakeup at the expense of higher power consumption. Another benefit is that it keeps all of the MCG clocks enabled, which can be useful for some of the asynchronous peripherals that can remain functional in Stop modes.

## **8.2.2 DMA Wakeup**

The DMA can be configured to wake up the device on a DMA request whenever it is placed in Stop mode. The wakeup is configured per DMA channel and is supported in Compute Operation, PSTOP, Stop, and VLPS low power modes.

When a DMA wakeup is detected in PSTOP, Stop or VLPS, then the device initiates a normal exit from the low power mode. This can include restoring the on-chip regulator and internal power switches, enabling the clock generators in the MCG, enabling the system and bus clocks (but not the core clock) and negating the Stop mode signal to the bus masters and bus slaves. The only difference is that the CPU remains in the low power mode with the CPU clock disabled.

During Compute Operation, a DMA wakeup initiates a normal exit from Compute Operation. This includes enabling the clocks and negating the Stop mode signal to the bus masters and bus slaves. The core clock always remains enabled during Compute Operation.

Because the DMA wakeup enables the clocks and negates the Stop mode signals to all bus masters and slaves, software needs to ensure that bus masters and slaves that are not involved with the DMA wakeup and transfer remain in a known state. That can be accomplished by disabling the modules before entry into the low power mode or by setting the Doze enable bit in selected modules.

After the DMA request that initiated the wakeup negates and the DMA completes the current transfer, the device transitions back into the original low power mode. This includes requesting all non-CPU bus masters to enter Stop mode and then requesting bus slaves to enter Stop mode. In Stop and VLPS modes, the MCG and PMC then also enter their appropriate modes.

**NOTE**

If the requested DMA transfer cannot cause the DMA request to negate, then the device remains in a higher power state until the low power mode is fully exited.

If the DMA request asserts during the Stop mode entry sequence (or reentry if the request asserts during a DMA wakeup), then an enabled DMA wakeup can cause an aborted entry into the low power mode, as well as cause the SMC to assert its Stop Abort flag.

An interrupt that occurs during a DMA wakeup causes an immediate exit from the low power mode (this is optional for Compute Operation) without impacting the DMA transfer.

A DMA wakeup can be generated by either a synchronous DMA request or an asynchronous DMA request. Not all peripherals can generate an asynchronous DMA request in Stop modes. In general, though, if a peripheral can generate synchronous DMA requests and also supports asynchronous interrupts in Stop modes, then it can generate an asynchronous DMA request.

### 8.2.3 Compute Operation

Compute Operation is an execution or compute-only mode of operation that keeps the CPU enabled with full access to the SRAM and Flash read port, but places all other bus masters and bus slaves into their stop mode. Compute Operation can be enabled in either Run mode or VLP Run mode.

**NOTE**

Do not enter any stop mode without first exiting Compute Operation.

Because Compute Operation reuses the stop mode logic (including the staged entry with bus masters disabled before bus slaves), any bus master or bus slave that can remain functional in stop mode also remains functional in Compute Operation, including generation of asynchronous interrupts and DMA requests. When enabling Compute Operation in Run mode, module functionality for bus masters and slaves is the equivalent of STOP mode. When enabling Compute Operation in VLP Run mode, module functionality for bus masters and slaves is the equivalent of VLPS mode. The MCG, PMC, SRAM and Flash read port are not affected by Compute Operation, although the Flash register interface is disabled.

During Compute Operation, the AIPS peripheral space is disabled and attempted accesses generate bus errors. The private peripheral space remains accessible during Compute Operation, including the MCM, NVIC, IOPORT and SysTick. Although access to the

GPIO registers via the IOPORT is supported, the GPIO port data input registers do not return valid data since clocks are disabled to the Port Control and Interrupt modules. By writing to the GPIO port data output registers, it is possible to control those GPIO ports that are configured as output pins.

Compute Operation is controlled by the CPO register in the MCM, which is only accessible to the CPU. Setting or clearing the CPOREQ bit in the MCM initiates entry or exit into Compute Operation. Only the core system interrupts (exceptions, including NMI and SysTick) and any edge sensitive interrupts can be serviced without exiting Compute Operation.

When entering Compute Operation, the CPOACK status bit indicates when entry has completed. When exiting Compute Operation in Run mode, the CPOACK status bit negates immediately. When exiting Compute Operation in VLP Run mode, the exit is delayed to allow the PMC to handle the change in power consumption. This delay means the CPOACK bit is polled to determine when the AIPS peripheral space can be accessed without generating a bus error.

The DMA wakeup is also supported during Compute Operation and causes the CPOACK status bit to clear and the AIPS peripheral space to be accessible for the duration of the DMA wakeup. At the completion of the DMA wakeup, the device transitions back into Compute Operation.

## 8.2.4 Peripheral Doze

Several peripherals support a peripheral Doze mode, where a register bit can be used to disable the peripheral for the duration of a low power mode. The Flash can also be placed in a low power state during Peripheral Doze via a register bit in the SIM.

Peripheral Doze is defined to include all of the modes of operation listed below.

- The CPU is in wait mode.
- The CPU is in stop mode, including the entry sequence and for the duration of a DMA wakeup.
- The CPU is in Compute Operation, including the entry sequence and for the duration of a DMA wakeup.

Peripheral Doze can therefore be used to disable selected bus masters or slaves for the duration of WAIT or VLPW mode. It can also be used to disable selected bus slaves immediately on entry into any stop mode (or Compute Operation), instead of waiting for the bus masters to acknowledge the entry as part of the stop entry sequence. Finally, it can be used to disable selected bus masters or slaves that should remain inactive during a DMA wakeup.

If the Flash is not being accessed during WAIT and PSTOP modes, then the Flash Doze mode can be used to reduce power consumption, at the expense of a slightly longer wakeup when executing code and vectors from Flash. It can also be used to reduce power consumption during Compute Operation when executing code and vectors from SRAM.

## 8.3 Power modes

The power management controller (PMC) provides multiple power options to allow the user to optimize power consumption for the level of functionality needed.

Depending on the stop requirements of the user application, a variety of stop modes are available that provide state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. The following table compares the various power modes available.

For each run mode there is a corresponding wait and stop mode. Wait modes are similar to ARM sleep modes. Stop modes (VLPS, STOP) are similar to ARM sleep deep mode. The very low power run (VLPR) operating mode can drastically reduce runtime power when the maximum bus frequency is not required to handle the application needs.

The three primary modes of operation are run, wait and stop. The WFI instruction invokes both wait and stop modes for the chip. The primary modes are augmented in a number of ways to provide lower power based on application needs.

**Table 8-1. Chip power modes**

| Chip mode                 | Description                                                                                                                                                                                                                                                                             | Core mode  | Normal recovery method |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|------------------------|
| Normal run                | Default mode out of reset; on-chip voltage regulator is on.                                                                                                                                                                                                                             | Run        | -                      |
| High Speed run            | Allows maximum performance of the chip. In this state the chip is able to operate at a faster frequency compared to normal mode.                                                                                                                                                        | Run        | -                      |
| Normal Wait - via WFI     | Allows peripherals to function while the core is in sleep mode, reducing power. NVIC remains sensitive to interrupts; peripherals continue to be clocked.                                                                                                                               | Sleep      | Interrupt              |
| Normal Stop - via WFI     | Places chip in static state. Lowest power mode that retains all registers while maintaining LVD protection. NVIC is disabled; AWIC is used to wake up from interrupt; peripheral clocks are stopped.                                                                                    | Sleep Deep | Interrupt              |
| VLPR (Very Low Power Run) | On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency. Reduced frequency Flash access mode (500 kHz); LVD off; internal oscillator provides a low power 4 MHz source for the core, the bus and the peripheral clocks. | Run        | -                      |

*Table continues on the next page...*

**Table 8-1. Chip power modes (continued)**

| Chip mode                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                              | Core mode  | Normal recovery method    |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|---------------------------|
| VLPW (Very Low Power Wait) -via WFI | Same as VLPR but with the core in sleep mode to further reduce power; NVIC remains sensitive to interrupts (FCLK = ON). On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency.                                                                                                                                                                                         | Sleep      | Interrupt                 |
| VLPS (Very Low Power Stop)-via WFI  | Places chip in static state with LVD operation off. Lowest power mode with ADC and pin interrupts functional. Peripheral clocks are stopped, but LPTimer, CMP can be used. NVIC is disabled (FCLK = OFF); AWIC is used to wake up from interrupt. On-chip voltage regulator is in a low power mode that supplies only enough power to run the chip at a reduced frequency. All SRAM is operating (content retained and I/O states held). | Sleep Deep | Interrupt                 |
| VLLS3 (Very Low Leakage Stop3)      | Most peripherals are disabled (with clocks stopped), but LLWU, LPTimer, CMP can be used. NVIC is disabled; LLWU is used to wake up.<br><br>TCM RAM remain powered on (content retained and I/O states held).                                                                                                                                                                                                                             | Sleep Deep | Wakeup Reset <sup>1</sup> |
| VLLS2 (Very Low Leakage Stop2)      | Most peripherals are disabled (with clocks stopped), but LLWU, LPTimer, CMP can be used. NVIC is disabled; LLWU is used to wake up.<br><br>The higher half portion of the DTCM RAM is powered off and the lower half portion of the DTCM RAM is powered on. The ITCM RAM is optionally powered on depending on SMC_STOPCTRL[RAM2PO] setting.                                                                                             | Sleep Deep | Wakeup Reset <sup>1</sup> |
| VLLS1 (Very Low Leakage Stop1)      | Most peripherals are disabled (with clocks stopped), but LLWU, LPTimer, CMP can be used. NVIC is disabled; LLWU is used to wake up.<br><br>All of TCM RAM are powered off. The 32-byte system register file remain powered for customer-critical data.                                                                                                                                                                                   | Sleep Deep | Wakeup Reset <sup>1</sup> |
| VLLS0 (Very Low Leakage Stop0)      | Most peripherals are disabled (with clocks stopped), but LLWU can be used. NVIC is disabled; LLWU is used to wake up                                                                                                                                                                                                                                                                                                                     | Sleep Deep | Wakeup Reset <sup>1</sup> |

1. Follows the reset flow with the LLWU interrupt flag set for the NVIC.

## 8.4 Module Operation in Low Power Modes

The following table illustrates the functionality of each module while the chip is in each of the low power modes. (Debug modules are discussed separately; see [Debug in Low Power Modes](#).) Number ratings (such as 2 MHz and 1 Mbps) represent the maximum frequencies or maximum data rates per mode. Also, these terms are used:

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- static = Module register states and associated memories are retained.
- powered = Memory is powered to retain contents.

- low power = Memory is powered to retain contents in a lower power state.
- OFF = Modules are powered off; module is in reset state upon wakeup.
- wakeup = Modules can serve as a wakeup source for the chip.

**Table 8-2. Module operation in low power modes**

| Modules                             | Stop                                                    | VLPR                                  | VLPW                         | VLPS                                        | VLLSx                                                     |

Table continues on the next page...

**Table 8-2. Module operation in low power modes (continued)**

| Modules | Stop   | VLPR | VLPW | VLPS   | VLLSx             |
|---------|--------|------|------|--------|-------------------|
| GPIO    | wakeup | FF   | FF   | wakeup | OFF, pins latched |

1. Using the LLWU module, the external pins available for this chip do not require the associated peripheral function to be enabled. It only requires the function controlling the pin (GPIO or peripheral) to be configured as an input to allow a transition to occur to the LLWU.
2. CMP in stop or VLPS supports high speed or low speed external pin to pin or external pin to DAC compares. CMP in VLLSx only supports low speed external pin to pin or external pin to DAC compares. Windowed, sampled & filtered modes of operation are not available while in stop, VLPS, or VLLSx modes.

## 8.5 Power modes shutdown sequencing

When entering stop or other low-power modes, the clocks are shut off in an orderly sequence to safely place the chip in the targeted low-power state. All low-power entry sequences are initiated by the core executing an WFI instruction. The ARM core's outputs, SLEEPDEEP and SLEEPING, trigger entry to the various low-power modes:

- System level wait and VLPW modes equate to: SLEEPING &  $\overline{\text{SLEEPDEEP}}$
- All other low power modes equate to: SLEEPING & SLEEPDEEP

When entering the non-wait modes, the chip performs the following sequence:

- Shuts off Core Clock and System Clock to the ARM Cortex-M7 core immediately.
- Polls stop acknowledge indications from the non-core crossbar masters (DMA , Ethernet), supporting peripherals (SPI, PIT, RNG) and the Flash Controller for indications that System (CPU) Clock and/or Bus/Flash Clock need to be left enabled to complete a previously initiated operation, effectively stalling entry to the targeted low power mode. When all acknowledges are detected, System Clock, Bus Clock and Flash Clock are turned off at the same time.
- MCG and Mode Controller shut off clock sources and/or the internal supplies driven from the on-chip regulator as defined for the targeted low power mode.

In wait modes, most of the system clocks are not affected by the low power mode entry. The Core Clock to the ARM Cortex-M7 core is shut off. Some modules support stop-in-wait functionality and have their clocks disabled under these configurations.

The debugger modules support a transition from stop, wait, VLPS, and VLPW back to a halted state when the debugger is enabled. This transition is initiated by setting the Debug Request bit in MDM-AP control register. As part of this transition, system clocking is re-established and is equivalent to normal run/VLPR mode clocking configuration.

## 8.6 Clock Gating

To conserve power, the clocks to most modules can be turned off using the SCGCx registers in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module. Prior to initializing a module, set the corresponding bit in the SCGCx register to enable the clock. Before turning off the clock, make sure to disable the module. For more details, refer to the clock distribution and SIM chapters.

## 8.7 Flash program restrictions

The flash memory on this device must not be programmed or erased while operating in High Speed Run or VLPR power modes.

# Chapter 9

## Security

### 9.1 Introduction

This device implements security based on the mode selected from the flash module. The following sections provide an overview of flash security and details the effects of security on non-flash modules.

### 9.2 Flash Security

The flash module provides security information to the MCU based on the state held by the FSEC[SEC] bits. The MCU, in turn, confirms the security request and limits access to flash resources. During reset, the flash module initializes the FSEC register using data read from the security byte of the flash configuration field.

#### NOTE

The security features apply only to external accesses via debug. CPU accesses to the flash are not affected by the status of FSEC.

In the unsecured state all flash commands are available to the programming interfaces (JTAG), as well as user code execution of Flash Controller commands. When the flash is secured (FSEC[SEC] = 00, 01, or 11), programmer interfaces are only allowed to launch mass erase operations and have no access to memory locations.

Further information regarding the flash security options and enabling/disabling flash security is available in the [Flash Memory Module](#).

## 9.3 Security Interactions with other Modules

The flash security settings are used by the SoC to determine what resources are available. The following sections describe the interactions between modules and the flash security settings or the impact that the flash security has on non-flash modules.

### 9.3.1 Security Interactions with Debug

When flash security is active the JTAG port cannot access the memory resources of the MCU. Boundary scan chain operations work, but debugging capabilities are disabled so that the debug port cannot read flash contents.

Although most debug functions are disabled, the debugger can write to the Flash Mass Erase in Progress bit in the MDM-AP Control register to trigger a mass erase (Erase All Blocks) command. A mass erase via the debugger is allowed even when some memory locations are protected.

When mass erase is disabled, mass erase via the debugger is blocked.

# Chapter 10

## Debug

### 10.1 Introduction

This device's debug is based on the ARM coresight architecture and is configured in each device to provide the maximum flexibility as allowed by the restrictions of the pinout and other available resources.

Four debug interfaces are supported:

- IEEE 1149.1 JTAG
- IEEE 1149.7 JTAG (cJTAG)
- Serial Wire Debug (SWD)
- ARM Real-Time Trace Interface

The basic Cortex-M7 debug architecture is very flexible. The following diagram shows the topology of the core debug architecture and its components.

**Figure 10-1. Cortex-M7 Debug Topology**

The following table presents a brief description of each one of the debug components.

**Table 10-1. Debug Components Description**

| Module                             | Description                                                                                                                                                                                                                                               |

## 10.2 The Debug Port

The configuration of the cJTAG module, JTAG controller, and debug port is illustrated in the following figure:

Figure 10-2. Modified Debug Port

The debug port comes out of reset in standard JTAG mode and is switched into either cJTAG or SWD mode by the following sequences. Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions.

### 10.2.1 JTAG-to-SWD change sequence

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111\_1001\_1110\_0111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

#### NOTE

See the ARM documentation for the CoreSight DAP Lite for restrictions.

### 10.2.2 JTAG-to-cJTAG change sequence

1. Reset the debug port

2. Set the control level to 2 via zero-bit scans
3. Execute the Store Format (STFMT) command (00011) to set the scan format register to 1149.7 scan format

## 10.3 Debug Port Pin Descriptions

The debug port pins default after POR to their JTAG functionality with the exception of JTAG\_TRST\_b and can be later reassigned to their alternate functionalities. In cJTAG and SWD modes JTAG\_TDI and JTAG\_TRST\_b can be configured to alternate GPIO functions.

**Table 10-2. Debug port pins**

## 10.4 JTAG status and control registers

Through the ARM Debug Access Port (DAP), the debugger has access to the status and control elements, implemented as registers on the DAP bus as shown in the following figure. These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also provide a means for the debugger to get updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

It is important to note that these DAP control and status registers are not memory mapped within the system memory map and are only accessible via the Debug Access Port (DAP) using JTAG or cJTAG. The MDM-AP is accessible as Debug Access Port 1 with the available registers shown in the table below.

**Table 10-3. MDM-AP Register Summary**

| Address     | Register | Description                                                        |
|-------------|----------|--------------------------------------------------------------------|
| 0x0100_0000 | Status   | See <a href="#">MDM-AP Status Register</a>                         |
| 0x0100_0004 | Control  | See <a href="#">MDM-AP Control Register</a>                        |
| 0x0100_00FC | ID       | Read-only identification register that always reads as 0x001C_0000 |

## 10.4.1 MDM-AP Control Register

**Table 10-4. MDM-AP Control register assignments**

| Bit | Name                                | Secure <sup>1</sup> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----|-------------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Flash Mass Erase in Progress        | Y                   | Set to cause mass erase. Cleared by hardware after mass erase operation completes.<br><br>When mass erase is disabled (via MEEN and SEC settings), the erase request does not occur and the Flash Mass Erase in Progress bit continues to assert until the next system reset.                                                                                                                                                                                                                                                              |
| 1   | Debug Disable                       | N                   | Set to disable debug. Once it is set, the MDM-AP register cannot be written and it can only be cleared by debug reset.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2   | Debug Request                       | N                   | Set to force the Core to halt.<br><br>If the Core is in a stop or wait mode, this bit can be used to wakeup the core and transition to a halted state.                                                                                                                                                                                                                                                                                                                                                                                     |
| 3   | System Reset Request                | N                   | Set to force a system reset. The system remains held in reset until this bit is cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 4   | Core Hold Reset                     | N                   | Configuration bit to control Core operation at the end of system reset sequencing.<br><br>0 Normal operation - release the Core from reset along with the rest of the system at the end of system reset sequencing.<br><br>1 Suspend operation - hold the Core in reset at the end of reset sequencing. Once the system enters this suspended state, clearing this control bit immediately releases the Core from reset and CPU operation begins.                                                                                          |
| 5   | VLLSx Debug Request (VLLDBGREQ)     | N                   | Set to configure the system to be held in reset after the next recovery from a VLLSx mode.<br><br>This bit holds the in reset when VLLSx modes are exited to allow the debugger time to re-initialize debug IP before the debug session continues.<br><br>The Mode Controller captures this bit logic on entry to VLLSx modes. Upon exit from VLLSx modes, the Mode Controller holds the in reset until VLLDBGACK is asserted.<br><br>The VLLDBGREQ bit clears automatically due to the POR reset generated as part of the VLLSx recovery. |
| 6   | VLLSx Debug Acknowledge (VLLDBGACK) | N                   | Set to release a being held in reset following a VLLSx recovery<br><br>This bit is used by the debugger to release the system reset when it is being held on VLLSx mode exit. The debugger re-initializes all debug IP and then assert this control bit to allow the Mode Controller to release the from reset and allow CPU operation to begin.<br><br>The VLLDBGACK bit is cleared by the debugger or can be left set because it clears automatically due to the POR reset generated as part of the next VLLSx recovery.                 |
| 7   | VLLSx Status Acknowledge            | N                   | Set this bit to acknowledge the DAP VLLS Status bit has been read. This acknowledge automatically clears the status bits.<br><br>This bit is used by the debugger to clear the sticky VLLSx mode entry status bits. This bit is asserted and cleared by the debugger.                                                                                                                                                                                                                                                                      |

## 10.4.2 MDM-AP Status Register

**Table 10-5. MDM-AP Status register assignments**

| Bit | Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | Flash Mass Erase Acknowledge | The Flash Mass Erase Acknowledge bit is cleared after any system reset. The bit is also cleared at launch of a mass erase command due to write of Flash Mass Erase in Progress bit in MDM AP Control Register. The Flash Mass Erase Acknowledge is set after Flash control logic has started the mass erase operation.<br><br>When mass erase is disabled (via MEEN and SEC settings), an erase request due to setting of Flash Mass Erase in Progress bit is not acknowledged.                                                              |
| 1   | Flash Ready                  | Indicate Flash has been initialized and debugger can be configured even if system is continuing to be held in reset via the debugger.                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2   | System Security              | Indicates the security state. When secure, the debugger does not have access to the system bus or any memory mapped peripherals. This bit indicates when the part is locked and no system bus access is possible.                                                                                                                                                                                                                                                                                                                            |
| 3   | System Reset                 | Indicates the system reset state.<br><br>0 System is in reset<br>1 System is not in reset                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4   | Reserved                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 5   | Mass Erase Enable            | Indicates if the MCU can be mass erased or not<br><br>0 Mass erase is disabled<br>1 Mass erase is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6   | Backdoor Access Key Enable   | Indicates if the MCU has the backdoor access key enabled.<br><br>0 Disabled<br>1 Enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 7   | LP Enabled                   | Decode of LPLLSM control bits to indicate that VLPS or VLLSx are the selected power mode the next time the ARM Core enters Deep Sleep.<br><br>0 Low Power Stop Mode is not enabled<br>1 Low Power Stop Mode is enabled<br><br>Usage intended for debug operation in which Run to VLPS is attempted. Per debug definition, the system actually enters the Stop state. A debugger should interpret deep sleep indication (with SLEEPDEEP and SLEEPING asserted), in conjunction with this bit asserted as the debugger-VLPS status indication. |
| 8   | Very Low Power Mode          | Indicates current power mode is VLPx. This bit is not 'sticky' and should always represent whether VLPx is enabled or not.<br><br>This bit is used to throttle JTAG TCK frequency up/down.                                                                                                                                                                                                                                                                                                                                                   |
| 9   | Reserved                     | Always read 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 10  | VLLSx Modes Exit             | This bit indicates an exit from VLLSx mode has occurred. The debugger loses communication while the system is in VLLSx (including access to this register). Once communication is reestablished, this bit indicates that the system had been in VLLSx. Since the debug modules lose their state during VLLSx modes, they need to be reconfigured.                                                                                                                                                                                            |

*Table continues on the next page...*

**Table 10-5. MDM-AP Status register assignments (continued)**

| Bit     | Name                    | Description                                                                                                                                                                                                                                                     |
|---------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         |                         | This bit is set during the VLLSx recovery sequence. The VLLSx Mode Exit bit is held until the debugger has had a chance to recognize that a VLLS mode was exited and is cleared by a write of 1 to the VLLSx Status Acknowledge bit in MDM AP Control register. |
| 11 – 15 | Reserved for future use | Always read 0.                                                                                                                                                                                                                                                  |
| 16      | Core Halted             | Indicates the Core has entered debug halt mode                                                                                                                                                                                                                  |
| 17      | Core SLEEPDEEP          | Indicates the Core has entered a low power mode                                                                                                                                                                                                                 |
| 18      | Core SLEEPING           | SLEEPING==1 and SLEEPDEEP==0 indicates wait or VLPW mode.<br>SLEEPING==0 and SLEEPDEEP==1 indicates stop or VLPS mode.                                                                                                                                          |
| 19 – 31 | Reserved for future use | Always read 0.                                                                                                                                                                                                                                                  |

## 10.5 Debug Resets

The debug system receives the following sources of reset:

- JTAG\_TRST\_b from an external signal. This signal is optional and may not be available in all packages.
- Debug reset (CDBG\_RSTREQ bit within the SWJ-DP CTRL/STAT register) in the TCLK domain that allows the debugger to reset the debug logic.
- TRST asserted via the cJTAG escape command.
- System POR reset

Conversely the debug system is capable of generating system reset using the following mechanism:

- A system reset in the DAP control register which allows the debugger to hold the system in reset.
- SYSRESETREQ bit in the NVIC application interrupt and reset control register
- A system reset in the DAP control register which allows the debugger to hold the Core in reset.

## 10.6 AHB-AP

AHB-AP provides the debugger access to all memory and registers in the system, including processor registers through the NVIC. System access is independent of the processor status. AHB-AP does not do back-to-back transactions on the bus, so all transactions are non-sequential. AHB-AP can perform unaligned and bit-band transactions. AHB-AP transactions bypass the FPB, so the FPB cannot remap AHB-AP

transactions. SWJ/SW-DP-initiated transaction aborts drive an AHB-AP-supported sideband signal called HABORT. This signal is driven into the Bus Matrix, which resets the Bus Matrix state, so that AHB-AP can access the Private Peripheral Bus for last ditch debugging such as read/stop/reset the core. AHB-AP transactions are little endian.

For a short period at the start of a system reset event the system security status is being determined and debugger access to all AHB-AP transactions is blocked. The MDM-AP Status register is accessible and can be monitored to determine when this initial period is completed. After this initial period, if system reset is held via assertion of the RESET pin, the debugger has access via the bus matrix to the private peripheral bus to configure the debug IP even while system reset is asserted. While in system reset, access to other memory and register resources, accessed over the Crossbar Switch, is blocked.

## **10.7 Instrumentation Trace Macrocell (ITM)**

The ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace -- Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace -- The DWT generates these packets, and the ITM emits them.
3. Time stamping -- Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M7 clock or the bitclock rate of the Serial Wire Viewer (SWV) output clocks the counter.
4. Global system timestamping. Timestamps can optionally be generated using a system-wide 64-bit count value.

## 10.8 Core Trace Connectivity with ETM

**Figure 10-4. Core Trace Connectivity with ETM only**

The figure above assumes the device contains an ETM.

The following combinations paths are supported:

1. ETM -> TPIU(4 pin or 2 pin parallel)
2. ITM->TPIU(1 pin SWO, 2 pin or 4 pin parallel)
3. ETM & ITM -> TPIU

## 10.9 Embedded Trace Macrocell v4 (ETM)

The Cortex-M7 Embedded Trace Macrocell (ETM-M7) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M7 supports the instruction trace only option.

The main features of an ETM are:

- tracing of 16-bit and 32-bit Thumb instructions
- four EmbeddedICE watchpoint inputs
- a Trace Start/Stop block with EmbeddedICE inputs
- one reduced function counter
- two external inputs

- a 64-byte FIFO queue
- global timestamping

## 10.10 TPIU

The TPIU acts as a bridge between the on-chip trace data from the Instrumentation Trace Macrocell (ITM) and Embedded Trace Macrocell (ETM), with separate IDs, to a data stream, encapsulating IDs where required, that is then captured by a Trace Port Analyzer (TPA). The TPIU is specially designed for low-cost debug. The TPIU provides five external signals, namely, TRACE\_CLKOUT, TRACE\_D0, TRACE\_D1, TRACE\_D2, and TRACE\_D3 that can be assigned to external pins. See Signal Multiplexing and Signal Descriptions for details.

## 10.11 DWT

The DWT is a unit that performs the following debug functionality:

- It contains four comparators that you can configure as a hardware watchpoint, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT\_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT\_COMP1, can also be used as a data comparator.
- The DWT contains counters for:
  - Clock cycles (CYCCNT)
  - Folded instructions
  - Load store unit (LSU) operations
  - Sleep cycles
  - CPI (all instruction cycles except for the first cycle)
  - Interrupt overhead

### NOTE

An event is emitted each time a counter overflows.

- The DWT can be configured to emit PC samples at defined intervals, and to emit interrupt event information.

## 10.12 Debug in Low Power Modes

In low power modes in which the debug modules are kept static or powered off, the debugger cannot gather any debug data for the duration of the low power mode. In the case that the debugger is held static, the debug port returns to full functionality as soon as the low power mode exits and the system returns to a state with active debug. In the case that the debugger logic is powered off, the debugger is reset on recovery and must be reconfigured once the low power mode is exited.

Power mode entry logic monitors Debug Power Up and System Power Up signals from the debug port as indications that a debugger is active. These signals can be changed in RUN, VLPR, WAIT and VLPW. If the debug signal is active and the system attempts to enter stop or VLPS, FCLK continues to run to support core register access. In these modes in which FCLK is left active the debug modules have access to core registers but not to system memory resources accessed via the crossbar.

With debug enabled, transitions from Run directly to VLPS are not allowed and result in the system entering Stop mode instead. Status bits within the MDM-AP Status register can be evaluated to determine this pseudo-VLPS state. Note with the debug enabled, transitions from Run--> VLPR --> VLPS are still possible but also result in the system entering Stop mode instead.

In VLLS mode all debug modules are powered off and reset at wakeup.

Going into a VLLSx mode causes all the debug controls and settings to be reset. To give time to the debugger to sync up with the HW, the MDM-AP Control register can be configured hold the system in reset on recovery so that the debugger can regain control and reconfigure debug logic prior to the system exiting reset and resuming operation.

### 10.12.1 Debug Module State in Low Power Modes

The following table shows the state of the debug modules in low power modes. These terms are used:

- FF = Full functionality. In VLPR and VLPW the system frequency is limited, but if a module does not have a limitation in its functionality, it is still listed as FF.
- static = Module register states and associated memories are retained.
- OFF = Modules are powered off; module is in reset state upon wakeup.

**Table 10-6. Debug Module State in Low Power Modes**

| Module     | STOP | VLPR | VLPW | VLPS | VLLSx |
|------------|------|------|------|------|-------|
| Debug Port | FF   | FF   | FF   | OFF  | OFF   |
| AHB-AP     | FF   | FF   | FF   | OFF  | OFF   |
| ITM        | FF   | FF   | FF   | OFF  | OFF   |
| TPIU       | FF   | FF   | FF   | OFF  | OFF   |
| DWT        | FF   | FF   | FF   | OFF  | OFF   |

## 10.13 Debug and security

When security is enabled (FSEC[SEC] != 10), the debug port capabilities are limited in order to prevent exploitation of secure data. In the secure state the debugger still has access to the MDM-AP Status Register and can determine the current security state of the device. In the case of a secure device, the debugger also has the capability of performing a mass erase operation via writes to the MDM-AP Control Register. In the case of a secure device that has mass erase disabled (FSEC[MEEN] = 10), attempts to mass erase via the debug interface are blocked.

# Chapter 11

## Signal Multiplexing and Signal Descriptions

### 11.1 Signal Multiplexing Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

The [Port Control](#) block controls which signal is present on the external pin. Reference that chapter to find which register controls the operation of a specific pin.

### 11.2 Signal Multiplexing Integration

This section summarizes how the module is integrated into the device. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 11-1. Signal multiplexing integration

Table 11-1. Reference links to related information

## 11.2.1 Port control and interrupt module features

- 32-pin ports

### NOTE

Not all pins are available on the device. See the following section for details.

- Each 32-pin port is assigned one interrupt.

**Table 11-2. Ports summary**

| Feature                        | Port A                                                            | Port B         | Port C         | Port D                       | Port E    |
|--------------------------------|-------------------------------------------------------------------|----------------|----------------|------------------------------|-----------|
| Pull select control            | Yes                                                               | Yes            | Yes            | Yes                          | Yes       |

| Interrupt and DMA request | Yes                                               | Yes    | Yes    | Yes    | Yes    |
| Digital glitch filter     | No                                                | No     | No     | Yes    | No     |

## 11.2.2 Clock gating

The clock to the port control module can be gated on and off using the SCGC5[PORTx] bits in the SIM module. These bits are cleared after any reset, which disables the clock to the corresponding module to conserve power. Prior to initializing the corresponding module, set SCGC5[PORTx] in the SIM module to enable the clock. Before turning off the clock, make sure to disable the module. For more details, refer to the clock distribution chapter.

## 11.2.3 Signal multiplexing constraints

1. A given peripheral function must be assigned to a maximum of one package pin. Do not program the same function to more than one pin.
2. To ensure the best signal timing for a given peripheral's interface, choose the pins in closest proximity to each other.

## 11.3 Pinout

### 11.3.1 KV5x Signal Multiplexing and Pin Assignments

The following table shows the signals available on each pin and the locations of these pins on the devices supported by this document. The Port Control Module is responsible for selecting which ALT functionality is available on each pin.

## Pinout

| 144<br>MAP<br>BGA | 144<br>LQFP | 100<br>LQFP | Pin Name           | Default                                | ALT0                                   | ALT1               | ALT2      | ALT3        | ALT4     | ALT5        | ALT6     | ALT7 | ALT8         | ALT9 |

### 11.3.2 KV5x Pinouts

The below figure shows the pinout diagram for the devices supported by this document. Many signals may be multiplexed onto a single pin. To determine what signals can be used on which pin, see the previous section.

## Pinout

|   | 1                                    | 2                                    | 3                                  | 4                                          | 5                  | 6     | 7                  | 8                 | 9                  | 10               | 11               | 12      |   |

# 11.4 Module Signal Description Tables

The following sections correlate the chip-level signal name with the signal name used in the module's chapter. They also briefly describe the signal function and direction.

