| MONPLL           | <p>Monitor PLL State</p> <p>These bits are used to control disabling of the fractional delay block when the chip PLL is unlocked and/or missing its input reference. The fractional delay block requires a continuous MHz clock from the PLL. If this clock turns off when the fractional delay block is being used, then the output of the fractional delay block can be stuck high or low even if the PLL restarts. When this control bit is set, PLL problems cause the fractional delay block to be disabled until the PLL returns to a locked state. Once the PLL is receiving a proper reference and is locked, the fractional delay block requires a 25 µs startup time just as if the FRCTRL[FRAC*_EN] bits had been turned off and turned on again.</p> <p>If PLL monitoring is disabled, then software should manually clear and then set the FRCTRL[FRAC*_EN] bits when the PLL loses its reference or loses lock. This will cause the fractional delay block to be disabled and restarted.</p> <p>If the fractional delay block is not being used, then the value of these bits do not matter.</p> <p>00 Not locked. Do not monitor PLL operation. Resetting of the fractional delay block in case of PLL losing lock will be controlled by software.</p> <p>01 Not locked. Monitor PLL operation to automatically disable the fractional delay block when the PLL encounters problems.</p> <p>10 Locked. Do not monitor PLL operation. Resetting of the fractional delay block in case of PLL losing lock will be controlled by software. These bits are write protected until the next reset.</p> <p>11 Locked. Monitor PLL operation to automatically disable the fractional delay block when the PLL encounters problems. These bits are write protected until the next reset.</p> |

**48.4.49 Fault Control Register (PWMx\_FCTRLn)**

For every 4-bit field in this register, the bits act on the fault inputs in order. For example, FLVL bits 15-12 act on faults 3-0, respectively.

Address: Base address + 18Ch offset + (5d × i), where i=0d to 0d

| FFLAG          | <p>Fault Flags</p> <p>These read-only flag is set within two CPU cycles after a transition to active on the FAULTx pin. Clear this bit by writing a logic one to it. A reset clears this field. While the reset value is 0, these bits may be set to 1 by the time they can be read depending on the state of the fault input signals.</p> <p>0 No fault on the FAULTx pin.<br/>1 Fault on the FAULTx pin.</p>                                                                                                                                                                                                                                |

## 48.4.51 Fault Filter Register (PWMx\_FFILTn)

The settings in this register are shared among each of the fault input filters within the fault channel.

Input filter considerations include:

- The FILT\_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT\_CNT value should be chosen to reduce the probability of noisy samples

causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the  $FILT\_CNT+3$  power.

- The values of  $FILT\_PER$  and  $FILT\_CNT$  must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting  $FILT\_PER$  to a non-zero value) introduces a latency of  $((FILT\_CNT+4) \times FILT\_PER \times IPBus \text{ clock period})$ . Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This is to ensure rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set  $FSTS[FFLAG]$  and  $FSTS[FFPIN]$ .

|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault. |
| 0     | There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs.                                                                                                                             |
| 1     | The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.                                                                                                                                        |

## 48.5 Functional Description

### 48.5.1 PWM Capabilities

This section describes some capabilities of the PWM module.

#### 48.5.1.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in [Figure 48-3](#).

**Figure 48-3. Center Aligned Example**

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

[Figure 48-3](#) also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center

alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

### 48.5.1.2 Edge Aligned PWMs

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as the following figure shows. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

**Figure 48-4. Edge Aligned Example (INIT=VAL2=VAL4)**

With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn off edge value and the voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

### 48.5.1.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases are applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as the following figure shows. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

**Figure 48-5. Phase Shifted Outputs Example**

An additional benefit of phase shifted PWMs appears in [Figure 48-6](#). In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching

requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

**Figure 48-6. Phase Shifted PWMs Applied to a Transformer Primary**

### 48.5.1.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method support two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWM\_A in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (force out logic) as the following figure shows. The DBLPWM signal can be run through the deadtime insertion logic.

Figure 48-7. Double Switching Output Example

### 48.5.1.5 ADC Triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. [Figure 48-8](#) shows how this is accomplished. When specifying

complementary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators are free to perform other functions. In this example, the software does not need to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

**Figure 48-8. Multiple Output Trigger Generation in Hardware**

Because each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. [Figure 48-9](#) shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower-frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In [Figure 48-9](#), *all* submodule comparators are shown being used for ADC trigger generation.

**Figure 48-9. Multiple Output Triggers Over Several PWM Cycles**

#### 48.5.1.6 Enhanced Capture Capabilities (E-Capture)

When a PWM pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

**Figure 48-10. Capture Capabilities of the E-Capture Circuit**

When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example, PWM\_X) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. Consider the following figure as an example. In this application the output of a PWM power stage is connected to the PWM\_X pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVAL0 register value from the CVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays. For details, refer to the separate discussion of deadtime distortion correction.

During deadtime, load inductance drives voltage with polarity that keeps inductive current flowing through diodes.

**Figure 48-11. Output Pulse Width Measurement Possible with the E-Capture Circuit**

#### 48.5.1.7 Synchronous Switching of Multiple Outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. Not only do all the changes occur synchronously on all submodule outputs, but they occur **IMMEDIATELY** after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called **FORCE\_OUT**. This signal originates from the local **FORCE** bit within the submodule, from submodule0, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next **FORCE\_OUT** event. This selection lays dormant until the **FORCE\_OUT** signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

## 48.5.2 Functional Details

This section describes the implementation of various sections of the PWM in greater detail.

The following figure is a high-level block diagram of output PWM generation.

Figure 48-12. High-Level Output PWM Generation Block Diagram

### 48.5.2.1 PWM Clocking

Figure 48-13 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT\_CLK, and AUX\_CLK. The EXT\_CLK goes to all of the submodules. The AUX\_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8-bit prescaler and MCTRL0[RUN] from submodule0 can control all of the submodules.

Figure 48-13. Clocking Block Diagram for Each PWM Submodule

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1-128. The prescaler bits, CTRL[PRSC], select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until MCTRL0[LDOK] is set and a new PWM reload cycle begins or CTRL[LDMOD] is set.

### 48.5.2.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using CTRL[LDFQ] and CTRL[FULL]. A half cycle reload option is also supported (CTRL[HALF]) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As illustrated in [Figure 48-14](#) the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

**Figure 48-14. Register Reload Logic**

### 48.5.2.3 Counter Synchronization

In the following figure, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.

**Figure 48-15. Submodule Timer Synchronization**

The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The PWM\_EXT\_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE\_OUT signal assuming that CTRL2[FRCEN] is set. As indicated by the preceding figure, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal.

#### 48.5.2.4 PWM Generation

Figure 48-16 illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register are used to control the turn-on edge, while a second comparator and VALx register control the turn-off edge.

### Figure 48-16. PWM Generation Hardware

The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a falling edge of the Local Sync signal, comparator 1 generates a rising edge. Comparator 1 is also hardwired to the reload logic to generate the full cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or

counter initialization, they can be used to modulate the duty cycle of the Local Sync signal, effectively turning it into an auxiliary PWM signal (PWM\_X) assuming that the PWM\_X pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating three PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The 16-bit comparators shown in [Figure 48-16](#) In addition, if both the set and reset of the flip-flop are asserted, then the flop output goes to 0.

### 48.5.2.5 Output Compare Capabilities

By using the VALx registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

In PWM generation, an output compare is initiated by programming a VALx register for a timer compare, which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWM\_A signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWM\_A signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

### 48.5.2.6 Force Out Logic

For each submodule, software can select between eight signal sources for the FORCE\_OUT signal: local CTRL2[FORCE], the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, the EXT\_SYNC signal from on- or off-chip, or the EXT\_FORCE signal from on- or off-chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master, EXT\_SYNC, or EXT\_FORCE signals should be selected.

Figure 48-17 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the PWM\_EXT\_A or PWM\_EXT\_B alternate external control signals. The selection can be determined ahead of time and, when a FORCE\_OUT event occurs, these values are presented to the signal selection mux that immediately switches the requested signal to the output of the mux for further processing downstream.

Figure 48-17. Force Out Logic

The local CTRL2[FORCE] signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the CTRL2[FORCE] of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT\_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

### 48.5.2.7 Independent or Complementary Channel Operation

Writing a logic one to CTRL2[INDEP] configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to CTRL2[INDEP] configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in [Figure 48-18](#) in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by MCTRL0[IPOL].

**Figure 48-18. Complementary Channel Pair**

Complementary operation allows the use of the deadtime insertion feature.