## 11.4.1 Core Modules

**Table 11-3. JTAG Signal Descriptions**

| Chip signal name | Module signal name     | Description              | I/O |
|------------------|------------------------|--------------------------|-----|
| JTAG_TMS         | JTAG_TMS/<br>SWD_DIO   | JTAG Test Mode Selection | I   |
| JTAG_TCLK        | JTAG_TCLK/<br>SWD_CLK  | JTAG Test Clock          | I   |
| JTAG_TDI         | JTAG_TDI               | JTAG Test Data Input     | I   |
| JTAG_TDO         | JTAG_TDO/<br>TRACE_SWO | JTAG Test Data Output    | O   |
| JTAG_TRST        | JTAG_TRST_b            | JTAG Reset               | I   |

**Table 11-4. SWD Signal Descriptions**

| Chip signal name | Module signal name    | Description       | I/O |
|------------------|-----------------------|-------------------|-----|
| SWD_DIO          | JTAG_TMS/<br>SWD_DIO  | Serial Wire Data  | I   |
| SWD_CLK          | JTAG_TCLK/<br>SWD_CLK | Serial Wire Clock | I   |

**Table 11-5. TPIU Signal Descriptions**

| Chip signal name | Module signal name     | Description                                                                                   | I/O |
|------------------|------------------------|-----------------------------------------------------------------------------------------------|-----|
| TRACE_CLKOUT     | TRACECLK               | Trace clock output from the ARM CoreSight debug block                                         | O   |
| TRACE_D[3:2]     | TRACEDATA              | Trace output data from the ARM CoreSight debug block used for 5-pin interface                 | O   |
| TRACE_D[1:0]     | TRACEDATA              | Trace output data from the ARM CoreSight debug block used for both 5-pin and 3-pin interfaces | O   |
| TRACE_SWO        | JTAG_TDO/<br>TRACE_SWO | Trace output data from the ARM CoreSight debug block over a single pin                        | O   |

## 11.4.2 System Modules

**Table 11-6. EWM Signal Descriptions**

| Chip signal name | Module signal name | Description                                                                                                                                                        | I/O |
|------------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| EWM_IN           | EWM_in             | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low. | I   |
| EWM_OUT          | EWM_out            | EWM reset out signal                                                                                                                                               | O   |

## 11.4.3 Clock Modules

**Table 11-7. OSC Signal Descriptions**

| Chip signal name | Module signal name | Description                     | I/O |
|------------------|--------------------|---------------------------------|-----|
| EXTALO           | EXTAL              | External clock/Oscillator input | I   |
| XTALO            | XTAL               | Oscillator output               | O   |

## 11.4.4 Memories and Memory Interfaces

**Table 11-8. FlexBus Signal Descriptions**

| Chip signal name         | Module signal name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | I/O |
|--------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| CLKOUT                   | FB_CLK             | FlexBus Clock Output                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | O   |
| FB_A[29:16]              | FB_A[29:16]        | Address Bus<br>When FlexBus is used in a multiplexed configuration, this bus is not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                            | O   |
| FB_AD[31:0] <sup>1</sup> | FB_AD31 - FB_AD0   | This is the address and data bus, FB_AD.<br>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.<br>The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0. | I/O |
| FB_CS[5:0] <sup>2</sup>  | FB_CS5–FB_CS0      | General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].                                                                                                                                                                                                                                                                                           | O   |

See CSCR[EXTS] and <a href="#">Extended Transfer Start/Address Latch Enable</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | O   |
| $\overline{\text{FB\_TA}}$ <sup>4</sup>                                                                                                                                                                           | $\overline{\text{FB\_TA}}$                                                                                                                            | <p>Transfer Acknowledge—Indicates that the external data transfer is complete. When <math>\overline{\text{FB\_TA}}</math> is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When <math>\overline{\text{FB\_TA}}</math> is asserted during a write transfer, the transfer is terminated.</p> <p>If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives <math>\overline{\text{FB\_TA}}</math> to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), <math>\overline{\text{FB\_TA}}</math> is generated internally after a specified number of wait states, or the external memory or peripheral may assert external <math>\overline{\text{FB\_TA}}</math> before the wait-state countdown to terminate the transfer early. The chip deasserts <math>\overline{\text{FB\_CS}}</math> one cycle after the last <math>\overline{\text{FB\_TA}}</math> is asserted. During read transfers, the external memory or peripheral must continue to drive data until <math>\overline{\text{FB\_TA}}</math> is recognized. For write transfers, the chip continues driving data one clock cycle after <math>\overline{\text{FB\_CS}}</math> is deasserted.</p> <p>The number of wait states is determined by CSCR or the external <math>\overline{\text{FB\_TA}}</math> input. If the external <math>\overline{\text{FB\_TA}}</math> is used, the external memory or peripheral has complete control of the number of wait states.</p> <p><b>Note:</b> External memory or peripherals should assert <math>\overline{\text{FB\_TA}}</math> only while the <math>\overline{\text{FB\_CS}}</math> signal to the external memory or peripheral is asserted.</p> <p>The CSPMCR register controls muxing of <math>\overline{\text{FB\_TA}}</math> with other signals. When the CSPMCR register does not allow fb_ta control, auto-acknowledge must be used (CSCR[AA] = 1'b1); otherwise the bus may hang.</p> | I   |

## 11.4.7 Communication Interfaces

**Table 11-25. Ethernet MII Signal Descriptions**

| Chip signal name | Module signal name | Description                                                                                                                                                                                                                                                                                                | I/O |
|------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII0_COL         | MII_COL            | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.                                                                                                                                                                 | I   |
| MII0_CRS         | MII_CRS            | Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the RMII_CRS_DV pin.                                                                                                                                                               | I   |
| MII0_MDC         | MII_MDC            | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.                                                                                                                                                                                                                 | O   |
| MII0_MDIO        | MII_MDIO           | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.                                                                                                                                                   | I/O |
| MII0_RXCLK       | MII_RXCLK          | In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.                                                                                                                                                                                                                                     | I   |
| MII0_RXDV        | MII_RXDV           | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal. | I   |

*Table continues on the next page...*

**Table 11-25. Ethernet MII Signal Descriptions (continued)**

| Chip signal name    | Module signal name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | I/O |
|---------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII0_RXD[3:0]       | MII_RXD[3:0]       | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.                                                                                                                                                                                                                                                                                                                                                                                                                                 | I   |
| MII0_RXER           | MII_RXER           | When asserted with RXDV, indicates the PHY detects an error in the current frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                               | I   |
| MII0_TXCLK          | MII_TXCLK          | Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | I   |
| MII0_TXD[3:0]       | MII_TXD[3:0]       | Serial output Ethernet data. Only valid during TXEN assertion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | O   |
| MII0_TXEN           | MII_TXEN           | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.                                                                                                                                                                                                                                                                                                                                              | O   |
| MII0_TXER           | MII_TXER           | When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.                                                                                                                                                                                                                                                                                                                                                                                                                                  | O   |
| ENET0_1588_TMR[3:0] | 1588_TMRn          | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMRn is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCRn.</p> <p>An interrupt can be triggered if ENET_TCSRn[TIE] is set. A DMA request can be triggered if ENET_TCSRn[TDRE] is set.</p> | I/O |
| ENET_1588_CLKIN     | ENET_1588_CLKIN    | Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                              | I   |

**Table 11-26. Ethernet RMII Signal Descriptions**

| Chip signal name                            | Module signal name | Description                                                                                                                                                                                                                                                                                                       | I/O |
|---------------------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| RMII0_MDC                                   | RMII_MDC           | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.                                                                                                                                                                                                                        | O   |
| RMII0_MDIO                                  | RMII_MDIO          | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.                                                                                                                                                          | I/O |
| RMII0_CRSDV                                 | RMII_CRSDV         | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. | I   |
| RMII0_RXD[1:0]                              | RMII_RXD[1:0]      | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.                                                                                                                                                                                                   | I   |
| RMII0_RXER                                  | RMII_RXER          | When asserted with RXDV, indicates the PHY detects an error in the current frame.                                                                                                                                                                                                                                 | I   |
| RMII0_TXD[1:0]                              | RMII_TXD[1:0]      | Serial output Ethernet data. Only valid during TXEN assertion.                                                                                                                                                                                                                                                    | O   |
| RMII0_TXEN                                  | RMII_TXEN          | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.                                                                                                                | O   |
| EXTAL clock or ENET_1588_CLKIN <sup>1</sup> | RMII_REF_CLK       | In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.                                                                                                                                                                                                                | I   |

1. The RMII clock source can be EXTAL clock or ENET\_1588\_CLKIN selected via SIM\_SOPT2[RMII\_SRC].

| PTB[31:0] <sup>1</sup> | PORTB31–PORTB0     | General-purpose input/output | I/O |

*Table continues on the next page...*

**Table 11-41. GPIO Signal Descriptions (continued)**

| Chip signal name       | Module signal name | Description                  | I/O |
|------------------------|--------------------|------------------------------|-----|
| PTC[31:0] <sup>1</sup> | PORTC31–PORTC0     | General-purpose input/output | I/O |
| PTD[31:0] <sup>1</sup> | PORTD31–PORTD0     | General-purpose input/output | I/O |
| PTE[31:0] <sup>1</sup> | PORTE31–PORTE0     | General-purpose input/output | I/O |

1. The available GPIO pins depends on the specific package. See the signal multiplexing section for which exact GPIO signals are available.

# Chapter 12

## Port Control and Interrupts (PORT)

### 12.1 Chip-specific PORT information

#### 12.1.1 Digital filter registers

The DFER, DFCR, and DFWR registers are available only with PORTD. PortA, B, C, and E do not have these registers.

### 12.2 Introduction

### 12.3 Overview

The Port Control and Interrupt (PORT) module provides support for port control, digital filtering, and external interrupt functions.

Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

#### 12.3.1 Features

The PORT module has the following features:

- Pin interrupt
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin

- Support for interrupt or DMA request configured per pin
- Asynchronous wake-up in low-power modes
- Pin interrupt is functional in all digital pin muxing modes
- Digital input filter on selected pins
  - Digital input filter for each pin, usable by any digital peripheral muxed onto the pin
  - Individual enable or bypass control field per pin
  - Selectable clock source for digital input filter with a five bit resolution on filter size
  - Functional in all digital pin multiplexing modes
- Port control
  - Individual pull control fields with pullup, pulldown, and pull-disable support
  - Individual drive strength field supporting high and low drive strength
  - Individual slew rate field supporting fast and slow slew rates
  - Individual input passive filter field supporting enable and disable of the individual input passive filter
  - Individual open drain field supporting enable and disable of the individual open drain output
  - Individual mux control field supporting analog or pin disabled, GPIO, and up to six chip-specific digital functions
  - Pad configuration fields are functional in all digital pin muxing modes.

## 12.3.2 Modes of operation

### 12.3.2.1 Run mode

In Run mode, the PORT operates normally.

### 12.3.2.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

### 12.3.2.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

In Stop mode, the digital input filters are bypassed unless they are configured to run from the LPO clock source.

### 12.3.2.4 Debug mode

In Debug mode, PORT operates normally.

## 12.4 External signal description

The table found here describes the PORT external signal.

**Table 12-1. Signal properties**

| Name        | Function           | I/O | Reset | Pull |
|-------------|--------------------|-----|-------|------|
| PORTx[31:0] | External interrupt | I/O | 0     | -    |

### NOTE

Not all pins within each port are implemented on each device.

## 12.5 Detailed signal description

The table found here contains the detailed signal description for the PORT interface.

**Table 12-2. PORT interface—detailed signal description**

| Signal      | I/O | Description         |                                                                                                                                                                         |
|-------------|-----|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PORTx[31:0] | I/O | External interrupt. |                                                                                                                                                                         |
|             |     | State meaning       | Asserted—pin is logic 1.<br>Negated—pin is logic 0.                                                                                                                     |
|             |     | Timing              | Assertion—may occur at any time and can assert asynchronously to the system clock.<br>Negation—may occur at any time and can assert asynchronously to the system clock. |

## 12.6 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

## PORT memory map

| Absolute address (hex) | Register name                                  | Width (in bits) | Access                | Reset value                 | Section/ page              |
|------------------------|------------------------------------------------|-----------------|-----------------------|-----------------------------|----------------------------|
| 4004_9000              | Pin Control Register n (PORTA_PCR0)            | 32              | R/W                   | <a href="#">See section</a> | <a href="#">12.6.1/186</a> |

## 12.6.1 Pin Control Register n (PORTx\_PCRn)

### NOTE

See the Signal Multiplexing and Pin Assignment chapter for the reset value of this device.

See the GPIO Configuration section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins that are not available in a reduced-pin package offering. Unbonded pins not available in a package are disabled by default to prevent them from consuming power.

Address: Base address + 0h offset + (4d × i), where i=0d to 31d

| FILT             | Filter Length<br><br>The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches, in clock cycles, that the digital filter absorbs for the enabled digital filters. Glitches that are longer than this register setting will pass through the digital filter, and glitches that are equal to or less than this register setting are filtered. Changing the filter length must be done only after all filters are disabled. |

## 12.7 Functional description

### 12.7.1 Pin control

Each port pin has a corresponding Pin Control register, PORT\_PCRn, associated with it.

The upper half of the Pin Control register configures the pin's capability to either interrupt the CPU or request a DMA transfer, on a rising/falling edge or both edges as well as a logic level occurring on the port pin. It also includes a flag to indicate that an interrupt has occurred.

The lower half of the Pin Control register configures the following functions for each pin within the 32-bit port.

- Pullup or pulldown enable
- Drive strength and slew rate configuration
- Open drain enable
- Passive input filter enable
- Pin Muxing mode

The functions apply across all digital pin muxing modes and individual peripherals do not override the configuration in the Pin Control register. For example, if an I<sup>2</sup>C function is enabled on a pin, that does not override the pullup or open drain configuration for that pin.

When the Pin Muxing mode is configured for analog or is disabled, all the digital functions on that pin are disabled. This includes the pullup and pulldown enables, output buffer enable, input buffer enable, and passive filter enable.

The LK bit (bit 15 of Pin Control Register  $PCR_n$ ) allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that pin control register are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each Pin Control register is retained when the PORT module is disabled.

Whenever a pin is configured in any digital pin muxing mode, the input buffer for that pin is enabled allowing the pin state to be read via the corresponding GPIO Port Data Input Register (GPIO\_PDIR) or allowing a pin interrupt or DMA request to be generated. If a pin is ever floating when its input buffer is enabled, then this can cause an increase in power consumption and must be avoided. A pin can be floating due to an input pin that is not connected or an output pin that has tri-stated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) will ensure a pin does not float when its input buffer is enabled; note that the internal pull resistor is automatically disabled whenever the output buffer is enabled allowing the Pull Enable bit to remain set. Configuring the Pin Muxing mode to disabled or analog will disable the pin's input buffer and results in the lowest power consumption.

## 12.7.2 Global pin control

The two global pin control registers allow a single register write to update the lower half of the pin control register on up to 16 pins, all with the same value. Registers that are locked cannot be written using the global pin control registers.

The global pin control registers are designed to enable software to quickly configure multiple pins within the one port for the same peripheral function. However, the interrupt functions cannot be configured using the global pin control registers.

The global pin control registers are write-only registers, that always read as 0.

## 12.7.3 External interrupts

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Active high level sensitive interrupt
- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin or at the output of the digital input filter, if the digital input digital filter is enabled. When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT\_ISFR or PORT\_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit the Low-Power mode.

### **12.7.4 Digital filter**

The digital filter capabilities of the PORT module are available in all digital Pin Muxing modes if the PORT module is enabled.

The clock used for all digital filters within one port can be configured between the bus clock or the LPO clock. This selection must be changed only when all digital filters for that port are disabled. If the digital filters for a port are configured to use the bus clock, then the digital filters are bypassed for the duration of Stop mode. While the digital filters

are bypassed, the output of each digital filter always equals the input pin, but the internal state of the digital filters remains static and does not update due to any change on the input pin.

The filter width in clock size is the same for all enabled digital filters within one port and must be changed only when all digital filters for that port are disabled.

The output of each digital filter is logic zero after system reset and whenever a digital filter is disabled. After a digital filter is enabled, the input is synchronized to the filter clock, either the bus clock or the LPO clock. If the synchronized input and the output of the digital filter remain different for a number of filter clock cycles equal to the filter width register configuration, then the output of the digital filter updates to equal the synchronized filter input.

The maximum latency through a digital filter equals three filter clock cycles plus the filter width configuration register.

# Chapter 13

## System Integration Module (SIM)

### 13.1 Introduction

The System Integration Module (SIM) provides system control and chip configuration registers.

#### 13.1.1 Features

Features of the SIM include:

- System clocking configuration
  - System clock divide values
  - Architectural clock gating control
- Peripheral clock source selection
- Flash and system RAM size configuration
- FlexTimer external clock, hardware trigger, and fault source selection
- UART0 and UART1 receive/transmit source selection/configuration
- Small Regulator configuration
- HSADC0/1 and ADC0 hardware triggers, and stop mode configuration
- Miscellaneous configuration for DAC, EWM, CMP and XBAR

## 13.2 Memory map and register definition

The SIM module contains many fields for selecting the clock source and dividers for various module clocks. See the [Clock Distribution](#) chapter for more information, including block diagrams and clock definitions.

### NOTE

The SIM registers can be written only in supervisor mode. In user mode, write accesses are blocked and will result in a bus error.

### NOTE

The SIM\_SOPT1 register is located at a different base address than the other SIM registers.

### SIM memory map

| Absolute address (hex) | Register name                                       | Width (in bits) | Access | Reset value                 | Section/ page               |

### 13.2.16 System Clock Divider Register 1 (SIM\_CLKDIV1)

When updating CLKDIV1, update all fields using the one write command. Attempting to write an invalid clock ratio to the CLKDIV1 register will cause the write to be ignored. The maximum divide ratio that can be programmed between core/system clock and the other divided clocks is divide by 8. When OUTDIV1 equals 0000 (divide by 1), the other dividers cannot be set higher than 0111 (divide by 8).

#### NOTE

The CLKDIV1 register cannot be written to when the device is in VLPR mode.

Address: 4004\_7000h base + 1044h offset = 4004\_8044h

| Bit   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0 |

## 13.2.27 Power Control Register (SIM\_PWRC)

### NOTE

Setting PMC\_REGSC[BGBE] before nanoedge regulator is enabled, because the regulator uses 1v reference of PMC.

Address: 4004\_7000h base + 1104h offset = 4004\_8104h

# Chapter 14

## Kinetis Flashloader

### 14.1 Chip-specific Kinetis Flashloader information

#### 14.1.1 Kinetis Flashloader pin configuration

The Kinetis flashloader application is preprogrammed into the Kinetis flash during manufacturing and enables flash programming without the need for a debugger. For this device, Kinetis flashloader supports UART, I2C, SPI, and CAN peripheral interfaces in communicating with the master/host in provisioning user application image on the flash. The below table shows the pin configuration used by the flashloader application for the supported peripherals.

**Table 14-1. Kinetis Flash Bootloader pin assignment**

| Peripheral interface | Assigned Pins    | Module Instance | ALTMUX column |
|----------------------|------------------|-----------------|---------------|
| UART                 | PTD6, UART0_RX   | 0               | 3             |
|                      | PTD7, UART0_TX   |                 |               |
| I2C                  | PTB0, I2C0_SCL   | 0               | 2             |
|                      | PTB1, I2C0_SDA   |                 |               |
| SPI                  | PTE16, SPI0_PCS0 | 0               | 2             |
|                      | PTE17, SPI0_SCK  |                 |               |
|                      | PTE18, SPI0_SOUT |                 |               |
|                      | PTE19, SPI0_SIN  |                 |               |
| FlexCAN              | PTB16, CAN0_TX   | 0               | 5             |
|                      | PTB17, CAN0_RX   |                 |               |

See [Kinetis Flashloader](#) for details.

## 14.2 Introduction

The Kinetis devices *that do not have an on-chip ROM* are shipped with the pre-programmed Kinetis Flashloader in the on-chip flash memory, for one-time, in-system factory programming. The Kinetis Flashloader's main task is to load a customer firmware image into the flash memory. The image on the flash has 2 programs: flashloader\_loader and flashloader. After a device reset, the flashloader\_loader program starts its execution first. The flashloader\_loader program copies the contents of flashloader image from the flash to the on-chip RAM; the device then switches execution to the flashloader program to execute from RAM.

For this device, the Kinetis Flashloader can interface with UART, CAN, I2C, and SPI peripherals in slave mode and respond to the commands sent by a master (or host) communicating on one of those ports. The host/master can be a firmware-download application running on a PC or an embedded host communicating with the Kinetis Flashloader. Regardless of the host/master (PC or embedded host), the Kinetis Flashloader always uses a command protocol to communicate with that host/master. Commands are provided to write to memory (flash or RAM), erase flash, and get/set flashloader options and property values. The host application can query the set of available commands.

This chapter describes Kinetis Flashloader features, functionality, command structure and which peripherals are supported.

Features supported by the Kinetis Flashloader :

- Supports UART, CAN, I2C, and SPI peripheral interfaces
- Automatic detection of the active peripheral
- UART and CAN peripherals with autobaud
- Common packet-based protocol for all peripherals
- Packet error detection and retransmission
- Protection of RAM used by the flashloader while it is running
- Provides command to read properties of the device, such as flash and RAM size

**Table 14-2. Commands supported by the Kinetis Flashloader**

| Command | Description                                                             | When flash security is enabled, then this command is |
|---------|-------------------------------------------------------------------------|------------------------------------------------------|
| Call    | Runs user application code and returns control to bootloader            | Not supported                                        |
| Execute | Run user application code that never returns control to the flashloader | Not supported                                        |

*Table continues on the next page...*

**Table 14-2. Commands supported by the Kinetis Flashloader (continued)**

| Command               | Description                                                                                        | When flash security is enabled, then this command is |
|-----------------------|----------------------------------------------------------------------------------------------------|------------------------------------------------------|
| FillMemory            | Fill a range of bytes in flash with a word pattern                                                 | Not supported                                        |
| FlashEraseAll         | Erase the entire flash array                                                                       | Not supported                                        |
| FlashEraseRegion      | Erase a range of sectors in flash                                                                  | Not supported                                        |
| FlashProgramOnce      | Writes data provided in a command packet to a specified range of bytes in the program once field   | Not supported                                        |
| FlashReadOnce         | Returns the contents of the program once field by given index and byte count                       | Not supported                                        |
| FlashReadResource     | Returns the contents of the IFR field or Flash firmware ID, by given offset, byte count and option | Not supported                                        |
| WriteMemory           | Write data to memory                                                                               | Not supported                                        |
| ReadMemory            | Read data from memory                                                                              | Not supported                                        |
| GetProperty           | Get the current value of a property                                                                | Supported                                            |
| Reset                 | Reset the chip                                                                                     | Supported                                            |
| SetProperty           | Attempt to modify a writable property                                                              | Supported                                            |
| FlashEraseAllUnsecure | Erase the entire flash array, including protected sectors                                          | Supported                                            |

## 14.3 Functional Description

The following sub-sections describe the Kinetis Flashloader functionality.

### 14.3.1 Memory Maps

While executing, the Kinetis Flashloader uses RAM memory.

The Kinetis Flashloader requires a minimum memory space of 32 KB of RAM. For Kinetis devices with less than this amount of on-chip RAM, the Kinetis Flashloader is not available.

### 14.3.2 Start-up Process

As the Kinetis Flashloader begins executing, flashloader operations begin:

1. The flashloader's temporary working area in RAM is initialized.
2. All supported peripherals are initialized.
3. The flashloader waits for communication to begin on a peripheral.

- There is no timeout for the active peripheral detection process.
- If communication is detected, then all inactive peripherals are shut down, and the command phase is entered.

**Figure 14-1. Kinetis Flashloader Start-up Flowchart**

### 14.3.3 Clock Configuration

### 14.3.4 Flashloader Protocol

This section explains the general protocol for the packet transfers between the host and the Kinetis Flashloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands may include an optional data phase:

- If the data phase is **incoming** (from host to flashloader ), then the data phase is part of the **original command**.
- If the data phase is **outgoing** (from flashloader to host), then the data phase is part of the **response command**.

#### **NOTE**

In all protocols (described in the next subsections), the Ack sent in response to a Command or Data packet can arrive at any time *before, during, or after* the Command/Data packet has processed.

#### 14.3.4.1 Command with no data phase

The protocol for a command with no data phase contains:

- Command packet (from host)
- Generic response command packet (to host)

**Figure 14-2. Command with No Data Phase**

#### 14.3.4.2 Command with incoming data phase

The protocol for a command with an incoming data phase contains:

- Command packet (from host)
- Generic response command packet (to host)
- Incoming data packets (from host)
- Generic response command packet (to host)

**Figure 14-3. Command with incoming data phase**

### NOTE

- The host may not send any further packets while it (the host) is waiting for the response to a command.
- If the Generic Response packet prior to the start of the data phase does not have a status of `kStatus_Success`, then the data phase is aborted.
- Data phases may be aborted by the receiving side by sending the final Generic Response early with a status of

kStatus\_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.

- The final Generic Response packet *sent after the data phase* includes the status for the entire operation.

#### 14.3.4.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:

- Command packet (from host)
- ReadMemory Response command packet (to host) (kCommandFlag\_HasDataPhase set)
- Outgoing data packets (to host)
- Generic response command packet (to host)

**Figure 14-4. Command with outgoing data phase**

### NOTE

- For the outgoing data phase sequence above, the data phase is really considered part of the response command.
- The host may not send any further packets while it (the host) is waiting for the response to a command.
- If the ReadMemory Response command packet prior to the start of the data phase does not contain the `kCommandFlag_HasDataPhase` flag, then the data phase is aborted.

- Data phases may be aborted by the host sending the final Generic Response early with a status of `kStatus_AbortDataPhase`. The sending side may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet *sent after the data phase* includes the status for the entire operation.

### 14.3.5 Flashloader Packet Types

The Kinetis Flashloader device works in slave mode. All data communication is initiated by a host, which is either a PC or an embedded host. The Kinetis Flashloader device is the target, which receives a command or data packet. All data communication between host and target is packetized.

#### NOTE

The term "target" refers to the "Kinetis Flashloader device."

There are 6 types of packets used in the device:

- Ping packet
- Ping Response packet
- Framing packet
- Command packet
- Data packet
- Response packet

All fields in the packets are in little-endian byte order.

#### 14.3.5.1 Ping packet

The Ping packet is the first packet sent from a host to the target (Kinetis Flashloader), to establish a connection on a selected peripheral. For a UART peripheral, the Ping packet is used to determine the baudrate. A Ping packet must be sent before any other communications. In response to a Ping packet, the target sends a Ping Response packet.

**Table 14-3. Ping Packet Format**

| Byte # | Value | Name       |
|--------|-------|------------|
| 0      | 0x5A  | start byte |
| 1      | 0xA6  | ping       |

Figure 14-5. Ping Packet Protocol Sequence

### 14.3.5.2 Ping Response Packet

The target (Kinetis Flashloader) sends a Ping Response packet back to the host after receiving a Ping packet. If communication is over a UART peripheral, the target uses the incoming Ping packet to determine the baud rate before replying with the Ping Response packet. Once the Ping Response packet is received by the host, the connection is established, and the host starts sending commands to the target (Kinetis Flashloader).

Table 14-4. Ping Response Packet Format

| Byte # | Value | Parameter                  |
|--------|-------|----------------------------|
| 0      | 0x5A  | start byte                 |
| 1      | 0xA7  | Ping response code         |
| 2      |       | Protocol bugfix            |
| 3      |       | Protocol minor             |
| 4      |       | Protocol major             |
| 5      |       | Protocol name = 'P' (0x50) |
| 6      |       | Options low                |
| 7      |       | Options high               |
| 8      |       | CRC16 low                  |
| 9      |       | CRC16 high                 |

### 14.3.5.3 Framing Packet

The framing packet is used for flow control and error detection, and it (the framing packet) wraps command and data packets as well.

**Table 14-5. Framing Packet Format**

| Byte #    | Value | Parameter                      |                                                                                                                                                                                                           |
|-----------|-------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0         | 0x5A  | start byte                     |                                                                                                                                                                                                           |
| 1         |       | packetType                     |                                                                                                                                                                                                           |
| 2         |       | length_low                     | Length is a 16-bit field that specifies the entire command or data packet size in bytes.                                                                                                                  |
| 3         |       | length_high                    |                                                                                                                                                                                                           |
| 4         |       | crc16_low                      | This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See the CRC16 algorithm after this table. |
| 5         |       | crc16_high                     |                                                                                                                                                                                                           |
| 6 . . . n |       | Command or Data packet payload |                                                                                                                                                                                                           |

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

**Table 14-6. Special Framing Packet Format**

| Byte # | Value   | Parameter  |
|--------|---------|------------|
| 0      | 0x5A    | start byte |
| 1      | 0xA $n$ | packetType |

The Packet Type field specifies the type of the packet from one of the defined types (below):

**Table 14-7. packetType Field**

| packetType | Name                            | Description                                                                            |
|------------|---------------------------------|----------------------------------------------------------------------------------------|
| 0xA1       | kFramingPacketType_Ack          | The previous packet was received successfully; the sending of more packets is allowed. |
| 0xA2       | kFramingPacketType_Nak          | The previous packet was corrupted and must be re-sent.                                 |
| 0xA3       | kFramingPacketType_AckAbort     | Data phase is being aborted.                                                           |
| 0xA4       | kFramingPacketType_Command      | The framing packet contains a command packet payload.                                  |
| 0xA5       | kFramingPacketType_Data         | The framing packet contains a data packet payload.                                     |
| 0xA6       | kFramingPacketType_Ping         | Sent to verify the other side is alive. Also used for UART autobaud.                   |
| 0xA7       | kFramingPacketType_PingResponse | A response to Ping; contains the framing protocol version number and options.          |

CRC16 algorithm:

## Functional Description

```
uint16_t crc16_update(const uint8_t * src, uint32_t lengthInBytes)
{
    uint32_t crc = 0;
    uint32_t j;
    for (j=0; j < lengthInBytes; ++j)
    {
        uint32_t i;
        uint32_t byte = src[j];
        crc ^= byte << 8;
        for (i = 0; i < 8; ++i)
        {
            uint32_t temp = crc << 1;
            if (crc & 0x8000)
            {
                temp ^= 0x1021;
            }
            crc = temp;
        }
    }
    return crc;
}
```

### 14.3.5.4 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

**Table 14-8. Command Packet Format**

| Command Packet Format (32 bytes) |        |        |             |                                            |                 |                 |                 |                 |                 |                 |
|----------------------------------|--------|--------|-------------|--------------------------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| Command Header (4 bytes)         |        |        |             | 28 bytes for Parameters (Max 7 parameters) |                 |                 |                 |                 |                 |                 |
| Tag                              | Flags  | Rsvd   | Param Count | Param1 (32-bit)                            | Param2 (32-bit) | Param3 (32-bit) | Param4 (32-bit) | Param5 (32-bit) | Param6 (32-bit) | Param7 (32-bit) |
| byte 0                           | byte 1 | byte 2 | byte 3      |                                            |                 |                 |                 |                 |                 |                 |

**Table 14-9. Command Header Format**

| Byte # | Command Header Field      |                                                        |
|--------|---------------------------|--------------------------------------------------------|
| 0      | Command or Response tag   | The command header is 4 bytes long, with these fields. |
| 1      | Flags                     |                                                        |
| 2      | Reserved. Should be 0x00. |                                                        |
| 3      | ParameterCount            |                                                        |

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. As mentioned earlier, command packets and data packets are embedded into framing packets for all of the transfers.

**Table 14-10. Commands that are supported**

| Command | Name                  |
|---------|-----------------------|
| 0x01    | FlashEraseAll         |
| 0x02    | FlashEraseRegion      |
| 0x03    | ReadMemory            |
| 0x04    | WriteMemory           |
| 0x05    | FillMemory            |
| 0x06    | FlashSecurityDisable  |
| 0x07    | GetProperty           |
| 0x08    | Reserved              |
| 0x09    | Execute               |
| 0x0A    | Call                  |
| 0x0B    | Reset                 |
| 0x0C    | SetProperty           |
| 0x0D    | FlashEraseAllUnsecure |
| 0x0E    | FlashProgramOnce      |
| 0x0F    | FlashReadOnce         |
| 0x10    | FlashReadResource     |
| 0x11    | Reserved              |

**Table 14-11. Responses that are supported**

| Response | Name            |
|----------|-----------------|
| 0xA0     | GenericResponse |

*Table continues on the next page...*

**Table 14-11. Responses that are supported (continued)**

| Response | Name                                                                                     |
|----------|------------------------------------------------------------------------------------------|
| 0xA3     | ReadMemoryResponse (used for sending responses to ReadMemory command only)               |
| 0xA7     | GetPropertyResponse (used for sending responses to GetProperty command only)             |
| 0xAF     | FlashReadOnceResponse (used for sending responses to FlashReadOnce command only)         |
| 0xB0     | FlashReadResourceResponse (used for sending responses to FlashReadResource command only) |

**Flags:** Each command packet contains a Flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets will follow in the command sequence. The number of bytes that will be transferred in the data phase is determined by a command-specific parameter in the parameters array.

**ParameterCount:** The number of parameters included in the command packet.

**Parameters:** The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to 7 parameters.

### 14.3.5.5 Data packet

The data packet carries just the data, either host sending data to target, or target sending data to host. The data transfer direction is determined by the last command sent from the host. The data packet is also wrapped within a framing packet, to ensure the correct packet data is received.

The contents of a data packet are simply the data itself. There are no other fields, so that the most data per packet can be transferred. Framing packets are responsible for ensuring that the correct packet data is received.

### 14.3.5.6 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse
- GetPropertyResponse
- ReadMemoryResponse

**GenericResponse:** After the Kinetis Flashloader has processed a command, the flashloader will send a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

**Table 14-12. GenericResponse Parameters**

| Byte # | Parameter   | Description                                                                                                                                                                                                                                                                                                                  |
|--------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 - 3  | Status code | The Status codes are errors encountered during the execution of a command by the target (Kinetis Flashloader). If a command succeeds, then a kStatus_Success code is returned. <a href="#">Table 14-48</a> , Kinetis Flashloader Status Error Codes, lists the status codes returned to the host by the Kinetis Flashloader. |
| 4 - 7  | Command tag | The Command tag parameter identifies the response to the command sent by the host.                                                                                                                                                                                                                                           |

**GetPropertyResponse:** The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

**Table 14-13. GetPropertyResponse Parameters**

| Byte # | Value | Parameter                                                                                                   |
|--------|-------|-------------------------------------------------------------------------------------------------------------|
| 0 - 3  |       | Status code                                                                                                 |
| 4 - 7  |       | Property value                                                                                              |
| ...    |       | ...                                                                                                         |
|        |       | Can be up to maximum 6 property values, limited to the size of the 32-bit command packet and property type. |

**ReadMemoryResponse:** The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a ReadMemoryResponse tag value (0xA3), the flags field set to kCommandFlag\_HasDataPhase (1).

The parameter count set to 2 for the status code and the data byte count parameters shown below.

**Table 14-14. ReadMemoryResponse Parameters**

| Byte # | Parameter       | Description                                       |
|--------|-----------------|---------------------------------------------------|
| 0 - 3  | Status code     | The status of the associated Read Memory command. |
| 4 - 7  | Data byte count | The number of bytes sent in the data phase.       |

### 14.3.6 Flashloader Command API

All Kinetis Flashloader command APIs follow the command packet format that is wrapped by the framing packet, as explained in previous sections.

- For a list of commands supported by the Flashloader, see [Table 14-2, Commands supported](#).
- For a list of status codes returned by the Kinetis Flashloader, see [Table 14-48, Kinetis Flashloader Status Error Codes](#).

#### 14.3.6.1 Call command

The Call command will execute a function that is written in memory at the address sent in the command. The address needs to be a valid memory location residing in accessible flash (internal or external) or in RAM. The command supports the passing of one 32-bit argument. Although the command supports a stack address, at this time the call will still take place using the current stack pointer. After execution of the function, a 32-bit return value will be returned in the generic response message.

**Table 14-15. Parameters for Call Command**

| Byte # | Command       |
|--------|---------------|
| 0 - 3  | Call address  |
| 4 - 7  | Argument word |
| 8 - 11 | Stack pointer |

**Figure 14-6. Protocol Sequence for Call Command**

**Response:** The target (Kinetis Flashloader) will return a GenericResponse packet with a status code either set to the return value of the function called or set to `kStatus_InvalidArgument` (105).

### 14.3.6.2 GetProperty command

The GetProperty command is used to query the flashloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

For a list of properties and their associated 32-bit property tags supported by the Kinetis Flashloader, see [Table 14-44](#).

The 32-bit property tag is the only parameter required for GetProperty command.

**Table 14-16. Parameters for GetProperty Command**

| Byte # | Command      |
|--------|--------------|
| 0 - 3  | Property tag |

Figure 14-7. Protocol Sequence for GetProperty Command

Table 14-17. GetProperty Command Packet Format (Example)

| GetProperty    | Parameter      | Value                            |
|----------------|----------------|----------------------------------|
| Framing packet | start byte     | 0x5A                             |
|                | packetType     | 0xA4, kFramingPacketType_Command |
|                | length         | 0x08 0x00                        |
|                | crc16          | 0x73 0xD4                        |
| Command packet | commandTag     | 0x07 – GetProperty               |
|                | flags          | 0x00                             |
|                | reserved       | 0x00                             |
|                | parameterCount | 0x01                             |
|                | propertyTag    | 0x00000001 - CurrentVersion      |

The GetProperty command has no data phase.

**Response:** In response to a GetProperty command, the target will send a GetPropertyResponse packet with the response tag set to 0xA7. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). The next table shows an example of a GetPropertyResponse packet.

Table 14-18. GetProperty Response Packet Format (Example)

| GetPropertyResponse | Parameter  | Value                            |
|---------------------|------------|----------------------------------|
| Framing packet      | start byte | 0x5A                             |
|                     | packetType | 0xA4, kFramingPacketType_Command |
|                     | length     | 0x0c 0x00 (12 bytes)             |

Table continues on the next page...

**Table 14-18. GetProperty Response Packet Format (Example) (continued)**

| GetPropertyResponse | Parameter      | Value                       |
|---------------------|----------------|-----------------------------|
|                     | crc16          | 0x07 0x7a                   |
| Command packet      | responseTag    | 0xA7                        |
|                     | flags          | 0x00                        |
|                     | reserved       | 0x00                        |
|                     | parameterCount | 0x02                        |
|                     | status         | 0x00000000                  |
|                     | propertyValue  | 0x0000014b - CurrentVersion |

### 14.3.6.3 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options in the Kinetis Flashloader. However, the SetProperty command can only change the value of properties that are writable—see [Table 14-44](#), Properties used by Get/SetProperty Commands. If you try to set a value for a read-only property, then the Kinetis Flashloader will return an error.

The property tag and the new value to set are the 2 parameters required for the SetProperty command.

**Table 14-19. Parameters for SetProperty Command**

| Byte # | Command        |
|--------|----------------|
| 0 - 3  | Property tag   |
| 4 - 7  | Property value |

Figure 14-8. Protocol Sequence for SetProperty Command

Table 14-20. SetProperty Command Packet Format (Example)

| SetProperty    | Parameter      | Value                                   |
|----------------|----------------|-----------------------------------------|
| Framing packet | start byte     | 0x5A                                    |
|                | packetType     | 0xA4, kFramingPacketType_Command        |
|                | length         | 0x0C 0x00                               |
|                | crc16          | 0x67 0x8D                               |
| Command packet | commandTag     | 0x0C – SetProperty with property tag 10 |
|                | flags          | 0x00                                    |
|                | reserved       | 0x00                                    |
|                | parameterCount | 0x02                                    |
|                | propertyTag    | 0x0000000A - VerifyWrites               |
|                | propertyValue  | 0x00000001                              |

The SetProperty command has no data phase.

**Response:** The target (Kinetis Flashloader) will return a GenericResponse packet with one of following status codes:

Table 14-21. SetProperty Response Status Codes

| Status Code             |
|-------------------------|
| kStatus_Success         |
| kStatus_ReadOnly        |
| kStatus_UnknownProperty |
| kStatus_InvalidArgument |

### 14.3.6.4 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory. If any flash regions are protected, then the FlashEraseAll command will fail and return an error status code. Executing the FlashEraseAll command will release flash security if it (flash security) was enabled, by setting the FTFE\_FSEC register. However, the FSEC field of the flash configuration field is erased, so unless it is reprogrammed, the flash security will be re-enabled after the next system reset. The Command tag for FlashEraseAll command is 0x01 set in the commandTag field of the command packet.

The FlashEraseAll command requires no parameters.

Figure 14-9. Protocol Sequence for FlashEraseAll Command

Table 14-22. FlashEraseAll Command Packet Format (Example)

| FlashEraseAll  | Parameter      | Value                                                                                                                                        |
|----------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Framing packet | start byte     | 0x5A                                                                                                                                         |
|                | packetType     | 0xA4, kFramingPacketType_Command                                                                                                             |
|                | length         | 0x04 0x00                                                                                                                                    |
|                | crc16          | 0xC4 0x2E                                                                                                                                    |
| Command packet | commandTag     | 0x01 - FlashEraseAll                                                                                                                         |
|                | flags          | 0x00                                                                                                                                         |
|                | reserved       | 0x00                                                                                                                                         |
|                | parameterCount | 0x00                                                                                                                                         |
|                | MemoryID       | <ul style="list-style-type: none"> <li>If MemoryID = 0x00h, then internal flash.</li> <li>If MemoryID = 0x01h, then QSPI0 memory.</li> </ul> |

The FlashEraseAll command has no data phase.

**Response:** The target (Kinetis Flashloader ) will return a GenericResponse packet with status code either set to kStatus\_Success for successful execution of the command, or set to an appropriate error status code.

### 14.3.6.5 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory or a specified range of flash within the connected SPI flash devices.

The start address and number of bytes are the 2 parameters required for the FlashEraseRegion command. The start and byte count parameters must be , or the FlashEraseRegion command will fail and return kStatus\_FlashAlignmentError (0x101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command will fail and return kStatus\_FlashAddressError (0x102). If any part of the region specified is protected, the FlashEraseRegion command will fail and return kStatus\_MemoryRangeInvalid (0x10200).

**Table 14-23. Parameters for FlashEraseRegion Command**

| Byte # | Parameter     |
|--------|---------------|
| 0 - 3  | Start address |
| 4 - 7  | Byte count    |

**Figure 14-10. Protocol Sequence for FlashEraseRegion Command**

**Table 14-24. FlashEraseRegion Command Packet Format (Example)**

| FlashEraseRegion | Parameter      | Value                              |
|------------------|----------------|------------------------------------|
| Framing packet   | start byte     | 0x5A                               |
|                  | packetType     | 0xA4, kFramingPacketType_Command   |
|                  | length         | 0x0C 0x00                          |
|                  | crc16          | 0xF9 0x A6                         |
| Command packet   | commandTag     | 0x02, kCommandTag_FlashEraseRegion |
|                  | flags          | 0x00                               |
|                  | reserved       | 0x00                               |
|                  | parameterCount | 0x02                               |
|                  | startAddress   | 0x00 0x00 0x00 0x00 (0x0000_0000)  |
|                  | byte count     | 0x00 0x04 0x00 0x00 (0x400)        |

The FlashEraseRegion command has no data phase.

**Response:** The target (Kinetis Flashloader ) will return a GenericResponse packet with one of following error status codes.

**Table 14-25. FlashEraseRegion Response Status Codes**

| Status Code                              |
|------------------------------------------|
| kStatus_Success (0x0)                    |
| kStatus_MemoryRangeInvalid (0x10200)     |
| kStatus_FlashAlignmentError (0x101)      |
| kStatus_FlashAddressError (0x102)        |
| kStatus_FlashAccessError (0x103)         |
| kStatus_FlashProtectionViolation (0x104) |
| kStatus_FlashCommandFailure (0x105)      |

### 14.3.6.6 FlashEraseAllUnsecure command

The FlashEraseAllUnsecure command performs a mass erase of the flash memory, including protected sectors. Flash security is immediately disabled if it (flash security) was enabled, and the FSEC byte in the flash configuration field at address 0x40C is programmed to 0xFE. However, if the mass erase enable option in the FSEC field is disabled, then the FlashEraseAllUnsecure command will fail.

The FlashEraseAllUnsecure command requires no parameters.

**Figure 14-11. Protocol Sequence for FlashEraseAll Command**

**Table 14-26. FlashEraseAllUnsecure Command Packet Format (Example)**

| FlashEraseAllUnsecure | Parameter      | Value                            |
|-----------------------|----------------|----------------------------------|
| Framing packet        | start byte     | 0x5A                             |
|                       | packetType     | 0xA4, kFramingPacketType_Command |
|                       | length         | 0x04 0x00                        |
|                       | crc16          | 0xF6 0x61                        |
| Command packet        | commandTag     | 0x0D - FlashEraseAllUnsecure     |
|                       | flags          | 0x00                             |
|                       | reserved       | 0x00                             |
|                       | parameterCount | 0x00                             |

The **FlashEraseAllUnsecure** command has no data phase.

**Response:** The target (Kinetis Flashloader) will return a **GenericResponse** packet with status code either set to **kStatus\_Success** for successful execution of the command, or set to an appropriate error status code.

#### 14.3.6.7 FillMemory command

The **FillMemory** command fills a range of bytes in memory with a data pattern. It follows the same rules as the **WriteMemory** command. The difference between **FillMemory** and **WriteMemory** is that a data pattern is included in **FillMemory** command parameter, and there is no data phase for the **FillMemory** command, while **WriteMemory** does have a data phase.

**Table 14-27. Parameters for FillMemory Command**

| Byte # | Command                                                                                                                                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 - 3  | Start address of memory to fill                                                                                                                                                                                                                                                                                                                 |
| 4 - 7  | Number of bytes to write with the pattern <ul style="list-style-type: none"> <li>The start address should be 32-bit aligned.</li> <li>The number of bytes must be evenly divisible by 4. (Note: for a part that uses FTFE flash, the start address should be 64-bit aligned, and the number of bytes must be evenly divisible by 8).</li> </ul> |
| 8 - 11 | 32-bit pattern                                                                                                                                                                                                                                                                                                                                  |

- To fill with a byte pattern (8-bit), the byte must be replicated 4 times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated 2 times in the 32-bit pattern.

For example, to fill a byte value with 0xFE, the word pattern would be 0xFEFEFEFE; to fill a short value 0x5AFE, the word pattern would be 0x5AFE5AFE.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be 32-bit or 64-bit aligned.
- If the VerifyWrites property is set to true, then writes to flash will also perform a flash verify program operation.

When writing to RAM, the start address need not be aligned, and the data will not be padded.

**Figure 14-12. Protocol Sequence for FillMemory Command**

**Table 14-28. FillMemory Command Packet Format (Example)**

| FillMemory     | Parameter      | Value                            |
|----------------|----------------|----------------------------------|
| Framing packet | start byte     | 0x5A                             |
|                | packetType     | 0xA4, kFramingPacketType_Command |
|                | length         | 0x10 0x00                        |
|                | crc16          | 0xE4 0x57                        |
| Command packet | commandTag     | 0x05 – FillMemory                |
|                | flags          | 0x00                             |
|                | Reserved       | 0x00                             |
|                | parameterCount | 0x03                             |
|                | startAddress   | 0x00007000                       |
|                | byteCount      | 0x00000800                       |
|                | patternWord    | 0x12345678                       |

The FillMemory command has no data phase.

**Response:** upon successful execution of the command, the target (Kinetis Flashloader) will return a GenericResponse packet with a status code set to kStatus\_Success, or to an appropriate error status code.

### 14.3.6.8 FlashProgramOnce command

The FlashProgramOnce command writes data (that is provided in a command packet) to a specified range of bytes in the program once field. Special care must be taken when writing to the program once field.

- The program once field only supports programming once, so any attempted to reprogram a program once field will get an error response.
- Writing to the program once field requires the byte count to be 4-byte aligned or 8-byte aligned.

The FlashProgramOnce command uses 3 parameters: index, byteCount, data.

**Table 14-29. Parameters for FlashProgramOnce Command**

| Byte #  | Command                                    |
|---------|--------------------------------------------|
| 0 - 3   | Index of program once field                |
| 4 - 7   | Byte count (must be evenly divisible by 4) |
| 8 - 11  | Data                                       |
| 12 - 16 | Data                                       |

Figure 14-13. Protocol Sequence for FlashProgramOnce Command

Table 14-30. FlashProgramOnce Command Packet Format (Example)

| FlashProgramOnce | Parameter      | Value                            |
|------------------|----------------|----------------------------------|
| Framing packet   | start byte     | 0x5A                             |
|                  | packetType     | 0xA4, kFramingPacketType_Command |
|                  | length         | 0x10 0x00                        |
|                  | crc16          | 0x7E4 0x89                       |
| Command packet   | commandTag     | 0x0E – FlashProgramOnce          |
|                  | flags          | 0                                |
|                  | reserved       | 0                                |
|                  | parameterCount | 3                                |
|                  | index          | 0x0000_0000                      |
|                  | byteCount      | 0x0000_0004                      |
|                  | data           | 0x1234_5678                      |

**Response:** upon successful execution of the command, the target (Kinetis Flashloader) will return a **GenericResponse** packet with a status code set to **kStatus\_Success**, or to an appropriate error status code.

#### 14.3.6.9 FlashReadOnce command

The **FlashReadOnce** command returns the contents of the program once field by given index and byte count. The **FlashReadOnce** command uses 2 parameters: index and byteCount.

Table 14-31. Parameters for FlashReadOnce Command

| Byte # | Parameter | Description                                      |
|--------|-----------|--------------------------------------------------|
| 0 - 3  | index     | Index of the program once field (to read from)   |
| 4 - 7  | byteCount | Number of bytes to read and return to the caller |

Figure 14-14. Protocol Sequence for FlashReadOnce Command

Table 14-32. FlashReadOnce Command Packet Format (Example)

| FlashReadOnce  | Parameter      | Value                |
|----------------|----------------|----------------------|
| Framing packet | start byte     | 0x5A                 |
|                | packetType     | 0xA4                 |
|                | length         | 0x0C 0x00            |
|                | crc            | 0xC1 0xA5            |
| Command packet | commandTag     | 0x0F – FlashReadOnce |
|                | flags          | 0x00                 |
|                | reserved       | 0x00                 |
|                | parameterCount | 0x02                 |
|                | index          | 0x0000_0000          |
|                | byteCount      | 0x0000_0004          |

Table 14-33. FlashReadOnce Response Format (Example)

| FlashReadOnce Response | Parameter  | Value |
|------------------------|------------|-------|
| Framing packet         | start byte | 0x5A  |
|                        | packetType | 0xA4  |

Table continues on the next page...

**Table 14-33. FlashReadOnce Response Format (Example) (continued)**

| FlashReadOnce Response | Parameter      | Value       |
|------------------------|----------------|-------------|
|                        | length         | 0x10 0x00   |
|                        | crc            | 0x3F 0x6F   |
| Command packet         | commandTag     | 0xAF        |
|                        | flags          | 0x00        |
|                        | reserved       | 0x00        |
|                        | parameterCount | 0x03        |
|                        | status         | 0x0000_0000 |
|                        | byteCount      | 0x0000_0004 |
|                        | data           | 0x1234_5678 |

**Response:** upon successful execution of the command, the target (Kinetis Flashloader) will return a FlashReadOnceResponse packet with a status code set to kStatus\_Success, a byte count and corresponding data read from Program Once Field upon successful execution of the command, or will return with a status code set to an appropriate error status code and a byte count set to 0.

#### 14.3.6.10 FlashReadResource command

The FlashReadResource command returns the contents of the IFR field or Flash firmware ID, by given offset, byte count, and option. The FlashReadResource command uses 3 parameters: start address, byteCount, option.

**Table 14-34. Parameters for FlashReadResource Command**

| Byte # | Parameter     | Command                                                  |
|--------|---------------|----------------------------------------------------------|
| 0 - 3  | start address | Start address of specific non-volatile memory to be read |
| 4 - 7  | byteCount     | Byte count to be read                                    |
| 8 - 11 | option        | 0: IFR<br>1: Flash firmware ID                           |

Figure 14-15. Protocol Sequence for FlashReadResource Command

Table 14-35. FlashReadResource Command Packet Format (Example)

| FlashReadResource | Parameter      | Value                    |
|-------------------|----------------|--------------------------|
| Framing packet    | start byte     | 0x5A                     |
|                   | packetType     | 0xA4                     |
|                   | length         | 0x10 0x00                |
|                   | crc            | 0xB3 0xCC                |
| Command packet    | commandTag     | 0x10 – FlashReadResource |
|                   | flags          | 0x00                     |
|                   | reserved       | 0x00                     |
|                   | parameterCount | 0x03                     |
|                   | startAddress   | 0x0000_0000              |
|                   | byteCount      | 0x0000_0008              |
|                   | option         | 0x0000_0001              |

**Table 14-36. FlashReadResource Response Format (Example)**

| FlashReadResource Response | Parameter      | Value       |
|----------------------------|----------------|-------------|
| Framing packet             | start byte     | 0x5A        |
|                            | packetType     | 0xA4        |
|                            | length         | 0x0C 0x00   |
|                            | crc            | 0xD2 0xB0   |
| Command packet             | commandTag     | 0xB0        |
|                            | flags          | 0x01        |
|                            | reserved       | 0x00        |
|                            | parameterCount | 0x02        |
|                            | status         | 0x0000_0000 |
|                            | byteCount      | 0x0000_0008 |

**Data phase:** The FlashReadResource command has a data phase. Because the target (Kinetis Flashloader ) works in slave mode, the host must pull data packets until the number of bytes of data *specified in the byteCount parameter of FlashReadResource command* are received by the host.

#### 14.3.6.11 WriteMemory command

The WriteMemory command writes data provided in the data phase to a specified range of bytes in memory (flash or RAM). However, if flash protection is enabled, then writes to protected sectors will fail.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be .
- If the VerifyWrites property is set to true, then writes to flash will also perform a flash verify program operation.

When writing to RAM, the start address need not be aligned, and the data will not be padded.

The start address and number of bytes are the 2 parameters required for WriteMemory command.

**Table 14-37. Parameters for WriteMemory Command**

| Byte # | Command       |
|--------|---------------|
| 0 - 3  | Start address |
| 4 - 7  | Byte count    |

### Figure 14-16. Protocol Sequence for WriteMemory Command

### Table 14-38. WriteMemory Command Packet Format (Example)

| WriteMemory    | Parameter      | Value                            |
|----------------|----------------|----------------------------------|
| Framing packet | start byte     | 0x5A                             |
|                | packetType     | 0xA4, kFramingPacketType_Command |
|                | length         | 0x0C 0x00                        |
|                | crc16          | 0x06 0x5A                        |
| Command packet | commandTag     | 0x04 - writeMemory               |
|                | flags          | 0x00                             |
|                | reserved       | 0x00                             |
|                | parameterCount | 0x02                             |

*Table continues on the next page...*

**Table 14-38. WriteMemory Command Packet Format (Example) (continued)**

| WriteMemory | Parameter    | Value      |
|-------------|--------------|------------|
|             | startAddress | 0x20000400 |
|             | byteCount    | 0x00000064 |

**Data Phase:** The WriteMemory command has a data phase; the host will send data packets until the number of bytes of data specified in the byteCount parameter of the WriteMemory command are received by the target.

**Response:** The target (Kinetis Flashloader ) will return a GenericResponse packet with a status code set to kStatus\_Success upon successful execution of the command, or to an appropriate error status code.

#### 14.3.6.12 Read memory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory accessible by the CPU and not protected by security.

The start address and number of bytes are the 2 parameters required for ReadMemory command.

**Table 14-39. Parameters for read memory command**

| Byte | Parameter     | Description                                  |
|------|---------------|----------------------------------------------|
| 0-3  | Start address | Start address of memory to read from         |
| 4-7  | Byte count    | Number of bytes to read and return to caller |

Figure 14-17. Command sequence for read memory

| ReadMemory     | Parameter      | Value                      |
|----------------|----------------|----------------------------|
| Framing packet | Start byte     | 0x5A0xA4,                  |
|                | packetType     | kFramingPacketType_Command |
|                | length         | 0x0C 0x00                  |
|                | crc16          | 0x1D 0x23                  |
| Command packet | commandTag     | 0x03 - readMemory          |
|                | flags          | 0x00                       |
|                | reserved       | 0x00                       |
|                | parameterCount | 0x02                       |
|                | startAddress   | 0x20000400                 |
|                | byteCount      | 0x00000064                 |

**Data Phase:** The ReadMemory command has a data phase. Since the target (Kinetis Flashloader) works in slave mode, the host need pull data packets until the number of bytes of data specified in the byteCount parameter of ReadMemory command are received by host.

**Response:** The target (Kinetis Flashloader) will return a GenericResponse packet with a status code either set to kStatus\_Success upon successful execution of the command, or set to an appropriate error status code.

### 14.3.6.13 FlashSecurityDisable command

The FlashSecurityDisable command performs the flash security disable operation, by comparing the 8-byte backdoor key (provided in the command) against the backdoor key stored in the flash configuration field (at address 0x400 in the flash).

The backdoor low and high words are the only parameters required for FlashSecurityDisable command.

**Table 14-40. Parameters for FlashSecurityDisable Command**

| Byte # | Command                |
|--------|------------------------|
| 0 - 3  | Backdoor key low word  |
| 4 - 7  | Backdoor key high word |

**Figure 14-18. Protocol Sequence for FlashSecurityDisable Command**

**Table 14-41. FlashSecurityDisable Command Packet Format (Example)**

| FlashSecurityDisable | Parameter        | Value                            |
|----------------------|------------------|----------------------------------|
| Framing packet       | start byte       | 0x5A                             |
|                      | packetType       | 0xA4, kFramingPacketType_Command |
|                      | length           | 0x0C 0x00                        |
|                      | crc16            | 0x43 0x7B                        |
| Command packet       | commandTag       | 0x06 - FlashSecurityDisable      |
|                      | flags            | 0x00                             |
|                      | reserved         | 0x00                             |
|                      | parameterCount   | 0x02                             |
|                      | Backdoorkey_low  | 0x04 0x03 0x02 0x01              |
|                      | Backdoorkey_high | 0x08 0x07 0x06 0x05              |

The FlashSecurityDisable command has no data phase.

**Response:** The target (Kinetis Flashloader) will return a GenericResponse packet with a status code either set to kStatus\_Success upon successful execution of the command, or set to an appropriate error status code.

#### 14.3.6.14 Execute command

The execute command results in the flashloader setting the program counter to the code at the provided jump address, R0 to the provided argument, and a Stack pointer to the provided stack pointer address. Prior to the jump, the system is returned to the reset state.

The Jump address, function argument pointer, and stack pointer are the parameters required for the Execute command.

**Table 14-42. Parameters for Execute Command**

| Byte # | Command               |
|--------|-----------------------|
| 0 - 3  | Jump address          |
| 4 - 7  | Argument word         |
| 8 - 11 | Stack pointer address |

The Execute command has no data phase.

**Response:** Before executing the Execute command, the target (Kinetis Flashloader) will validate the parameters and return a GenericResponse packet with a status code either set to kStatus\_Success or an appropriate error status code.

### 14.3.6.15 Reset command

The Reset command will result in flashloader resetting the chip.

The Reset command requires no parameters.

Figure 14-19. Protocol Sequence for Reset Command

Table 14-43. Reset Command Packet Format (Example)

| Reset          | Parameter      | Value                            |
|----------------|----------------|----------------------------------|
| Framing packet | start byte     | 0x5A                             |
|                | packetType     | 0xA4, kFramingPacketType_Command |
|                | length         | 0x04 0x00                        |

|                | parameterCount | 0x00                             |

The Reset command has no data phase.

**Response:** The target (Kinetis Flashloader) will return a GenericResponse packet with status code set to kStatus\_Success, before resetting the chip.

## 14.4 Peripherals Supported

This section describes the peripherals supported by the Kinetis Flashloader.

### 14.4.1 I2C Peripheral

The Kinetis Flashloader supports loading data into flash via the I2C peripheral, where the I2C peripheral serves as the I2C slave. A 7-bit slave address is used during the transfer.

The Kinetis Flashloader uses 0x10 as the I2C slave address, and supports 400 kbps as the I2C baud rate.

Because the I2C peripheral serves as an I2C slave device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

- An incoming packet is sent by the host with a selected I2C slave address and the direction bit is set as write.
- An outgoing packet is read by the host with a selected I2C slave address and the direction bit is set as read.
- 0x00 will be sent as the response to host if the target is busy with processing or preparing data.

The following flow charts demonstrate the communication flow of how the host reads ping packet, ACK and response from the target.

**Figure 14-20. Host reads ping response from target via I2C**

Figure 14-21. Host reads ACK packet from target via I2C

Figure 14-22. Host reads response from target via I2C

## 14.4.2 SPI Peripheral

The Kinetis Flashloader supports loading data into flash via the SPI peripheral, where the SPI peripheral serves as a SPI slave.

The Kinetis Flashloader supports 400 kbps as the SPI baud rate.

The SPI peripheral uses the following bus attributes:

- Clock Phase = 1 (Second Edge)
- Clock Polarity = 1 (Active Low)

Because the SPI peripheral serves as a SPI slave device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

The transfer on SPI is slightly different from I2C:

- Host will receive 1 byte after it sends out any byte.
- Received bytes should be ignored when host is sending out bytes to target
- Host starts reading bytes by sending 0x00s to target
- The byte 0x00 will be sent as response to host if target is under the following conditions:
  - Processing incoming packet
  - Preparing outgoing data
  - Received invalid data

The SPI bus configuration is:

- Phase = 1; data is sampled on rising edges
- Polarity = 1; idle is high
- MSB is transmitted first

For any transfer where the target does not have actual data to send, the target (slave) is responsible for ensuring that 0x00 bytes will be returned to the host (master). The host uses framing packets to identify real data and not "dummy" 0x00 bytes (which do not have framing packets).

The following flowcharts demonstrate how the host reads a ping response, an ACK and a command response from target via SPI.

**Figure 14-23. Host reads ping packet from target via SPI**

Figure 14-24. Host reads ACK from target via SPI

Figure 14-25. Host reads response from target via SPI

### 14.4.3 UART Peripheral

The Kinetis Flashloader integrates an autobaud detection algorithm for the UART peripheral, thereby providing flexible baud rate choices.

**Autobaud feature:** If UART $n$  is used to connect to the flashloader, then the UART $n$ \_RX pin must be kept high and not left floating during the detection phase in order to comply with the autobaud detection algorithm. After the flashloader detects the ping packet (0x5A 0xA6) on UART $n$ \_RX, the flashloader firmware executes the autobaud sequence. If the baudrate is successfully detected, then the flashloader will send a ping packet response [(0x5A 0xA7), protocol version (4 bytes), protocol version options (2 bytes) and crc16 (2 bytes)] at the detected baudrate. The Kinetis Flashloader then enters a loop, waiting for flashloader commands via the UART peripheral.

### NOTE

- The autobaud feature requires a ping packet with a higher accuracy (+/-3%), or the ping packet will be ignored as noise.
- The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed UART transmission mode (8-bit data, no parity bit and 1 stop bit). If the bytes of the ping packet are sent one-by-one with more than 80 ms delay between them, then the autobaud detection algorithm may calculate an incorrect baud rate. In this case, the autobaud detection state machine should be reset.

**Supported baud rates:** The baud rate is closely related to the MCU core and system clock frequencies. Typical baud rates supported are 9600, 19200, 38400, 57600, and 115200.

**Packet transfer:** After autobaud detection succeeds, flashloader communications can take place over the UART peripheral. The following flow charts show:

- How the host detects an ACK from the target
- How the host detects a ping response from the target
- How the host detects a command response from the target

Figure 14-26. Host reads an ACK from target via UART

Figure 14-27. Host reads a ping response from target via UART

**Figure 14-28. Host reads a command response from target via UART**

#### 14.4.4 CAN (or FlexCAN) Peripheral

The Kinetis Flashloader supports loading data into flash via the FlexCAN peripheral. Transfers to FlexCAN are supported at several predefined speeds:

- 125 kHz
- 250 kHz
- 500 kHz
- 1 MHz (the default transfer rate)

The host application must use one of the several supported speeds for FlexCAN. In Flashloader, it supports automatic speed detection within supported speeds. The Flashloader will enter the listen mode in the beginning with the initial speed (default speed 1 MHz). Once the host sends a ping to a specific node, it will generate traffic on the FlexCAN bus. Because the Flashloader is in a listen mode, it will be able to check if the local node speed is correct, by detecting errors.

- If there is an error, then some transfers may not be at the right speed.
- The Flashloader will change the speed setting and check again.
- If there is no error, it means that the transfer speed is correct, and it changes the settings back to normal receiving mode, to see if there is a package for this node.
- The host side should also have reasonable time tolerance during the automatic speed detection period. If there is a timeout, it means that there is no response from the specific node, or there is a real error (and it should report the error to the application).

The following flowcharts show how the host reads a ping packet, ACK and response from the target.

**Figure 14-29. Host reads an ACK from target via FlexCAN**

**Figure 14-30. Host reads a ping response from target via FlexCAN**

Figure 14-31. Host reads a command response from target via FlexCAN

## 14.5 Get/SetProperty Command Properties

This section lists the properties of the GetProperty and SetProperty commands.

**Table 14-44. Properties used by Get/SetProperty Commands, sorted by Value**

| Property                             | Writable | Tag Value | Size | Description                                                                                                                                                           |
|--------------------------------------|----------|-----------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 14.5.1 Property Definitions

Get/Set property definitions are provided in this section.

### 14.5.1.1 CurrentVersion Property

The value of this property is a 4-byte structure containing the current version of the flashloader.

**Table 14-45. Fields of CurrentVersion property:**

| Bits  | [31:24]           | [23:16]       | [15:8]        | [7:0]          |
|-------|-------------------|---------------|---------------|----------------|
| Field | Name = 'K' (0x4B) | Major version | Minor version | Bugfix version |

### 14.5.1.2 AvailablePeripherals Property

The value of this property is a bitfield that lists the peripherals supported by the flashloader and the hardware on which it is running.

**Table 14-46. Peripheral bits:**

| Bit        | [31:7]   | [6]      | [5]      | [4]      | [3]       | [2]       | [1]       | [0]  |
|------------|----------|----------|----------|----------|-----------|-----------|-----------|------|
| Peripheral | Reserved | Reserved | Reserved | Reserved | CAN Slave | SPI Slave | I2C Slave | UART |

If the peripheral is available, then the corresponding bit will be set in the property value. All reserved bits must be set to 0.

### 14.5.1.3 AvailableCommands Property

This property value is a bitfield with set bits indicating the commands enabled in the flashloader. Only commands that can be sent from the host to the target are listed in the bitfield. Response commands such as GenericResponse are excluded.

The bit number that identifies whether a command is present is the command's tag value minus 1. 1 is subtracted from the command tag because the lowest command tag value is 0x01. To get the bit mask for a given command, use this expression:

$$\text{mask} = 1 \ll (\text{tag} - 1)$$

**Table 14-47. Command bits:**

## 14.6 Kinetis Flashloader Status Error Codes

This section describes the status error codes that the Kinetis Flashloader returns to the host.

**Table 14-48. Kinetis Flashloader Status Error Codes, sorted by Value**

| Error Code                       | Value | Description                                                |
|----------------------------------|-------|------------------------------------------------------------|
| kStatus_Success                  | 0     | Operation succeeded without error.                         |
| kStatus_Fail                     | 1     | Operation failed with a generic error.                     |
| kStatus_ReadOnly                 | 2     | Requested value cannot be changed because it is read-only. |
| kStatus_OutOfRange               | 3     | Requested value is out of range.                           |
| kStatus_InvalidArgument          | 4     | The requested command's argument is undefined.             |
| kStatus_Timeout                  | 5     | A timeout occurred.                                        |
| kStatus_FlashSizeError           | 100   | Not used.                                                  |
| kStatus_FlashAlignmentError      | 101   | Address or length does not meet required alignment.        |
| kStatus_FlashAddressError        | 102   | Address or length is outside addressable memory.           |
| kStatus_FlashAccessError         | 103   | The FTFE_FSTAT[ACCERR] bit is set.                         |
| kStatus_FlashProtectionViolation | 104   | The FTFE_FSTAT[FPVIOL] bit is set.                         |
| kStatus_FlashCommandFailure      | 105   | The FTFE_FSTAT[MGSTAT0] bit is set.                        |
| kStatus_FlashUnknownProperty     | 106   | Unknown Flash property.                                    |
| kStatus_FlashEraseKeyError       | 107   | The key provided does not match the programmed flash key.  |
| kStatus_FlashRegionExecuteOnly   | 108   | The area of flash is protected as execute only.            |
| kStatus_I2C_SlaveTxUnderrun      | 200   | I2C Slave TX Underrun error.                               |
| kStatus_I2C_SlaveRxOverrun       | 201   | I2C Slave RX Overrun error.                                |
| kStatus_I2C_ArbitrationLost      | 202   | I2C Arbitration Lost error.                                |
| kStatus_SPI_SlaveTxUnderrun      | 300   | SPI Slave TX Underrun error.                               |
| kStatus_SPI_SlaveRxOverrun       | 301   | SPI Slave RX Overrun error.                                |

Table continues on the next page...

**Table 14-48. Kinetis Flashloader Status Error Codes, sorted by Value (continued)**

| Error Code                       | Value | Description                                                                                        |
|----------------------------------|-------|----------------------------------------------------------------------------------------------------|
| kStatus_SPI_Timeout              | 302   | SPI transfer timed out.                                                                            |
| kStatus_SPI_Busy                 | 303   | SPI instance is already busy performing a transfer.                                                |
| kStatus_SPI_NoTransferInProgress | 304   | Attempt to abort a transfer when no transfer was in progress.                                      |
| kStatus_UnknownCommand           | 10000 | The requested command value is undefined.                                                          |
| kStatus_SecurityViolation        | 10001 | Command is disallowed because flash security is enabled.                                           |
| kStatus_AbortDataPhase           | 10002 | Abort the data phase early.                                                                        |
| kStatusMemoryRangeInvalid        | 10200 | Memory range conflicts with a protected region.                                                    |
| kStatus_UnknownProperty          | 10300 | The requested property value is undefined.                                                         |
| kStatus_ReadOnlyProperty         | 10301 | The requested property value cannot be written.                                                    |
| kStatus_InvalidPropertyValue     | 10302 | The specified property value is invalid.                                                           |
| kStatus_AppCrcCheckPassed        | 10400 | CRC check is valid and passed.                                                                     |
| kStatus_AppCrcCheckFailed        | 10401 | CRC check is valid but failed.                                                                     |
| kStatus_AppCrcCheckInactive      | 10402 | CRC check is inactive.                                                                             |
| kStatus_AppCrcCheckInvalid       | 10403 | CRC check is invalid, because the BCA is invalid or the CRC parameters are unset (all 0xFF bytes). |
| kStatus_AppCrcCheckOutOfRange    | 10404 | CRC check is valid but addresses are out of range.                                                 |

# Chapter 15

## Reset Control Module (RCM)

### 15.1 Introduction

Information found here describes the registers of the Reset Control Module (RCM). The RCM implements many of the reset functions for the chip. See the chip's reset chapter for more information.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the RCM.

### 15.2 Reset memory map and register descriptions

The RCM Memory Map/Register Definition can be found here.

The Reset Control Module (RCM) registers provide reset status information and reset filter control.

#### NOTE

The RCM registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

#### RCM memory map

| Absolute address (hex) | Register name                                | Width (in bits) | Access | Reset value | Section/ page              |
|------------------------|----------------------------------------------|-----------------|--------|-------------|----------------------------|
| 4007_F000              | System Reset Status Register 0 (RCM_SRS0)    | 8               | R      | 82h         | <a href="#">15.2.1/296</a> |
| 4007_F001              | System Reset Status Register 1 (RCM_SRS1)    | 8               | R      | 00h         | <a href="#">15.2.2/297</a> |
| 4007_F004              | Reset Pin Filter Control register (RCM_RPFC) | 8               | R/W    | 00h         | <a href="#">15.2.3/299</a> |
| 4007_F005              | Reset Pin Filter Width register (RCM_RPFW)   | 8               | R/W    | 00h         | <a href="#">15.2.4/300</a> |

*Table continues on the next page...*

## RCM memory map (continued)

| Absolute address (hex) | Register name                                     | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|---------------------------------------------------|-----------------|--------|-------------|----------------------------|
| 4007_F008              | Sticky System Reset Status Register 0 (RCM_SSRS0) | 8               | R/W    | 82h         | <a href="#">15.2.5/301</a> |
| 4007_F009              | Sticky System Reset Status Register 1 (RCM_SSRS1) | 8               | R/W    | 00h         | <a href="#">15.2.6/302</a> |

## 15.2.1 System Reset Status Register 0 (RCM\_SRS0)

This register includes read-only status flags to indicate the source of the most recent reset. The reset state of these bits depends on what caused the MCU to reset.

**NOTE**

The reset value of this register depends on the reset source:

- POR (including LVD) — 0x82
- LVD (without POR) — 0x02
- VLLS mode wakeup due to  $\overline{\text{RESET}}$  pin assertion — 0x41
- VLLS mode wakeup due to other wakeup sources — 0x01
- Other reset — a bit is set if its corresponding reset source caused the reset

Address: 4007\_F000h base + 0h offset = 4007\_F000h

| Bit   | 7   | 6   | 5    | 4 | 3   | 2   | 1   | 0      |
|-------|-----|-----|------|---|-----|-----|-----|--------|
| Read  | POR | PIN | WDOG | 0 | LOL | LOC | LVD | WAKEUP |
| Write |     |     |      |   |     |     |     |        |
| Reset | 1   | 0   | 0    | 0 | 0   | 0   | 1   | 0      |

## RCM\_SRS0 field descriptions

| Field     | Description                                                                                                                                                                                                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>POR  | <p>Power-On Reset</p> <p>Indicates a reset has been caused by the power-on detection logic. Because the internal supply voltage was ramping up at the time, the low-voltage reset (LVD) status bit is also set to indicate that the reset occurred while the internal supply was below the LVD threshold.</p> <p>0 Reset not caused by POR<br/>1 Reset caused by POR</p> |
| 6<br>PIN  | <p>External Reset Pin</p> <p>Indicates a reset has been caused by an active-low level on the external <math>\overline{\text{RESET}}</math> pin.</p> <p>0 Reset not caused by external reset pin<br/>1 Reset caused by external reset pin</p>                                                                                                                             |
| 5<br>WDOG | <p>Watchdog</p>                                                                                                                                                                                                                                                                                                                                                          |

Table continues on the next page...

**RCM\_SRS0 field descriptions (continued)**

| Field         | Description                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 15.2.3 Reset Pin Filter Control register (RCM\_RPFC)

#### NOTE

The reset values of bits 2-0 are for Chip POR only. They are unaffected by other reset types.

#### NOTE

The bus clock filter is reset when disabled or when entering stop mode. The LPO filter is reset when disabled .

Address: 4007\_F000h base + 4h offset = 4007\_F004h

| 11110 | Bus clock filter count is 31 |
| 11111 | Bus clock filter count is 32 |

**15.2.5 Sticky System Reset Status Register 0 (RCM\_SSRS0)**

This register includes status flags to indicate all reset sources since the last POR, LVD or VLLS Wakeup that have not been cleared by software. Software can clear the status flags by writing a logic one to a flag.

Address: 4007\_F000h base + 8h offset = 4007\_F008h

# Chapter 16

## System Mode Controller (SMC)

### 16.1 Introduction

The System Mode Controller (SMC) is responsible for sequencing the system into and out of all low-power Stop and Run modes.

Specifically, it monitors events to trigger transitions between power modes while controlling the power, clocks, and memories of the system to achieve the power consumption and functionality of that mode.

This chapter describes all the available low-power modes, the sequence followed to enter/exit each mode, and the functionality available while in each of the modes.

The SMC is able to function during even the deepest low power modes.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the SMC.

### 16.2 Modes of operation

The ARM CPU has three primary modes of operation:

- Run
- Sleep
- Deep Sleep

The WFI or WFE instruction is used to invoke Sleep and Deep Sleep modes. Run, Wait, and Stop are the common terms used for the primary operating modes of Kinetis microcontrollers.

The following table shows the translation between the ARM CPU modes and the Kinetis MCU power modes.

| ARM CPU mode | MCU mode |
|--------------|----------|
| Sleep        | Wait     |
| Deep Sleep   | Stop     |

Accordingly, the ARM CPU documentation refers to sleep and deep sleep, while the Kinetis MCU documentation normally uses wait and stop.

In addition, Kinetis MCUs also augment Stop, Wait, and Run modes in a number of ways. The power management controller (PMC) contains a run and a stop mode regulator. Run regulation is used in normal run, wait and stop modes. Stop mode regulation is used during all very low power and low leakage modes. During stop mode regulation, the bus frequencies are limited in the very low power modes.

The SMC provides the user with multiple power options. The Very Low Power Run (VLPR) mode can drastically reduce run time power when maximum bus frequency is not required to handle the application needs. From Normal Run mode, the Run Mode (RUNM) field can be modified to change the MCU into VLPR mode when limited frequency is sufficient for the application. From VLPR mode, a corresponding wait (VLPW) and stop (VLPS) mode can be entered.

Depending on the needs of the user application, a variety of stop modes are available that allow the state retention, partial power down or full power down of certain logic and/or memory. I/O states are held in all modes of operation. Several registers are used to configure the various modes of operation for the device.

The following table describes the power modes available for the device.

**Table 16-1. Power modes**

| Mode  | Description                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RUN   | The MCU can be run at full speed and the internal supply is fully regulated, that is, in run regulation. This mode is also referred to as Normal Run mode.                                                             |
| HSRUN | The MCU can be run at a faster frequency compared with RUN mode and the internal supply is fully regulated. See the Power Management chapter for details about the maximum allowable frequencies.                      |
| WAIT  | The core clock is gated off. The system clock continues to operate. Bus clocks, if enabled, continue to operate. Run regulation is maintained.                                                                         |
| STOP  | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.                                                     |
| VLPR  | The core, system, bus, and flash clock maximum frequencies are restricted in this mode. See the Power Management chapter for details about the maximum allowable frequencies.                                          |
| VLPW  | The core clock is gated off. The system, bus, and flash clocks continue to operate, although their maximum frequency is restricted. See the Power Management chapter for details on the maximum allowable frequencies. |
| VLPS  | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid.                                                     |

*Table continues on the next page...*

**Table 16-1. Power modes (continued)**

| Mode  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLLS3 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic. All system RAM contents are retained and I/O states are held. Internal logic states are not retained.                                                                                                |
| VLLS2 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and the system RAM3 partition. The system RAM2 partition can be optionally retained using STOPCTRL[RAM2PO].                                                                                           |
| VLLS1 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and all system RAM. I/O states are held. Internal logic states are not retained.                                                                                                                      |
| VLLS0 | The core clock is gated off. System clocks to other masters and bus clocks are gated off after all stop acknowledge signals from supporting peripherals are valid. The MCU is placed in a low leakage mode by powering down the internal logic and all system RAM. I/O states are held. Internal logic states are not retained. The 1kHz LPO clock is disabled and the power on reset (POR) circuit can be optionally enabled using STOPCTRL[PORPO]. |

## 16.3 Memory map and register descriptions

Information about the registers related to the system mode controller can be found here.