### 48.5.2.8 Deadtime Insertion Logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

**Figure 48-19. Deadtime Insertion Logic**

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

### Note

To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. But the transistor's characteristics may make its switching-off time longer than switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in the following figure.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

Figure 48-20. Deadtime Insertion

#### 48.5.2.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See the following figure.

**Figure 48-21. Deadtime Distortion**

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the . This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the current for that pair, as the preceding figure shows. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWMX, for that driver
- The state of the odd/even correction bit, MCTRL0[IPOL], for that driver

To correct deadtime distortion, software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

#### 48.5.2.8.2 Manual Correction

To detect the current status, the voltage on each PWMX pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in CTRL[DT]. CTRL[DT] is a timing marker especially indicating when to toggle between PWM value registers. Software can then set MCTRL0[IPOL] to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to CTRL[DT] values.

**Figure 48-22. Current-status Sense Scheme for Deadtime Correction**

Both D flip-flops latch low, CTRL[DT] = 00, during deadtime periods if current is large and flowing out of the complementary circuit. See the preceding figure. Both D flip-flops latch the high, CTRL[DT] = 11, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results will be CTRL[DT] = b10. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

**Figure 48-23. Output Voltage Waveforms**

### 48.5.2.9 Fractional Delay Logic

For applications where more resolution than a single IPBus clock period is needed, the fractional delay logic can be used to achieve fine resolution on the rising and falling edges of the PWM\_A and PWM\_B outputs and fine resolution for the PWM period. Enable the use of the fractional delay logic by setting FRCTRL[FRACx\_EN]. The FRACVALx registers act as a fractional clock cycle addition to the turn on and turn off count specified by the VAL2, VAL3, VAL4, or VAL5 registers. The FRACVAL1 register acts as a fractional increase in the PWM period as defined by VAL1. If FRACVAL1 is programmed to a non-zero value, then the largest value for the VAL1 register is 0xFFFFE for unsigned usage or 0x7FFE for signed usage. This limit is needed in order to avoid counter rollovers when accumulating the fractional additional period.

The results of the fractional delay logic depend on whether or not the PWM submodule has an analog nano-edge placer block available.

### 48.5.2.9.1 Fractional Delay Logic with Nano-Edge Placement Block

Using the micro-edge placer block requires that the Fast-Peripheral clock be set within a valid frequency range (see the data sheet of this device for minimum and maximum values) and the core/system clock must be programmed to be 2x the Fast Peripheral clock. The nano-edge placer is powered up by setting `FRCTRL[FRAC_PU]`. Enable fine edge control on the various PWM edges by setting `FRCTRL[FRACx_EN]`. The fractional values in the `FRACVALx` registers allow placing the PWM edge or PWM period to a granularity of 1/32 of the IPBus clock period. For example, if you desire the rising edge of the PWMA output to occur at a count of 12.25, then program `VAL2` with 0x000C and `FRACVAL2` with 0x4000. Using `FRACVAL1` will adjust the PWM period with the same granularity of 1/32 of a clock period.

If the `FRCTRL[FRAC_PU]` bits in all of the submodules are clear, then the nano-edge placer is powered down, and alternate clock frequencies can be used without the nano-edge placement feature.

### 48.5.2.9.2 Fractional Delay Logic without Nano-Edge Placement Block

For submodules that are not supported by the nano-edge placer, the PWM can use dithering to simulate fine edge control. Enable this feature by setting the `FRCTRL[FRAC1_EN]`, `FRCTRL[FRAC23_EN]`, and `FRCTRL[FRAC45_EN]` bits. It is unnecessary to set `FRCTRL[FRAC_PU]`. The PWM period or the PWM edges will dither from the nearest whole number values to achieve an average value that is equivalent to the programmed fractional value. The added cycles are based on the accumulation of the fractional component. For example, if you want the PWM period to be 50.25 clock cycles, then program `VAL1` with 0x0032 and `FRACVAL1` with 0x4000. The PWM period will be 50 cycles long most of the time, but will occasionally be 51 cycles long to achieve a long-term average of 50.25 cycles.

In submodules that are not supported by a nano-edge placer, the clock frequency is not required to be any specific value to achieve proper operation.

### 48.5.2.10 Output Logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic (refer to the figure) are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic

between the pin and the transistor. Therefore, it is imperative that the user program OCTRL[POLA] and OCTRL[POLB] before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the OCTRL[PWMxFS] fields.

**Figure 48-24. Output Logic**

#### 48.5.2.11 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure is a block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8 bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8 bit value that is specified by the user (EDGCMPlx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. this feature is useful for

dividing down high frequency signals for capture processing so that capture interrupts don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt after "n" events have been counted.

**Figure 48-25. Enhanced Capture (E-Capture) Logic**

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by CAPTCTRLx[EDGx1] and CAPTCTRLx[EDGx0], whose functionality is listed in the preceding figure. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

### 48.5.2.12 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via FCTRL[FLVL]. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of OCTRL[PWMxFS].

The fault decoder disables PWM pins selected by the fault logic and the disable mapping (DISMAPn) registers. The following figure shows an example of the fault disable logic. Each bank of bits in DISMAPn control the mapping for a single PWM pin. See the following table.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.

Figure 48-26. Fault Decoder for PWM\_A

Table 48-2. Fault Mapping

| PWM Pin | Controlling Register Bits |
|---------|---------------------------|
| PWM_A   | DISMAP0[DIS0A]            |
| PWM_B   | DISMAP0[DIS0B]            |
| PWM_X   | DISMAP0[DIS0X]            |

#### 48.5.2.12.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with `FFILT[FILT_PER]`. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using `FFILT[FILT_CNT]`. Setting `FFILT[FILT_PER]` to all 0 disables the input filter for a given `FAULTx` pin.

Upon detecting a logic 0 on the filtered `FAULTx` pin (or a logic 1 if `FCTRL[FLVLx]` is set), the corresponding `FSTS[FFPINx]` and fault flag, `FSTS[FFLAGx]`, bits are set. `FSTS[FFPINx]` remains set as long as the filtered `FAULTx` pin is zero. Clear `FSTS[FFLAGx]` by writing a logic 1 to `FSTS[FFLAGx]`.

If the `FIEx`, `FAULTx` pin interrupt enable bit is set, `FSTS[FFLAGx]` generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears `FSTS[FFLAGx]` by writing a logic one to the bit
- Software clears the `FIEx` bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the `FAULTx` inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

#### 48.5.2.12.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, `FCTRL[FAUTOx]`, configures faults from the `FAULTx` pin for automatic clearing.

When `FCTRL[FAUTOx]` is set, disabled PWM pins are enabled when the `FAULTx` pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If `FSTS[FFULLx]` is set, then the disabled PWM pins are enabled at the start of a full cycle. If `FSTS[FHALFx]` is set, then the disabled PWM pins are enabled at the start of a half cycle. Clearing `FSTS[FFLAGx]` does not affect disabled PWM pins when `FCTRL[FAUTOx]` is set.

Figure 48-27. Automatic Fault Clearing

### 48.5.2.12.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits, FCTRL[FSAFEx], are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See the first following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.
- If the fault safety mode bits, FCTRL[FSAFEx], are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The filter detects a logic one on the FAULTx pin at the start of the next PWM full or half cycle boundary. See the second following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

**Figure 48-28. Manual Fault Clearing (FCTRL[FSAFE]=0)**

**Figure 48-29. Manual Fault Clearing (FCTRL[FSAFE]=1)**

### Note

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or PWM\_EXT\_A and PWM\_EXT\_B. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, MCTRL0[RUN] equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, MCTRL0[RUN] equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

#### 48.5.2.12.4 Fault Testing

FTST[FTEST] is used to simulate a fault condition on each of the fault inputs within that fault channel.

### 48.5.3 PWM Generator Loading

### 48.5.3.1 Load Enable

MCTRL0[LDOK] enables loading of the following PWM generator parameters:

- The prescaler divisor—from CTRL[PRSC]
- The PWM period and pulse width—from the INIT and VALx registers

MCTRL0[LDOK] allows software to finish calculating all of these PWM parameters so they can be synchronously updated. The CTRL[PRSC], INIT, and VALx registers are loaded by software into a set of outer buffers. When MCTRL0[LDOK] is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transferred to the inner set of registers immediately upon setting MCTRL0[LDOK] if CTRL[LDMOD] is set. Set MCTRL0[LDOK] by reading it when it is a logic zero and then writing a logic one to it. After loading, MCTRL0[LDOK] is automatically cleared.