Different SMC registers reset on different reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

### NOTE

The SMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

### NOTE

Before executing the WFI instruction, the last register written to must be read back. This ensures that all register writes associated with setting up the low power mode being entered have completed before the MCU enters the low power mode. Failure to do this may result in the low power mode not being entered correctly.

## SMC memory map

| Absolute address (hex) | Register name                               | Width (in bits) | Access | Reset value                 | Section/ page              |
|------------------------|---------------------------------------------|-----------------|--------|-----------------------------|----------------------------|
| 4007_E000              | Power Mode Protection register (SMC_PMPROT) | 8               | R/W    | <a href="#">See section</a> | <a href="#">16.3.1/308</a> |
| 4007_E001              | Power Mode Control register (SMC_PMCTRL)    | 8               | R/W    | <a href="#">See section</a> | <a href="#">16.3.2/309</a> |

### 16.3.1 Power Mode Protection register (SMC\_PMPROT)

This register provides protection for entry into any low-power run or stop mode. The enabling of the low-power run or stop mode occurs by configuring the Power Mode Control register (PMCTRL).

The PMPROT register can be written only once after any system reset.

If the MCU is configured for a disallowed or reserved power mode, the MCU remains in its current power mode. For example, if the MCU is in normal RUN mode and AVLP is 0, an attempt to enter VLPR mode using PMCTRL[RUNM] is blocked and PMCTRL[RUNM] remains 00b, indicating the MCU is still in Normal Run mode.

#### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the Reset section details for more information.

Address: 4007\_E000h base + 0h offset = 4007\_E000h

| Bit   | 7      | 6 | 5    | 4 | 3 | 2 | 1     | 0 |
|-------|--------|---|------|---|---|---|-------|---|
| Read  | AHSRUN | 0 | AVLP | 0 | 0 | 0 | AVLLS | 0 |
| Write |        |   |      |   |   |   |       |   |
| Reset | 0      | 0 | *    | 0 | 0 | 0 | 0     | 0 |

\* Notes:

- AVLP field: When booting in run mode, the reset value is 0. When booting in VLPR mode, the reset value is 1.

### SMC\_PMPROT field descriptions

**16.3.2 Power Mode Control register (SMC\_PMCTRL)**

The PMCTRL register controls entry into low-power Run and Stop modes, provided that the selected power mode is allowed via an appropriate setting of the protection (PMPROT) register.

**NOTE**

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

### 16.3.3 Stop Control Register (SMC\_STOPCTRL)

The STOPCTRL register provides various control bits allowing the user to fine tune power consumption during the stop mode selected by the STOPM field.

#### NOTE

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

**16.3.4 Power Mode Status register (SMC\_PMSTAT)**

PMSTAT is a read-only, one-hot register which indicates the current power mode of the system.

**NOTE**

This register is reset on Chip POR not VLLS and by reset types that trigger Chip POR not VLLS. It is unaffected by reset types that do not trigger Chip POR not VLLS. See the Reset section details for more information.

Address: 4007\_E000h base + 3h offset = 4007\_E003h

## 16.4 Functional description

### 16.4.1 Power mode transitions

The following figure shows the power mode state transitions available on the chip. Any reset will initially bring the MCU back to the normal RUN state. However, in order to minimize peak power consumption, the RUNM bits in the PMCTRL register can be reset to VLPR via Flash IFR settings, causing the SMC to begin transitioning the MCU into VLPR mode during the reset recovery sequence.

Figure 16-1. Power mode state diagram

The following table defines triggers for the various state transitions shown in the previous figure.

Table 16-2. Power mode transition triggers

| Transition # | From | To   | Trigger conditions                                                                                                                          |
|--------------|------|------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 1            | RUN  | WAIT | Sleep-now or sleep-on-exit modes entered with SLEEPDEEP clear, controlled in System Control Register in ARM core.<br>See note. <sup>1</sup> |
|              | WAIT | RUN  | Interrupt or Reset                                                                                                                          |
| 2            | RUN  | STOP | PMCTRL[RUNM]=00, PMCTRL[STOPM]=000 <sup>2</sup>                                                                                             |

|              | VLPS  | RUN   | Interrupt and VLPS mode was entered directly from RUN or Reset                                                                                                                                                                                                                                                                                                                                                                                                               |
| 8            | RUN   | VLLSx | PMPROT[AVLLS]=1, PMCTRL[STOPM]=100, STOPCTRL[LLSM]=x (VLLSx), Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core.                                                                                                                                                                                                                                                                                       |
|              | VLLSx | RUN   | Wakeup from enabled LPTMR input source or RESET pin                                                                                                                                                                                                                                                                                                                                                                                                                          |

*Table continues on the next page...*

**Table 16-2. Power mode transition triggers (continued)**

| Transition # | From  | To    | Trigger conditions                                                                                                                                                                     |
|--------------|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9            | VLPR  | VLLSx | PMPROT[AVLLS]=1, PMCTRL[STOPM]=100, STOPCTRL[LLSM]=x (VLLSx), Sleep-now or sleep-on-exit modes entered with SLEEPDEEP set, which is controlled in System Control Register in ARM core. |
| 12           | RUN   | HSRUN | Set PMPROT[AHSRUN]=1, PMCTRL[RUNM]=11.                                                                                                                                                 |
|              | HSRUN | RUN   | Set PMCTRL[RUNM]=00 or<br>Reset                                                                                                                                                        |

1. If debug is enabled, the core clock remains to support debug.
2. If PMCTRL[STOPM]=000 and STOPCTRL[PSTOPO]=01 or 10, then only a Partial Stop mode is entered instead of STOP
3. If PMCTRL[STOPM]=000 and STOPCTRL[PSTOPO]=00, then VLPS mode is entered instead of STOP. If PMCTRL[STOPM]=000 and STOPCTRL[PSTOPO]=01 or 10, then only a Partial Stop mode is entered instead of VLPS

## 16.4.2 Power mode entry/exit sequencing

When entering or exiting low-power modes, the system must conform to an orderly sequence to manage transitions safely.

The SMC manages the system's entry into and exit from all power modes. This diagram illustrates the connections of the SMC with other system components in the chip that are necessary to sequence the system through all power modes.

**Figure 16-2. Low-power system components and connections**

### 16.4.2.1 Stop mode entry sequence

Entry into a low-power stop mode (Stop, VLPS, VLLSx) is initiated by a CPU executing the WFI instruction. After the instruction is executed, the following sequence occurs:

1. The CPU clock is gated off immediately.
2. Requests are made to all non-CPU bus masters to enter Stop mode.
3. After all masters have acknowledged they are ready to enter Stop mode, requests are made to all bus slaves to enter Stop mode.
4. After all slaves have acknowledged they are ready to enter Stop mode, all system and bus clocks are gated off.
5. Clock generators are disabled in the MCG.
6. The on-chip regulator in the PMC and internal power switches are configured to meet the power consumption goals for the targeted low-power mode.

### 16.4.2.2 Stop mode exit sequence

Exit from a low-power stop mode is initiated either by a reset or an interrupt event. The following sequence then executes to restore the system to a run mode (RUN or VLPR):

1. The on-chip regulator in the PMC and internal power switches are restored.
2. Clock generators are enabled in the MCG.
3. System and bus clocks are enabled to all masters and slaves.
4. The CPU clock is enabled and the CPU begins servicing the reset or interrupt that initiated the exit from the low-power stop mode.

### 16.4.2.3 Aborted stop mode entry

If an interrupt occurs during a stop entry sequence, the SMC can abort the transition early and return to RUN mode without completely entering the stop mode. An aborted entry is possible only if the interrupt occurs before the PMC begins the transition to stop mode regulation. After this point, the interrupt is ignored until the PMC has completed its transition to stop mode regulation. When an aborted stop mode entry sequence occurs, SMC\_PMCCTRL[STOPA] is set to 1.

### 16.4.2.4 Transition to wait modes

For wait modes (WAIT and VLPW), the CPU clock is gated off while all other clocking continues, as in RUN and VLPR mode operation. Some modules that support stop-in-wait functionality have their clocks disabled in these configurations.

### 16.4.2.5 Transition from stop modes to Debug mode

The debugger module supports a transition from STOP, WAIT, VLPS, and VLPW back to a Halted state when the debugger has been enabled. As part of this transition, system clocking is re-established and is equivalent to the normal RUN and VLPR mode clocking configuration.

## 16.4.3 Run modes

The run modes supported by this device can be found here.

- Run (RUN)

- Very Low-Power Run (VLPR)
- High Speed Run (HSRUN)

### 16.4.3.1 RUN mode

This mode is selected after any reset. In order to reduce peak power consumption, however, the SMC begins transitioning the device into VLPR mode during the reset recovery sequence. When the ARM processor exits reset, it sets up the stack, program counter (PC), and link register (LR):

- The processor reads the start SP (SP\_main) from vector-table offset 0x000
- The processor reads the start PC from vector-table offset 0x004
- LR is set to 0xFFFF\_FFFF.

To reduce power in this mode, disable the clocks to unused modules.

### 16.4.3.2 Very-Low Power Run (VLPR) mode

In VLPR mode, the on-chip voltage regulator is put into a stop mode regulation state. In this state, the regulator is designed to supply enough current to the MCU over a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules using their corresponding clock gating control bits in the SIM's registers.

Before entering this mode, the following conditions must be met:

- The MCG must be configured in a mode which is supported during VLPR. See the Power Management details for information about these MCG modes.
- All clock monitors in the MCG must be disabled.
- The maximum frequencies of the system, bus, flash, and core are restricted. See the Power Management details about which frequencies are supported.
- Mode protection must be set to allow VLP modes, that is, PMPROT[AVLP] is 1.
- PMCTRL[RUNM] must be set to 10b to enter VLPR.
- Flash programming/erasing is not allowed.

#### NOTE

Do not increase the clock frequency while in VLPR mode, because the regulator is slow in responding and cannot manage fast load transitions. In addition, do not modify the clock source in the MCG module or any clock divider registers. Module clock enables in the SIM can be set, however should only be cleared one at a time to limit load transitions.

To reenter Normal Run mode, clear PMCTRL[RUNM]. PMSTAT is a read-only status register that can be used to determine when the system has completed an exit to RUN mode. When PMSTAT=RUN, the system is in run regulation and the MCU can run at full speed in any clock mode. If a higher execution frequency is desired, poll PMSTAT until it is set to RUN when returning from VLPR mode.

Any reset will initially cause the device to exit to RUN mode, however Flash IFR settings can be used to return the part to VLPR during the MCU reset flow.

### 16.4.3.3 High Speed Run (HSRUN) mode

In HSRUN mode, the on-chip voltage regulator remains in a run regulation state, but with a slightly elevated voltage output. In this state, the MCU is able to operate at a faster frequency compared to normal RUN mode. For the maximum allowable frequencies, see the Power Management chapter.

While in this mode, the following restrictions must be adhered to:

- The maximum allowable change in frequency of the system, bus, flash or core clocks is restricted to 2x (double the frequency).
- Before exiting HSRUN mode, clock frequencies should be reduced back down to those acceptable in RUN mode.
- Stop mode entry is not supported from HSRUN.
- Modifications to clock gating control bits are prohibited.
- Flash programming/erasing is not allowed.

To enter HSRUN mode, set PMPROT[AHSRUN] to allow HSRUN and then set PMCTRL[RUNM]=HSRUN. Before increasing clock frequencies, the PMSTAT register should be polled to determine when the system has completed entry into HSRUN mode. To reenter normal RUN mode, clear PMCTRL[RUNM]. Any reset also clears PMCTRL[RUNM] and causes the system to exit to normal RUN mode after the MCU exits its reset flow.

### 16.4.4 Wait modes

This device contains two different wait modes which are listed here.

- Wait
- Very-Low Power Wait (VLPW)

### 16.4.4.1 WAIT mode

WAIT mode is entered when the ARM core enters the Sleep-Now or Sleep-On-Exit modes while SLEEPDEEP is cleared. The ARM CPU enters a low-power state in which it is not clocked, but peripherals continue to be clocked provided they are enabled.

When an interrupt request occurs, the CPU exits WAIT mode and resumes processing in RUN mode, beginning with the stacking operations leading to the interrupt service routine.

A system reset causes an exit from WAIT mode, temporarily returning the device to RUN mode before transitioning into VLPR during the device reset flow.

### 16.4.4.2 Very-Low-Power Wait (VLPW) mode

VLPW mode is entered by entering the Sleep-Now or Sleep-On-Exit mode while SLEEPDEEP is cleared and the device is in VLPR mode.

In VLPW, the on-chip voltage regulator remains in its stop regulation state. In this state, the regulator is designed to supply enough current to the device at a reduced frequency. To further reduce power in this mode, disable the clocks to unused modules.

VLPR mode restrictions also apply to VLPW.

When an interrupt from VLPW occurs, the device returns to VLPR mode to execute the interrupt service routine.

A system reset causes an exit from VLPW mode, temporarily returning the device to RUN mode before transitioning into VLPR during the device reset flow.

## 16.4.5 Stop modes

This device contains a variety of stop modes to meet your application needs.

The stop modes range from:

- a stopped CPU, with all I/O, logic, and memory states retained, and certain asynchronous mode peripherals operating

to:

- a powered down CPU, with only I/O and a small register file retained, very few asynchronous mode peripherals operating, while the remainder of the MCU is powered down.

The choice of stop mode depends upon the user's application, and how power usage and state retention versus functional needs and recovery time may be traded off.

The various stop modes are selected by setting the appropriate fields in PMPROT and PMCTRL. The selected stop mode is entered during the sleep-now or sleep-on-exit entry with the SLEEPDEEP bit set in the System Control Register in the ARM core.

The available stop modes are:

- Normal Stop (STOP)
- Very-Low Power Stop (VLPS)
- Very-Low-Leakage Stop (VLLSx)

### **16.4.5.1 STOP mode**

STOP mode is entered via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core.

The MCG module can be configured to leave the reference clocks running.

A module capable of providing an asynchronous interrupt to the device takes the device out of STOP mode and returns the device to normal RUN mode. Refer to the device's Power Management chapter for peripheral, I/O, and memory operation in STOP mode. When an interrupt request occurs, the CPU exits STOP mode and resumes processing, beginning with the stacking operations leading to the interrupt service routine.

A system reset will cause an exit from STOP mode, temporarily returning the device to RUN mode before transitioning into VLPR during the MCU reset flow.

### **16.4.5.2 Very-Low-Power Stop (VLPS) mode**

The two ways in which VLPS mode can be entered are listed here.

- Entry into stop via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core while the MCU is in VLPR mode and PMCTRL[STOPM] = 010 or 000.
- Entry into stop via the sleep-now or sleep-on-exit with the SLEEPDEEP bit set in the System Control Register in the ARM core while the MCU is in normal RUN mode and PMCTRL[STOPM] = 010. When VLPS is entered directly from RUN mode, exit to VLPR is disabled by hardware and the system will always exit back to RUN.

In VLPS, the on-chip voltage regulator remains in its stop regulation state as in VLPR.

A module capable of providing an asynchronous interrupt to the device takes the device out of VLPS and returns the device to VLPR mode.

A system reset will cause an exit from VLPS mode, temporarily returning the device to RUN mode before transitioning into VLPR during the MCU reset flow.

### 16.4.5.3 Very-Low-Leakage Stop (VLLSx) modes

This device contains these very low leakage modes:

- VLLS3
- VLLS2
- VLLS1
- VLLS0

VLLSx is often used in this document to refer to all of these modes.

All VLLSx modes can be entered from normal RUN or VLPR modes.

The MCU enters the configured VLLS mode if:

- In Sleep-Now or Sleep-On-Exit mode, the SLEEPDEEP bit is set in the System Control Register in the ARM core, and
- The device is configured as shown in [Table 16-2](#).

In VLLS, the on-chip voltage regulator is in its stop-regulation state while most digital logic is powered off.

Before entering VLLS mode, the user should configure the Low-Leakage Wake-up (LLWU) module to enable the desired wakeup sources. The available wake-up sources in VLLS are detailed in the chip configuration details for this device.

After wakeup from VLLS, the device returns to normal RUN mode with a pending LLWU interrupt. If VLLS was entered from VLPR mode, then the MCU will begin VLPR entry shortly after wakeup. In the LLWU interrupt service routine (ISR), the user can poll the LLWU module wake-up flags to determine the source of the wake-up.

When entering VLLS, each I/O pin is latched as configured before executing VLLS. Because all digital logic in the MCU is powered off, all port and peripheral data is lost during VLLS. This information must be restored before PMC\_REGSC[ACKISO] is set.

An asserted  $\overline{\text{RESET}}$  pin will cause an exit from any VLLS mode, temporarily returning the device to normal RUN mode before transitioning into VLPR during the MCU reset flow. When exiting VLLS via the  $\overline{\text{RESET}}$  pin, RCM\_SRS[PIN] and RCM\_SRS[WAKEUP] are set.

### 16.4.6 Debug in low power modes

When the MCU is secure, the device disables/limits debugger operation. When the MCU is unsecure, the ARM debugger can assert two power-up request signals:

- System power up, via SYSPWR in the Debug Port Control/Stat register
- Debug power up, via CDBGPWRUPREQ in the Debug Port Control/Stat register

When asserted while in RUN, WAIT, VLPR, or VLPR the mode controller drives a corresponding acknowledge for each signal, that is, both CDBGPWRUPACK and CSYSPWRUPACK. When both requests are asserted, the mode controller handles attempts to enter STOP and VLPS by entering an emulated stop state. In this emulated stop state:

- the regulator is in run regulation,
- the MCG-generated clock source is enabled,
- all system clocks, except the core clock, are disabled,
- the debug module has access to core registers, and
- access to the on-chip peripherals is blocked.

No debug is available while the MCU is in VLLS modes.

Entering into a VLLS mode causes all of the debug controls and settings to be powered off. To give time to the debugger to sync with the MCU, the MDM AP Control Register includes a Very-Low-Leakage Debug Request (VLLDBGREQ) bit that is set to configure the Reset Controller logic to hold the system in reset after the next recovery from a VLLS mode. This bit allows the debugger time to reinitialize the debug module before the debug session continues.

The MDM AP Control Register also includes a Very Low Leakage Debug Acknowledge (VLLDBGACK) bit that is set to release the ARM core being held in reset following a VLLS recovery. The debugger reinitializes all debug IP, and then asserts the VLLDBGACK control bit to allow the RCM to release the ARM core from reset and allow CPU operation to begin.

The VLLDBGACK bit is cleared by the debugger (or can be left set as is) or clears automatically due to the reset generated as part of the next VLLS recovery.

# Chapter 17

## Miscellaneous Control Module (MCM)

### 17.1 Introduction

The Miscellaneous Control Module (MCM) provides miscellaneous control functions and contains Cortex-M7 local memory descriptors.

#### 17.1.1 Features

The MCM includes the following features:

- Program-visible information on the platform configuration and revision
- Floating Point Exception monitor and interrupt control
- Local memory descriptors (ITCM, D0TCM, D1TCM, ICACHE, and DCACHE)

### 17.2 Memory map/register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

**MCM memory map**

| Absolute address (hex) | Register name                                        | Width (in bits) | Access | Reset value                 | Section/page               |
|------------------------|------------------------------------------------------|-----------------|--------|-----------------------------|----------------------------|
| E008_0000              | Processor core type (MCM_PCT)                        | 32              | R      | AC70_0000h                  | <a href="#">17.2.1/326</a> |
| E008_000C              | Control Register (MCM_CR)                            | 32              | R/W    | <a href="#">See section</a> | <a href="#">17.2.2/327</a> |
| E008_0010              | Interrupt Status and Control Register (MCM_ISCR)     | 32              | R/W    | 0000_0000h                  | <a href="#">17.2.3/328</a> |
| E008_0034              | Compute Only Operation Control Register (MCM_CPO)    | 32              | R/W    | 0000_0000h                  | <a href="#">17.2.4/330</a> |
| E008_0400              | Local Memory General Descriptor Register (MCM_LMEM0) | 32              | R      | <a href="#">See section</a> | <a href="#">17.2.5/332</a> |
| E008_0404              | Local Memory General Descriptor Register (MCM_LMEM1) | 32              | R      | <a href="#">See section</a> | <a href="#">17.2.5/332</a> |

*Table continues on the next page...*

## MCM memory map (continued)

| Absolute address (hex) | Register name                                        | Width (in bits) | Access | Reset value                 | Section/ page              |
|------------------------|------------------------------------------------------|-----------------|--------|-----------------------------|----------------------------|

| E008_040C              | Local Memory General Descriptor Register (MCM_LMEM3) | 32              | R      | <a href="#">See section</a> | <a href="#">17.2.5/332</a> |
| E008_0410              | Local Memory General Descriptor Register (MCM_LMEM4) | 32              | R      | <a href="#">See section</a> | <a href="#">17.2.5/332</a> |

## 17.2.1 Processor core type (MCM\_PCT)

The PCT is a 16-bit read-only register specifying the architecture of the processor core within the platform in the device. The state of this register is defined by a module input signal; it can only be read from the IPS programming model. Any attempted write is ignored.

Address: E008\_0000h base + 0h offset = E008\_0000h

|       |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

17.2.3 Interrupt Status and Control Register (MCM\_ISCR)

The MCM\_ISCR register defines the configuration and reports status for a number of core-related interrupt exception conditions. The MCM\_ISCR register includes the enable and status bits associated with the core’s floating-point exceptions. The individual event indicators are first qualified with their exception enables and then logically summed to form an interrupt request sent to the core’s NVIC. Bits 15-8 are read-only indicator flags based on the processor’s FPSCR register. Attempted writes to these bits are ignored. Once set, the flags remain asserted until software clears the corresponding FPSCR bit.

Address: E008\_0000h base + 10h offset = E008\_0010h

MCM\_ISCR field descriptions

## 17.3 Functional description

This section describes the functional description of MCM module.

### 17.3.1 Interrupts

The MCM's interrupt is generated if any of the following is true:

- FPU input denormal interrupt is enabled (FIDCE) and an input is denormalized (FIDC)
- FPU inexact interrupt is enabled (FIXCE) and a number is inexact (FIXC)
- FPU underflow interrupt is enabled (FUFCE) and an underflow occurs (FUFC)
- FPU overflow interrupt is enabled (FOFCE) and an overflow occurs (FOFC)
- FPU divide-by-zero interrupt is enabled (FDZCE) and a divide-by-zero occurs (FDZC)
- FPU invalid operation interrupt is enabled (FDZCE) and an invalid occurs (FDZC)

#### 17.3.1.1 Determining the interrupt source

To determine the exact interrupt source:

1. Qualify the floating point interrupt flags:
  - a. Form MCM\_ISCR[31:16]&&MCM\_ISCR[15:0]
  - b. Search the result for asserted flags, which indicate the exact interrupt sources

## Chapter 18

# Miscellaneous System Control Module (MSCM)

### 18.1 Overview

The Miscellaneous System Control Module (MSCM) contains CPU configuration registers and on-chip memory controller registers.

### 18.2 Chip Configuration and Boot

The device configuration is defined by e-fuse bits, supported memory sizes and packing options. Collectively, these configuration bits define an RCON (reset configuration) value.

Once the cores have fetched the needed reset vector(s), it is expected they read core and system configuration information from a globally-accessible slave peripheral that properly converts the information into more appropriate values. More specifically, the cores access configuration information from a common set of peripheral addresses and the chip configuration logic properly evaluates based on the requesting processor and returns the appropriate value for the given processor, including core identification.

As an example, there is a single 32-bit read-only location for the core identification. A 32-bit read from this location returns a four character ASCII string: 0x43\_4D\_37\_02 ("Cortex-M7, version r0p2").

The programming model associated with the core configuration information is included as part of the Miscellaneous System Control Module (MSCM). It specifically includes multiple views of the processor configuration; one that is available generically to the cores and others that are available to any bus masters in the system.

## 18.3 MSCM Memory Map/Register Definition

### 18.3.1 CPU Configuration Memory Map and Registers

The CPU configuration portion of the MSCM module provides a set of memory-mapped read-only addresses defining the processor setup. This portion of the MSCM programming model can only be accessed with privileged mode 32-bit read references; any other access type or size are terminated with an error. If the processor is logically not included in the chip configuration, reads of its configuration registers return zeroes.

The CPU Configuration registers are organized based on the logical processor number (not any type of physical port number) and partitioned into three equal sections:

- Offset addresses 0x000 - 0x01F define the generic processor "x" configuration. This region is only accessible to the processor cores; reads by non-core bus masters are treated as RAZ (read as zero) accesses.
- Offset addresses 0x020-0x03F define the configuration information for processor 0 (CP0). This region is accessible to any bus master.
- Offset addresses 0x040 - 0x05F define the configuration information for processor 1 (CP1). This region is accessible to any bus master. For uniprocessor chip configurations, reads of this section are treated as RAZ (read as zero).

Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

**MSCM memory map**

| Absolute address (hex) | Register name                                       | Width (in bits) | Access | Reset value                 | Section/ page               |

**18.3.2 Processor X Type Register (MSCM\_CPxTYPE)**

The register provides a CPU-specific response indicating the personality of the core making the access. The 32 bit response includes 3 ASCII characters defining the CPU type along with a byte defining the logical revision number. The logical revision number follows ARM's rYpZ nomenclature.

Address: 4000\_1000h base + 0h offset = 4000\_1000h

### 18.3.3 Processor X Number Register (MSCM\_CPxNUM)

The register provides a CPU-specific response indicating the logical processor number of the core making the access. In single processor configurations, the logical processor number is always zero; in dual core configurations, the boot (or primary) core is assigned number 0 while the secondary core is defined as number 1.

Address: 4000\_1000h base + 4h offset = 4000\_1004h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

### 18.3.4 Processor X Master Register (MSCM\_CPxMASTER)

The register provides a CPU-specific response indicating the physical bus master number of the core making the access. The 32 bit response defines the physical master number for processor x.

A privileged read from the CM7 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

Address: 4000\_1000h base + 8h offset = 4000\_1008h

- \* Notes:
- PPN field: See the bit field description.

MSCM\_CPxMASTER field descriptions

### 18.3.6 Processor X Configuration 1 Register (MSCM\_CPxCFG1)

The register provides a CPU-specific response detailing configuration information, in this case, information on a Level 2 cache (if present).

Address: 4000\_1000h base + 14h offset = 4000\_1014h

**18.3.7 Processor X Configuration 3 Register (MSCM\_CPxCFG3)**

The register provides CPU-specific response detailing configuration information, in this case, information on processor options. A privileged read from the CM7 returns the appropriate processor information. Reads from any other bus master return all zeroes. Attempted user mode or write accesses are terminated with an error.

Address: 4000\_1000h base + 1Ch offset = 4000\_101Ch

### 18.3.8 Processor 0 Type Register (MSCM\_CP0TYPE)

The register defines the personality of processor 0 (CPU0). The 32 bit response includes 3 ASCII characters defining the CPU type along with a byte defining the logical revision number. The logical revision number follows ARM's rYpZ nomenclature.

A privileged read for *any bus master* returns processor 0 (CP0) information.

Address: 4000\_1000h base + 20h offset = 4000\_1020h

- \* Notes:
- PERSONALITY field: See bit field description
  - RYPZ field: See bit field description

#### MSCM\_CP0TYPE field descriptions

| Field               | Description                                                                                                                                                                                          |

| RYPZ                | <p>Processor 0 Revision</p> <p>This field defines the processor revision for CP0:</p> <p>0x00 corresponds to the r0p0 core release.</p> <p>0x01 corresponds to the r0p1 core release.</p> <p>...</p> |

18.3.9 Processor 0 Number Register (MSCM\_CP0NUM)

The register defines the logical processor number of processor 0 (CPU0). In single processor configurations, the logical processor number is always zero; in dual core configurations, the boot (or primary) core is assigned number 0 while the secondary core is defined as number 1.

Address: 4000\_1000h base + 24h offset = 4000\_1024h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |

18.3.10 Processor 0 Master Register (MSCM\_CP0MASTER)

The register defines the physical bus master number of processor 0 (CPU0).

A privileged read for *any bus master* returns processor 0 (CPU0) information. Attempted user mode or write accesses are terminated with an error.

Address: 4000\_1000h base + 28h offset = 4000\_1028h

### 18.3.13 Processor 0 Configuration 3 Register (MSCM\_CP0CFG3)

The register details processor 0 (CPU0) configuration information, in this case, information on processor options. A privileged read for *any bus master* returns processor 0 (CPU0) information. Attempted user mode or write accesses are terminated with an error.

Address: 4000\_1000h base + 3Ch offset = 4000\_103Ch

### 18.3.14 Processor 1 Type Register (MSCM\_CP1TYPE)

The register defines the personality of processor 1 (CPU1). The 32 bit response includes 3 ASCII characters defining the CPU type along with a byte defining the logical revision number. The logical revision number follows ARM's rYpZ nomenclature.

A privileged read from *any bus master* returns processor 1 (CP1) information. For uniprocessor chip configurations, reads of this register are treated as RAZ.

Address: 4000\_1000h base + 40h offset = 4000\_1040h

**18.3.15 Processor 1 Number Register (MSCM\_CP1NUM)**

The register defines the logical processor number of processor 1 (CPU1). In single processor configurations, the logical processor number is always zero; in dual core configurations, the boot (or primary) core is assigned number 0 while the secondary core is defined as number 1.

| Field | Description                 |
|-------|-----------------------------|
|       | For secondary core, CPN = 1 |

### 18.3.16 Processor 1 Master Register (MSCM\_CP1MASTER)

The register defines the physical bus master number for processor 1 (CPU1).

A privileged read from *any bus master* returns processor 1 (CPU1) information. For uniprocessor chip configurations, reads of this register are treated as RAZ. Attempted user mode or write accesses are terminated with an error.

Address: 4000\_1000h base + 48h offset = 4000\_1048h

## 18.3.19 Processor 1 Configuration 3 Register (MSCM\_CP1CFG3)

The register details processor 1 (CPU1) configuration information, in this case, information on processor options. A privileged read from *any bus master* returns processor 1 (CP1) information. For uniprocessor chip configurations, reads of this register are treated as RAZ. Attempted user mode or write accesses are terminated with an error.

18.3.20 On-Chip Memory Descriptor Register (MSCM\_OCMDRn)

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information on the attached memories as well as configurable controls (where appropriate).

Privileged 32-bit reads from a processor core or the debugger return the appropriate processor information. Reads from any other bus master return all zeroes. Privileged writes from a processor core or the debugger to writeable registers update the appropriate fields. Privileged writes from other bus masters are ignored. Attempted user mode accesses or any access with a size other than 32 bits are terminated with an error.

Address: 4000\_1000h base + 400h offset + (4d × i), where i=0d to 2d

## \* Notes:

- The reset values are different for the individual OCMDR registers. OCMDR0: 0xCB0A\_9000; OCMDR1: 0xC304\_1000; OCMDR2: 0xC704\_1000

# Chapter 19

## Power Management Controller (PMC)

### 19.1 Introduction

The power management controller (PMC) contains the internal voltage regulator, power on reset (POR), and low voltage detect system (LVD) and high voltage detect system (HVD).

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the PMC.

### 19.2 Features

A list of included PMC features can be found here.

- Internal voltage regulator
- Active POR providing brown-out detect
- Low-voltage detect supporting two low-voltage trip points with four warning levels per trip point
- High-voltage detect supporting two high-voltage trip points

### 19.3 Low-voltage detect (LVD) system

This device includes a system to guard against low-voltage conditions. This protects memory contents and controls MCU system states during supply voltage variations.

The system is comprised of a power-on reset (POR) circuit and a LVD circuit with a user-selectable trip voltage: high ( $V_{LVDH}$ ) or low ( $V_{LVDL}$ ). The trip voltage is selected by LVDSC1[LVDV]. The LVD is disabled upon entering VLPx and VLLSx modes.

Two flags are available to indicate the status of the low-voltage detect system:

- The Low Voltage Detect Flag in the Low Voltage Status and Control 1 Register (LVDSC1[LVDF]) operates in a level sensitive manner. LVDSC1[LVDF] is set when the supply voltage falls below the selected trip point (VLVD). LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC1[LVDF] remains set.
- The Low Voltage Warning Flag (LVWF) in the Low Voltage Status and Control 2 Register (LVDSC2[LVWF]) operates in a level sensitive manner. LVDSC2[LVWF] is set when the supply voltage falls below the selected monitor trip point (VLVW). LVDSC2[LVWF] is cleared by writing one to LVDSC2[LVWACK], but only if the internal supply has returned above the trip point; otherwise, LVDSC2[LVWF] remains set.

### **19.3.1 LVD reset operation**

By setting LVDSC1[LVDRE], the LVD generates a reset upon detection of a low-voltage condition. The low-voltage detection threshold is determined by LVDSC1[LVDV]. After an LVD reset occurs, the LVD system holds the MCU in reset until the supply voltage rises above this threshold. The LVD field in the SRS register of the RCM module (RCM\_SRS[LVD]) is set following an LVD or power-on reset.

### **19.3.2 LVD interrupt operation**

By configuring the LVD circuit for interrupt operation (LVDSC1[LVDIE] set and LVDSC1[LVDRE] clear), LVDSC1[LVDF] is set and an LVD interrupt request occurs upon detection of a low voltage condition. LVDSC1[LVDF] is cleared by writing 1 to LVDSC1[LVDACK].

### **19.3.3 Low-voltage warning (LVW) interrupt operation**

The LVD system contains a Low-Voltage Warning Flag (LVWF) in the Low Voltage Detect Status and Control 2 Register to indicate that the supply voltage is approaching, but is above, the LVD voltage. The LVW also has an interrupt, which is enabled by setting LVDSC2[LVWIE]. If enabled, an LVW interrupt request occurs when LVDSC2[LVWF] is set. LVDSC2[LVWF] is cleared by writing 1 to LVDSC2[LVWACK].

LVDSC2[LVWV] selects one of the four trip voltages:

- Highest:  $V_{LVW4}$
- Two mid-levels:  $V_{LVW3}$  and  $V_{LVW2}$
- Lowest:  $V_{LVW1}$

## 19.4 High-voltage detect (HVD) system

This device includes a system to guard against high-voltage conditions.

The system is comprised of a HVD circuit with a user-selectable trip voltage: high ( $V_{HVDH}$ ) or low ( $V_{HVDL}$ ). The trip voltage is selected by  $HVDSC1[HVDV]$ . The HVD is disabled upon entering VLPx and VLLSx modes.

A flag is available to indicate the status of the high-voltage detect system:

- The High Voltage Detect Flag in the High Voltage Status and Control 1 Register ( $HVDSC1[HVDF]$ ) operates in a level sensitive manner.  $HVDSC1[HVDF]$  is set when the supply voltage rises above the selected trip point ( $VHVD$ ).  $HVDSC1[HVDF]$  is cleared by writing 1 to  $HVDSC1[HVDACK]$ , but only if the internal supply has returned below the trip point; otherwise,  $HVDSC1[LVDF]$  remains set.

### 19.4.1 HVD reset operation

By setting  $HVDSC1[HVDRE]$ , the HVD generates a reset upon detection of a high-voltage condition. The high-voltage detection threshold is determined by  $HVDSC1[HVDV]$ . After an HVD reset occurs, the HVD system holds the MCU in reset until the supply voltage falls below this threshold. The LVD field in the SRS register of the RCM module ( $RCM\_SRS[LVD]$ ) is set following an HVD reset.

### 19.4.2 HVD interrupt operation

By configuring the HVD circuit for interrupt operation ( $HVDSC1[HVDIE]$  set and  $HVDSC1[HVDRE]$  clear),  $HVDSC1[HVDF]$  is set and an HVD interrupt request occurs upon detection of a high voltage condition.  $HVDSC1[HVDF]$  is cleared by writing 1 to  $HVDSC1[HVDACK]$ .

## 19.5 I/O retention

When in VLLS modes, the I/O states are held on a wake-up event (with the exception of wake-up by reset event) until the wake-up has been acknowledged via a write to REGSC[ACKISO]. In the case of VLLS exit via a RESET pin, the I/O are released and default to their reset state. In this case, no write to REGSC[ACKISO] is needed.

## 19.6 Memory map and register descriptions

Details about the PMC registers can be found here.

### NOTE

Different portions of PMC registers are reset only by particular reset types. Each register's description provides details. For more information about the types of reset on this chip, refer to the Reset section details.

The PMC registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

### PMC memory map

| Absolute address (hex) | Register name                                                  | Width (in bits) | Access | Reset value | Section/ page              |
|------------------------|----------------------------------------------------------------|-----------------|--------|-------------|----------------------------|

| 4007_D002              | Regulator Status And Control register (PMC_REGSC)              | 8               | R/W    | 24h         | <a href="#">19.6.3/365</a> |
| 4007_D00B              | High Voltage Detect Status And Control 1 register (PMC_HVDSC1) | 8               | R/W    | 01h         | <a href="#">19.6.4/366</a> |

### 19.6.1 Low Voltage Detect Status And Control 1 register (PMC\_LVDSC1)

This register contains status and control bits to support the low voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC1 settings. To protect systems that must have LVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC\_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact LVD trip voltages.