### 48.5.3.2 Load Frequency

CTRL[LDFQ] selects an integral loading frequency of one to 16 PWM reload opportunities. CTRL[LDFQ] takes effect at every PWM reload opportunity, regardless the state of MCTRL0[LDOK]. CTRL[HALF] and CTRL[FULL] control reload timing. If CTRL[FULL] is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If CTRL[HALF] is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both CTRL[HALF] and CTRL[FULL] are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

**Figure 48-30. Full Cycle Reload Frequency Change**

**Figure 48-31. Half Cycle Reload Frequency Change**

**Figure 48-32. Full and Half Cycle Reload Frequency Change**

### 48.5.3.3 Reload Flag

At every reload opportunity the PWM Reload Flag (STS[RF]) is set. Setting STS[RF] happens even if an actual reload is prevented by MCTRL0[LDOK]. If the PWM reload interrupt enable bit, INTEN[RIE], is set, the STS[RF] flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When INTEN[RIE] is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

**Figure 48-33. PWMF Reload Interrupt Request**

### 48.5.3.4 Reload Errors

Whenever one of the VALx, FRACVALx, or CTRL[PRSC] registers is updated, the STS[RUF] flag is set to indicate that the data is not coherent. STS[RUF] will be cleared by a successful reload which consists of the reload signal while MCTRL0[LDOK] is set. If STS[RUF] is set and MCTRL0[LDOK] is clear when the reload signal occurs, a reload error has taken place and STS[REF] is set. If STS[RUF] is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

### 48.5.3.5 Initialization

Initialize all registers and set MCTRL0[LDOK] before setting MCTRL0[RUN].

#### Note

Even if MCTRL0[LDOK] is not set, setting MCTRL0[RUN] also sets the STS[RF] flag. To prevent a CPU interrupt request, clear INTEN[RIE] before setting MCTRL0[RUN].

The PWM generator uses the last values loaded if MCTRL0[RUN] is cleared and then set while MCTRL0[LDOK] equals zero.

When MCTRL0[RUN] is cleared:

- The STS[RF] flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

## 48.6 Resets

All PWM registers are reset to their default values upon any system reset.

The reset forces all registers to their reset states and tri-states the PWM outputs.

## 48.7 Interrupts

Each of the submodules within the eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

**Table 48-3. Interrupt Summary**

| Core Interrupt | Interrupt Flag                                                                                    | Interrupt Enable                                                                                                          | Name                                | Description                      |
|----------------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|-------------------------------------|----------------------------------|
| PWM_CMP0       | SM0STS[CMPIE]                                                                                     | SM0INTEN[CMPIE]                                                                                                           | Submodule 0 compare interrupt       | Compare event has occurred       |
| PWM_CAP0       | SM0STS[CFA1],<br>SM0STS[CFA0],<br>SM0STS[CFB1],<br>SM0STS[CFB0],<br>SM0STS[CFX1],<br>SM0STS[CFX0] | SM0INTEN[CFA1IE],<br>SM0INTEN[CFA0IE],<br>SM0INTEN[CFB1IE],<br>SM0INTEN[CFB0IE],<br>SM0INTEN[CFX1IE],<br>SM0INTEN[CFX0IE] | Submodule 0 input capture interrupt | Input capture event has occurred |
| PWM_RELOAD0    | SM0STS[RF]                                                                                        | SM0INTEN[RIE]                                                                                                             | Submodule 0 reload interrupt        | Reload event has occurred        |
| PWM_CMP1       | SM1STS[CMPIE]                                                                                     | SM1INTEN[CMPIE]                                                                                                           | Submodule 1 compare interrupt       | Compare event has occurred       |

## 48.8 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered VALx registers.

**Table 48-4. DMA Summary**

| DMA Request              | DMA Enable       | Name                                        | Description                                   |
|--------------------------|------------------|---------------------------------------------|-----------------------------------------------|
| Submodule 0 read request | SM0DMAEN[CX0DE]  | SM0 Capture FIFO X0 read request            | SM0CVAL0 contains a value to be read          |
|                          | SM0DMAEN[CX1DE]  | SM0 Capture FIFO X1 read request            | SM0CVAL1 contains a value to be read          |
|                          | SM0DMAEN[CA0DE]  | SM0 Capture FIFO A0 read request            | SM0CVAL2 contains a value to be read          |
|                          | SM0DMAEN[CA1DE]  | SM0 Capture FIFO A1 read request            | SM0CVAL3 contains a value to be read          |
|                          | SM0DMAEN[CB0DE]  | SM0 Capture FIFO B0 read request            | SM0CVAL4 contains a value to be read          |
|                          | SM0DMAEN[CB1DE]  | SM0 Capture FIFO B1 read request            | SM0CVAL5 contains a value to be read          |
|                          | SM0DMAEN[CAPTDE] | SM0 Capture FIFO read request source select | Selects source of submodule0 read DMA request |

Table continues on the next page...

**Table 48-4. DMA Summary (continued)**

| DMA Request               | DMA Enable       | Name                                        | Description                                   |
|---------------------------|------------------|---------------------------------------------|-----------------------------------------------|
| Submodule 0 write request | SM0DMAEN[VALDE]  | SM0VALx write request                       | SM0VALx registers need to be updated          |
| Submodule 1 read request  | SM1DMAEN[CX0DE]  | SM1 Capture FIFO X0 read request            | SM1CVAL0 contains a value to be read          |
|                           | SM1DMAEN[CX1DE]  | SM1 Capture FIFO X1 read request            | SM1CVAL1 contains a value to be read          |
|                           | SM1DMAEN[CA0DE]  | SM1 Capture FIFO A0 read request            | SM1CVAL2 contains a value to be read          |
|                           | SM1DMAEN[CA1DE]  | SM1 Capture FIFO A1 read request            | SM1CVAL3 contains a value to be read          |
|                           | SM1DMAEN[CB0DE]  | SM1 Capture FIFO B0 read request            | SM1CVAL4 contains a value to be read          |
|                           | SM1DMAEN[CB1DE]  | SM1 Capture FIFO B1 read request            | SM1CVAL5 contains a value to be read          |
|                           | SM1DMAEN[CAPTDE] | SM1 Capture FIFO read request source select | Selects source of submodule1 read DMA request |
| Submodule 1 write request | SM1DMAEN[VALDE]  | SM1VALx write request                       | SM1VALx registers need to be updated          |
| Submodule 2 read request  | SM2DMAEN[CX0DE]  | SM2 Capture FIFO X0 read request            | SM2CVAL0 contains a value to be read          |
|                           | SM2DMAEN[CX1DE]  | SM2 Capture FIFO X1 read request            | SM2CVAL1 contains a value to be read          |
|                           | SM2DMAEN[CA0DE]  | SM2 Capture FIFO A0 read request            | SM2CVAL2 contains a value to be read          |
|                           | SM2DMAEN[CA1DE]  | SM2 Capture FIFO A1 read request            | SM2CVAL3 contains a value to be read          |
|                           | SM2DMAEN[CB0DE]  | SM2 Capture FIFO B0 read request            | SM2CVAL4 contains a value to be read          |
|                           | SM2DMAEN[CB1DE]  | SM2 Capture FIFO B1 read request            | SM2CVAL5 contains a value to be read          |
|                           | SM2DMAEN[CAPTDE] | SM2 Capture FIFO read request source select | Selects source of submodule2 read DMA request |
| Submodule 2 write request | SM2DMAEN[VALDE]  | SM2VALx write request                       | SM2VALx registers need to be updated          |
| Submodule 3 read request  | SM3DMAEN[CX0DE]  | SM3 Capture FIFO X0 read request            | SM3CVAL0 contains a value to be read          |
|                           | SM3DMAEN[CX1DE]  | SM3 Capture FIFO X1 read request            | SM3CVAL1 contains a value to be read          |
|                           | SM3DMAEN[CA0DE]  | SM3 Capture FIFO A0 read request            | SM3CVAL2 contains a value to be read          |
|                           | SM3DMAEN[CA1DE]  | SM3 Capture FIFO A1 read request            | SM3CVAL3 contains a value to be read          |
|                           | SM3DMAEN[CB0DE]  | SM3 Capture FIFO B0 read request            | SM3CVAL4 contains a value to be read          |

# Chapter 49

## Periodic Interrupt Timer (PIT)

### 49.1 Chip-specific PIT information

#### 49.1.1 PIT Instantiations

This device contains one PIT module with four channels.

#### 49.1.2 PIT/DMA Periodic Trigger Assignments

The PIT generates periodic trigger events to the DMA Mux as shown in the table below.

**Table 49-1. PIT channel assignments for periodic DMA triggering**

| DMA Channel Number | PIT Channel   |
|--------------------|---------------|
| DMA Channel 0      | PIT Channel 0 |
| DMA Channel 1      | PIT Channel 1 |
| DMA Channel 2      | PIT Channel 2 |
| DMA Channel 3      | PIT Channel 3 |

#### 49.1.3 PIT/ADC Triggers

PIT triggers are selected as ADCx trigger sources using the SIM\_SOPT7[ADCxTRGSEL] fields. For more details, refer to SIM chapter.

### 49.1.4 PIT Trigger Output Assignments

The PIT timer channels are used to trigger other peripheral events such as ADC acquisitions or DMA transfers. On this device the following assignments have been made for each of the PIT channels.