### NOTE

The LVDV bits are reset solely on a POR Only event. The register's other bits are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the Reset section details.

*Table continues on the next page...*

**PMC\_LVDSC1 field descriptions (continued)**

| Field | Description                                       |
|-------|---------------------------------------------------|
| 00    | Low trip point selected ( $V_{LVD} = V_{LVDL}$ )  |
| 01    | High trip point selected ( $V_{LVD} = V_{LVDH}$ ) |
| 10    | Reserved                                          |
| 11    | Reserved                                          |

**19.6.2 Low Voltage Detect Status And Control 2 register (PMC\_LVDSC2)**

This register contains status and control bits to support the low voltage warning function.

While the device is in the very low power or low leakage modes, the LVD system is disabled regardless of LVDSC2 settings.

See the device's data sheet for the exact LVD trip voltages.

**NOTE**

The LVW trip voltages depend on LVWV and LVDV.

**NOTE**

LVWV is reset solely on a POR Only event. The other fields of the register are reset on Chip Reset Not VLLS. For more information about these reset types, refer to the Reset section details.

Address: 4007\_D000h base + 1h offset = 4007\_D001h

**19.6.3 Regulator Status And Control register (PMC\_REGSC)**

The PMC contains an internal voltage regulator. The voltage regulator design uses a bandgap reference that is also available through a buffer as input to certain internal peripherals, such as the CMP and ADC. The internal regulator provides a status bit (REGONS) indicating the regulator is in run regulation.

**NOTE**

This register is reset on Chip Reset Not VLLS and by reset types that trigger Chip Reset not VLLS. See the Reset section details for more information.

### 19.6.4 High Voltage Detect Status And Control 1 register (PMC\_HVDSC1)

This register contains status and control bits to support the high voltage detect function. This register should be written during the reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

While the device is in the very low power or low leakage modes, the HVD system is disabled regardless of HVDSC1 settings. To protect systems that must have HVD always on, configure the Power Mode Protection (PMPROT) register of the SMC module (SMC\_PMPROT) to disallow any very low power or low leakage modes from being enabled.

See the device's data sheet for the exact HVD trip voltages.

### NOTE

This register is reset solely on a POR Only event. For more information about these reset types, refer to the Reset section details.

# Chapter 20

## Low-Leakage Wakeup Unit (LLWU)

### 20.1 Chip-specific LLWU information

This chip uses the following internal peripheral and external pin inputs as wakeup sources to the LLWU module:

- LLWU\_Px are external pin inputs. Any digital function multiplexed on the pin can be selected as the wakeup source. See the chip's signal multiplexing table for the digital signal options.
- LLWU\_M0IF-M7IF are connections to the internal peripheral interrupt flags.

#### NOTE

$\overline{\text{RESET}}$  is also a wakeup source, in addition to LLWU pins, and can be diagnosed by reading the System Reset Status Registers within the RCM.

**Table 20-1. Wakeup sources for LLWU inputs**

| Input    | Wakeup source      |  | Input     | Wakeup source      |
|----------|--------------------|--|-----------|--------------------|
| LLWU_P0  | PTE1/LLWU_P0 pin   |  | LLWU_P20  | PTE18/LLWU_P20 pin |
| LLWU_P1  | PTE2/LLWU_P1 pin   |  | LLWU_P21  | PTE25/LLWU_P21 pin |
| LLWU_P2  | PTE4/LLWU_P2 pin   |  | LLWU_P22  | PTA10/LLWU_P22 pin |
| LLWU_P3  | PTA4/LLWU_P3 pin   |  | LLWU_P23  | PTA11/LLWU_P23 pin |
| LLWU_P4  | PTA13/LLWU_P4 pin  |  | LLWU_P24  | PTD8/LLWU_P24 pin  |
| LLWU_P5  | PTB0/LLWU_P5 pin   |  | LLWU_P25  | PTD11/LLWU_P25 pin |
| LLWU_P6  | PTC1/LLWU_P6 pin   |  | LLWU_P26  | Reserved           |
| LLWU_P7  | PTC3/LLWU_P7 pin   |  | LLWU_P27  | Reserved           |
| LLWU_P8  | PTC4/LLWU_P8 pin   |  | LLWU_P28  | Reserved           |
| LLWU_P9  | PTC5/LLWU_P9 pin   |  | LLWU_P29  | Reserved           |
| LLWU_P10 | PTC6/LLWU_P10 pin  |  | LLWU_P30  | Reserved           |
| LLWU_P11 | PTC11/LLWU_P11 pin |  | LLWU_P31  | Reserved           |
| LLWU_P12 | PTD0/LLWU_P12 pin  |  | LLWU_M0IF | LPTMR <sup>1</sup> |
| LLWU_P13 | PTD2/LLWU_P13 pin  |  | LLWU_M1IF | CMP0               |

*Table continues on the next page...*

**Table 20-1. Wakeup sources for LLWU inputs (continued)**

| Input    | Wakeup source      |  | Input     | Wakeup source |
|----------|--------------------|--|-----------|---------------|
| LLWU_P14 | PTD4/LLWU_P14 pin  |  | LLWU_M2IF | CMP1          |
| LLWU_P15 | PTD6/LLWU_P15 pin  |  | LLWU_M3IF | CMP2/3        |
| LLWU_P16 | PTE6/LLWU_P16 pin  |  | LLWU_M4IF | Reserved      |
| LLWU_P17 | PTE9/LLWU_P17 pin  |  | LLWU_M5IF | Reserved      |
| LLWU_P18 | PTE10/LLWU_P18 pin |  | LLWU_M6IF | Reserved      |
| LLWU_P19 | PTE17/LLWU_P19 pin |  | LLWU_M7IF | Reserved      |

1. Requires the peripheral and the peripheral interrupt to be enabled. The LLWU's WUME bit enables the internal module flag as a wakeup input. After wakeup, the flags are cleared based on the peripheral clearing mechanism.

## 20.2 Introduction

The LLWU module allows the user to select up to 29 external pins and up to 8 internal modules as interrupt wake-up sources from low-leakage power modes.

The input sources are described in the device's chip configuration details. Each of the available wake-up sources can be individually enabled.

The  $\overline{\text{RESET}}$  pin is an additional source for triggering an exit from low-leakage power modes, and causes the MCU to exit VLLS through a reset flow.

The LLWU module also includes optional digital pin filters for the external wakeup pins.

See [AN4503: Power Management for Kinetis MCUs](#) for further details on using the LLWU.

### 20.2.1 Features

The LLWU module features include:

- Support for up to 29 external input pins and up to 8 internal modules with individual enable bits for MCU interrupt from low leakage modes
- Input sources may be external pins or from internal peripherals capable of running in VLLS. See the chip configuration information for wakeup input sources for this device.
- External pin wake-up inputs, each of which is programmable as falling-edge, rising-edge, or any change
- Wake-up inputs that are activated after MCU enters a low-leakage power mode
- Optional digital filters provided to qualify an external pin detect. Note that when the LPO clock is disabled, the filters are disabled and bypassed.

## 20.2.2 Modes of operation

The LLWU module becomes functional on entry into a low-leakage power mode. After recovery from VLLS, the LLWU continues to detect wake-up events until the user has acknowledged the wake-up via a write to PMC\_REGSC[ACKISO].

### 20.2.2.1 VLLS modes

All wakeup and reset events result in VLLS exit via a reset flow.

### 20.2.2.2 Non-low leakage modes

The LLWU is not active in all non-low leakage modes where detection and control logic are in a static state. The LLWU registers are accessible in non-low leakage modes and are available for configuring and reading status when bus transactions are possible.

When the wake-up pin filters are enabled, filter operation begins immediately. If a low leakage mode is entered within five LPO clock cycles of an active edge, the edge event will be detected by the LLWU.

### 20.2.2.3 Debug mode

When the chip is in Debug mode and then enters a VLLSx mode, no debug logic works in the fully-functional low-leakage mode. Upon an exit from the VLLSx mode, the LLWU becomes inactive.

## 20.2.3 Block diagram

The following figure is the block diagram for the LLWU module.

Figure 20-1. LLWU block diagram

## 20.3 LLWU signal descriptions

The signal properties of LLWU are shown in the table found [here](#).

The external wakeup input pins can be enabled to detect either rising-edge, falling-edge, or on any change.

**Table 20-2. LLWU signal descriptions**

| Signal  | Description               | I/O |
|---------|---------------------------|-----|
| LLWU_Pn | Wakeup inputs (n = 0- 28) | I   |

## 20.4 Memory map/register definition

The LLWU includes the following registers:

- Wake-up source enable registers
  - Enable external pin input sources
  - Enable internal peripheral interrupt sources
- Wake-up flag registers
  - Indication of wakeup source that caused exit from a low-leakage power mode includes external pin or internal module interrupt
- Wake-up pin filter enable registers

### NOTE

The LLWU registers can be written only in supervisor mode. Write accesses in user mode are blocked and will result in a bus error.

All LLWU registers are reset by Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. Each register's displayed reset value represents this subset of reset types. LLWU registers are unaffected by reset types that do not trigger Chip Reset not VLLS. For more information about the types of reset on this chip, refer to the [Introduction](#) details.

### LLWU memory map

| Absolute address (hex) | Register name                         | Width (in bits) | Access | Reset value | Section/ page              |
|------------------------|---------------------------------------|-----------------|--------|-------------|----------------------------|
| 4007_C000              | LLWU Pin Enable 1 register (LLWU_PE1) | 8               | R/W    | 00h         | <a href="#">20.4.1/374</a> |
| 4007_C001              | LLWU Pin Enable 2 register (LLWU_PE2) | 8               | R/W    | 00h         | <a href="#">20.4.2/375</a> |
| 4007_C002              | LLWU Pin Enable 3 register (LLWU_PE3) | 8               | R/W    | 00h         | <a href="#">20.4.3/376</a> |

## 20.4.1 LLWU Pin Enable 1 register (LLWU\_PE1)

LLWU\_PE1 contains the field to enable and select the edge detect type for the external wakeup input pins LLWU\_P3-LLWU\_P0.

## NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

## 20.4.5 LLWU Pin Enable 5 register (LLWU\_PE5)

LLWU\_PE5 contains the field to enable and select the edge detect type for the external wakeup input pins LLWU\_P19-LLWU\_P16.

### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset

types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

## 20.4.6 LLWU Pin Enable 6 register (LLWU\_PE6)

LLWU\_PE6 contains the field to enable and select the edge detect type for the external wakeup input pins LLWU\_P23-LLWU\_P20.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

## 20.4.7 LLWU Pin Enable 7 register (LLWU\_PE7)

LLWU\_PE7 contains the field to enable and select the edge detect type for the external wakeup input pins LLWU\_P27-LLWU\_P24.

### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

**20.4.9 LLWU Module Enable register (LLWU\_ME)**

LLWU\_ME contains the bits to enable the internal module flag as a wakeup input source for inputs MWUF7-MWUF0.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

**20.4.10 LLWU Pin Flag 1 register (LLWU\_PF1)**

LLWU\_PF1 contains the wakeup flags indicating which wakeup source caused the MCU to exit VLLS mode. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

## 20.4.12 LLWU Pin Flag 3 register (LLWU\_PF3)

LLWU\_PF3 contains the wakeup flags indicating which wakeup source caused the MCU to exit VLLS mode. For VLLS, this is the source causing the MCU reset flow.

The external wakeup flags are read-only and clearing a flag is accomplished by a write of a 1 to the corresponding WUFx bit. The wakeup flag (WUFx), if set, will remain set if the associated WUPEx bit is cleared.

### NOTE

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

**20.4.14 LLWU Module Flag 5 register (LLWU\_MF5)**

LLWU\_MF5 contains the wakeup flags indicating which internal wakeup source caused the MCU to exit VLLS mode. For VLLS, this is the source causing the MCU reset flow.

For internal peripherals that are capable of running in a low-leakage power mode, such as a real time clock module or CMP module, the flag from the associated peripheral is accessible as the MWUFx bit. The flag will need to be cleared in the peripheral instead of writing a 1 to the MWUFx bit.

**NOTE**

This register is reset on Chip Reset not VLLS and by reset types that trigger Chip Reset not VLLS. It is unaffected by reset types that do not trigger Chip Reset not VLLS. See the [Introduction](#) details for more information.

## 20.5 Functional description

This low-leakage wakeup unit (LLWU) module allows internal peripherals and external input pins as a source of wakeup from low-leakage modes.

It is operational only in VLLSx modes.

The LLWU module contains pin enables for each external pin and internal module. For each external pin, the user can disable or select the edge type for the wakeup with the following options:

- Falling-edge
- Rising-edge
- Either-edge

When an external pin is enabled as a wakeup source, the pin must be configured as an input pin.

The LLWU implements optional 3-cycle glitch filters, based on the LPO clock. A detected external pin is required to remain asserted until the enabled glitch filter times out. Additional latency of up to 2 cycles is due to synchronization, which results in a total of up to 5 cycles of delay before the detect circuit alerts the system to the wakeup or reset event when the filter function is enabled. wakeup detect filters are available for selected external pins. Glitch filtering is not provided on the internal modules.

For internal module interrupts, the WUMEx bit enables the associated module interrupt as a wakeup source.

### 20.5.1 VLLS modes

For any wakeup from VLLS, recovery is always via a reset flow and RCM\_SRS[WAKEUP] is set indicating the low-leakage mode was active. State retention data is lost and I/O will be restored after PMC\_REGSC[ACKISO] has been written.

A VLLS exit event due to  $\overline{\text{RESET}}$  pin assertion causes an exit via a system reset. State retention data is lost and the I/O states immediately return to their reset state. The RCM\_SRS[WAKEUP] and RCM\_SRS[PIN] bits are set and the system executes a reset flow before CPU operation begins with a reset vector fetch.

## 20.5.2 Initialization

For an enabled peripheral wakeup input, the peripheral flag must be cleared by software before entering VLLSx mode to avoid an immediate exit from the mode.

Flags associated with external input pins, filtered and unfiltered, must also be cleared by software prior to entry to VLLSx mode.

After enabling an external pin filter or changing the source pin, wait at least five LPO clock cycles before entering VLLSx mode to allow the filter to initialize.

### NOTE

After recovering from a VLLS mode, user must restore chip configuration before clearing PMC\_REGSC[ACKISO]. In particular, pin configuration for enabled LLWU wake-up pins must be restored to avoid any LLWU flag from being falsely set when PMC\_REGSC[ACKISO] is cleared.

The signal selected as a wake-up source pin must be a digital pin, as selected in the pin mux control.

# Chapter 21

## Crossbar Switch (AXBS)

### 21.1 Chip-specific AXBS information

#### 21.1.1 Crossbar Switch Master Assignments - with System MPU

The masters connected to the crossbar switch are assigned as follows:

| Master port number | Master module             | Default Priority |
|--------------------|---------------------------|------------------|
| 0                  | Cortex-M7 AHBP            | 0                |
| 1                  | Cortex-M7 AXI (via PL301) | 1                |
| 2                  | DMA                       | 2                |
| 3                  | ENET                      | 3                |
| 4                  | —                         | 0                |
| 5                  | —                         | 0                |
| 6                  | —                         | 0                |
| 7                  | —                         | 0                |

#### 21.1.2 Crossbar Switch Slave Assignments - with System MPU

The slaves connected to the crossbar switch are assigned as follows:

| Slave port number | Slave module   | Protected by FSL MPU?             |
|-------------------|----------------|-----------------------------------|
| 0                 | Flash          | Yes                               |
| 1                 | Cortex-M7 AHBS | Yes                               |
| 2                 | AIPS0/BME2     | No. Protection built into bridge. |
| 3                 | AIPS1/BME2     | No. Protection built into bridge. |
| 4                 | FlexBus        | Yes                               |

*Table continues on the next page...*

| Slave port number | Slave module | Protected by FSL MPU? |
|-------------------|--------------|-----------------------|
| 5                 | OCRAM0       | Yes                   |
| 6                 | Flash EEERAM | Yes                   |
| 7                 | —            | —                     |

### 21.1.3 PRS register reset values

This device contains 4 AXBS bus masters.

The AXBS\_PRS $n$  registers reset to 0000\_3210h.

## 21.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

### 21.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation
  - Allows concurrent accesses from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 32-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support

## 21.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The  $CRS_n$  and  $PRS_n$  registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

### NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

**21.3.1 Priority Registers Slave (AXBS\_PRSn)**

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

**NOTE**

Valid values for the Mn priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains less than five masters, values 0 to 3 are valid. Writing other values will result in an error.
- If the chip contains five or more masters, valid values are 0 to n-1, where n is the number of masters attached to the Crossbar Switch. Other values will result in an error.

**NOTE**

See the chip-specific crossbar information for the reset value of this register.

Address: 4000\_4000h base + 0h offset + (256d × i), where i=0d to 7d

**21.3.2 Control Register (AXBS\_CRSn)**

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

**NOTE**

See the chip-specific crossbar information for the reset value of this register.

Address: 4000\_4000h base + 10h offset + (256d × i), where i=0d to 7d

**21.3.3 Master General Purpose Control Register (AXBS\_MGPCRn)**

The MGPCR controls only whether the master's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters. The MGPCR can be accessed only in Supervisor mode with 32-bit accesses.

**NOTE**

If there are fewer than eight master ports, only the registers associated with those masters are present. Register addresses associated with master ports that are not present are reserved. Please see this module's chip-specific information for which master ports are present on this module.

Address: 4000\_4000h base + 800h offset + (256d × i), where i=0d to 7d

## 21.4 Functional Description

### 21.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed- or undefined-length burst transfer it retains control of the slave port until that transfer completes. Based on

MGPCR[AULB], the master either retains control of the slave port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority master.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRSn[PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRSn[PCTL].

### **21.4.2 Register coherency**

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

The MGPCR<sub>x</sub>[AULB] bits are the exception to this rule. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the slave bus cycle to write them will have already terminated successfully. If the MGPCR<sub>x</sub>[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the master on that master port.

### **21.4.3 Arbitration**

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

### 21.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

**Figure 21-1. Undefined length burst example**

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

#### Note

Fixed-length burst accesses are not affected by the AULB bits.  
All fixed-length burst accesses lock out arbitration until the last beat of the fixed-length burst.

### 21.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRSn). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

#### NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

**Table 21-1. How the Crossbar Switch grants control of a slave port to a master**

| When                                                                                                                                                                                                                                                           | Then the Crossbar Switch grants control to the requesting master                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Both of the following are true: <ul style="list-style-type: none"> <li>The current master is not running a transfer.</li> <li>The new requesting master's priority level is higher than that of the current master.</li> </ul>                                 | At the next clock edge                                                                                                                                                                      |

| Both of the following are true: <ul style="list-style-type: none"> <li>The current master is running an undefined length burst transfer.</li> <li>The requesting master's priority level is higher than that of the current master.</li> </ul>                 | At the next arbitration point for the undefined length burst transfer<br><br><b>NOTE:</b> Arbitration points for an undefined length burst are defined in the MGPCR for each master.        |
| The requesting master's priority level is lower than the current master.                                                                                                                                                                                       | At the conclusion of one of the following cycles: <ul style="list-style-type: none"> <li>An IDLE cycle</li> <li>A non-IDLE cycle to a location other than the current slave port</li> </ul> |

### 21.4.3.3 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

### 21.4.3.4 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRSn), the crossbar switch responds with a bus error and the registers are not updated.

## 21.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

### NOTE

- During configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS<sub>n</sub>[RO].

## Chapter 22

# Peripheral Bridge (AIPS-Lite)

## 22.1 Chip-specific AIPS-Lite information

### 22.1.1 Master Privilege Register A (AIPSx\_MPRA) reset value

The reset value of AIPSx\_MPRA register for this device is 7770\_0000h.

## 22.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 4 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

### 22.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Programming model provides memory protection functionality

## 22.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 4-KB boundaries. Each peripheral is allocated one or more 4-KB block(s) of the memory map.

## 22.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

**22.3.1 Master Privilege Register A (AIPSx\_MPRA)**

The MPRA specifies identical 4-bit fields defining the access-privilege level associated with a bus master to various peripherals on the chip. The register provides one field per bus master.

**NOTE**

At reset, the default value loaded into the MPRA fields is chip-specific. See the chip configuration details for the value of a particular device.

A register field that maps to an unimplemented master or peripheral behaves as read-only-zero.

Each master is assigned a logical ID from 0 to 15. See the master logical ID assignment table in the chip-specific AIPS information.

Address: Base address + 0h offset

## 22.3.2 Peripheral Access Control Register (AIPSx\_PACRn)

Each PACR register consists of eight 4-bit PACR fields. Each PACR field defines the access levels for a particular peripheral. The mapping between a peripheral and its PACR field is shown in the table below. The peripheral assignment to each PACR is defined by the memory map slot that the peripheral is assigned to. See this chip's memory map for the assignment of a particular peripheral.

The following table shows the location of each peripheral slot's PACR field in the PACR registers.

| Offset | Register | [31:28] | [27:24] | [23:20] | [19:16] | [15:12] | [11:8]  | [7:4]   | [3:0]   |
|--------|----------|---------|---------|---------|---------|---------|---------|---------|---------|
| 0x20   | PACRA    | PACR0   | PACR1   | PACR2   | PACR3   | PACR4   | PACR5   | PACR6   | PACR7   |
| 0x24   | PACRB    | PACR8   | PACR9   | PACR10  | PACR11  | PACR12  | PACR13  | PACR14  | PACR15  |

### NOTE

The register field descriptions for PACR A-D, which control peripheral slots 0-31, are shown below. The following section, [Peripheral Access Control Register \(AIPS\\_PACRn\)](#), shows the register field descriptions for PACR E-P. All PACR registers are identical. They are divided into two sections because they occupy two non-contiguous address spaces.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d

**22.3.3 Peripheral Access Control Register (AIPSx\_PACR<sub>n</sub>)**

This section describes PACR registers E-P, which control peripheral slots 32-127. See [Peripheral Access Control Register \(AIPS\\_PACR<sub>n</sub>\)](#) for the description of these registers.

Address: Base address + 40h offset + (4d × i), where i=0d to 11d

## 22.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

### **22.4.1 Access support**

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. All accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

## Chapter 23

# System Memory Protection Unit (MPU)

## 23.1 Chip-specific MPU information

### 23.1.1 MPU Slave Port Assignments

The memory-mapped resources protected by the MPU are:

**Table 23-1. MPU Slave Port Assignments**

| Source                | MPU Slave Port Assignment | Destination      |
|-----------------------|---------------------------|------------------|
| Crossbar slave port 0 | MPU slave port 0          | Flash Controller |
| Crossbar slave port 1 | MPU slave port 1          | TCM backdoor     |
| Crossbar slave port 4 | MPU slave port 2          | Flexbus          |
| Crossbar slave port 5 | MPU slave port 3          | OCRAM            |
| Crossbar slave port 6 | MPU slave port 4          | Flash EECRAM     |

### 23.1.2 MPU Logical Bus Master Assignments

The logical bus master assignments for the MPU are:

**Table 23-2. MPU Logical Bus Master Assignments**

| MPU Logical Bus Master Number | Bus Master                                                       |
|-------------------------------|------------------------------------------------------------------|
| 0                             | Core (Cortex-M7 normal requests from both AXI and AHBP buses)    |
| 1                             | Debugger (Cortex-M7 debug requests from both AXI and AHBP buses) |
| 2                             | DMA2                                                             |
| 3                             | ENET                                                             |

### 23.1.3 MPU access violation indications

Access violations detected by the MPU are signaled to the appropriate bus master as shown below:

**Table 23-3. Access violation indications**

| Bus master | Core indication                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Core       | MPU violations result in either a bus error (interrupt vector #5) or a hard fault (interrupt vector #3) depending on the state of the core and its NVIC; See ARM documentation for details. |
| Debugger   | The STICKYERROR flag is set in the Debug Port Control/Status Register.                                                                                                                      |
| DMA        | DMA Error Interrupt vector                                                                                                                                                                  |
| ENET       | DMA Error Interrupt vector                                                                                                                                                                  |

### 23.1.4 Reset values for RGD0 registers

At reset, the MPU is enabled with a single region descriptor (RGD0) that maps the entire 4 GB address space with read, write and execute permissions given to the core, debugger and the DMA bus masters.

The following table shows the chip-specific reset values for RGD0 and RGDAAC0.

**Table 23-4. Reset values for RGD0 registers**

| Register   | Reset value |
|------------|-------------|
| RGD0_WORD0 | 0000_0000h  |
| RGD0_WORD1 | FFFF_FFFFh  |
| RGD0_WORD2 | 0061_F7DFh  |
| RGD0_WORD3 | 0000_0001h  |
| RGDAAC0    | 0061_F7DFh  |

### 23.1.5 Write access restrictions for RGD0 registers

In addition to configuring the initial state of RGD0, the MPU implements further access control on writes to the RGD0 registers. Specifically, the MPU assigns a priority scheme where the debugger is treated as the highest priority master followed by the core and then all the remaining masters.

The MPU does not allow writes from the core to affect the RGD0 start or end addresses nor the permissions associated with the debugger; it can only write the permission fields associated with the other masters.

These protections (summarized below) guarantee that the debugger always has access to the entire address space and those rights cannot be changed by the core or any other bus master.

**Table 23-5. Write Access to RGD0 Registers**

| Bus Master        | Write Access?                                                                                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Core              | Partial. The Core cannot write to the following registers or register fields: <ul style="list-style-type: none"> <li>• RGD0_WORD0, RGD0_WORD1, RGD0_WORD3</li> <li>• RGD0_WORD2[M1SM, M1UM]</li> <li>• RGDAAC0[M1SM, M1UM]</li> </ul> <p><b>NOTE:</b> Changes to the RGD0_WORD2 alterable fields should be done via a write to RGDAAC0.</p> |
| Debugger          | Yes                                                                                                                                                                                                                                                                                                                                         |
| All other masters | No                                                                                                                                                                                                                                                                                                                                          |

## 23.2 Introduction

The memory protection unit (MPU) provides hardware access control for all memory references generated in the device.

## 23.3 Overview

The MPU concurrently monitors all system bus transactions and evaluates their appropriateness using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with a protection error response.

### 23.3.1 Block diagram

A simplified block diagram of the MPU module is shown in the following figure.

**Figure 23-1. MPU block diagram**

The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and the access protection error. For details of the access evaluation macro, see [Access evaluation macro](#).

### 23.3.2 Features

The MPU implements a two-dimensional hardware array of memory region descriptors and the crossbar slave ports to continuously monitor the legality of every memory reference generated by each bus master in the system.

The feature set includes:

- 12 program-visible 128-bit region descriptors, accessible by four 32-bit words each
  - Each region descriptor defines a modulo-32 byte space, aligned anywhere in memory

- Region sizes can vary from 32 bytes to 4 Gbytes
- Two access control permissions defined in a single descriptor word
  - Masters 0–3: read, write, and execute attributes for supervisor and user accesses
  - Masters 4–7: read and write attributes
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
- Alternate programming model view of the access control permissions word
- Priority given to granting permission over denying access for overlapping region descriptors
- Detects access protection errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the MPU inhibits the bus cycle being sent to the targeted slave device.
- Error registers, per slave port, capture the last faulting address, attributes, and other information
- Global MPU enable/disable control bit

## 23.4 Memory map/register definition

The programming model is partitioned into three groups:

- Control/status registers
- The data structure containing the region descriptors
- The alternate view of the region descriptor access control values

The programming model can be referenced using only 32-bit accesses. The programming model can be accessed only in supervisor mode.

Attempted references of the following types generate an error termination:

- Non-32-bit references
- Accesses in user mode
- References to undefined—that is, reserved—addresses
- References with a non-supported access type, such as a write access to a read-only register or a read access of a write-only register

**NOTE**

See the chip configuration details for any chip-specific register information in this module.

**MPU memory map**

| Absolute address (hex) | Register name                                   | Width (in bits) | Access | Reset value                 | Section/ page              |

**23.4.2 Error Address Register, slave port n (MPU\_EAR<sub>n</sub>)**

When the MPU detects an access error on slave port n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR[SPERR<sub>n</sub>] is set. Additional information about the faulting access is captured in the corresponding EDR<sub>n</sub> at the same time. This register and the corresponding EDR<sub>n</sub> contain the most recent access error; there are no hardware interlocks with CESR[SPERR<sub>n</sub>], as the error registers are always loaded upon the occurrence of each protection violation.

23.4.3 Error Detail Register, slave port n (MPU\_EDR<sub>n</sub>)

When the MPU detects an access error on slave port n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR[SPERR<sub>n</sub>] is set. Information on the faulting address is captured in the corresponding EAR<sub>n</sub> register at the same time. This register and the corresponding EAR<sub>n</sub> register contain the most recent access error; there are no hardware interlocks with CESR[SPERR<sub>n</sub>] as the error registers are always loaded upon the occurrence of each protection violation.

| 31–5<br>SRTADDR | <p>Start Address</p> <p>Defines the most significant bits of the 0-modulo-32 byte start address of the memory region.</p> |
| Reserved        | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                        |

23.4.5 Region Descriptor n, Word 1 (MPU\_RGDn\_WORD1)

The second word of the region descriptor defines the 31-modulo-32 byte end address of the memory region. Writes to this register clear the region descriptor’s valid bit (RGDn\_WORD3[VLD]).

Address: 4000\_D000h base + 404h offset + (16d × i), where i=0d to 11d

- \* Notes:
  - Reset value of RGD0\_WORD1 is FFFF\_FFFFh
  - Reset value of RGD[1:11]\_WORD1 is 0000\_001Fh

MPU\_RGDn\_WORD1 field descriptions

| Field           | Description                                                                                                                                                                         |

| Reserved        | This field is reserved.                                                                                                                                                             |

23.4.6 Region Descriptor n, Word 2 (MPU\_RGDn\_WORD2)

The third word of the region descriptor defines the access control rights of the memory region. The access control privileges depend on two broad classifications of bus masters:

- Bus masters 0–3 have a 5-bit field defining separate privilege rights for user and supervisor mode accesses. Each of these bus masters optionally includes a process identification field (if implemented for the master) within the definition.
- Bus masters 4–7 are limited to separate read and write permissions.

For the privilege rights of bus masters 0–3, there are three flags associated with this function:

- Read (r) refers to accessing the referenced memory address using an operand (data) fetch

- Write (w) refers to updating the referenced memory address using a store (data) instruction
- Execute (x) refers to reading the referenced memory address using an instruction fetch

Writes to RGDn\_WORD2 clear the region descriptor's valid bit (RGDn\_WORD3[VLD]). If only updating the access controls, write to RGDAACn instead because stores to these locations do not affect the descriptor's valid bit.

Address: 4000\_D000h base + 408h offset + (16d × i), where i=0d to 11d

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | Provides a masking capability so that multiple process identifiers can be included as part of the region hit determination. If a bit in PIDMASK is set, then the corresponding PID bit is ignored in the comparison. This field and PID are included in the region hit determination if RGDn_WORD2[MxPE] is set. For more information on the handling of the PID and PIDMASK, see "Access Evaluation - Hit Determination." |
| 15–1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                    |

**23.4.8 Region Descriptor Alternate Access Control n (MPU\_RGDAACn)**

Because software may adjust only the access controls within a region descriptor (RGDn\_WORD2) as different tasks execute, an alternate programming view of this 32-bit entity is available. Writing to this register does not affect the descriptor's valid bit.

Address: 4000\_D000h base + 800h offset + (4d × i), where i=0d to 11d

## 23.5 Functional description

In this section, the functional operation of the MPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

### 23.5.1 Access evaluation macro

The basic operation of the MPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in the following figure, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD<sub>n</sub>) and performs two major functions:

- Region hit determination
- Detection of an access protection violation

The following figure shows a functional block diagram.