PIT channel 0 output - XBARA\_IN42, XBARB\_IN24

PIT channel 1 output - XBARA\_IN43 , XBARB\_IN25

PIT channel 2 output - XBARA\_IN50

PIT channel 3 output - XBARA\_IN51

Routing the PIT channel outputs via XBARA/B provide options to periodically trigger events on other peripherals such as ADC, CMPs, Timers.

## 49.2 Introduction

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

### 49.2.1 Block diagram

The following figure shows the block diagram of the PIT module.

**Figure 49-1. Block diagram of the PIT**

### NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

## 49.2.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

## 49.3 Signal description

The PIT module has no external pins.

## 49.4 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.

**PIT memory map**

| Absolute address (hex) | Register name                                   | Width (in bits) | Access | Reset value | Section/ page               |

### 49.4.1 PIT Module Control Register (PIT\_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

Address: 4003\_7000h base + 0h offset = 4003\_7000h

**PIT\_MCR field descriptions**

| Field            | Description                                                                                                                                                                                                                       |

## 49.4.2 PIT Upper Lifetime Timer Register (PIT\_LTMR64H)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 4003\_7000h base + E0h offset = 4003\_70E0h

**PIT\_LTMR64H field descriptions**

| Field | Description                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| LTH   | Life Timer value<br><br>Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1. |

## 49.4.3 PIT Lower Lifetime Timer Register (PIT\_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 4003\_7000h base + E4h offset = 4003\_70E4h

**PIT\_LTMR64L field descriptions**

| Field | Description      |
|-------|------------------|
| LTL   | Life Timer value |

## PIT\_LTMR64L field descriptions (continued)

| Field | Description                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------|
|       | Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read. |

## 49.4.4 Timer Load Value Register (PIT\_LDVALn)

These registers select the timeout period for the timer interrupts.

Access: User read/write

Address: 4003\_7000h base + 100h offset + (16d × i), where i=0d to 3d

|       |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

## PIT\_LDVALn field descriptions

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TSV   | <p>Timer Start Value</p> <p>Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.</p> |

## 49.4.5 Current Timer Value Register (PIT\_CVALn)

These registers indicate the current timer position.

Access: User read only

Address: 4003\_7000h base + 104h offset + (16d × i), where i=0d to 3d

|       |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

## 49.5 Functional description

This section provides the functional description of the module.

### 49.5.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

#### 49.5.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

**Figure 49-2. Stopping and starting a timer**

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

**Figure 49-3. Modifying running timer period**

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

**Figure 49-4. Dynamically setting a new load value**

### 49.5.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

### 49.5.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

### 49.5.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

## 49.6 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.
- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every  $5.12 \text{ ms} / 20 \text{ ns} = 256,000$  cycles and Timer 3 every  $30 \text{ ms} / 20 \text{ ns} = 1,500,000$  cycles. The value for the LDVAL register trigger is calculated as:

$\text{LDVAL trigger} = (\text{period} / \text{clock period}) - 1$

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

## 49.7 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

## 49.8 Example configuration for the lifetime timer

To configure the lifetime timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

## **Chapter 50**

# **Serial Peripheral Interface (SPI)**

## **50.1 Chip-specific SPI information**

### **50.1.1 SPI instantiation information**

This chip contains three SPI modules. Each has RX and TX FIFO depth of 4 and the width for each entry is 4-byte, as well as DMA support.

### **50.1.2 SPI clocking**

The SPI module is clocked by the fast peripheral clock (the SPI refers to it as system clock). The module has an internal divider, with a minimum divide of two. So, the SPI can run at a maximum frequency of fast peripheral clock/2.

### **50.1.3 Number of CTARs**

SPI CTAR registers define different transfer attribute configurations. The SPI module supports up to eight CTAR registers. This device supports two CTARs on the instances of the SPI.

In master mode, the CTAR registers define combinations of transfer attributes, such as frame size, clock phase, clock polarity, data bit ordering, baud rate, and various delays. In slave mode only CTAR0 is used, and a subset of its bitfields sets the slave transfer attributes.

## 50.1.4 TX FIFO size

**Table 50-1. SPI transmit FIFO size**

| SPI Module | Transmit FIFO size |
|------------|--------------------|
| SPI0       | 4                  |
| SPI1       | 4                  |
| SPI2       | 4                  |

## 50.1.5 RX FIFO Size

SPI supports up to 16-bit frame size during reception.

**Table 50-2. SPI receive FIFO size**

| SPI Module | Receive FIFO size |
|------------|-------------------|
| SPI0       | 4                 |
| SPI1       | 4                 |
| SPI2       | 4                 |

## 50.1.6 Number of PCS signals

The following table shows the number of peripheral chip select signals available per SPI module.

**Table 50-3. SPI PCS signals**

| SPI Module | PCS Signals  |
|------------|--------------|
| SPI0       | SPI_PCS[5:0] |
| SPI1       | SPI_PCS[3:0] |
| SPI2       | SPI_PCS[1:0] |

## 50.1.7 SPI Operation in Low Power Modes

In VLPR and VLPW modes the SPI is functional; however, the reduced system frequency also reduces the max frequency of operation for the SPI. In VLPR and VLPW modes the max SPI\_CLK frequency is 2MHz.

In stop and VLPS modes, the clocks to the SPI module are disabled. The module is not functional, but it is powered so that it retains state.

There is one way to wake from stop mode via the SPI, which is explained in the following section.

### 50.1.7.1 Using GPIO Interrupt to Wake from stop mode

Here are the steps to use a GPIO to create a wakeup upon reception of SPI data in slave mode:

1. Point the GPIO interrupt vector to the desired interrupt handler.
2. Enable the GPIO input to generate an interrupt on either the rising or falling edge (depending on the polarity of the chip select signal).
3. Enter Stop or VLPS mode and Wait for the GPIO interrupt.

#### NOTE

It is likely that in using this approach the first word of data from the SPI host might not be received correctly. This is dependent on the transfer rate used for the SPI, the delay between chip select assertion and presentation of data, and the system interrupt latency.

### 50.1.8 SPI Doze Mode

The Doze mode for the SPI module is the same as the Wait and VLPW modes for the chip.

### 50.1.9 SPI Interrupts

The SPI has multiple sources of interrupt requests. However, these sources are OR'd together to generate a single interrupt request per SPI module to the interrupt controller. When an SPI interrupt occurs, read the SPI\_SR to determine the exact interrupt source.

### 50.1.10 SPI clocks

This table shows the SPI module clocks and the corresponding chip clocks.

**Table 50-4. SPI clock connections**

| Module clock | Chip clock |
|--------------|------------|
| System Clock | Bus Clock  |

### 50.1.11 Writing SPI Transmit FIFO

In Master mode, only 32-bit write accesses are supported for the PUSH register, the top TX FIFO entry. In Slave mode, 8-bit, 16-bit and 32-bit write accesses are supported for the PUSH register, although each write increments the write pointer.

## 50.2 Introduction

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device.

### 50.2.1 Block Diagram

The block diagram of this module is as follows:

Figure 50-1. SPI Block Diagram

## 50.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - two transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 16
    - SPI frames longer than 16 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
- 6 peripheral chip selects (PCSeS), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSeS) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:

- End of Queue reached (EOQF)
- TX FIFO is not full (TFFF)
- Transfer of current frame complete (TCF)
- Attempt to transmit with an empty Transmit FIFO (TFUF)
- RX FIFO is not empty (RFDF)
- Frame received while Receive FIFO is full (RFOF)
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
  - Support for Stop mode
  - Support for Doze mode

### **50.2.3 Interface configurations**

#### **50.2.3.1 SPI configuration**

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

**Figure 50-2. SPI with queues and DMA**

## 50.2.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- Chip-specific modes:
  - External Stop mode
  - Debug mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

### 50.2.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK

- SOUT
- PCS[x]

#### **50.2.4.2 Slave Mode**

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{SS}$  signals are configured as inputs and driven by an SPI bus master.

#### **50.2.4.3 Module Disable Mode**

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

#### **50.2.4.4 External Stop Mode**

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

#### **50.2.4.5 Debug Mode**

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the chip is in debug mode.
- If the bit is cleared, the chip debug mode has no effect on the module.