**Figure 23-2. MPU access evaluation macro**

### 23.5.1.1 Hit determination

To determine whether the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[31:5] >= RGDn_Word0[SRTADDR]) & (addr[31:5] <= RGDn_Word1[ENDADDR])) &
RGDn_Word3[VLD]
```

where `addr` is the current reference address, `RGDn_Word0[SRTADDR]` and `RGDn_Word1[ENDADDR]` are the start and end addresses, and `RGDn_Word3[VLD]` is the valid bit.

#### NOTE

The MPU does not verify that `ENDADDR ≥ SRTADDR`.

In addition to the comparison of the reference address versus the region descriptor's start and end addresses, the optional process identifier is examined against the region descriptor's PID and PIDMASK fields. A process identifier hit term is formed as follows:

```
pid_hit = ~RGDn_Word2[MxPE] |
((current_pid |
RGDn_Word3[PIDMASK]) == (RGDn_Word3[PID] | RGDn_Word3[PIDMASK]))
```

where the `current_pid` is the selected process identifier from the current bus master, and `RGD $n$ _Word3[PID]` and `RGD $n$ _Word3[PIDMASK]` are the process identifier fields from region descriptor  $n$ . For bus masters that do not output a process identifier, the MPU forces the `pid_hit` term to assert.

### 23.5.1.2 Privilege violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master and supervisor/user mode signals, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

**Table 23-6. Protection violation definition**

| Description            | MxUM |   |   | Protection violation?      |
|------------------------|------|---|---|----------------------------|
|                        | r    | w | x |                            |
| Instruction fetch read | —    | — | 0 | Yes, no execute permission |
|                        | —    | — | 1 | No, access is allowed      |
| Data read              | 0    | — | — | Yes, no read permission    |
|                        | 1    | — | — | No, access is allowed      |
| Data write             | —    | 0 | — | Yes, no write permission   |
|                        | —    | 1 | — | No, access is allowed      |

### 23.5.2 Putting it all together and error terminations

For each slave port monitored, the MPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports a protection error for three conditions:

- If the access does not hit in any region descriptor, a protection error is reported.
- If the access hits in a single region descriptor and that region signals a protection violation, a protection error is reported.
- If the access hits in multiple (overlapping) regions and all regions signal protection violations, a protection error is reported.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see [Application information](#).

### 23.5.3 Power management

Disabling the MPU by clearing CESR[VLD] minimizes power dissipation. To minimize the power dissipation of an enabled MPU, invalidate unused region descriptors by clearing the associated RGDn\_Word3[VLD] bits.

## 23.6 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGDn\_Word3[VLD]. Setting CESR[VLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire MPU is disabled (CESR[VLD]=0).

### Note

A region descriptor must be set to allow access to the MPU registers if further changes are needed.

## 23.7 Application information

In an operational system, interfacing with the MPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGDn, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes. (Clearing RGDn\_Word3[VLD] deletes/removes an existing memory region.)
- Altering only access privileges—To not affect the valid bit, write to the alternate version of the access control word (RGDAACn), so there are no coherency issues involved with the update. When the write completes, the memory region's access rights switch instantaneously to the new value.

- Changing a region's start and end addresses—Write a minimum of three words to the region descriptor (RGD $n$ \_Word{0,1,3}). Word 0 and 1 redefine the start and end addresses, respectively. Word 3 re-enables the region descriptor valid bit. In most situations, all four words of the region descriptor are rewritten.
- Accessing the MPU—Allocate a region descriptor to restrict MPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and EAR $n$  and EDR $n$  capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R $n$ . CESR[SPERR] signals which error registers contain captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters:

- The two processors: CP0, CP1
- Two DMA engines: DMA1, a traditional data movement engine transferring data between RAM and peripherals and DMA2, a second engine transferring data to/from the RAM only

Consider the following region descriptor assignments:

**Table 23-7. Overlapping region descriptor example**

| Region description    | RGDn |   | CP0 | CP1 | DMA1 | DMA2 |                  |
|-----------------------|------|---|-----|-----|------|------|------------------|
| CP0 code              | 0    |   | rwX | r-- | —    | —    | Flash            |
| CP1 code              | 1    |   | r-- | rwX | —    | —    |                  |
| CP0 data & stack      | 2    |   | rw- | —   | —    | —    | RAM              |
| CP0 → CP1 shared data | 2    | 3 | r-- | r-- | —    | —    |                  |
| CP1 → CP0 shared data | 4    |   |     |     |      |      |                  |
| CP1 data & stack      | 4    |   | —   | rw- | —    | —    |                  |
| Shared DMA data       | 5    |   | rw- | rw- | rw   | rw   |                  |
| MPU                   | 6    |   | rw- | rw- | —    | —    | Peripheral space |
| Peripherals           | 7    |   | rw- | rw- | rw   | —    |                  |

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map: flash, RAM, and peripheral space. Each region indicates the specific permissions for each of the four bus masters and this definition provides an appropriate set of shared, private and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1 and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has  $(rw- \mid r--)$  =  $(rw-)$  permissions, while CP1 has  $(--- \mid r--)$  =  $(r--)$  permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has  $(r-- \mid ---)$  =  $(r--)$  permission, while CP1 has  $(rw- \mid r--)$  =  $(rw-)$  permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the IPS bus is partitioned into two regions:

- One containing the MPU's programming model accessible only to the two processor cores
- The remaining peripheral region accessible to both processors and the traditional DMA1 master

This example shows one possible application of the capabilities of the MPU in a typical system.

# Chapter 24

## Bit Manipulation Engine2 (BME2)

### 24.1 Introduction

The Bit Manipulation Engine with the BME2 definition (BME2) provides hardware support for atomic read-modify-write memory operations to the first 1 Mbyte of slave peripheral address space in Cortex-M based microcontrollers. The second generation BME2 provides similar atomic read-modify-write capabilities to a larger peripheral address space versus the original implementation. The BME terminology is meant to be equivalent to BME2 throughout this chapter.

This architectural capability is also known as "decorated storage" as it defines a mechanism for providing additional semantics for load and store operations to memory-mapped peripherals beyond just the reading and writing of data values to the addressed memory locations. In the BME definition, the "decoration", that is, the additional semantic information, is encoded into the peripheral address used to reference the memory. The BME2 definition supports up to two AIPS bus controllers, each capable of addressing 512 KB of peripheral address space. BME2 supports an 8-bit or less data field width for bit field inserts and extracts, regardless of reference size. All other BME2 operations are exactly the same as the original definition.

By combining the basic load and store instructions of the ARM Cortex-M instruction set architecture (v6M, v7M) with the concept of decorated storage provided by BME, the resulting implementation provides a robust and efficient read-modify-write capability. The resulting architectural capability defined by this core platform function is targeted at the manipulation of n-bit fields in peripheral registers and is consistent with I/O hardware addressing in the Embedded C standard. For most BME commands, a single core read or write bus cycle is converted into an atomic read-modify-write, that is, an indivisible "read followed by a write" bus sequence.

BME decorated references are only available on system bus transactions generated by the processor core and DMA, and targeted at the 1024 KB peripheral address space based at 0x4000\_0000. The decoration semantic is embedded into address bits[28:20], creating a

448 MB space at addresses 0x4400\_0000–0x5FFF\_FFFF; these bits are stripped out of the actual address sent to the peripheral bus controller and used by the BME to define and control its operation.

### 24.1.1 Features

The key features of the BME2 include:

- Lightweight implementation of decorated storage for selected address spaces
- Additional access semantics encoded into the reference address
- Resides between crossbar switch slave port(s) and their associated peripheral bridge bus controller(s)
- Two-stage pipeline design matching the AHB system bus protocol
- Combinationally passes non-decorated accesses to peripheral bridge bus controllers
- Conversion of decorated loads and stores from processor core into atomic read-modify-writes
- Decorated loads support unsigned bit field extracts, load-and-`{set,clear}` 1-bit operations
- Decorated stores support bit field inserts, logical AND, OR, and XOR operations
- Support for byte, halfword and word-sized decorated operations
- Supports minimum signal toggling on AHB output bus to reduce power dissipation

### 24.1.2 Modes of operation

The BME modules do not support any special modes of operation. As memory-mapped devices located on crossbar slave AHB system bus ports, BME responds strictly on the basis of memory addresses for accesses to the SRAM\_U and AIPS controllers.

All functionality associated with the BME modules reside in the core platform's clock domain; this includes their connections with the crossbar slave ports, SRAM\_U, and the AIPS controllers.

## 24.2 Memory map and register definition

The BME module provides a memory-mapped capability and does not include any programming model registers.

The exact set of functions supported by the BME are detailed in the [Functional description](#).

The generic BME2 definition supports a 1024 KB address space based at 0x4000\_0000.... For this device, the upper 4 KB of this address space is not supported, so the BME2 functionality covers the  $(512 + 512 - 4 = 1020)$  KB space at 0x4000\_0000 - 0x400F\_EFFF. The decorated address space is mapped to the 448 MB region located at 0x4400\_0000–0x5FFF\_FFFF.

## 24.3 Functional description

Information found here details the specific functions supported by the BME.

Recall the combination of the basic load and store instructions of the Cortex-M instruction set architecture (v6M, v7M) plus the concept of decorated storage provided by the BME provides a robust and efficient read-modify-write capability. The resulting architectural capability defined by this core platform function is targeted at the manipulation of n-bit fields in peripheral registers and RAM and is consistent with I/O hardware addressing in the Embedded C standard. For most BME commands, a single core read or write bus cycle is converted into an atomic read-modify-write, that is, an indivisible "read followed by a write" bus sequence.

Consider decorated store operations first, then decorated loads.

### 24.3.1 BME decorated stores

The functions supported by the BME's decorated stores include three logical operators (AND, OR, XOR) plus a bit field insert.

For all these operations, BME converts a single decorated AHB store transaction into a 2-cycle atomic read-modify-write sequence, where the combined read-modify operation is performed in the first AHB data phase, and then the write is performed in the second AHB data phase.

A generic timing diagram of a decorated store showing a peripheral bit field insert operation is shown as follows:

## Functional description

**Figure 24-1. Decorated store: bit field insert timing diagram**

All the decorated store operations follow the same execution template shown in [Figure 24-1](#), a two-cycle read-modify-write operation:

1. Cycle x, 1st AHB address phase: Write from input bus is translated into a read operation on the output bus using the actual memory address (with the decoration removed) and then captured in a register.
2. Cycle x+1, 2nd AHB address phase: Write access with the registered (but actual) memory address is output
3. Cycle x+1, 1st AHB data phase: Memory read data is modified using the input bus write data and the function defined by the decoration and captured in a data register; the input bus cycle is stalled.
4. Cycle x+2, 2nd AHB data phase: Registered write data is sourced onto the output write data bus.

### NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

### 24.3.1.1 Decorated store logical AND (AND)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read;
2. It is then modified by performing a logical AND operation using the write data operand sourced for the system bus cycle
3. Finally, the result of the AND operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

|        | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4   | 3 | 2 | 1 | 0 |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|-----|---|---|---|---|
| ioandb | 0  | 1  | 0  | 0  | 0  | 1  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   |     |   |   |   |   |
| ioandh | 0  | 1  | 0  | 0  | 0  | 1  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0   |   |   |   |   |
| ioandw | 0  | 1  | 0  | 0  | 0  | 1  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 0 |   |   |   |   |
|        |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |     |   |   |   |   |

**Figure 24-2. Decorated store address: logical AND**

See [Figure 24-2](#) where `addr[30:29] = 10` for peripheral, `addr[28:26] = 001` specifies the AND operation, and `mem_addr[19:0]` specifies the address offset into the space based at a `0x4000_0000` for peripherals. The "-" indicates an address bit "don't care".

The decorated AND write operation is defined in the following pseudo-code as:

```
ioand<sz>(accessAddress, wdata)           // decorated store AND
tmp  = mem[accessAddress & 0xE0FFFFFF, size] // memory read
tmp  = tmp & wdata                          // modify
mem[accessAddress & 0xE0FFFFFF, size] = tmp // memory write
```

where the operand size `<sz>` is defined as `b`(yte, 8-bit), `h`(alfword, 16-bit) and `w`(ord, 32-bit). This notation is used throughout the document.

In the cycle definition tables, the notations `AHB_ap` and `AHB_dp` refer to the address and data phases of the BME AHB transaction. The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-1. Cycle definitions of decorated store: logical AND**

| Pipeline stage | Cycle                                                 |                                                           |        |
|----------------|-------------------------------------------------------|-----------------------------------------------------------|--------|
|                | x                                                     | x+1                                                       | x+2    |
| BME AHB_ap     | Forward addr to memory;<br>Decode decoration; Convert | Recirculate captured addr +<br>attr to memory as slave_wt | <next> |

|                | x                                                     | x+1                                                                                | x+2                                             |
|                | master_wt to slave_rd;<br>Capture address, attributes |                                                                                    |                                                 |
| BME AHB_dp     | <previous>                                            | Perform memory read; Form (rdata & wdata) and capture destination data in register | Perform write sending registered data to memory |

### 24.3.1.2 Decorated store logical OR (OR)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read.
2. It is then modified by performing a logical OR operation using the write data operand sourced for the system bus cycle.
3. Finally, the result of the OR operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

|       | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4   | 3 | 2 | 1 | 0 |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|-----|---|---|---|---|
| ioorb | 0  | 1  | 0  | 0  | 1  | 0  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   |     |   |   |   |   |
| ioorh | 0  | 1  | 0  | 0  | 1  | 0  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0   |   |   |   |   |
| ioorw | 0  | 1  | 0  | 0  | 1  | 0  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 0 |   |   |   |   |
|       |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |     |   |   |   |   |

**Figure 24-3. Decorated address store: logical OR**

See [Figure 24-3](#), where  $\text{addr}[30:29] = 10$  for peripheral,  $\text{addr}[28:26] = 010$  specifies the OR operation, and  $\text{mem\_addr}[19:0]$  specifies the address offset into the space based at a  $0x4000\_0000$  for peripherals. The "-" indicates an address bit "don't care".

The decorated OR write operation is defined in the following pseudo-code as:

```
ioor<sz>(accessAddress, wdata)           // decorated store OR

tmp   = mem[accessAddress & 0xE00FFFFF, size] // memory read
tmp   = tmp | wdata                          // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp   // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-2. Cycle definitions of decorated store: logical OR**

| Pipeline stage | Cycle                                                                                                          |                                                                                          |                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|----------------------------------------------------|
|                | x                                                                                                              | x+1                                                                                      | x+2                                                |
| BME AHB_ap     | Forward addr to memory;<br>Decode decoration; Convert<br>master_wt to slave_rd;<br>Capture address, attributes | Recirculate captured addr +<br>attr to memory as slave_wt                                | <next>                                             |
| BME AHB_dp     | <previous>                                                                                                     | Perform memory read; Form<br>(rdata   wdata) and capture<br>destination data in register | Perform write sending<br>registered data to memory |

### 24.3.1.3 Decorated store logical XOR (XOR)

This command performs an atomic read-modify-write of the referenced memory location.

1. First, the location is read.
2. It is then modified by performing a logical XOR (exclusive-OR) operation using the write data operand sourced for the system bus cycle.
3. Finally, the result of the XOR operation is written back into the referenced memory location.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The core performs the required write data lane replication on byte and halfword transfers.

|        | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| ioxorb | 0  | 1  | 0  | 0  | 1  | 1  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| ioxorh | 0  | 1  | 0  | 0  | 1  | 1  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 |   |   |   |   |
| ioxorw | 0  | 1  | 0  | 0  | 1  | 1  | -  | -  | -  | -  | -  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 |   | 0 |   |   |
|        |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Figure 24-4. Decorated address store: logical XOR**

See [Figure 24-4](#), where `addr[30:29] = 10` for peripheral, `addr[28:26] = 011` specifies the XOR operation, and `mem_addr[19:0]` specifies the address offset into the peripheral space based at a `0x4000_0000` for peripherals. The "-" indicates an address bit "don't care".

The decorated XOR write operation is defined in the following pseudo-code as:

```

ioxor<sz>(accessAddress, wdata)           // decorated store XOR

tmp    = mem[accessAddress & 0xE0FFFFFF, size] // memory read
tmp    = tmp ^ wdata                          // modify
mem[accessAddress & 0xE0FFFFFF, size] = tmp    // memory write

```

The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-3. Cycle definitions of decorated store: logical XOR**

| Pipeline Stage | Cycle                                                                                                       |                                                                                    |                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|-------------------------------------------------|
|                | x                                                                                                           | x+1                                                                                | x+2                                             |
| BME AHB_ap     | Forward addr to memory;<br>Decode decoration; Convert master_wt to slave_rd;<br>Capture address, attributes | Recirculate captured addr + attr to memory as slave_wt                             | <next>                                          |
| BME AHB_dp     | <previous>                                                                                                  | Perform memory read; Form (rdata ^ wdata) and capture destination data in register | Perform write sending registered data to memory |

#### 24.3.1.4 Decorated store bit field insert (BFI)

This command inserts a bit field contained in the write data operand, defined by LSB position (b) and the bit field width (w+1), into the memory "container" defined by the access size associated with the store instruction using an atomic read-modify-write sequence.

The data size is specified by the write operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). For BME2, the data field width (addr[22:20]) for bit field inserts and extracts is limited to an 8-bit or less value, regardless of reference size.

#### NOTE

The maximum bit field width is 8 bits. The core performs the required write data lane replication on byte and halfword transfers.

The BFI operation can be used to insert a single bit into a peripheral. For this case, the w field is simply set to 0, indicating a bit field width of 1.

|        | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| iobfib | 0  | 1  | 0  | 1  | -  | -  | b  | b  | b  | w  | w  | w  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| iobfih | 0  | 1  | 0  | 1  | -  | b  | b  | b  | b  | w  | w  | w  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 |   |   |   |   |
| iobfiw | 0  | 1  | 0  | 1  | b  | b  | b  | b  | b  | w  | w  | w  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 |   | 0 |   |   |
|        |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Figure 24-5. Decorated address store: bit field insert**

where addr[30:29]=10 for peripheral, addr[28]=1 signals a BFI operation, addr[27:23] is "b", the LSB identifier, addr[22:20] is "w", the bit field width minus 1 identifier, and addr[19:0] specifies the address offset into the peripheral space based at 0x4000\_0000. The "-" indicates an address bit "don't care".

The decorated BFI write operation is defined in the following pseudo-code as:

```
iobfi<sz>(accessAddress, wdata)           // decorated bit field insert

tmp    = mem[accessAddress & 0xE00FFFFF, size] // memory read
mask   = ((1 << (w+1)) - 1) << b           // generate bit mask
tmp    = tmp & ~mask                       // modify
        | wdata & mask
mem[accessAddress & 0xE00FFFFF, size] = tmp // memory write
```

The write data operand (wdata) associated with the store instruction contains the bit field to be inserted. It must be properly aligned within the right-aligned container, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword, or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd\_efgh". For all cases, w is 2, signaling a bit field width of 3.

```
if b = 0 and the decorated store (strb) Rt register[7:0] = ----_xyz,
    then destination is "abcd_ xyz"
if b = 1 and the decorated store (strb) Rt register[7:0] = ----_xyz-,
    then destination is "abcd_ xyzh"
if b = 2 and the decorated store (strb) Rt register[7:0] = ---x_ yz--,
    then destination is "abcx_ yzgh"
if b = 3 and the decorated store (strb) Rt register[7:0] = --xy_ z---,
    then destination is "abxy_ zfgh"
if b = 4 and the decorated store (strb) Rt register[7:0] = -xyz_ ----,
    then destination is "axyz_ efgh"
if b = 5 and the decorated store (strb) Rt register[7:0] = xyz- _----,
    then destination is "xyzd_ efgh"
if b = 6 and the decorated store (strb) Rt register[7:0] = yz-- _----,
    then destination is "yzcd_ efgh"
if b = 7 and the decorated store (strb) Rt register[7:0] = z--- _----,
    then destination is "zbcd_ efgh"
```

Note from the example, when the starting bit position plus the field width exceeds the container size, only part of the source bit field is inserted into the destination memory location. Stated differently, if  $(b + w + 1) > \text{container\_width}$ , only the low-order " $\text{container\_width} - b$ " bits are actually inserted.

The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-4. Cycle definitions of decorated store: bit field insert**

| Pipeline stage | Cycle                                                                                                          |                                                                                                                                                       |                                                    |

### 24.3.2 BME decorated loads

The functions supported by the BME's decorated loads include two single-bit load-and-  
{set, clear} operators plus unsigned bit field extracts.

For the two load-and-  
{set, clear} operations, BME converts a single decorated AHB load transaction into a two-cycle atomic read-modify-write sequence, where the combined read-modify operations are performed in the first AHB data phase, and then the write is performed in the second AHB data phase as the original read data is returned to the processor core. For an unsigned bit field extract, the decorated load transaction is stalled for one cycle in the BME as the data field is extracted, then aligned and returned to the processor in the second AHB data phase. This is the only decorated transaction that is not an atomic read-modify-write, as it is a simple data read.

A generic timing diagram of a decorated load showing a peripheral load-and-set 1-bit operation is shown as follows.

**Figure 24-6. Decorated load: load-and-set 1-bit field insert timing diagram**

Decorated load-and-`{set, clear}` 1-bit operations follow the execution template shown in the above figure: a 2-cycle read-modify-write operation:

1. Cycle x, first AHB address phase: Read from input bus is translated into a read operation on the output bus with the actual memory address (with the decoration removed) and then captured in a register
2. Cycle x+1, second AHB address phase: Write access with the registered (but actual) memory address is output
3. Cycle x+1, first AHB data phase: The "original" 1-bit memory read data is captured in a register, while the 1-bit field is set or clear based on the function defined by the decoration with the modified data captured in a register; the input bus cycle is stalled
4. Cycle x+2, second AHB data phase: The selected original 1-bit is right-justified, zero-filled and then driven onto the input read data bus, while the registered write data is sourced onto the output write data bus

**NOTE**

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

A generic timing diagram of a decorated load showing an unsigned peripheral bit field operation is shown in the following figure.

**Figure 24-7. Decorated load: unsigned bit field insert timing diagram**

The decorated unsigned bit field extract follows the same execution template shown in the above figure, a 2-cycle read operation:

- Cycle x, 1st AHB address phase: Read from input bus is translated into a read operation on the output bus with the actual memory address (with the decoration removed) and then captured in a register
- Cycle x+1, 2nd AHB address phase: Idle cycle

- Cycle x+1, 1st AHB data phase: A bit mask is generated based on the starting bit position and the field width; the mask is AND'ed with the memory read data to isolate the bit field; the resulting data is captured in a data register; the input bus cycle is stalled
- Cycle x+2, 2nd AHB data phase: Registered data is logically right-aligned for proper alignment and driven onto the input read data bus

### NOTE

Any wait states inserted by the slave device are simply passed through the BME back to the master input bus, stalling the AHB transaction cycle for cycle.

#### 24.3.2.1 Decorated load: load-and-clear 1 bit (LAC1)

This command loads a 1-bit field defined by the LSB position (b) into the core's general purpose destination register (Rt) and zeroes the bit in the memory space after performing an atomic read-modify-write sequence.

The extracted 1-bit data field from the memory address is right-justified and zero-filled in the operand returned to the core.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

|         |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Figure 24-8. Decorated load address: load-and-clear 1 bit**

See [Figure 24-8](#) where `addr[30:29] = 01` for SRAM\_U, `addr[30:29] = 10` for peripherals, `addr[28:26] = 010` specifies the load-and-clear 1 bit operation, `addr[25:21]` is "b", the bit identifier, and `mem_addr[19:0]` specifies the address offset into the space based at `0x2000_0000` for SRAM\_U, and `0x4000_0000` for peripherals. The "-" indicates an address bit "don't care".

The decorated load-and-clear 1-bit read operation is defined in the following pseudo-code as:

```

rdata = iolac1<sz>(accessAddress)           // decorated load-and-clear 1

tmp    = mem[accessAddress & 0xE0FFFFFF, size] // memory read
mask   = 1 << b                               // generate bit mask
rdata  = (tmp & mask) >> b                     // read data returned to core

```

## Functional description

```
tmp    = tmp & ~mask           // modify
mem[accessAddress & 0xE0FFFFFF, size] = tmp // memory write
```

The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-5. Cycle definitions of decorated load: load-and-clear 1 bit**

| Pipeline Stage | Cycle                                                                        |                                                                                                                                       |                                                                                       |

### 24.3.2.2 Decorated Load: Load-and-Set 1 Bit (LAS1)

This command loads a 1-bit field defined by the LSB position (b) into the core's general purpose destination register (Rt) and sets the bit in the memory space after performing an atomic read-modify-write sequence.

The extracted one bit data field from the memory address is right justified and zero filled in the operand returned to the core.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit).

|         | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| iolaslw | 0  | 1  | 0  | 0  | 1  | 1  | b  | b  | b  | b  | b  | -  | mem_addr |    |    |    |    |    |    |    |    |    |   |   |   |   |   | 0 |   | 0 |   |   |
|         |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Figure 24-9. Decorated load address: load-and-set 1 bit**

where  $\text{addr}[30:29] = 01$  for SRAM\_U,  $\text{addr}[30:29] = 10$  for peripherals,  $\text{addr}[28:26] = 011$  specifies the load-and-set 1 bit operation,  $\text{addr}[25:21]$  is "b", the bit identifier, and  $\text{mem\_addr}[19:0]$  specifies the address offset into the space based at 0x2000\_0000 for SRAM\_U, and 0x4000\_0000 for peripherals. The "-" indicates an address bit "don't care".

The decorated Load-and-Set 1 Bit read operation is defined in the following pseudo-code as:

```

rdata = iolas1<sz>(accessAddress)           // decorated load-and-set 1

tmp  = mem[accessAddress & 0xE00FFFFF, size] // memory read
mask = 1 << b                               // generate bit mask
rdata = (tmp & mask) >> b                    // read data returned to core
tmp  = tmp | mask                            // modify
mem[accessAddress & 0xE00FFFFF, size] = tmp  // memory write

```

The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-6. Cycle definitions of decorated load: load-and-set 1-bit**

| Pipeline Stage | Cycle                                                                        |                                                                                                                                      |                                                                                       |

|                | x                                                                            | x+1                                                                                                                                  | x+2                                                                                   |
| BME AHB_ap     | Forward addr to memory;<br>Decode decoration; Capture<br>address, attributes | Recirculate captured addr +<br>attr to memory as slave_wt                                                                            | <next>                                                                                |
| BME AHB_dp     | <previous>                                                                   | Perform memory read; Form<br>bit mask; Extract bit from<br>rdata; Form (rdata   mask)<br>and capture destination data<br>in register | Return extracted bit to master;<br>Perform write sending<br>registered data to memory |

### 24.3.2.3 Decorated load unsigned bit field extract (UBFX)

This command extracts a bit field defined by LSB position (b) and the bit field width (w +1) from the memory "container" defined by the access size associated with the load instruction using a two-cycle read sequence.

The extracted bit field from the memory address is right-justified and zero-filled in the operand returned to the core. Recall this is the only decorated operation that does not perform a memory write, that is, UBFX only performs a read.

The data size is specified by the read operation and can be byte (8-bit), halfword (16-bit) or word (32-bit). The maximum bit field width is 8 bits, regardless of reference size.

The use of a UBFX operation is recommended to extract a single bit. For this case, the w field is simply set to 0, indicating a bit field width of 1.

**Figure 24-10. Decorated load address: unsigned bit field extract**

See [Figure 24-10](#), where  $\text{addr}[30:29] = 10$  for peripherals,  $\text{addr}[28] = 1$  specifies the unsigned bit field extract operation,  $\text{addr}[27:23]$  is "b", the LSB identifier,  $\text{addr}[22:20]$  is "w", the bit field width minus 1 identifier, and  $\text{mem\_addr}[19:0]$  specifies the address offset into the space based at  $0x4000\_0000$  for peripherals. The "-" indicates an address bit "don't care".

The decorated unsigned bit field extract read operation is defined in the following pseudo-code as:

```
rdata = ioubfx<sz>(accessAddress)           // unsigned bit field extract

tmp   = mem[accessAddress & 0xE0FFFFFF, size] // memory read
mask  = ((1 << (w+1)) - 1) << b              // generate bit mask
rdata = (tmp & mask) >> b                    // read data returned to core
```

Like the BFI operation, when the starting bit position plus the field width exceeds the container size, only part of the source bit field is extracted from the destination memory location. Stated differently, if  $(b + w + 1) > \text{container\_width}$ , only the low-order " $\text{container\_width} - b$ " bits are actually extracted. The cycle-by-cycle BME operations are detailed in the following table.

**Table 24-7. Cycle definitions of decorated load: unsigned bit field extract**

| Pipeline Stage | Cycle                                                                        |                                                                                                           |                                                                               |
|----------------|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|

## 24.4 Application information

In this section, GNU assembler macros with C expression operands are presented as examples of the required instructions to perform decorated operations.

This section specifically presents a partial `bme.h` file defining the assembly language expressions for decorated logical stores: AND, OR, and XOR. Comparable functions for BFI and the decorated loads are more complex and available in the complete BME header file.

These macros use the same function names presented in [Functional description](#).

```
#define IOANDW(ADDR, WDATA) \
    __asm("ldr    r3, =(1<<26);" \
          "orr    r3, %[addr];" \
```

```

"mov    r2, %[wdata];"      \
"str     r2, [r3];"         \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOANDH(ADDR,WDATA)  \
__asm("ldr    r3, =(1<<26);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"strh    r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOANDB(ADDR,WDATA) \
__asm("ldr    r3, =(1<<26);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"strb    r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOORW(ADDR,WDATA)  \
__asm("ldr    r3, =(1<<27);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"str     r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOORH(ADDR,WDATA)  \
__asm("ldr    r3, =(1<<27);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"strh    r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOORB(ADDR,WDATA)  \
__asm("ldr    r3, =(1<<27);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"strb    r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOXORW(ADDR,WDATA) \
__asm("ldr    r3, =(3<<26);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"str     r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOXORH(ADDR,WDATA) \
__asm("ldr    r3, =(3<<26);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"strh    r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

#define IOXORB(ADDR,WDATA) \
__asm("ldr    r3, =(3<<26);" \
"orr     r3, %[addr];"       \
"mov     r2, %[wdata];"      \
"strb    r2, [r3];"          \
:: [addr] "r" (ADDR), [wdata] "r" (WDATA) : "r2", "r3");

```

# Chapter 25

## Direct Memory Access Multiplexer (DMAMUX)

### 25.1 Chip-specific DMAMUX information

#### 25.1.1 DMA MUX request sources

The following table shows the DMA MUX assignments for Channels 0 to 15 of the DMA Controller.

**Table 25-1. DMA MUX 0 request sources - Channels 0-15**

| Source Number | Peripheral Assignment | Description                                                                                                        |
|---------------|-----------------------|--------------------------------------------------------------------------------------------------------------------|
| 0             | Channel disabled      | —                                                                                                                  |
| 1             | Reserved Not used     | —                                                                                                                  |
| 2             | UART0 Receive         | Receive                                                                                                            |
| 3             | UART0 Transmit        | Transmit                                                                                                           |
| 4             | UART1 Recieve         | Receive                                                                                                            |
| 5             | UART1 Transmit        | Transmit                                                                                                           |
| 6             | flexPWM0_WR0          | Submodule 0 DMA request to update PWM buffers                                                                      |
| 7             | flexPWM0_WR1          | Submodule 1 DMA request to update PWM buffers                                                                      |
| 8             | flexPWM0_WR2          | Submodule 2 DMA request to update PWM buffers                                                                      |
| 9             | flexPWM0_WR3          | Submodule 3 DMA request to update PWM buffers                                                                      |
| 10            | flexPWM0_CP0          | Submodule 0 DMA request for input capture on any of the Capture FIFO ( OR of 6 capture circuits X0,X1,A0,A1,B0,B1) |
| 11            | flexPWM0_CP1          | Submodule 1 DMA request for input capture on any of the Capture FIFO ( OR of 6 capture circuits X0,X1,A0,A1,B0,B1) |

*Table continues on the next page...*

**Table 25-1. DMA MUX 0 request sources - Channels 0-15 (continued)**

| Source Number | Peripheral Assignment | Description                                                                                                       |
|---------------|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| 12            | flexPWM0_CP2          | Submodule 2 DMA request for input capture on any of the Capture FIFO (OR of 6 capture circuits X0,X1,A0,A1,B0,B1) |
| 13            | flexPWM0_CP3          | Submodule 3 DMA request for input capture on any of the Capture FIFO (OR of 6 capture circuits X0,X1,A0,A1,B0,B1) |
| 14            | FlexCAN0              | DMA request on Receiev mailbox level                                                                              |
| 15            | FlexCAN1              | DMA request on Receiev mailbox level                                                                              |

**Table 25-1. DMA MUX 0 request sources - Channels 0-15 (continued)**

| Source Number | Peripheral Assignment  | Description |
|---------------|------------------------|-------------|
| 47            | PDB1                   | —           |
| 48            | PDB0                   | —           |
| 49            | control module Port A  | —           |
| 50            | control module Port B  | —           |
| 51            | control module Port C  | —           |
| 52            | control module Port D  | —           |
| 53            | control module Port E  | —           |
| 54            | FTM3 Ch4               | Channel 4   |
| 55            | FTM3 Ch5               | Channel 5   |
| 56            | FTM3 Ch6               | Channel 6   |
| 57            | FTM3 Ch7               | Channel 7   |
| 58            | —                      | —           |
| 59            | —                      | —           |
| 60            | DMA MUX always enabled | —           |
| 61            | DMA MUX always enabled | —           |
| 62            | DMA MUX always enabled | —           |
| 63            | DMA MUX always enabled | —           |

The following table shows the DMA MUX assignments for Channels 16 to 31 of the DMA Controller.

**Table 25-2. DMA MUX 0 request sources - Channels 16-31**

| Source Number | Peripheral Assignment | Description                                                                                                       |
|---------------|-----------------------|-------------------------------------------------------------------------------------------------------------------|
| 0             | Channel disabled      | —                                                                                                                 |
| 1             | Reserved Not used     | —                                                                                                                 |
| 2             | UART2 Receive         | Receive                                                                                                           |
| 3             | UART2 Transmit        | Transmit                                                                                                          |
| 4             | UART3 Recieve         | Receive                                                                                                           |
| 5             | UART3 Transmit        | Transmit                                                                                                          |
| 6             | flexPWM1_WR0          | Submodule 0 DMA request to update PWM buffers                                                                     |
| 7             | flexPWM1_WR1          | Submodule 1 DMA request to update PWM buffers                                                                     |
| 8             | flexPWM1_WR2          | Submodule 2 DMA request to update PWM buffers                                                                     |
| 9             | flexPWM1_WR3          | Submodule 3 DMA request to update PWM buffers                                                                     |
| 10            | flexPWM1_CP0          | Submodule 0 DMA request for input capture on any of the Capture FIFO (OR of 6 capture circuits X0,X1,A0,A1,B0,B1) |

## 25.1.2 DMA transfers via PIT trigger

The PIT module can trigger a DMA transfer on the first four DMA channels. The assignments are detailed at [PIT/DMA Periodic Trigger Assignments](#).

## 25.2 Introduction

### 25.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 32 DMA channels. This process is illustrated in the following figure.

**Figure 25-1. DMAMUX block diagram**

## 25.2.2 Features

The DMAMUX module provides these features:

- Up to 59 peripheral slots and up to four always-on slots can be routed to 32 channels.
- 32 independently selectable DMA channel routers.
  - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

## 25.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

## 25.3 External signal description

The DMAMUX has no external pins.

## 25.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

**DMAMUX memory map**

**25.4.1 Channel Configuration register (DMAMUX\_CHCFGn)**

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

**NOTE**

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 4002\_1000h base + 0h offset + (1d × i), where i=0d to 31d

## 25.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

## 25.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

### Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 25-2. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

**Figure 25-3. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

**Figure 25-4. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5  $\mu$ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

## 25.5.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in [Modes of operation](#).

## 25.5.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are four additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

## 25.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 25.6.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 25.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.

3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

# Chapter 26

## Enhanced Direct Memory Access (eDMA)

### 26.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

#### 26.1.1 eDMA system block diagram

[Figure 26-1](#) illustrates the components of the eDMA system, including the eDMA module ("engine").

Figure 26-1. eDMA system block diagram

26.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 26-1. eDMA engine submodules

| Submodule    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address path | <p>This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI<sub>n</sub>[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.</p> <p>When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes</p> |

Table continues on the next page...

**Table 26-1. eDMA engine submodules (continued)**

| Submodule                         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | the new values for the TCDn_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCDn_CITER field, and a possible fetch of the next TCDn from memory as part of a scatter/gather operation.                                                                                                                                                                                                                                                                 |
| Data path                         | <p>This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.</p> <p>The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).</p>                                           |
| Program model/channel arbitration | This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).                                                                                                                                                                                                                                                                         |
| Control                           | This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write. |

The transfer-control descriptor local memory is further partitioned into:

**Table 26-2. Transfer control descriptor memory**

| Submodule         | Description                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory controller | This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled. |
| Memory array      | TCD storage for each channel's transfer profile.                                                                                                                                                                                                                                                |

### 26.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module,  $n$  is used to reference the channel number.

## 26.2 Modes of operation

The eDMA operates in the following modes:

**Table 26-3. Modes of operation**

| Mode   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal | <p>In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.</p> <p>A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.</p> |
| Debug  | <p>DMA operation is configurable in Debug mode via the control register:</p> <ul style="list-style-type: none"> <li>• If CR[EDBG] is cleared, the DMA continues to operate.</li> <li>• If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.</li> </ul>                                                                                                                                                                         |
| Wait   | Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.                                                                                                                                                                                                                                                                                                                                                                                                    |

## 26.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

### 26.3.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD<sub>*n*</sub> definition is presented as 11 registers of 16 or 32 bits.

### 26.3.2 TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

## 26.3.3 TCD structure

## 26.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

### DMA memory map

| Absolute address (hex) | Register name                                    | Width (in bits) | Access                | Reset value | Section/ page               |
|------------------------|--------------------------------------------------|-----------------|-----------------------|-------------|-----------------------------|

**26.3.5 Control Register (DMA\_CR)**

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

**NOTE**

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn\_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn\_SADDR) or destination address (TCDn\_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn\_SADDR), to the final destination address (TCDn\_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn\_SLAST and TCDn\_DLAST\_SGA) are used to compute the next TCDn\_SADDR and TCDn\_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn\_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn\_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

### DMA\_CR field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–18<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 17<br>CX          | Cancel Transfer<br><br>0 Normal operation<br>1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.                                                                                                                                          |
| 16<br>ECX         | Error Cancel Transfer<br><br>0 Normal operation<br>1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt. |
| 15–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 8<br>GRP0PRI      | Channel Group 0 Priority<br><br>Group 0 priority level when fixed priority group arbitration is enabled.                                                                                                                                                                                                                                                                                                                                                                                                             |
| 7<br>EMLM         | Enable Minor Loop Mapping<br><br>0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field.<br>1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.                                                                                                            |
| 6<br>CLM          | Continuous Link Mode<br><br><b>NOTE:</b> Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.                                                                                                           |

Table continues on the next page...

**DMA\_CR field descriptions (continued)**

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | 0 A minor loop channel link made to itself goes through channel arbitration before being activated again.<br>1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop. |
| 5<br>HALT     | Halt DMA Operations<br>0 Normal operation<br>1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.                                                                                                                                                                                                                                                                           |
| 4<br>HOE      | Halt On Error<br>0 Normal operation<br>1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.                                                                                                                                                                                                                                                                                                  |
| 3<br>ERGA     | Enable Round Robin Group Arbitration<br>0 Fixed priority arbitration is used for selection among the groups.<br>1 Round robin arbitration is used for selection among the groups.                                                                                                                                                                                                                                                                             |
| 2<br>ERCA     | Enable Round Robin Channel Arbitration<br>0 Fixed priority arbitration is used for channel selection within each group.<br>1 Round robin arbitration is used for channel selection within each group.                                                                                                                                                                                                                                                         |
| 1<br>EDBG     | Enable Debug<br>0 When in debug mode, the DMA continues to operate.<br>1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.                                                                                                                                                                                    |
| 0<br>Reserved | This field is reserved.<br>Reserved                                                                                                                                                                                                                                                                                                                                                                                                                           |

**26.3.6 Error Status Register (DMA\_ES)**

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See [Fault reporting and handling](#) for more details.