### **50.3 Module signal descriptions**

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

**Table 50-5. Module signal descriptions**

| Signal                  | Master mode                                             | Slave mode       | I/O |
|-------------------------|---------------------------------------------------------|------------------|-----|
| PCS0/ $\overline{SS}$   | Peripheral Chip Select 0 (O)                            | Slave Select (I) | I/O |
| PCS[1:3]                | Peripheral Chip Selects 1–3                             | (Unused)         | O   |
| PCS4                    | Peripheral Chip Select 4                                | (Unused)         | O   |
| PCS5/ $\overline{PCSS}$ | Peripheral Chip Select 5 /Peripheral Chip Select Strobe | (Unused)         | O   |
| SCK                     | Serial Clock (O)                                        | Serial Clock (I) | I/O |
| SIN                     | Serial Data In                                          | Serial Data In   | I   |
| SOUT                    | Serial Data Out                                         | Serial Data Out  | O   |

### 50.3.1 PCS0/ $\overline{SS}$ —Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

#### NOTE

Do not tie the SPI slave select pin to ground. Otherwise, SPI cannot function properly.

### 50.3.2 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 50.3.3 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 50.3.4 PCS5/ $\overline{\text{PCSS}}$ —Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

### 50.3.5 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

### 50.3.6 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

### 50.3.7 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

## 50.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

## SPI memory map

| Absolute address (hex) | Register name                                                             | Width (in bits) | Access | Reset value | Section/ page                |
|------------------------|---------------------------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 4002_C000              | Module Configuration Register (SPI0_MCR)                                  | 32              | R/W    | 0000_4001h  | <a href="#">50.4.1/1429</a>  |
| 4002_C008              | Transfer Count Register (SPI0_TCR)                                        | 32              | R/W    | 0000_0000h  | <a href="#">50.4.2/1432</a>  |
| 4002_C00C              | Clock and Transfer Attributes Register (In Master Mode) (SPI0_CTAR0)      | 32              | R/W    | 7800_0000h  | <a href="#">50.4.3/1433</a>  |

## 50.4.1 Module Configuration Register (SPIx\_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: Base address + 0h offset

**50.4.2 Transfer Count Register (SPIx\_TCR)**

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

**50.4.3 Clock and Transfer Attributes Register (In Master Mode) (SPIx\_CTARn)**

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

When the module is configured as a SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

Address: Base address + Ch offset + (4d × i), where i=0d to 1d

| 31<br>DBR | Double Baud Rate<br><br>Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock |

| 30–27<br>FMSZ | <p>Frame Size</p> <p>The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     |                |     |                |   |     |     |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |
| 26<br>CPOL    | <p>Clock Polarity</p> <p>Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge.</p> <p><b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.</p> <p>0 The inactive state value of SCK is low.<br/>1 The inactive state value of SCK is high.</p>                                                                                                                                                                                                           |     |                |     |                |   |     |     |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |
| 25<br>CPHA    | <p>Clock Phase</p> <p>Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.</p> <p>0 Data is captured on the leading edge of SCK and changed on the following edge.<br/>1 Data is changed on the leading edge of SCK and captured on the following edge.</p>                                                                                                                                                                                                                                                                                                                                                                                          |     |                |     |                |   |     |     |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |
| 24<br>LSBFE   | <p>LSB First</p> <p>Specifies whether the LSB or MSB of the frame is transferred first.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |     |                |     |                |   |     |     |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |

| 23–22<br>PCSSCK | PCS to SCK Delay Prescaler<br><br>Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer <a href="#">PCS to SCK Delay (<math>t_{CSC}</math>)</a> for more details.<br><br>00 PCS to SCK Prescaler value is 1.<br>01 PCS to SCK Prescaler value is 3.<br>10 PCS to SCK Prescaler value is 5.<br>11 PCS to SCK Prescaler value is 7.                                                                                                                                                          |
| 21–20<br>PASC   | After SCK Delay Prescaler<br><br>Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. Refer <a href="#">After SCK Delay (<math>t_{ASC}</math>)</a> for more details.<br><br>00 Delay after Transfer Prescaler value is 1.<br>01 Delay after Transfer Prescaler value is 3.<br>10 Delay after Transfer Prescaler value is 5.<br>11 Delay after Transfer Prescaler value is 7.                                                                                                                         |
| 19–18<br>PDT    | Delay after Transfer Prescaler<br><br>Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer <a href="#">Delay after Transfer (<math>t_{DT}</math>)</a> for more details.<br><br>00 Delay after Transfer Prescaler value is 1.<br>01 Delay after Transfer Prescaler value is 3.<br>10 Delay after Transfer Prescaler value is 5.<br>11 Delay after Transfer Prescaler value is 7. |
| 17–16<br>PBR    | Baud Rate Prescaler<br><br>Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate.<br><br>00 Baud Rate Prescaler value is 2.<br>01 Baud Rate Prescaler value is 3.<br>10 Baud Rate Prescaler value is 5.<br>11 Baud Rate Prescaler value is 7.                                                                                                                                  |
| 15–12<br>CSSCK  | PCS to SCK Delay Scaler<br><br>Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation:<br>$t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$<br>The following table lists the delay scaler values.                                                                                                                                                                                        |

| 11–8<br>ASC | <p>After SCK Delay Scaler</p> <p>Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation:</p> <p><math>t_{ASC} = (1/f_P) \times PASC \times ASC</math></p> <p>See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer <a href="#">After SCK Delay (t<sub>ASC</sub> )</a> for more details.</p>                                                                                                                     |                    |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |      |      |      |       |      |       |      |       |
| 7–4<br>DT   | <p>Delay After Transfer Scaler</p> <p>Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame.</p> <p>In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation:</p> <p><math>t_{DT} = (1/f_P) \times PDT \times DT</math></p> <p>See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values.</p> |                    |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |      |      |      |       |      |       |      |       |
| BR          | <p>Baud Rate Scaler</p> <p>Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation:</p>                                                                                                                                                                                                                                                                                                                                                                                                         |                    |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |      |      |      |       |      |       |      |       |

## 50.4.4 Clock and Transfer Attributes Register (In Slave Mode) (SPIx\_CTARn\_SLAVE)

When the module is configured as an SPI bus slave, the CTAR0 register is used.

Address: Base address + Ch offset + (0d × i), where i=0d to 0d

**50.4.5 Status Register (SPIx\_SR)**

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: Base address + 2Ch offset

| 19<br>RFOF       | Receive FIFO Overflow Flag<br><br>Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it.<br><br>0 No Rx FIFO overflow.<br>1 Rx FIFO overflow has occurred.                                      |
| 18<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                           |
| 17<br>RFDF       | Receive FIFO Drain Flag<br><br>Provides a method for the module to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty.<br><br>0 RX FIFO is empty.<br>1 RX FIFO is not empty. |
| 16<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                           |
| 15–12<br>TXCTR   | TX FIFO Counter<br><br>Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.                                                                                     |
| 11–8<br>TXNXTPTR | Transmit Next Pointer<br><br>Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.                                                                                                                                      |
| 7–4<br>RXCTR     | RX FIFO Counter<br><br>Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.                                                                                                                      |
| POPNXTPTR        | Pop Next Pointer<br><br>Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.                                                                                                                                                                                             |

## 50.4.6 DMA/Interrupt Request Select and Enable Register (SPIx\_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

**50.4.7 PUSH TX FIFO Register In Master Mode (SPIx\_PUSHR)**

Specifies data to be transferred to the TX FIFO. An 8- or 16-bit write access transfers all 32 bits to the TX FIFO. In Master mode, the register transfers 16 bits of data and 16 bits of command information. A read access of PUSHR returns the topmost TX FIFO entry.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: Base address + 34h offset

## 50.4.9 POP RX FIFO Register (SPIx\_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: Base address + 38h offset

SPIx\_RXFRn field descriptions (continued)

| Field | Description |
|-------|-------------|
|-------|-------------|

50.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module has the following configuration

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPIx\_MCR is 0b00.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See [Clock and Transfer Attributes Register \(In Master Mode\) \(SPI\\_CTARn\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

Figure 50-3. Serial protocol overview

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The SPI configuration shares transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

### 50.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

## 50.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

### 50.5.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(SPI\\_PUSHR\)](#) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

### 50.5.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

### 50.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS\_TXF] bit disables the TX FIFO, and setting the MCR[DIS\_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO is disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

### 50.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 4 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

#### 50.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO by writing to the PUSHHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller

indicates that a write to PUSHHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

#### 50.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR\_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

#### 50.5.2.5 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

### 50.5.2.5.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

### 50.5.2.5.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX\_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

## 50.5.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

**Figure 50-4. Communications clock prescalers and scalers**

### 50.5.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

**Table 50-9. Baud rate computation example**

| $f_p$   | PBR  | Prescaler | BR     | Scaler | DBR | Baud rate |
|---------|------|-----------|--------|--------|-----|-----------|
| 100 MHz | 0b00 | 2         | 0b0000 | 2      | 0   | 25 Mb/s   |
| 20 MHz  | 0b00 | 2         | 0b0000 | 2      | 1   | 10 Mb/s   |

#### NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 50.5.3.2 PCS to SCK Delay ( $t_{csc}$ )

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 50-6](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR<sub>x</sub> registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