**26.3.7 Enable Request Register (DMA\_ERQ)**

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

## Memory map/register definition

Address: 4000\_8000h base + Ch offset = 4000\_800Ch

### 26.3.8 Enable Error Interrupt Register (DMA\_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

Address: 4000\_8000h base + 14h offset = 4000\_8014h

**26.3.9 Clear Enable Error Interrupt Register (DMA\_CEEI)**

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 18h offset = 4000\_8018h

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAEE | 0 |   |   | CEEI |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**26.3.10 Set Enable Error Interrupt Register (DMA\_SEEI)**

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 19h offset = 4000\_8019h

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | SAEE | 0 |   |   | SEEI |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

| SEEI          | Set Enable Error Interrupt<br><br>Sets the corresponding bit in EEI                                                   |

26.3.11 Clear Enable Request Register (DMA\_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Ah offset = 4000\_801Ah

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAER | 0 |   |   | CERQ |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

DMA\_CERQ field descriptions

| Field         | Description                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------|

| CERQ          | Clear Enable Request<br><br>Clears the corresponding bit in ERQ.                                                 |

### 26.3.12 Set Enable Request Register (DMA\_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Bh offset = 4000\_801Bh

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | SAER | 0 |   |   | SERQ |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**DMA\_SERQ field descriptions**

| Field         | Description                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------|

| SERQ          | Set Enable Request<br>Sets the corresponding bit in ERQ.                                               |

26.3.13 Clear DONE Status Bit Register (DMA\_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Ch offset = 4000\_801Ch

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CADN | 0 |   |   | CDNE |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

| CDNE          | Clear DONE Bit<br><br>Clears the corresponding bit in TCDn_CSR[DONE]                                                                |

### 26.3.14 Set START Bit Register (DMA\_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Dh offset = 4000\_801Dh

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 7   | 6    | 5 | 4 | 3 | 2    | 1 | 0 |
| Read  | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |
| Write | NOP | SAST | 0 |   |   | SSRT |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**DMA\_SSRT field descriptions**

| Field         | Description                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>NOP      | No Op enable<br>0 Normal operation<br>1 No operation, ignore the other bits in this register                                                       |
| 6<br>SAST     | Set All START Bits (activates all channels)<br>0 Set only the TCDn_CSR[START] bit specified in the SSRT field<br>1 Set all bits in TCDn_CSR[START] |

| SSRT          | Set START Bit<br>Sets the corresponding bit in TCDn_CSR[START]                                                                                     |

26.3.15 Clear Error Register (DMA\_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Eh offset = 4000\_801Eh

|       |     |      |   |   |   |      |   |   |

### 26.3.16 Clear Interrupt Request Register (DMA\_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 4000\_8000h base + 1Fh offset = 4000\_801Fh

## 26.3.17 Interrupt Request Register (DMA\_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

Address: 4000\_8000h base + 24h offset = 4000\_8024h

**26.3.18 Error Register (DMA\_ERR)**

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

## Memory map/register definition

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEL. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

**26.3.19 Hardware Request Status Register (DMA\_HRS)**

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

**NOTE**

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Address: 4000\_8000h base + 34h offset = 4000\_8034h

| Bit   | 31    | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |

**26.3.21 Channel n Priority Register (DMA\_DCHPRIn)**

When fixed-priority channel arbitration is enabled ( $CR[ERCA] = 0$ ), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: 4000\_8000h base + 100h offset + (1d × i), where i=0d to 31d

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15–11<br>SMOD | Source Address Modulo<br><br>0 Source address modulo feature is disabled<br>≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. |
| 10–8<br>SSIZE | Source data transfer size<br><br><b>NOTE:</b> Using a Reserved value causes a configuration error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**26.3.25 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA\_TCDn\_NBYTES\_MLNO)**

This register, or one of the next two registers (TCD\_NBYTES\_MLOFFNO, TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD\_NBYTES\_MLOFFNO and TCD\_NBYTES\_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 4000\_8000h base + 1008h offset + (32d × i), where i=0d to 31d

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |
|       | <b>NOTE:</b> An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.                                                                                                                                                                                                                                                                                                                                                                          |

**26.3.26 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA\_TCDn\_NBYTES\_MLOFFNO)**

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD\_NBYTES\_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

| NBYTES      | Minor Byte Transfer Count<br><br>Number of bytes to be transferred in each service request of the channel.<br><br>As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. |

**26.3.27 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA\_TCDn\_NBYTES\_MLOFFYES)**

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD\_NBYTES\_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

## Memory map/register definition

Address: 4000\_8000h base + 1008h offset + (32d × i), where i=0d to 31d

## DMA\_TCDn\_CSR field descriptions (continued)

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p>Otherwise:</p> <ul style="list-style-type: none"> <li>After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7<br>DONE       | <p>Channel Done</p> <p>This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated.</p> <p><b>NOTE:</b> This bit must be cleared to write the MAJORELINK or ESG bits.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 6<br>ACTIVE     | <p>Channel Active</p> <p>This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 5<br>MAJORELINK | <p>Enable channel-to-channel linking on major loop complete</p> <p>As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.</p> <p><b>NOTE:</b> To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</p> <p>0 The channel-to-channel linking is disabled.<br/>1 The channel-to-channel linking is enabled.</p>                                                                                                                                                                                |
| 4<br>ESG        | <p>Enable Scatter/Gather Processing</p> <p>As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory.</p> <p><b>NOTE:</b> To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</p> <p>0 The current channel's TCD is normal format.<br/>1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.</p> |
| 3<br>DREQ       | <p>Disable Request</p> <p>If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero.</p> <p>0 The channel's ERQ bit is not affected.<br/>1 The channel's ERQ bit is cleared when the major loop is complete.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2<br>INTHALF    | <p>Enable an interrupt when major counter is half complete.</p> <p>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER &gt;&gt; 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress.</p> <p><b>NOTE:</b> If BITER = 1, do not use INTHALF. Use INTMAJOR instead.</p>                                                                                                                            |

## 26.4 Functional description

The operation of the eDMA is described in the following subsections.

### 26.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

**Figure 26-2. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel  $n$ . Channel activation via software and the  $\text{TCD}_n\text{-CSR}[\text{START}]$  bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for  $\text{TCD}_n$ . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

**Figure 26-3. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

Figure 26-4. eDMA operation, part 3

### 26.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx\_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.

- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

### NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST\_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn\_CITER[E\_LINK] bit does not equal the TCDn\_BITER[E\_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error

occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx\_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA\_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

### **NOTE**

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx\_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 26.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

### 26.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

#### 26.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

### NOTE

All architectures will not meet the assumptions listed above.  
See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

**Table 26-4. eDMA peak transfer rates (Mbytes/sec)**

| System Speed, Width | Internal SRAM-to-Internal SRAM | 32 bit internal peripheral bus-to-Internal SRAM | Internal SRAM-to-32 bit internal peripheral bus |
|---------------------|--------------------------------|-------------------------------------------------|-------------------------------------------------|
| 66.7 MHz, 32 bit    | 133.3                          | 66.7                                            | 53.3                                            |
| 83.3 MHz, 32 bit    | 166.7                          | 83.3                                            | 66.7                                            |
| 100.0 MHz, 32 bit   | 200.0                          | 100.0                                           | 80.0                                            |
| 133.3 MHz, 32 bit   | 266.7                          | 133.3                                           | 106.7                                           |
| 150.0 MHz, 32 bit   | 300.0                          | 150.0                                           | 120.0                                           |

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

#### 26.4.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 26-5. Hardware service request process

| Cycle                                                     |                                                  | Description                                                                                                                                                                                                                                            |
|-----------------------------------------------------------|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| With internal peripheral bus read and internal SRAM write | With SRAM read and internal peripheral bus write |                                                                                                                                                                                                                                                        |
| 1                                                         |                                                  | eDMA peripheral request is asserted.                                                                                                                                                                                                                   |
| 2                                                         |                                                  | The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD <sub>n</sub> _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD <sub>n</sub> word 7.                         |
| 3                                                         |                                                  | Channel arbitration begins.                                                                                                                                                                                                                            |
| 4                                                         |                                                  | Channel arbitration completes. The transfer control descriptor local memory read is initiated.                                                                                                                                                         |
| 5–6                                                       |                                                  | The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles                                                              |
| 7                                                         |                                                  | The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.         |
| 8–11                                                      | 8–12                                             | The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.                                                                                                         |
| 12                                                        | 13                                               | This cycle represents the data phase of the last destination write.                                                                                                                                                                                    |
| 13                                                        | 14                                               | The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD <sub>n</sub> fields into the local memory. The TCD <sub>n</sub> word 7 is read and checked for channel linking or scatter/gather requests. |
| 14                                                        | 15                                               | The appropriate fields in the first part of the TCD <sub>n</sub> are written back into the local memory.                                                                                                                                               |
| 15                                                        | 16                                               | The fields in the second part of the TCD <sub>n</sub> are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.                                                                                      |
| 16                                                        | 17                                               | The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.                                                                          |

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles ( $4 + (4+5)/2 + 3$ ). This is the time from Cycle 4 to Cycle  $x + 5$ . The resulting peak request rate, as a function of the system frequency, is shown in the following table.

**Table 26-6. eDMA peak request rate (MReq/sec)**

| System frequency (MHz) | Request rate<br>with zero wait states | Request rate<br>with wait states |
|------------------------|---------------------------------------|----------------------------------|
| 66.6                   | 7.4                                   | 5.8                              |
| 83.3                   | 9.2                                   | 7.2                              |
| 100.0                  | 11.1                                  | 8.7                              |
| 133.3                  | 14.8                                  | 11.6                             |
| 150.0                  | 16.6                                  | 13.0                             |

A general formula to compute the peak request rate with overlapping requests is:

$$\text{PEAKreq} = \text{freq} / [ \text{entry} + (1 + \text{read\_ws}) + (1 + \text{write\_ws}) + \text{exit} ]$$

where:

**Table 26-7. Peak request formula operands**

| Operand  | Description                                             |
|----------|---------------------------------------------------------|
| PEAKreq  | Peak request rate                                       |
| freq     | System frequency                                        |
| entry    | Channel startup (4 cycles)                              |
| read_ws  | Wait states seen during the system bus read data phase  |
| write_ws | Wait states seen during the system bus write data phase |
| exit     | Channel shutdown (3 cycles)                             |

### 26.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 1) + (1 + 3) + 3 ] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an internal peripheral bus to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 2) + (1 + 1) + 3 ] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate would be:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a `TCDn_CSR[START]` bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

### Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

## 26.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 26.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the `DCHPRIn` registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.

5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
  - Software: setting the TCD $n$ \_CSR[START]
  - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD $n$ \_SADDR, to the destination, as defined by TCD $n$ \_DADDR, continue until the number of bytes specified by TCD $n$ \_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD $n$ \_SADDR, TCD $n$ \_DADDR, and TCD $n$ \_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 26-8. TCD Control and Status fields**

| TCD $n$ _CSR field name | Description                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------|
| START                   | Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware) |
| ACTIVE                  | Status bit indicating the channel is currently in execution                                                             |
| DONE                    | Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)           |
| D_REQ                   | Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service          |
| BWC                     | Control bits for throttling bandwidth control of a channel                                                              |
| E_SG                    | Control bit to enable scatter-gather feature                                                                            |
| INT_HALF                | Control bit to enable interrupt when major loop is half complete                                                        |
| INT_MAJ                 | Control bit to enable interrupt when major loop completes                                                               |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 26-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

Figure 26-6. Memory array terms

## 26.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx\_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

### 26.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 26.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

### 26.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration, Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

## 26.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

### 26.5.4.1 Single request

To perform a simple transfer of  $n$  bytes of data with one activation, set the major loop to one ( $TCDn\_CITER = TCDn\_BITER = 1$ ). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the  $TCDn\_CSR[DONE]$  bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCDn\_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes:  $\text{TCDn\_SADDR} = 0\text{x}1000$ ,  $\text{TCDn\_DADDR} = 0\text{x}2000$ ,  $\text{TCDn\_CITER} = 1$  ( $\text{TCDn\_BITER}$ ).
7. The eDMA engine writes:  $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$ ,  $\text{TCDn\_CSR}[\text{DONE}] = 1$ ,  $\text{INT}[n] = 1$ .
8. The channel retires and the eDMA goes idle or services the next channel.

### 26.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:  $\text{TCDn\_CSR}[\text{DONE}] = 0$ ,  $\text{TCDn\_CSR}[\text{START}] = 0$ ,  $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$ .
4. eDMA engine reads: channel  $\text{TCDn}$  data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
  - a. Read byte from location  $0\text{x}1000$ , read byte from location  $0\text{x}1001$ , read byte from  $0\text{x}1002$ , read byte from  $0\text{x}1003$ .
  - b. Write 32-bits to location  $0\text{x}2000 \rightarrow$  first iteration of the minor loop.
  - c. Read byte from location  $0\text{x}1004$ , read byte from location  $0\text{x}1005$ , read byte from  $0\text{x}1006$ , read byte from  $0\text{x}1007$ .
  - d. Write 32-bits to location  $0\text{x}2004 \rightarrow$  second iteration of the minor loop.
  - e. Read byte from location  $0\text{x}1008$ , read byte from location  $0\text{x}1009$ , read byte from  $0\text{x}100A$ , read byte from  $0\text{x}100B$ .
  - f. Write 32-bits to location  $0\text{x}2008 \rightarrow$  third iteration of the minor loop.

- g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32-bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes:  $TCDn\_SADDR = 0x1010$ ,  $TCDn\_DADDR = 0x2010$ ,  $TCDn\_CITER = 1$ .
7. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ .
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes:  $TCDn\_CSR[DONE] = 0$ ,  $TCDn\_CSR[START] = 0$ ,  $TCDn\_CSR[ACTIVE] = 1$ .
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
  - b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
  - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
  - d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
  - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
  - f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
  - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
  - h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes:  $TCDn\_SADDR = 0x1000$ ,  $TCDn\_DADDR = 0x2000$ ,  $TCDn\_CITER = 2$  ( $TCDn\_BITER$ ).
15. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ ,  $TCDn\_CSR[DONE] = 1$ ,  $INT[n] = 1$ .

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

### 26.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a  $2^4$  byte (16-byte) size queue.

**Table 26-9. Modulo example**

| Transfer Number | Address    |
|-----------------|------------|
| 1               | 0x12345670 |
| 2               | 0x12345674 |
| 3               | 0x12345678 |
| 4               | 0x1234567C |
| 5               | 0x12345670 |
| 6               | 0x12345674 |

## 26.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

### 26.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD $n$ \_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD $n$ \_CSR[START] bit and the TCD $n$ \_CSR[ACTIVE] bit. The minor-loop-

complete condition is indicated by both bits reading zero after the `TCDn_CSR[START]` was set. Polling the `TCDn_CSR[ACTIVE]` bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

| Stage | TCD <sub>n</sub> _CSR bits |        |      | State                                            |
|-------|----------------------------|--------|------|--------------------------------------------------|
|       | START                      | ACTIVE | DONE |                                                  |
| 1     | 1                          | 0      | 0    | Channel service request via software             |
| 2     | 0                          | 1      | 0    | Channel is executing                             |
| 3a    | 0                          | 0      | 0    | Channel has completed the minor loop and is idle |
| 3b    | 0                          | 0      | 1    | Channel has completed the major loop and is idle |

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

| Stage | TCD <sub>n</sub> _CSR bits |        |      | State                                                              |
|-------|----------------------------|--------|------|--------------------------------------------------------------------|
|       | START                      | ACTIVE | DONE |                                                                    |
| 1     | 0                          | 0      | 0    | Channel service request via hardware (peripheral request asserted) |
| 2     | 0                          | 1      | 0    | Channel is executing                                               |
| 3a    | 0                          | 0      | 0    | Channel has completed the minor loop and is idle                   |
| 3b    | 0                          | 0      | 1    | Channel has completed the major loop and is idle                   |

For both activation types, the major-loop-complete status is explicitly indicated via the `TCDn_CSR[DONE]` bit.

The `TCDn_CSR[START]` bit is cleared automatically when the channel begins execution regardless of how the channel activates.

### 26.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_NBYTES` values if read while a channel executes. The true values of the `SADDR`, `DADDR`, and `NBYTES` are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, `SADDR` and

DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

### 26.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The `TCDn_CSR[ACTIVE]` bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two `TCDn_CSR[ACTIVE]` bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

## 26.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the `TCDn_CSR[START]` bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The `TCDn_CITER[E_LINK]` field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set `TCD12_CSR[START]` bit

2. Minor loop done → set TCD12\_CSR[START] bit
3. Minor loop done → set TCD12\_CSR[START] bit
4. Minor loop done, major loop done → set TCD7\_CSR[START] bit

When minor loop linking is enabled ( $\text{TCDn\_CITER[E\_LINK]} = 1$ ), the  $\text{TCDn\_CITER[CITER]}$  field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled ( $\text{TCDn\_CITER[E\_LINK]} = 0$ ), the  $\text{TCDn\_CITER[CITER]}$  field uses a 15-bit vector to form the current iteration count. The bits associated with the  $\text{TCDn\_CITER[LINKCH]}$  field are concatenated onto the CITER value to increase the range of the CITER.

### Note

The  $\text{TCDn\_CITER[E\_LINK]}$  bit and the  $\text{TCDn\_BITER[E\_LINK]}$  bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e., use another channel's TCD, at the end of a loop.

**Table 26-10. Channel Linking Parameters**

| Desired Link Behavior     | TCD Control Field Name | Description                                                                    |
|---------------------------|------------------------|--------------------------------------------------------------------------------|
| Link at end of Minor Loop | CITER[E_LINK]          | Enable channel-to-channel linking on minor loop completion (current iteration) |
|                           | CITER[LINKCH]          | Link channel number when linking at end of minor loop (current iteration)      |
| Link at end of Major Loop | CSR[MAJOR_E_LINK]      | Enable channel-to-channel linking on major loop completion                     |
|                           | CSR[MAJOR_LINKCH]      | Link channel number when linking at end of major loop                          |

## 26.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 26.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 26.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e\_link bit during channel execution (see the diagram in [TCD structure](#)). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e\_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e\_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e\_link bit.
2. Read back the TCD.major.e\_link bit.
3. Test the TCD.major.e\_link request status:
  - If TCD.major.e\_link = 1, the dynamic link attempt was successful.
  - If TCD.major.e\_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e\_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

### 26.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e\_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e\_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e\_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e\_link and TCD.e\_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link or TCD.e\_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

#### 26.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e\_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCD.dlast\_sga field with the scatter/gather address.
4. Write 1b to the TCD.e\_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e\_sg request status and TCD.major.linkch value:

If e\_sg = 1b, the dynamic link attempt was successful.

If e\_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e\_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e\_sg value cleared the e\_sg bit).

### 26.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast\_sga field as a TCD identification (ID).

1. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

2. Write the TCD.dlast\_sga field with the scatter/gather address.
3. Write 1b to the TCD.e\_sg bit.
4. Read back the TCD.e\_sg bit.
5. Test the TCD.e\_sg request status:

If e\_sg = 1b, the dynamic link attempt was successful.

If e\_sg = 0b, read the 32 bit TCD dlast\_sga field.

If e\_sg = 0b and the dlast\_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If  $e\_sg = 0b$  and the  $dlast\_sga$  changed, the dynamic link attempt was successful (the new TCD's  $e\_sg$  value cleared the  $e\_sg$  bit).

## 26.5.8 Lockstep

This chip contains an eDMA Checker which, when enabled, operates in Lockstep mode with the primary eDMA, executing the exact same transfer profiles. The eDMA Checker checks to ensure the primary eDMA is operating correctly. A block diagram is shown below.

### 26.5.8.1 Initialization

To prevent the eDMA Checker from generating a false comparison error after power-on-reset, the eDMA's data output buffer must be initialized prior to enabling the Checker. To initialize the eDMA data output buffer, the eDMA must perform a one or more 32-bit data transfers using any data value.

### 26.5.8.2 Errors

To handle source-address errors (SAE), perform the following steps.

1. Fix the addressing error.
2. Clear the error bit in [Error Register \(DMA\\_ERR\)](#).
3. Start the channel in a normal fashion.

#### NOTE

[Error Status Register \(DMA\\_ES\)](#) is read-only; the bits cannot be cleared. It saves the last recorded error. The VLD bit shows the user whether any error bits in the Error Register are set, thus indicating an error occurred that hasn't been cleared.

## Chapter 27

# External Watchdog Monitor (EWM)

## 27.1 Chip-specific EWM information

### 27.1.1 EWM clocks

This table shows the EWM clocks and the corresponding chip clocks.

**Table 27-1. EWM clock connections**

| Module clock    | Chip clock      |
|-----------------|-----------------|
| Low Power Clock | 1 kHz LPO Clock |

#### NOTE

In CLKCTRL[CLKSEL] of this device, lpo\_clk[0] is the only available low power clock source. lpo\_clk[3:1] are reserved.

### 27.1.2 EWM low-power modes

This table shows the EWM low-power modes and the corresponding chip low-power modes.

**Table 27-2. EWM low-power modes**

| Module mode | Chip mode  |
|-------------|------------|
| Wait        | Wait, VLPW |
| Stop        | Stop, VLPS |

### 27.1.3 $\overline{\text{EWM\_OUT}}$ pin state in low power modes

During Wait, Stop, and VLLS modes, the  $\overline{\text{EWM\_OUT}}$  pin preserve its state before entering Wait, Stop, or VLLS mode. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from VLLS mode, the pin returns to its reset state after clearing PMC\_REGSC[ACKISO].

## 27.2 Introduction

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the  $\overline{\text{RESET}}$  pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent  $\overline{\text{EWM\_out}}$  signal that when asserted resets or places an external circuit into a safe mode. The  $\overline{\text{EWM\_out}}$  signal is asserted upon the EWM counter time-out. An optional external input EWM\_in is provided to allow additional control of the assertion of  $\overline{\text{EWM\_out}}$  signal.

### 27.2.1 Features

Features of EWM module include:

- Independent LPO\_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO\_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of  $\overline{\text{EWM\_out}}$ .

- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 15 (*EWM\_refresh\_time*) peripheral bus clock cycles.
- One output port,  $\overline{\text{EWM\_out}}$ , when asserted is used to reset or place the external circuit into safe mode.
- One Input port,  $\overline{\text{EWM\_in}}$ , allows an external circuit to control the assertion of the  $\overline{\text{EWM\_out}}$  signal.

## 27.2.2 Modes of Operation

This section describes the module's operating modes.

### 27.2.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 15 (*EWM\_refresh\_time*) peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

### 27.2.2.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

### 27.2.2.3 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

### 27.2.3 Block Diagram

This figure shows the EWM block diagram.

Figure 27-1. EWM Block Diagram

## 27.3 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

**Table 27-3. EWM Signal Descriptions**

| Signal                       | Description                                                                                                                                                        | I/O |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| EWM_in                       | EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low. | I   |
| $\overline{\text{EWM\_out}}$ | EWM reset out signal                                                                                                                                               | O   |
| lpo_clk[3:0]                 | Low power clock sources for running counter                                                                                                                        | I   |

## 27.4 Memory Map/Register Definition

This section contains the module memory map and registers.

### EWM memory map

| Absolute address (hex) | Register name                               | Width (in bits) | Access                | Reset value | Section/ page              |
|------------------------|---------------------------------------------|-----------------|-----------------------|-------------|----------------------------|
| 4006_1000              | Control Register (EWM_CTRL)                 | 8               | R/W                   | 00h         | <a href="#">27.4.1/597</a> |
| 4006_1001              | Service Register (EWM_SERV)                 | 8               | W<br>(always reads 0) | 00h         | <a href="#">27.4.2/598</a> |
| 4006_1002              | Compare Low Register (EWM_CMPL)             | 8               | R/W                   | 00h         | <a href="#">27.4.3/598</a> |
| 4006_1003              | Compare High Register (EWM_CMPH)            | 8               | R/W                   | FFh         | <a href="#">27.4.4/599</a> |
| 4006_1004              | Clock Control Register (EWM_CLKCTRL)        | 8               | R/W                   | 00h         | <a href="#">27.4.5/600</a> |
| 4006_1005              | Clock Prescaler Register (EWM_CLKPRESCALER) | 8               | R/W                   | 00h         | <a href="#">27.4.6/600</a> |

### 27.4.1 Control Register (EWM\_CTRL)

The CTRL register is cleared by any reset.

#### NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

Address: 4006\_1000h base + 0h offset = 4006\_1000h

| Bit   | 7 | 6 | 5 | 4 | 3     | 2    | 1     | 0     |
|-------|---|---|---|---|-------|------|-------|-------|
| Read  | 0 |   |   |   | INTEN | INEN | ASSIN | EWMEN |
| Write |   |   |   |   |       |      |       |       |
| Reset | 0 | 0 | 0 | 0 | 0     | 0    | 0     | 0     |

**EWM\_CTRL field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                            |
| 3<br>INTEN      | Interrupt Enable.<br><br>This bit when set and $\overline{\text{EWM\_out}}$ is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.                                                                                               |
| 2<br>INEN       | Input Enable.<br><br>This bit when set, enables the EWM_in port.                                                                                                                                                                                                                                   |
| 1<br>ASSIN      | EWM_in's Assertion State Select.<br><br>Default assert state of the EWM_in signal is logic zero. Setting the ASSIN bit inverts the assert state of EWM_in signal to a logic one.                                                                                                                   |
| 0<br>EWMEN      | EWM enable.<br><br>This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the $\overline{\text{EWM\_out}}$ signal. This bit when unset, keeps the EWM module disabled. It cannot be re-enabled until a next reset, due to the write-once nature of this bit. |

**27.4.2 Service Register (EWM\_SERV)**

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

Address: 4006\_1000h base + 1h offset = 4006\_1001h

|       |         |   |   |   |   |   |   |   |
|-------|---------|---|---|---|---|---|---|---|
| Bit   | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | 0       |   |   |   |   |   |   |   |
| Write | SERVICE |   |   |   |   |   |   |   |
| Reset | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EWM\_SERV field descriptions**

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SERVICE | The EWM refresh mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM refresh is invalid if either of the following conditions is true. <ul style="list-style-type: none"> <li>The first or second data byte is not written correctly.</li> <li>The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called <i>EWM_refresh_time</i>.</li> </ul> |

**27.4.3 Compare Low Register (EWM\_CMPL)**

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

Address: 4006\_1000h base + 2h offset = 4006\_1002h

|       |          |   |   |   |   |   |   |   |
|-------|----------|---|---|---|---|---|---|---|
| Bit   | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | COMPAREL |   |   |   |   |   |   |   |
| Write |          |   |   |   |   |   |   |   |
| Reset | 0        | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**EWM\_CMPL field descriptions**

| Field    | Description                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMPAREL | To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum refresh time is required. |

**27.4.4 Compare High Register (EWM\_CMPH)**

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset.  
Writing this register more than once generates a bus transfer error.

**NOTE**

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

Address: 4006\_1000h base + 3h offset = 4006\_1003h

|       |          |   |   |   |   |   |   |   |
|-------|----------|---|---|---|---|---|---|---|
| Bit   | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | COMPAREH |   |   |   |   |   |   |   |
| Write |          |   |   |   |   |   |   |   |
| Reset | 1        | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

**EWM\_CMPH field descriptions**

| Field    | Description                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMPAREH | To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum refresh time is required. |

## 27.4.5 Clock Control Register (EWM\_CLKCTRL)

This CLKCTRL register is reset to 0x00 after a CPU reset.

### NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

### NOTE

User should select the required low power clock before enabling the EWM.

Address: 4006\_1000h base + 4h offset = 4006\_1004h

|       |   |   |   |   |   |   |        |   |
|-------|---|---|---|---|---|---|--------|---|
| Bit   | 7 | 6 | 5 | 4 | 3 | 2 | 1      | 0 |
| Read  | 0 |   |   |   |   |   | CLKSEL |   |
| Write |   |   |   |   |   |   |        |   |

## 27.4.6 Clock Prescaler Register (EWM\_CLKPRESCALER)

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

### NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

### NOTE

Write the required prescaler value before enabling the EWM.

### NOTE

The implementation of this register is chip-specific. See the Chip Configuration details.

Address: 4006\_1000h base + 5h offset = 4006\_1005h

## 27.5 Functional Description

The following sections describe functional details of the EWM module.

### NOTE

When the BUS\_CLK is lost, then EWM module doesn't generate the EWM\_out signal and no refresh operation is possible

### 27.5.1 The EWM\_out Signal

The EWM\_out is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM\_out could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM\_out signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.

The EWM\_out signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM\_in pin is enabled and EWM\_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM\_out pin)

The  $\overline{\text{EWM\_out}}$  is asserted after any reset by the virtue of the external pull-down mechanism on the  $\overline{\text{EWM\_out}}$  signal. Then, to deassert the  $\overline{\text{EWM\_out}}$  signal, set EWMEN bit in the CTRL register to enable the EWM.

If the  $\overline{\text{EWM\_out}}$  signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the  $\overline{\text{EWM\_out}}$  signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

### **Note**

$\overline{\text{EWM\_out}}$  pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

## **27.5.2 The EWM\_in Signal**

The EWM\_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the  $\overline{\text{EWM\_out}}$  signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the  $\overline{\text{EWM\_out}}$  signal that controls the gating circuit.

The EWM\_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM\_in functionality (setting the CTRL[INEN] bit), the EWM\_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the  $\overline{\text{EWM\_out}}$  stays in the deasserted state; otherwise, the  $\overline{\text{EWM\_out}}$  output signal is asserted.

### **Note**

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM\_in pin is deasserted.

## **27.5.3 EWM Counter**

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

## 27.5.4 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1),  $\overline{\text{EWM\_out}}$  is asserted.

## 27.5.5 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

**Table 27-4. EWM Refresh Mechanisms**

| Condition                                                                               | Mechanism                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| An EWM refresh action completes when:<br>$\text{CMPL} < \text{Counter} < \text{CMPH}$ . | The software behaves as expected and the EWM counter is reset to zero. The $\overline{\text{EWM\_out}}$ output signal remains in the deasserted state if, during the EWM refresh action, the $\overline{\text{EWM\_in}}$ input has been in deasserted state.. |
| An EWM refresh action completes when<br>$\text{Counter} < \text{CMPL}$                  | The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the $\overline{\text{EWM\_out}}$ output signal is asserted irrespective of the input $\overline{\text{EWM\_in}}$ .                                            |
| Counter value reaches CMPH prior to completion of EWM refresh action.                   | Software has not refreshed the EWM. The EWM counter is reset to zero and the $\overline{\text{EWM\_out}}$ output signal is asserted irrespective of the input $\overline{\text{EWM\_in}}$ .                                                                   |

## 27.5.6 EWM Interrupt

When  $\overline{\text{EWM\_out}}$  is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect  $\overline{\text{EWM\_out}}$ . The  $\overline{\text{EWM\_out}}$  signal can be deasserted only by forcing a system reset.

### 27.5.7 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

### 27.5.8 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK\_DIV]. This divided clock is used to run the EWM counter.

#### NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

## Watchdog Timer (WDOG)

### 28.1 Chip-specific WDOG information

#### 28.1.1 WDOG clocks

This table shows the WDOG module clocks and the corresponding chip clocks.

**Table 28-1. WDOG clock connections**

| Module clock     | Chip clock                                                   |
|------------------|--------------------------------------------------------------|
| LPO Oscillator   | 1 kHz LPO Clock or MCGIRCLK depending on SIM_WDOGC[WDOGCLKS] |
| Alt Clock        | Bus Clock                                                    |
| Fast Test Clock  | Bus Clock                                                    |
| System Bus Clock | Bus Clock                                                    |

#### 28.1.2 WDOG low-power modes

This table shows the WDOG low-power modes and the corresponding chip low-power modes.

**Table 28-2. WDOG low-power modes**

| Module mode | Chip mode  |
|-------------|------------|
| Wait        | Wait, VLPW |
| Stop        | Stop, VLPS |
| Power Down  | VLLSx      |

## 28.2 Introduction

The Watchdog Timer (WDOG) keeps a watch on the system functioning and resets it in case of its failure. Reasons for failure include run-away software code and the stoppage of the system clock that in a safety critical system can lead to serious consequences. In such cases, the watchdog brings the system into a safe state of operation. The watchdog monitors the operation of the system by expecting periodic communication from the software, generally known as servicing or refreshing the watchdog. If this periodic refreshing does not occur, the watchdog resets the system.

## 28.3 Features

The features of the Watchdog Timer (WDOG) include:

- Clock source input independent from CPU/bus clock. Choice between two clock sources:
  - Low-power oscillator (LPO)
  - External system clock
- Unlock sequence for allowing updates to write-once WDOG control/configuration bits.
- All WDOG control/configuration bits are writable once only within 256 bus clock cycles of being unlocked.
  - You need to always update these bits after unlocking within 256 bus clock cycles. Failure to update these bits resets the system.
- Programmable time-out period specified in terms of number of WDOG clock cycles.
- Ability to test WDOG timer and reset with a flag indicating watchdog test.
  - Quick test—Small time-out value programmed for quick test.
  - Byte test—Individual bytes of timer tested one at a time.
  - Read-only access to the WDOG timer—Allows dynamic check that WDOG timer is operational.

**NOTE**

Reading the watchdog timer counter while running the watchdog on the bus clock might not give the accurate counter value.

- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to reset.
- Robust refresh mechanism
  - Write values of 0xA602 and 0xB480 to WDOG Refresh Register within 20 bus clock cycles.
- Count of WDOG resets as they occur.
- Configurable interrupt on time-out to provide debug breadcrumbs. This is followed by a reset after 256 bus clock cycles.

## 28.4 Functional overview

**Figure 28-1. WDOG operation**

The preceding figure shows the operation of the watchdog. The values for N and K are:

- N = 256
- K = 20

The watchdog is a fail safe mechanism that brings the system into a known initial state in case of its failure due to CPU clock stopping or a run-away condition in code execution. In its simplest form, the watchdog timer runs continuously off a clock source and expects to be serviced periodically, failing which it resets the system. This ensures that the software is executing correctly and has not run away in an unintended direction. Software can adjust the period of servicing or the time-out value for the watchdog timer to meet the needs of the application.

You can select a windowed mode of operation that expects the servicing to be done only in a particular window of the time-out period. An attempted servicing of the watchdog outside this window results in a reset. By operating in this mode, you can get an indication of whether the code is running faster than expected. The window length is also user programmable.

If a system fails to update/refresh the watchdog due to an unknown and persistent cause, it will be caught in an endless cycle of resets from the watchdog. To analyze the cause of such conditions, you can program the watchdog to first issue an interrupt, followed by a reset. In the interrupt service routine, the software can analyze the system stack to aid debugging.

To enhance the independence of watchdog from the system, it runs off an independent LPO oscillator clock. You can also switch over to an alternate clock source if required, through a control register bit.

### 28.4.1 Unlocking and updating the watchdog

As long as `ALLOW_UPDATE` in the watchdog control register is set, you can unlock and modify the write-once-only control and configuration registers:

1. Write `0xC520` followed by `0xD928` within 20 bus clock cycles to a specific unlock register (`WDOG_UNLOCK`).
2. Wait one bus clock cycle. You cannot update registers on the bus clock cycle immediately following the write of the unlock sequence.
3. An update window equal in length to the watchdog configuration time (`WCT`) opens. Within this window, you can update the configuration and control register bits.

These register bits can be modified only once after unlocking.

If none of the configuration and control registers is updated within the update window, the watchdog issues a reset, that is, interrupt-then-reset, to the system. Trying to unlock the watchdog within the `WCT` after an initial unlock has no effect. During the update operation, the watchdog timer is not paused and continues running in the background. After the update window closes, the watchdog timer restarts and the watchdog functions according to the new configuration.

The update feature is useful for applications that have an initial, non-safety critical part, where the watchdog is kept disabled or with a conveniently long time-out period. This means the application coder does not have to frequently service the watchdog. After the critical part of the application begins, the watchdog can be reconfigured as needed.

The watchdog issues a reset, that is, interrupt-then-reset if enabled, to the system for any of these invalid unlock sequences:

- Write any value other than 0xC520 or 0xD928 to the unlock register.
- ALLOW\_UPDATE is set and a gap of more than 20 bus clock cycles is inserted between the writing of the unlock sequence values.

An attempted refresh operation between the two writes of the unlock sequence and in the WCT time following a successful unlock, goes undetected. Also, see [Watchdog Operation with 8-bit access](#) for guidelines related to 8-bit accesses to the unlock register.

### Note

A context switch during unlocking and refreshing may lead to a watchdog reset.

## 28.4.2 Watchdog configuration time (WCT)

To prevent unintended modification of the watchdog's control and configuration register bits, you are allowed to update them only within a period of 256 bus clock cycles after unlocking. This period is known as the watchdog configuration time (WCT). In addition, these register bits can be modified only once after unlocking them for editing, even after reset.

You must unlock the registers within WCT after system reset, failing which the WDOG issues a reset to the system. In other words, you must write at least the first word of the unlocking sequence within the WCT after reset. After this is done, you have a further 20 bus clock cycles, the maximum allowed gap between the words of the unlock sequence, to complete the unlocking operation. Thereafter, to make sure that you do not forget to configure the watchdog, the watchdog issues a reset if none of the WDOG control and configuration registers is updated in the WCT after unlock. After the close of this window or after the first write, these register bits are locked out from any further changes.

The watchdog timer keeps running according to its default configuration through unlocking and update operations that can extend up to a maximum total of  $2 \times \text{WCT} + 20$  bus clock cycles. Therefore, it must be ensured that the time-out value for the watchdog is always greater than  $2 \times \text{WCT} + 20$  bus clock cycles.

Updates in the write-once registers take effect only after the WCT window closes with the following exceptions for which changes take effect immediately:

- Stop, Wait, and Debug mode enable
- IRQ\_RST\_EN

The operations of refreshing the watchdog goes undetected during the WCT.

### 28.4.3 Refreshing the watchdog

A robust refreshing mechanism has been chosen for the watchdog. A valid refresh is a write of 0xA602 followed by 0xB480 within 20 bus clock cycles to watchdog refresh register. If these two values are written more than 20 bus cycles apart or if something other than these two values is written to the register, a watchdog reset, or interrupt-then-reset if enabled, is issued to the system. A valid refresh makes the watchdog timer restart on the next bus clock. Also, an attempted unlock operation in between the two writes of the refresh sequence goes undetected. See [Watchdog Operation with 8-bit access](#) for guidelines related to 8-bit accesses to the refresh register.

### 28.4.4 Windowed mode of operation

In this mode of operation, a restriction is placed on the point in time within the time-out period at which the watchdog can be refreshed. The refresh is considered valid only when the watchdog timer increments beyond a certain count as specified by the watchdog window register. This is known as refreshing the watchdog within a window of the total time-out period. If a refresh is attempted before the timer reaches the window value, the watchdog generates a reset, or interrupt-then-reset if enabled. If there is no refresh at all, the watchdog times out and generates a reset or interrupt-then-reset if enabled.

### 28.4.5 Watchdog disabled mode of operation

When the watchdog is disabled through the WDOG\_EN bit in the watchdog status and control register, the watchdog timer is reset to zero and is disabled from counting until you enable it or it is enabled again by the system reset. In this mode, the watchdog timer cannot be refreshed—there is no requirement to do so while the timer is disabled. However, the watchdog still generates a reset, or interrupt-then-reset if enabled, on a non-time-out exception. See [Generated Resets and Interrupts](#). You need to unlock the watchdog before enabling it. A system reset brings the watchdog out of the disabled mode.