**Table 50-10. PCS to SCK delay computation example**

| $f_{sys}$ | PCSSCK | Prescaler | CSSCK  | Scaler | PCS to SCK Delay |
|-----------|--------|-----------|--------|--------|------------------|
| 100 MHz   | 0b01   | 3         | 0b0100 | 32     | 0.96 $\mu$ s     |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 50.5.3.3 After SCK Delay ( $t_{ASC}$ )

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 50-6](#) and [Figure 50-7](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR<sub>x</sub> registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

**Table 50-11. After SCK Delay computation example**

| $f_p$   | PASC | Prescaler | ASC    | Scaler | After SCK Delay |
|---------|------|-----------|--------|--------|-----------------|
| 100 MHz | 0b01 | 3         | 0b0100 | 32     | 0.96 $\mu$ s    |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 50.5.3.4 Delay after Transfer ( $t_{DT}$ )

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 50-6](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR<sub>x</sub> registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

**Table 50-12. Delay after Transfer computation example**

| $f_p$   | PDT  | Prescaler | DT     | Scaler | Delay after Transfer |
|---------|------|-----------|--------|--------|----------------------|
| 100 MHz | 0b01 | 3         | 0b1110 | 32768  | 0.98 ms              |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the  $t_{DT}$  delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

### 50.5.3.5 Peripheral Chip Select Strobe Enable ( $\overline{\text{PCSS}}$ )

The  $\overline{\text{PCSS}}$  signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR,  $\overline{\text{PCSS}}$  provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the  $\overline{\text{PCSS}}$  signal relative to PCS signals.

**Figure 50-5. Peripheral Chip Select Strobe timing**

The delay between the assertion of the PCS signals and the assertion of  $\overline{\text{PCSS}}$  is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between  $\overline{\text{PCSS}}$  negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the  $t_{\text{pcssck}}$  delay.

**Table 50-13. Peripheral Chip Select Strobe Assert computation example**

| $f_{\text{P}}$ | PCSSCK | Prescaler | Delay before Transfer |
|----------------|--------|-----------|-----------------------|
| 100 MHz        | 0b11   | 7         | 70.0 ns               |

The following table shows an example of how to compute the  $t_{\text{pasc}}$  delay.

**Table 50-14. Peripheral Chip Select Strobe Negate computation example**

| $f_{\text{P}}$ | PASC | Prescaler | Delay after Transfer |
|----------------|------|-----------|----------------------|
| 100 MHz        | 0b11 | 7         | 70.0 ns              |

The  $\overline{\text{PCSS}}$  signal is not supported when Continuous Serial Communication SCK mode is enabled.

**NOTE**

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

**50.5.4 Transfer formats**

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

### 50.5.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

**Figure 50-6. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)**

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the  $t_{CSC}$  delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signals. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 50.5.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

**Figure 50-7. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)**

The master initiates the transfer by asserting the PCS signal to the slave. After the  $t_{CSC}$  delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signal. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 50.5.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI\_MCR[SMPL\_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL\_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- $T_{csc}$  - PCS to SCK assertion delay
- $T_{acs}$  - After SCK PCS negation delay
- $T_{su_{ms}}$  - master SIN setup time
- $T_{hd_{ms}}$  - master SIN hold time
- $T_{vd_{sl}}$  - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$  - data setup time on slave data input
- $T_{hd_{sl}}$  - data hold time on slave data input
- $T_{sys}$  - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and  $F_{sys}/F_{sck} = 4$ . Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

### Note

In the following diagrams,  $f_{\text{sys}}$  represents the protocol clock frequency from which the Baud frequency  $f_{\text{sck}}$  is derived.

**Figure 50-8. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{\text{sck}} = f_{\text{sys}}/4$ )**

Figure 50-9. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/2$ )

Figure 50-10. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/3$ )

#### 50.5.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT

signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

### NOTE

When MTFE=1 with continuous SCK enabled (MCR [CONT\_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSH[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked.

Figure 50-11. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/2$ )

Figure 50-12. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/3$ )

Figure 50-13. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/4$ )

#### 50.5.4.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

**Figure 50-14. Example of non-continuous format (CPHA=1, CONT=0)**

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers ( $t_{DT}$ ) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

**Figure 50-15. Example of continuous transfer (CPHA=1, CONT=1)**

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX\_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

### **NOTE**

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

## **50.5.5 Continuous Serial Communications Clock**

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT\_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT\_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer ( $t_{DT}$ ) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

### NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR\_TXF] field before initiating transfer.

**Figure 50-16. Continuous SCK Timing Diagram (CONT=0)**

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

**Figure 50-17. Continuous SCK timing diagram (CONT=1)**

### 50.5.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the  $\overline{SS}$  signal is asserted and any time when transmit data is ready and  $\overline{SS}$  signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the  $\overline{SS}$  negates before that last SCK edge, the data from shift register is lost.

### 50.5.7 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

**Table 50-15. Interrupt and DMA request conditions**

| Condition          | Flag | Interrupt | DMA |
|--------------------|------|-----------|-----|
| End of Queue (EOQ) | EOQF | Yes       | -   |
| TX FIFO Fill       | TFFF | Yes       | Yes |
| Transfer Complete  | TCF  | Yes       | -   |
| TX FIFO Underflow  | TFUF | Yes       | -   |

*Table continues on the next page...*

**Table 50-15. Interrupt and DMA request conditions (continued)**

| Condition        | Flag | Interrupt | DMA |
|------------------|------|-----------|-----|
| RX FIFO Drain    | RFDF | Yes       | Yes |
| RX FIFO Overflow | RFOF | Yes       | -   |

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

### 50.5.7.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF\_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

### 50.5.7.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF\_RE bit in the RSER is set. The TFFF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

#### NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

### 50.5.7.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF\_RE bit is set in the RSER.

### 50.5.7.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF\_RE bit in the RSER is set, an interrupt request is generated.

### 50.5.7.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF\_RE bit in the RSER is set. The RFDF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

### 50.5.7.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF\_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

## 50.5.8 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

### 50.5.8.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

### 50.5.8.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS\_TXF and DIS\_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

## 50.6 Initialization/application information

This section describes how to initialize the module.

### 50.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO by writing a 1 to the CLR\_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR\_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI\_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

### 50.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR\_TXF and CLR\_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

### 50.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

### 50.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

#### NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

**Table 50-16. Baud rate values (bps)**

|                         |      | Baud rate divider prescaler values |       |       |       |
|-------------------------|------|------------------------------------|-------|-------|-------|
|                         |      | 2                                  | 3     | 5     | 7     |
| Baud Rate Scaler Values | 2    | 25.0M                              | 16.7M | 10.0M | 7.14M |
|                         | 4    | 12.5M                              | 8.33M | 5.00M | 3.57M |
|                         | 6    | 8.33M                              | 5.56M | 3.33M | 2.38M |
|                         | 8    | 6.25M                              | 4.17M | 2.50M | 1.79M |
|                         | 16   | 3.12M                              | 2.08M | 1.25M | 893k  |
|                         | 32   | 1.56M                              | 1.04M | 625k  | 446k  |
|                         | 64   | 781k                               | 521k  | 312k  | 223k  |
|                         | 128  | 391k                               | 260k  | 156k  | 112k  |
|                         | 256  | 195k                               | 130k  | 78.1k | 55.8k |
|                         | 512  | 97.7k                              | 65.1k | 39.1k | 27.9k |
|                         | 1024 | 48.8k                              | 32.6k | 19.5k | 14.0k |
|                         | 2048 | 24.4k                              | 16.3k | 9.77k | 6.98k |

*Table continues on the next page...*

**Table 50-16. Baud rate values (bps) (continued)**

|  |       | Baud rate divider prescaler values |       |       |       |
|--|-------|------------------------------------|-------|-------|-------|
|  |       | 2                                  | 3     | 5     | 7     |
|  | 4096  | 12.2k                              | 8.14k | 4.88k | 3.49k |
|  | 8192  | 6.10k                              | 4.07k | 2.44k | 1.74k |
|  | 16384 | 3.05k                              | 2.04k | 1.22k | 872   |
|  | 32768 | 1.53k                              | 1.02k | 610   | 436   |

### 50.6.5 Delay settings

The following table shows the values for the Delay after Transfer ( $t_{DT}$ ) and CS to SCK Delay ( $T_{CSC}$ ) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

#### NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

**Table 50-17. Delay values**

|                     |       | Delay prescaler values |               |               |               |
|---------------------|-------|------------------------|---------------|---------------|---------------|
|                     |       | 1                      | 3             | 5             | 7             |
| Delay scaler values | 2     | 20.0 ns                | 60.0 ns       | 100.0 ns      | 140.0 ns      |
|                     | 4     | 40.0 ns                | 120.0 ns      | 200.0 ns      | 280.0 ns      |
|                     | 8     | 80.0 ns                | 240.0 ns      | 400.0 ns      | 560.0 ns      |
|                     | 16    | 160.0 ns               | 480.0 ns      | 800.0 ns      | 1.1 $\mu$ s   |
|                     | 32    | 320.0 ns               | 960.0 ns      | 1.6 $\mu$ s   | 2.2 $\mu$ s   |
|                     | 64    | 640.0 ns               | 1.9 $\mu$ s   | 3.2 $\mu$ s   | 4.5 $\mu$ s   |
|                     | 128   | 1.3 $\mu$ s            | 3.8 $\mu$ s   | 6.4 $\mu$ s   | 9.0 $\mu$ s   |
|                     | 256   | 2.6 $\mu$ s            | 7.7 $\mu$ s   | 12.8 $\mu$ s  | 17.9 $\mu$ s  |
|                     | 512   | 5.1 $\mu$ s            | 15.4 $\mu$ s  | 25.6 $\mu$ s  | 35.8 $\mu$ s  |
|                     | 1024  | 10.2 $\mu$ s           | 30.7 $\mu$ s  | 51.2 $\mu$ s  | 71.7 $\mu$ s  |
|                     | 2048  | 20.5 $\mu$ s           | 61.4 $\mu$ s  | 102.4 $\mu$ s | 143.4 $\mu$ s |
|                     | 4096  | 41.0 $\mu$ s           | 122.9 $\mu$ s | 204.8 $\mu$ s | 286.7 $\mu$ s |
|                     | 8192  | 81.9 $\mu$ s           | 245.8 $\mu$ s | 409.6 $\mu$ s | 573.4 $\mu$ s |
|                     | 16384 | 163.8 $\mu$ s          | 491.5 $\mu$ s | 819.2 $\mu$ s | 1.1 ms        |
|                     | 32768 | 327.7 $\mu$ s          | 983.0 $\mu$ s | 1.6 ms        | 2.3 ms        |
|                     | 65536 | 655.4 $\mu$ s          | 2.0 ms        | 3.3 ms        | 4.6 ms        |

### 50.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 50-18. TX FIFO pointers and counter

#### 50.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBASE} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXTPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

### 50.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

# Chapter 51

## 10/100-Mbps Ethernet MAC (ENET)

### 51.1 Chip-specific ENET information

#### 51.1.1 Ethernet Clocking Options

The Ethernet module uses the following clocks:

- The device's system clock is connected to the module clock, as named in the [Ethernet chapter](#). The minimum system clock frequency for 100 Mbps operation is
- An externally-supplied 25 MHz MII clock or 50 MHz RMII clock. This clock is used as the timing reference for the external MII or RMII interface.
- A time-stamping clock for the IEEE 1588 timers.

For more details on the Ethernet module clocking options, see [Ethernet Clocking](#).

#### 51.1.2 RMII Clocking

On this device, RMII\_REF\_CLK is internally tied to EXTAL. See [Clock Distribution](#) for clocking requirements.

#### 51.1.3 IEEE 1588 Timers

The ethernet module includes a four channel timer module for IEEE 1588 timestamping. The timer supports input capture (rising, falling, or both edges), output compare (toggle or pulse with programmable polarity). The timer matches on greater than or equal (the 1588 can skip numbers, so the counter might not ever exactly match the compare value).

The counter is able to operate asynchronously to the ethernet bus by using one of four clock sources. See [Ethernet Clocking](#) for more details.

### 51.1.4 Ethernet Operation in Low Power Modes

The Ethernet module is not fully operational in any low power modes. However, the module does support magic packet detection that can generate a wakeup in stop mode if enabled.

During low power operation:

- The MAC transmit logic is disabled
- The core FIFO receive/transmit functions are disabled
- The MAC receive logic is kept in normal mode, but it ignores all traffic from the line except magic packets.

The receive logic needed for magic packet detection is clocked using the externally-supplied MII or RMII clock. This allows for the wakeup functionality in stop mode. No Ethernet operation, including magic packet wakeup, is supported in VLPx modes.

#### 51.1.4.1 IEEE 1588 Timer Operation in Low Power Modes

The 1588 counter and 1588 timer channels can continue operating in low power modes provided their clock is enabled in that mode.

The 1588 timer channels can also generate an interrupt to exit the low power mode if the clock is enabled in that mode.

### 51.1.5 Ethernet Doze Mode

The doze mode for the Ethernet module is the same as the wait and VLPW modes for the chip.

### 51.1.6 Ethernet Interrupts

The Ethernet has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate an interrupt request. See below for a summary:

| Interrupt request         | Interrupt source                                                                                         |
|---------------------------|----------------------------------------------------------------------------------------------------------|
| IEEE 1588 timer interrupt | <ul style="list-style-type: none"> <li>• Time stamp available</li> <li>• 1588 timer interrupt</li> </ul> |

*Table continues on the next page...*

| Interrupt request                 | Interrupt source                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transmit interrupt                | <ul style="list-style-type: none"> <li>• Transmit frame interrupt</li> <li>• Transmit buffer interrupt</li> </ul>                                                                                                                                                                                                                          |
| Receive interrupt                 | <ul style="list-style-type: none"> <li>• Receive frame interrupt</li> <li>• Receive buffer interrupt</li> </ul>                                                                                                                                                                                                                            |
| Error and miscellaneous interrupt | <ul style="list-style-type: none"> <li>• Wake-up</li> <li>• Payload receive error</li> <li>• Babbling receive error</li> <li>• Babbling transmit error</li> <li>• Graceful stop complete</li> <li>• MII interrupt – Data transfer done</li> <li>• Ethernet bus error</li> <li>• Late collision</li> <li>• Collision retry limit</li> </ul> |

### 51.1.7 Ethernet event signal

The event signal output is not supported on this device. Therefore, ATCR[PINPER] has no effect.

## 51.2 Introduction

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

## 51.3 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

### 51.3.1 Features

The MAC-NET core includes the following features.

#### 51.3.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable

- Pause frame generation additionally controllable by user application offering flexible traffic flow control
- Optional forwarding of received pause frames to the user application
- Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors

### 51.3.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive

- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

### **51.3.1.3 IEEE 1588 features**

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

## 51.4 External signal description

### NOTE

The MII column pertains only to devices that support MII.

| MII     | RMII | Description                                                                                                                                         | I/O |
|---------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII_COL | —    | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.          | I   |
| MII_CRS | —    | Carrier sense. When asserted, indicates transmit or receive medium is not idle.<br><br>In RMII mode, this signal is present on the RMII_CRS_DV pin. | I   |

## External signal description

| MII          | RMII          | Description                                                                                                                                                                                                                                                                                                       | I/O |
|--------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII_MDC      | RMII_MDC      | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.                                                                                                                                                                                                                        | O   |
| MII_MDIO     | RMII_MDIO     | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.                                                                                                                                                          | I/O |
| MII_RXCLK    | —             | In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.                                                                                                                                                                                                                                            | I   |
| MII_RXDV     | RMII_CRS_DV   | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. | I   |
| MII_RXD[3:0] | RMII_RXD[1:0] | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.                                                                                                                                                                                                   | I   |
| MII_RXER     | RMII_RXER     | When asserted with RXDV, indicates the PHY detects an error in the current frame.                                                                                                                                                                                                                                 | I   |
| MII_TXCLK    | —             | Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.                                                                                                                                                                                                                                      | I   |
| MII_TXD[3:0] | RMII_TXD[1:0] | Serial output Ethernet data. Only valid during TXEN assertion.                                                                                                                                                                                                                                                    | O   |
| MII_TXEN     | RMII_TXEN     | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.                                                                                                                | O   |
| MII_TXER     | —             | When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.                                                                                                                                                                                                    | O   |

Table continues on the next page...

| MII                   | RMII                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | I/O |

| —                     | RMII_REF_CLK          | In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | I   |
| 1588_TMR <sub>n</sub> | 1588_TMR <sub>n</sub> | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<sub>n</sub> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<sub>n</sub> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<sub>n</sub>.</p> <p>An interrupt can be triggered if ENET_TCSR<sub>n</sub>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<sub>n</sub>[TDRE] is set.</p> | I/O |
| ENET_1588_CLKIN       | ENET_1588_CLKIN       | Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | I   |

## 51.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 51-1. Register map summary**

| Offset Address  | Section               | Description                                            |
|-----------------|-----------------------|--------------------------------------------------------|
| 0x0000 – 0x01FF | Configuration         | Core control and status registers                      |
| 0x0200 – 0x03FF | Statistics counters   | MIB and Remote Network Monitoring (RFC 2819) registers |
| 0x0400 – 0x0430 | 1588 control          | 1588 adjustable timer (TSM) and 1588 frame control     |
| 0x0600 – 0x07FC | Capture/Compare block | Registers for the Capture/Compare block                |