### 28.4.6 Low-power modes of operation

The low-power modes of operation of the watchdog are described in the following table:

**Table 28-3. Low-power modes of operation**

| Mode       | Behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wait       | If the WDOG is enabled (WAIT_EN = 1), it can run on bus clock or low-power oscillator clock (CLK_SRC = x) to generate interrupt (IRQ_RST_EN=1) followed by a reset on time-out. After reset the WDOG reset counter increments by one.                                                                                                                                                                                                                                                                                                          |
| Stop       | Where the bus clock is gated, the WDOG can run only on low-power oscillator clock (CLK_SRC=0) if it is enabled in stop (STOP_EN=1). In this case, the WDOG runs to time-out twice, and then generates a reset from its backup circuitry. Therefore, if you program the watchdog to time-out after 100 ms and then enter such a stop mode, the reset will occur after 200 ms. Also, in this case, no interrupt will be generated irrespective of the value of IRQ_RST_EN bit. After WDOG reset, the WDOG reset counter will also not increment. |
| Power-Down | The watchdog is <ul style="list-style-type: none"> <li>powered off in VLLSx mode</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 28.4.7 Debug modes of operation

You can program the watchdog to disable in debug modes through DBG\_EN in the watchdog control register. This results in the watchdog timer pausing for the duration of the mode. Register read/writes are still allowed, which means that operations like refresh, unlock, and so on are allowed. Upon exit from the mode, the timer resumes its operation from the point of pausing.

The entry of the system into the debug mode does not excuse it from compulsorily configuring the watchdog in the WCT time after unlock, unless the system bus clock is gated off, in which case the internal state machine pauses too. Failing to do so still results in a reset, or interrupt-then-reset, if enabled, to the system. Also, all of the exception conditions that result in a reset to the system, as described in [Generated Resets and Interrupts](#), are still valid in this mode. So, if an exception condition occurs and the system bus clock is on, a reset occurs, or interrupt-then-reset, if enabled.

The entry into Debug mode within WCT after reset is treated differently. The WDOG timer is kept reset to zero and there is no need to unlock and configure it within WCT. You must not try to refresh or unlock the WDOG in this state or unknown behavior may result. Upon exit from this mode, the WDOG timer restarts and the WDOG has to be unlocked and configured within WCT.

## 28.5 Testing the watchdog

For IEC 60730 and other safety standards, the expectation is that anything that monitors a safety function must be tested, and this test is required to be fault tolerant. To test the watchdog, its main timer and its associated compare and reset logic must be tested. To

this end, two tests are implemented for the watchdog, as described in [Quick Test](#) and [Byte Test](#). A control bit is provided to put the watchdog into functional test mode. There is also an overriding test-disable control bit which allows the functional test mode to be disabled permanently. After it is set, this test-disable bit can only be cleared by a reset.

These two tests achieve the overall aim of testing the counter functioning and the compare and reset logic.

### Note

Do not enable the watchdog interrupt during these tests. If required, you must ensure that the effective time-out value is greater than WCT time. See [Generated Resets and Interrupts](#) for more details.

To run a particular test:

1. Select either quick test or byte test..
2. Set a certain test mode bit to put the watchdog in the functional test mode. Setting this bit automatically switches the watchdog timer to a fast clock source. The switching of the clock source is done to achieve a faster time-out and hence a faster test.

In a successful test, the timer times out after reaching the programmed time-out value and generates a system reset.

### Note

After emerging from a reset due to a watchdog test, unlock and configure the watchdog. The refresh and unlock operations and interrupt are not automatically disabled in the test mode.

## 28.5.1 Quick test

In this test, the time-out value of watchdog timer is programmed to a very low value to achieve quick time-out. The only difference between the quick test and the normal mode of the watchdog is that TESTWDOG is set for the quick test. This allows for a faster test of the watchdog reset mechanism.

## 28.5.2 Byte test

The byte test is a more thorough a test of the watchdog timer. In this test, the timer is split up into its constituent byte-wide stages that are run independently and tested for time-out against the corresponding byte of the time-out value register. The following figure explains the splitting concept:

**Figure 28-2. Watchdog timer byte splitting**

Each stage is an 8-bit synchronous counter followed by combinational logic that generates an overflow signal. The overflow signal acts as an enable to the  $N + 1$ th stage.

In the test mode, when an individual byte,  $N$ , is tested, byte  $N - 1$  is loaded forcefully with 0xFF, and both these bytes are allowed to run off the clock source. By doing so, the overflow signal from stage  $N - 1$  is generated immediately, enabling counter stage  $N$ . The  $N$ th stage runs and compares with the  $N$ th byte of the time-out value register. In this way, the byte  $N$  is also tested along with the link between it and the preceding stage. No other stages,  $N - 2$ ,  $N - 3$ ... and  $N + 1$ ,  $N + 2$ ... are enabled for the test on byte  $N$ . These disabled stages, except the most significant stage of the counter, are loaded with a value of 0xFF.

## 28.6 Backup reset generator

The backup reset generator generates the final reset which goes out to the system. It has a backup mechanism which ensures that in case the bus clock stops and prevents the main state machine from generating a reset exception/interrupt, the watchdog timer's time-out is separately routed out as a reset to the system. Two successive timer time-outs without an intervening system reset result in the backup reset generator routing out the time-out signal as a reset to the system.

## 28.7 Generated resets and interrupts

The watchdog generates a reset in the following events, also referred to as exceptions:

- A watchdog time-out
- Failure to unlock the watchdog within WCT time after system reset deassertion
- No update of the control and configuration registers within the WCT window after unlocking. At least one of the following registers must be written to within the WCT window to avoid reset:
  - WDOG\_ST\_CTRL\_H, WDOG\_ST\_CTRL\_L
  - WDOG\_TO\_VAL\_H, WDOG\_TO\_VAL\_L
  - WDOG\_WIN\_H, WDOG\_WIN\_L
  - WDOG\_PRESCALER
- A value other than the unlock sequence or the refresh sequence is written to the unlock and/or refresh registers, respectively.
- A gap of more than 20 bus cycles exists between the writes of two values of the unlock sequence.
- A gap of more than 20 bus cycles exists between the writes of two values of the refresh sequence.

The watchdog can also generate an interrupt. If IRQ\_RST\_EN is set, then on the above mentioned events WDOG\_ST\_CTRL\_L[INT\_FLG] is set, generating an interrupt. A watchdog reset is also generated WCT time later to ensure the watchdog is fault tolerant. The interrupt can be cleared by writing 1 to INT\_FLG.

The gap of WCT between interrupt and reset means that the WDOG time-out value must be greater than WCT. Otherwise, if the interrupt was generated due to a time-out, a second consecutive time-out will occur in that WCT gap. This will trigger the backup reset generator to generate a reset to the system, prematurely ending the interrupt service routine execution. Also, jobs such as counting the number of watchdog resets would not be done.

## 28.8 Memory map and register definition

This section consists of the memory map and register descriptions.

### WDOG memory map

| Absolute address (hex) | Register name                                            | Width (in bits) | Access | Reset value | Section/ page               |

**WDOG\_STCTRL field descriptions**

| Field        | Description                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>INTFLG | Interrupt flag. It is set when an exception occurs. IRQRSTEN = 1 is a precondition to set this flag. INTFLG = 1 results in an interrupt being issued followed by a reset, WCT later. The interrupt can be cleared by writing 1 to this bit. It also gets cleared on a system reset. |
| Reserved     | This field is reserved.<br><br><b>NOTE:</b> Do not modify this field value.                                                                                                                                                                                                         |

**28.8.3 Watchdog Time-out Value Register High (WDOG\_TOVALH)**

Address: 4005\_2000h base + 4h offset = 4005\_2004h

|       |           |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|-----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TOVALHIGH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |           |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0         | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |

**WDOG\_TOVALH field descriptions**

| Field     | Description                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| TOVALHIGH | Defines the upper 16 bits of the 32-bit time-out value for the watchdog timer. It is defined in terms of cycles of the watchdog clock. |

**28.8.4 Watchdog Time-out Value Register Low (WDOG\_TOVALL)**

The time-out value of the watchdog must be set to a minimum of four watchdog clock cycles. This is to take into account the delay in new settings taking effect in the watchdog clock domain.

Address: 4005\_2000h base + 6h offset = 4005\_2006h

|       |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| Write |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0        | 1  | 0  | 0  | 1  | 0  | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 |

**WDOG\_TOVALL field descriptions**

| Field    | Description                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------|
| TOVALLOW | Defines the lower 16 bits of the 32-bit time-out value for the watchdog timer. It is defined in terms of cycles of the watchdog clock. |

## 28.8.5 Watchdog Window Register High (WDOG\_WINH)

### NOTE

You must set the Window Register value lower than the Time-out Value Register.

Address: 4005\_2000h base + 8h offset = 4005\_2008h

|       |         |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|---------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15      | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WINHIGH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |         |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0       | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### WDOG\_WINH field descriptions

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WINHIGH | Defines the upper 16 bits of the 32-bit window for the windowed mode of operation of the watchdog. It is defined in terms of cycles of the watchdog clock. In this mode, the watchdog can be refreshed only when the timer has reached a value greater than or equal to this window length. A refresh outside this window resets the system or if IRQRSTEN is set, it interrupts and then resets the system. |

## 28.8.6 Watchdog Window Register Low (WDOG\_WINL)

### NOTE

You must set the Window Register value lower than the Time-out Value Register.

Address: 4005\_2000h base + Ah offset = 4005\_200Ah

|       |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WINLOW |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |

### WDOG\_WINL field descriptions

| Field  | Description                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WINLOW | Defines the lower 16 bits of the 32-bit window for the windowed mode of operation of the watchdog. It is defined in terms of cycles of the pre-scaled watchdog clock. In this mode, the watchdog can be refreshed only when the timer reaches a value greater than or equal to this window length value. A refresh outside of this window resets the system or if IRQRSTEN is set, it interrupts and then resets the system. |

### 28.8.7 Watchdog Refresh register (WDOG\_REFRESH)

Address: 4005\_2000h base + Ch offset = 4005\_200Ch

|       |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WDOGREFRESH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 1           | 0  | 1  | 1  | 0  | 1  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### WDOG\_REFRESH field descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WDOGREFRESH | Watchdog refresh register. A sequence of 0xA602 followed by 0xB480 within 20 bus clock cycles written to this register refreshes the WDOG and prevents it from resetting the system. Writing a value other than the above mentioned sequence or if the sequence is longer than 20 bus cycles, resets the system, or if IRQRSTEN is set, it interrupts and then resets the system. |

### 28.8.8 Watchdog Unlock register (WDOG\_UNLOCK)

Address: 4005\_2000h base + Eh offset = 4005\_200Eh

|       |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | WDOGUNLOCK |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 1          | 1  | 0  | 1  | 1  | 0  | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 |

#### WDOG\_UNLOCK field descriptions

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WDOGUNLOCK | Writing the unlock sequence values to this register to makes the watchdog write-once registers writable again. The required unlock sequence is 0xC520 followed by 0xD928 within 20 bus clock cycles. A valid unlock sequence opens a window equal in length to the WCT within which you can update the registers. Writing a value other than the above mentioned sequence or if the sequence is longer than 20 bus cycles, resets the system or if IRQRSTEN is set, it interrupts and then resets the system. The unlock sequence is effective only if ALLOWUPDATE is set. |

### 28.8.9 Watchdog Timer Output Register High (WDOG\_TMROUTH)

Address: 4005\_2000h base + 10h offset = 4005\_2010h

|       |              |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|--------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit   | 15           | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | TIMEROUTHIGH |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |              |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0            | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### WDOG\_TMROUTH field descriptions

| Field        | Description                                                 |
|--------------|-------------------------------------------------------------|
| TIMEROUTHIGH | Shows the value of the upper 16 bits of the watchdog timer. |

### 28.8.10 Watchdog Timer Output Register Low (WDOG\_TMROUTL)

During Stop mode, the WDOG\_TIMER\_OUT will be caught at the pre-stop value of the watchdog timer. After exiting Stop mode, a maximum delay of 1 WDOG\_CLK cycle + 3 bus clock cycles will occur before the WDOG\_TIMER\_OUT starts following the watchdog timer.

Address: 4005\_2000h base + 12h offset = 4005\_2012h

| Bit   | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Read  | TIMEROUTLOW |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0           | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### WDOG\_TMROUTL field descriptions

| Field       | Description                                                 |
|-------------|-------------------------------------------------------------|
| TIMEROUTLOW | Shows the value of the lower 16 bits of the watchdog timer. |

### 28.8.11 Watchdog Reset Count register (WDOG\_RSTCNT)

Address: 4005\_2000h base + 14h offset = 4005\_2014h

| Bit   | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Read  | RSTCNT |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Write |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0      | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### WDOG\_RSTCNT field descriptions

| Field  | Description                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RSTCNT | Counts the number of times the watchdog resets the system. This register is reset only on a POR. Writing 1 to the bit to be cleared enables you to clear the contents of this register. |

### 28.8.12 Watchdog Prescaler register (WDOG\_PRESC)

Address: 4005\_2000h base + 16h offset = 4005\_2016h

| Bit   | 15 | 14 | 13 | 12 | 11 | 10       | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|----|----|----|----|----|----------|---|---|---|---|---|---|---|---|---|---|
| Read  | 0  |    |    |    |    | PRESCVAL |   |   | 0 |   |   |   |   |   |   |   |
| Write |    |    |    |    |    |          |   |   |   |   |   |   |   |   |   |   |
| Reset | 0  | 0  | 0  | 0  | 0  | 1        | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**WDOG\_PRESC field descriptions**

| Field             | Description                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                          |
| 10–8<br>PRESCVAL  | 3-bit prescaler for the watchdog clock source. A value of zero indicates no division of the input WDOG clock. The watchdog clock is divided by (PRESCVAL + 1) to provide the prescaled WDOG_CLK. |
| Reserved          | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                          |

## 28.9 Watchdog operation with 8-bit access

### 28.9.1 General guideline

When performing 8-bit accesses to the watchdog's 16-bit registers where the intention is to access both the bytes of a register, place the two 8-bit accesses one after the other in your code.

### 28.9.2 Refresh and unlock operations with 8-bit access

One exception condition that generates a reset to the system is the write of any value other than those required for a legal refresh/update sequence to the respective refresh and unlock registers.

For an 8-bit access to these registers, writing a correct value requires at least two bus clock cycles, resulting in an invalid value in the registers for one cycle. Therefore, the system is reset even if the intention is to write a correct value to the refresh/unlock register. Keeping this in mind, the exception condition for 8-bit accesses is slightly modified.

Whereas the match for a correct value for a refresh/unlock sequence is as according to the original definition, the match for an incorrect value is done byte-wise on the refresh/unlock rather than for the whole 16-bit value. This means that if the high byte of the refresh/unlock register contains any value other than high bytes of the two values that make up the sequence, it is treated as an exception condition, leading to a reset or interrupt-then-reset. The same holds true for the lower byte of the refresh or unlock register. Take the refresh operation that expects a write of 0xA602 followed by 0xB480 to the refresh register, as an example.

**Table 28-4. Refresh for 8-bit access**

|                      | WDOG_REFRESH[15:8] | WDOG_REFRESH[7:0] | Sequence value1 or value2 match     | Mismatch exception |
|----------------------|--------------------|-------------------|-------------------------------------|--------------------|
| <b>Current Value</b> | 0xB4               | 0x80              | Value2 match                        | No                 |
| <b>Write 1</b>       | 0xB4               | 0x02              | No match                            | No                 |
| <b>Write 2</b>       | 0xA6               | 0x02              | Value1 match                        | No                 |
| <b>Write 3</b>       | 0xB4               | 0x02              | No match                            | No                 |
| <b>Write 4</b>       | 0xB4               | 0x80              | Value2 match.<br>Sequence complete. | No                 |
| <b>Write 5</b>       | 0x02               | 0x80              | No match                            | Yes                |

As shown in the preceding table, the refresh register holds its reset value initially. Thereafter, two 8-bit accesses are performed on the register to write the first value of the refresh sequence. No mismatch exception is registered on the intermediate write, Write1. The sequence is completed by performing two more 8-bit accesses, writing in the second value of the sequence for a successful refresh. It must be noted that the match of value2 takes place only when the complete 16-bit value is correctly written, write4. Hence, the requirement of writing value2 of the sequence within 20 bus clock cycles of value1 is checked by measuring the gap between write2 and write4.

It is reiterated that the condition for matching values 1 and 2 of the refresh or unlock sequence remains unchanged. The difference for 8-bit accesses is that the criterion for detecting a mismatch is less strict. Any 16-bit access still needs to adhere to the original guidelines, mentioned in the sections [Refreshing the Watchdog](#).

## 28.10 Restrictions on watchdog operation

This section mentions some exceptions to the watchdog operation that may not be apparent to you.

- **Restriction on unlock/refresh operations**—In the period between the closure of the WCT window after unlock and the actual reload of the watchdog timer, unlock and refresh operations need not be attempted.
- **The update and reload of the watchdog timer** happens two to three watchdog clocks after WCT window closes, following a successful configuration on unlock.
- **Clock Switching Delay**—The watchdog uses glitch-free multiplexers at two places – one to choose between the LPO oscillator input and alternate clock input, and the other to choose between the watchdog functional clock and fast clock input for

watchdog functional test. A maximum time period of ~2 clock A cycles plus ~2 clock B cycles elapses from the time a switch is requested to the occurrence of the actual clock switch, where clock A and B are the two input clocks to the clock mux.

- For the windowed mode, there is a two to three bus clock latency between the watchdog counter going past the window value and the same registering in the bus clock domain.
- For proper operation of the watchdog, the watchdog clock must be at least five times slower than the system bus clock at all times. An exception is when the watchdog clock is synchronous to the bus clock wherein the watchdog clock can be as fast as the bus clock.
- WCT must be equivalent to at least three watchdog clock cycles. If not ensured, this means that even after the close of the WCT window, you have to wait for the synchronized system reset to deassert in the watchdog clock domain, before expecting the configuration updates to take effect.
- The time-out value of the watchdog should be set to a minimum of four watchdog clock cycles. This is to take into account the delay in new settings taking effect in the watchdog clock domain.
- You must take care not only to refresh the watchdog within the watchdog timer's actual time-out period, but also provide enough allowance for the time it takes for the refresh sequence to be detected by the watchdog timer, on the watchdog clock.
- Updates cannot be made in the bus clock cycle immediately following the write of the unlock sequence, but one bus clock cycle later.
- It should be ensured that the time-out value for the watchdog is always greater than  $2 \times \text{WCT time} + 20$  bus clock cycles.
- An attempted refresh operation, in between the two writes of the unlock sequence and in the WCT time following a successful unlock, will go undetected.
- Trying to unlock the watchdog within the WCT time after an initial unlock has no effect.
- The refresh and unlock operations and interrupt are not automatically disabled in the watchdog functional test mode.
- After emerging from a reset due to a watchdog functional test, you are still expected to go through the mandatory steps of unlocking and configuring the watchdog. The watchdog continues to be in its functional test mode and therefore you should pull the watchdog out of the functional test mode within WCT time of reset.

## Restrictions on watchdog operation

- After emerging from a reset due to a watchdog functional test, you still need to go through the mandatory steps of unlocking and configuring the watchdog.
- You must ensure that both the clock inputs to the glitchless clock multiplexers are alive during the switching of clocks. Failure to do so results in a loss of clock at their outputs.
- There is a gap of two to three watchdog clock cycles from the point that stop mode is entered to the watchdog timer actually pausing, due to synchronization. The same holds true for an exit from the stop mode, this time resulting in a two to three watchdog clock cycle delay in the timer restarting. In case the duration of the stop mode is less than one watchdog clock cycle, the watchdog timer is not guaranteed to pause.
- Consider the case when the first refresh value is written, following which the system enters stop mode with system bus clk still on. If the second refresh value is not written within 20 bus cycles of the first value, the system is reset, or interrupt-then-reset if enabled.

# Chapter 29

## Crossbar AND/OR/INVERT (AOI) Module

### 29.1 Chip-specific AOI information

#### 29.1.1 AOI signal assignment

The AOI block has 16 input signals that are connected directly to the 16 output signals of XBARB. The AOI has 4 output signals that are connected to XBARA inputs.

**Table 29-1. AOI signal assignment**

| AOI Input | Assigned Output | AOI Output      | Assigned Input |
|-----------|-----------------|-----------------|----------------|
| AOI_IN0   | XBARB_OUT0      | —               | —              |
| AOI_IN1   | XBARB_OUT1      | —               | —              |
| AOI_IN2   | XBARB_OUT2      | AND_OR_INVERT_0 | XBARA_IN46     |
| AOI_IN3   | XBARB_OUT3      | —               | —              |

## 29.2 Introduction

The AND/OR/INVERT module (known simply as the AOI module) supports the generation of a configurable number of EVENT signals. Each output EVENT<sub>n</sub> is a configurable and/or/invert function of four associated AOI inputs: A<sub>n</sub>, B<sub>n</sub>, C<sub>n</sub>, and D<sub>n</sub>.

This module is designed to be integrated in conjunction with one or more inter-peripheral crossbar switch (XBAR) modules. A crossbar switch is typically used to select the 4\*n AOI inputs from among available peripheral outputs and GPIO signals. The n EVENT<sub>n</sub> outputs from the AOI module are typically used as additional inputs to a second crossbar switch, adding to it the ability to connect to its outputs an arbitrary 4-input boolean function of its other inputs.

The AOI controller is a slave peripheral module connecting event input indicators from a variety of device modules and generating event output signals that can be routed to an inter-peripheral crossbar switch or other peripherals. Its programming model is accessed through the standard IPS (Sky Blue) slave interface. The module is designed to be very configurable in terms of the functionality of its integrated AOI functions.

### 29.2.1 Overview

The AOI module supports a configurable number of event outputs, where each event output represents a user-programmed combinational boolean function based on four event inputs. The key features of this module include:

- Four dedicated inputs for each event output
- User-programmable combinational boolean function evaluation for each event output
- Memory-mapped device connected to a slave peripheral (IPS) bus
- Configurable number of event outputs

#### NOTE

The connections from the AOI module outputs to other functions is SoC-specific.

**Figure 29-1. Simplified AOI Block Diagram**

## 29.2.2 Features

The major features of the AOI module are summarized below:

- Highly programmable module for creating combinational boolean events for use as hardware triggers
  - Each channel has four event inputs and one output
  - Evaluates a combinational boolean expression as the sum of four products where each product term includes all four selected input sources available as true or complement values
  - Event output is formed as purely combinational logic and operates as a hardware trigger
- Memory-mapped device connected to the slave peripheral (IPS) bus
  - Programming model organized per channel for simplified software

## 29.2.3 Modes of Operation

The AOI module does not support any special modes of operation. As shown in [Figure 29-1](#), its operation is primarily controlled by the selected event inputs and outputs.

Additionally, as a memory-mapped device located on the slave peripheral bus, it responds based strictly on memory address for accesses to its programming model.

The AOI module resides in the slave peripheral *bus clock domain*.

## 29.3 External Signal Description

The AOI module does not directly support any external interfaces. There may be package input signals (indirectly) connected to the module as event inputs, but since the *AOI does not include any input synchronization hardware*, this function must be handled before the event input signals are routed into the module.

## 29.4 Memory Map and Register Descriptions

The AOI module supports access to its programming model via a 16-bit peripheral bus connection. The module is designed to support 16-bit accesses only. Functionality for accesses of other widths is undefined.

The AOI module supports a specific number of event outputs. Each output EVENT<sub>n</sub> outputs a four-term AOI function of four binary inputs: An, Bn, Cn, and Dn. A pair of 16-bit registers configures this four-term AOI function: The two registers BFCRT01<sub>n</sub> and BFCRT23<sub>n</sub> define the configuration for the evaluation of the Boolean function defining EVENT<sub>n</sub>, where *n* is the event output channel number. The BFCRT01<sub>n</sub> register defines the configuration of product terms 0 and 1, and the BFCRT23<sub>n</sub> register defines the configuration of product terms 2 and 3.

The AOI module provides a universal Boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (An, Bn, Cn, Dn). Specifically, the EVENT<sub>n</sub> output is defined by the following "4 x 4" Boolean expression:

```
EVENTn
= (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 0
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 1
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 2
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 3
```

where each selected input of each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses 8 bits of configuration information, 2 bits for each of the four selected event inputs. The resulting logic provides a simple yet powerful Boolean function evaluation for defining an event output.

These AOI functions are combinational in nature and are intended to be sampled and used synchronously.

### AOI memory map

| Absolute address (hex) | Register name                                                                               | Width (in bits) | Access | Reset value | Section/ page              |
|------------------------|---------------------------------------------------------------------------------------------|-----------------|--------|-------------|----------------------------|

## 29.5 Functional Description

The AOI is a highly programmable module for creating combinational boolean outputs for use as hardware triggers. Each AOI output channel, as shown in [Figure 29-1](#), has one logic function:

- Evaluation of a combinational boolean expression as a sum of four products where each product term includes all four selected input sources available as true or complement values

A typical application of the AOI module is to be integrated with one or more inter-peripheral crossbar switch modules as illustrated in the following figure. The 20 external inputs are shared by two crossbar switch modules. The crossbar switch on the top is used to select the inputs to four 4-input AOI functions in the AOI module. The outputs of these four AOI functions are output from the AOI module and are added to the original 20 external inputs to provide a total of 24 inputs to the bottom crossbar switch. As a result, the bottom crossbar can not only direct any of the original 20 external inputs to any of its outputs, it can also now direct any one of four 4-input AOI functions of those external inputs to any of its outputs.

Figure 29-2. Integration Example of AOI with two Inter-Peripheral Crossbar Switches

### 29.5.1 Configuration Examples for the Boolean Function Evaluation

This section presents examples of the programming model configuration for simple boolean expressions.

The AOI module provides a universal boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (A, B, C, D). Specifically, the event output is defined by the following “4 x 4” boolean expression:

```
EVENTn
= (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 0
| (0, An, ~An, 1) & (0, Bn, ~Bn, 1) & (0, Cn, ~Cn, 1) & (0, Dn, ~Dn, 1) // product term 1
```

$$\begin{aligned} & | (0, A_n, \sim A_n, 1) \& (0, B_n, \sim B_n, 1) \& (0, C_n, \sim C_n, 1) \& (0, D_n, \sim D_n, 1) // \text{ product term 2} \\ & | (0, A_n, \sim A_n, 1) \& (0, B_n, \sim B_n, 1) \& (0, C_n, \sim C_n, 1) \& (0, D_n, \sim D_n, 1) // \text{ product term 3} \end{aligned}$$

where each selected input term in each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses eight bits of configuration information, two bits for each of the four selected event inputs. The actual boolean expression implemented in each channel is:

```
EVENTn
= (PT0_AC[0] & A | PT0_AC[1] & ~A) // product term 0
  & (PT0_BC[0] & B | PT0_BC[1] & ~B)
  & (PT0_CC[0] & C | PT0_CC[1] & ~C)
  & (PT0_DC[0] & D | PT0_DC[1] & ~D)

| (PT1_AC[0] & A | PT1_AC[1] & ~A) // product term 1
  & (PT1_BC[0] & B | PT1_BC[1] & ~B)
  & (PT1_CC[0] & C | PT1_CC[1] & ~C)
  & (PT1_DC[0] & D | PT1_DC[1] & ~D)

| (PT2_AC[0] & A | PT2_AC[1] & ~A) // product term 2
  & (PT2_BC[0] & B | PT2_BC[1] & ~B)
  & (PT2_CC[0] & C | PT2_CC[1] & ~C)
  & (PT2_DC[0] & D | PT2_DC[1] & ~D)

| (PT3_AC[0] & A | PT3_AC[1] & ~A) // product term 3
  & (PT3_BC[0] & B | PT3_BC[1] & ~B)
  & (PT3_CC[0] & C | PT3_CC[1] & ~C)
  & (PT3_DC[0] & D | PT3_DC[1] & ~D)
```

where the bits of the combined {BFECRT01n,BFCRT23n} registers correspond to the  $PT\{0-3\}_{A,B,C,D}C[1:0]$  terms in the equation.

Consider the settings of the combined 32-bit {BFECRT01n,BFCRT23n} registers for several simple boolean expressions as shown in [Table 29-2](#).

**Table 29-2. IEVENT\_BFECRn Values for Simple Boolean Expressions**

| Event Output Expression | PT0       | PT1    | PT2 | PT3 | {BFCRT01, BFCRT23}                  |

| A + B + C + D           | A         | B      | C   | D   | 01111111_11011111_11110111_11111101 |
| (A & ~B) + (~A & B)     | A & ~B    | ~A & B | 0   | 0   | 01101111_10011111_00000000_00000000 |

As can be seen in these examples, the resulting logic provides a simple yet powerful boolean function evaluation for defining an event output.

## 29.5.2 AOI Timing Between Inputs and Outputs

Each EVENTn output of the AOI module is a combination function of its four dedicated inputs An, Bn, Cn, and Dn. Propagation through the AOI and any associated inter-peripheral crossbar switch modules is intended to be single bus clock cycle.

# Chapter 30

## Inter-Peripheral Crossbar Switch A (XBARA)

### 30.1 Chip-specific XBARA information

See [Clock definitions](#) for clock distribution details.

#### 30.1.1 XBARA input signal assignment

Table 30-1. XBARA input assignment

| XBARA Input | Assigned Output |
|-------------|-----------------|
| XBARA_IN0   | VSS             |
| XBARA_IN1   | VDD             |
| XBARA_IN2   | XB_IN2          |
| XBARA_IN3   | XB_IN3          |
| XBARA_IN4   | XB_IN4          |

## 30.2 Introduction

### 30.2.1 Overview

This module implements an array of M N-input combinational muxes. All muxes share the same N inputs in the same order, but each mux has its own independent select field.

The intended application of this module is to provide a flexible crossbar switch function that allows any input (typically from external GPIO or internal module outputs) to be connected to any output (typically to external GPIO or internal module inputs) under user control. This is used to allow user configuration of data paths between internal modules and between internal modules and GPIO.

A subset of the muxes can be configured to support edge detection and either interrupt or DMA request generation based on detected signal edges on the mux output. This allows signal transitions on the signals feeding the crossbar to trigger interrupts or initiate data transfers via DMA into or out of other system modules.

### 30.2.2 Features

The XBAR module design includes these distinctive features:

- M identical N-input muxes with individual select fields.
- Edge detection with associated interrupt or DMA request generation for a subset of mux outputs.
- Memory mapped registers with IPBus interface for select and control fields.
- Register write protection input signal.

### 30.2.3 Modes of Operation

The XBAR module design operates in only a single mode of operation: Functional Mode. The various counting modes are detailed in [Functional Mode](#).

### 30.2.4 Block Diagram

The block diagram for XBAR is shown in [Figure 30-1](#).

Figure 30-1. XBAR Block Diagram

30.3 Signal Descriptions

The following table summarizes the module's external signals.

Table 30-3. Control Signal Properties

| Name                  | I/O Type | Function                            | Reset State | Notes |
|-----------------------|----------|-------------------------------------|-------------|-------|
| XBAR_OUT [0:NUMOUT-1] | O        | Mux Outputs with configurable width | *           |       |
| XBAR_IN [0:NUMIN-1]   | I        | Mux Inputs with configurable width  | *           |       |
| DMA_REQ               | O        | DMA request                         | 0           |       |
| INT_REQ               | O        | Interrupt request                   | 0           |       |
| DMA_ACK               | I        | DMA acknowledge                     | 0           |       |

At reset, each output XBAR\_OUT[\*] contains the reset value of the signal driving XBAR\_IN[0].

### 30.3.1 XBAR\_OUT[0:NUM\_OUT-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR\_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR\_OUT[n] = XBAR\_IN[SELn].

### 30.3.2 XBAR\_IN[0:NUM\_IN-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

### 30.3.3 DMA\_REQ[n] - DMA Request Output(s)

DMA\_REQ[n] is a DMA request to the DMA controller.

### 30.3.4 DMA\_ACK[n] - DMA Acknowledge Input(s)

DMA\_ACK[n] is a DMA acknowledge input from the DMA controller.

### 30.3.5 INT\_REQ[n] - Interrupt Request Output(s)

INT\_REQ[n] is an interrupt request output to the interrupt controller.

## 30.4 Memory Map and Register Descriptions

The XBAR module has select registers and control registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR\_IN[\*]) is muxed to each mux output (XBAR\_OUT[\*]). There is one SELn field per mux and therefore one per XBAR\_OUT output. Crossbar output XBAR\_OUT[n]

presents the value of XBAR\_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR\_IN and XBAR\_OUT are application specific and are described in the Chip Configuration details.

The XBAR control registers configure edge detection, interrupt, and DMA features for a subset of the XBAR\_OUT[\*] outputs.

### 30.4.31 Crossbar A Control Register 0 (XBARA\_CTRL0)

Use this register to configure edge detection, interrupt, and DMA features for the XBAR\_OUT0 and XBAR\_OUT1 outputs.

The XBAR\_CTRL registers are organized similarly to the XBAR\_SEL registers, with control fields for two XBAR\_OUT outputs in each register. In control register 0, the LSBs contain the control fields for XBAR\_OUT0, and the MSBs contain the control fields for XBAR\_OUT1.

Address: 4005\_9000h base + 3Ch offset = 4005\_903Ch

| Bit   | 15 | 14 | 13 | 12   | 11    | 10 | 9    | 8    |

**30.4.32 Crossbar A Control Register 1 (XBARA\_CTRL1)**

Use this register to configure edge detection, interrupt, and DMA features for the XBAR\_OUT2 and XBAR\_OUT3 outputs.

The XBAR\_CTRL registers are organized similarly to the XBAR\_SEL registers, with control fields for two XBAR\_OUT outputs in each register. In control register 1, the LSBs contain the control fields for XBAR\_OUT2, and the MSBs contain the control fields for XBAR\_OUT3.

Address: 4005\_9000h base + 3Eh offset = 4005\_903Eh

| Bit   | 15 | 14 | 13 | 12   | 11    | 10 | 9    | 8    |
|-------|----|----|----|------|-------|----|------|------|
| Read  | 0  |    |    | STS3 | EDGE3 |    | IEN3 | DEN3 |

## 30.5 Functional Description

### 30.5.1 General

The XBAR module has only one mode of operation, functional mode.

## 30.5.2 Functional Mode

The value of each mux output is  $\text{XBAR\_OUT}[n] = \text{XBAR\_IN}[\text{SELn}]$ . The SELn select values are configured in the XBAR\_SEL registers. All muxes share the same inputs in the same order.

A subset of XBAR\_OUT[\*] outputs has dedicated control fields in a Crossbar Control (XBAR\_CTRL) register. Control fields provide the ability to perform edge detection on the corresponding XBAR\_OUT output. Edge detection in turn can optionally be used to trigger an interrupt or DMA request. The intention is that, by detecting specified edges on signals propagating through the Crossbar, interrupts or DMA requests can be triggered to perform data transfers to or from other system components.

Control fields include an edge status field (STS), an detected edge type field (EDGE), and interrupt and DMA enable fields (DEN and IEN). STSn is set to 1 when an edge consistent with EDGEN occurs on XBAR\_OUT[n]. STSn is cleared by writing 1 to it. Writing 0 as no effect. See [Interrupts and DMA Requests](#) for details on the use of STSn for DMA and interrupt request generation.

## 30.6 Resets

The XBAR module can be reset by only a hard reset, which forces all registers to their reset state.

## 30.7 Clocks

All sequential functionality is controlled by the Bus Clock.

## 30.8 Interrupts and DMA Requests

For each XBAR\_OUT[\*] output with XBAR\_CTRL register support, DMA or interrupt functionality can be enabled by setting the corresponding XBAR\_CTRL register bit DENn or IENn to 1. DENn and IENn should not be set to 1 at the same time for the same output XBAR\_OUT[n].

Setting DEN<sub>n</sub> to 1 enables DMA functionality for XBAR\_OUT[n]. When DMA functionality is enabled, the output DMA\_REQ[n] reflects the value of STS<sub>n</sub>. Thus the DMA request asserts when the edge specified by EDGE<sub>n</sub> is detected on XBAR\_OUT[n]. Also, a rising edge on DMA\_ACK[n] sets STS<sub>n</sub> to zero and thus clears the DMA request. When DEN is 0, DMA\_REQ[n] is held low and DMA\_ACK[n] is ignored.

Setting IEN<sub>n</sub> to 1 enables interrupt functionality for XBAR\_OUT[n]. When interrupt functionality is enabled, the output INT\_REQ[n] reflects the value of STS<sub>n</sub>. Thus the interrupt request asserts when the edge specified by EDGE<sub>n</sub> is detected on XBAR\_OUT[n]. The interrupt request is cleared by writing a 1 to STS<sub>n</sub>. When IEN<sub>n</sub> is 0, INT\_REQ[n] is held low.

DEN<sub>n</sub> and IEN<sub>n</sub> should not be set to 1 at the same time for the same output XBAR\_OUT[n].

# Chapter 31

## Inter-Peripheral Crossbar Switch B (XBARB)

### 31.1 Chip-specific XBARB information

See [Clock definitions](#) for clock distribution details.

#### 31.1.1 XBARB signal input assignment

Table 31-1. XBARB signal input assignment

| XBARB Input | Assigned Output                 |
|-------------|---------------------------------|
| XBARB_IN0   | CMP0_OUT                        |
| XBARB_IN1   | CMP1_OUT                        |
| XBARB_IN2   | CMP2_OUT                        |
| XBARB_IN3   | CMP3_OUT                        |
| XBARB_IN4   | FTM0_CH_alITRIG                 |
| XBARB_IN5   | FTM0_INIT                       |
| XBARB_IN6   | FTM3_CH_alITRIG                 |
| XBARB_IN7   | FTM3_INIT                       |
| XBARB_IN8   | PWM0_OUT_TRIG00/PWM0_OUT_TRIG01 |
| XBARB_IN9   | PWM0_OUT_TRIG10/PWM0_OUT_TRIG11 |
| XBARB_IN10  | PWM0_OUT_TRIG20/PWM0_OUT_TRIG21 |
| XBARB_IN11  | PWM0_OUT_TRIG30/PWM0_OUT_TRIG31 |