## ENET memory map

| Absolute address (hex) | Register name                                              | Width (in bits) | Access | Reset value | Section/ page                |
|------------------------|------------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 400C_0004              | Interrupt Event Register (ENET_EIR)                        | 32              | w1c    | 0000_0000h  | <a href="#">51.5.1/1490</a>  |

**51.5.1 Interrupt Event Register (ENET\_EIR)**

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

**NOTE**

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 400C\_0000h base + 4h offset = 400C\_0004h

**ENET\_EIR field descriptions (continued)**

| Field             | Description                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24<br>RXB         | Receive Buffer Interrupt<br><br>Indicates a receive buffer descriptor is not the last in the frame has been updated.                                                                                                                                                                                       |
| 23<br>MII         | MII Interrupt.<br><br>Indicates that the MII has completed the data transfer requested.                                                                                                                                                                                                                    |
| 22<br>EBERR       | Ethernet Bus Error<br><br>Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation. |
| 21<br>LC          | Late Collision<br><br>Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.                                                                                                          |
| 20<br>RL          | Collision Retry Limit<br><br>Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.                                         |
| 19<br>UN          | Transmit FIFO Underrun<br><br>Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.                                                                                                 |
| 18<br>PLR         | Payload Receive Error<br><br>Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.                                                                                                                                    |
| 17<br>WAKEUP      | Node Wakeup Request Indication<br><br>Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.                                                                                                                                                        |
| 16<br>TS_AVAIL    | Transmit Timestamp Available<br><br>Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.                                                                                                                                                                 |
| 15<br>TS_TIMER    | Timestamp Timer<br><br>The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].                                  |

## 51.5.2 Interrupt Mask Register (ENET\_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 400C\_0000h base + 8h offset = 400C\_0008h

### 51.5.3 Receive Descriptor Active Register (ENET\_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 400C\_0000h base + 10h offset = 400C\_0010h

### 51.5.4 Transmit Descriptor Active Register (ENET\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 400C\_0000h base + 14h offset = 400C\_0014h

**51.5.5 Ethernet Control Register (ENET\_ECR)**

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 400C\_0000h base + 24h offset = 400C\_0024h

**51.5.6 MII Management Frame Register (ENET\_MMFR)**

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

**51.5.7 MII Speed Control Register (ENET\_MSCR)**

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of IPS bus clock frequency.

**Table 51-2. Programming Examples for MSCR**

| Internal module clock frequency | MSCR [MII_SPEED] | MDC frequency |
|---------------------------------|------------------|---------------|
| 25 MHz                          | 0x4              | 2.50 MHz      |
| 33 MHz                          | 0x6              | 2.36 MHz      |
| 40 MHz                          | 0x7              | 2.50 MHz      |

*Table continues on the next page...*

**Table 51-2. Programming Examples for MSCR (continued)**

| Internal module clock frequency | MSCR [MII_SPEED] | MDC frequency |
|---------------------------------|------------------|---------------|
| 50 MHz                          | 0x9              | 2.50 MHz      |
| 66 MHz                          | 0xD              | 2.36 MHz      |

| 0<br>GTS       | <p>Graceful Transmit Stop</p> <p>When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.</p> |

51.5.11 Physical Address Lower Register (ENET\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 400C\_0000h base + E4h offset = 400C\_00E4h

ENET\_PALR field descriptions

| Field  | Description                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PADDR1 | Pause Address<br><br>Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames. |

51.5.12 Physical Address Upper Register (ENET\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 400C\_0000h base + E8h offset = 400C\_00E8h

### 51.5.13 Opcode/Pause Duration Register (ENET\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

### 51.5.14 Descriptor Individual Upper Address Register (ENET\_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 400C\_0000h base + 118h offset = 400C\_0118h

| GADDR2 | Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0. |

### 51.5.18 Transmit FIFO Watermark Register (ENET\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to '0', the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to '1'. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

## Memory map/register definition

Address: 400C\_0000h base + 144h offset = 400C\_0144h

## 51.5.19 Receive Descriptor Ring Start Register (ENET\_RDSR)

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

### NOTE

This register must be initialized prior to operation

Address: 400C\_0000h base + 180h offset = 400C\_0180h

|       |             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**51.5.20 Transmit Buffer Descriptor Ring Start Register (ENET\_TDSR)**

TDSR provides a pointer to the beginning of the circular transmit buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

**NOTE**

This register must be initialized prior to operation.

Address: 400C\_0000h base + 184h offset = 400C\_0184h

**51.5.21 Maximum Receive Buffer Size Register (ENET\_MRBR)**

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- R\_BUF\_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX\_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, the lower four bits are set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

**NOTE**

This register must be initialized before operation.

Address: 400C\_0000h base + 188h offset = 400C\_0188h

| RX_ALMOST_EMPTY  | <p>Value Of The Receive FIFO Almost Empty Threshold</p> <p>Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.</p> |

## 51.5.25 Receive FIFO Almost Full Threshold (ENET\_RAFL)

|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set. |

| TX_ALMOST_FULL   | <p>Value Of The Transmit FIFO Almost Full Threshold</p> <p>Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).</p> <p>When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information.</p> <p><b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.</p> |

## 51.5.29 Transmit Inter-Packet Gap (ENET\_TIPG)

#### ENET\_FTRL field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–14<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                          |
| TRUNC_FL          | Frame Truncation Length<br><br>Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].<br><br><b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit. |

### 51.5.31 Transmit Accelerator Function Configuration (ENET\_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 400C\_0000h base + 1C0h offset = 400C\_01C0h

|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COUNT | Number of octets for frames received without error<br><br><b>NOTE:</b> Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR). |

## 51.5.87 Adjustable Timer Control Register (ENET\_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

Address: 400C\_0000h base + 400h offset = 400C\_0400h

## ENET\_ATCR field descriptions (continued)

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9<br>RESTART  | <p>Reset Timer</p> <p>Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.</p> <p><b>NOTE:</b> The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.</p> |

### ENET\_ATPER field descriptions

| Field  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PERIOD | Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 ( $1 \times 10^9$ ) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. |

**ENET\_ATPER field descriptions (continued)**

| Field | Description                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <b>NOTE:</b> The value of PERIOD has the following constraint:<br>$2^{32} - \text{ENET\_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET\_ATINC}[\text{INC}] \geq \text{PERIOD} > 0.$ |

|       | <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p> |

## 51.6 Functional description

This section provides a complete functional description of the MAC-NET core.

### 51.6.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

Figure 51-2. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

Figure 51-3. VLAN-tagged MAC frame format overview

Table 51-3. MAC frame definition

| Term                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame length                   | Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.                                                                                                                                                                                                                                                                                                                                                                 |
| Payload length                 | <div>The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first.<ul style="list-style-type: none"><li>If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li><li>If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li></ul></div> |
| Destination and source address | 48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .                                                                                                                                                                                                                                                                                                                                                 |

## Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

### 51.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 51-4. Pause Frame Format (Values in Hex)**

|                |    |    |    |    |    |      |     |                               |    |    |    |          |    |
|----------------|----|----|----|----|----|------|-----|-------------------------------|----|----|----|----------|----|
| 1              | 2  | 3  | 4  | 5  | 6  | 7    | 8   | 9                             | 10 | 11 | 12 | 13       | 14 |
| 55             | 55 | 55 | 55 | 55 | 55 | 55   | D5  | 01                            | 80 | C2 | 00 | 00       | 01 |
| Preamble       |    |    |    |    |    |      | SFD | Multicast Destination Address |    |    |    |          |    |
| 15             | 16 | 17 | 18 | 19 | 20 | 21   | 22  | 23                            | 24 | 25 | 26 | 27 –68   |    |
| 00             | 00 | 00 | 00 | 00 | 00 | 88   | 08  | 00                            | 01 | hi | lo | 00       |    |
| Source Address |    |    |    |    |    | Type |     | Opcode                        |    | P1 | P2 | pad (42) |    |
| 69             | 70 | 71 | 72 |    |    |      |     |                               |    |    |    |          |    |
| 26             | 6B | AE | 0A |    |    |      |     |                               |    |    |    |          |    |
| CRC-32         |    |    |    |    |    |      |     |                               |    |    |    |          |    |

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

### 51.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

## 51.6.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 51.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 51-5. Ethernet type value examples**

| Type   | Description                                                              |
|--------|--------------------------------------------------------------------------|
| 0x8100 | VLAN-tagged frame. The actual type is found 4 octets later in the frame. |
| 0x0800 | IPv4                                                                     |
| 0x0806 | ARP                                                                      |
| 0x86DD | IPv6                                                                     |

### 51.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 51-6. IPv4 header format**

|                     |    |    |    |     |    |    |    |          |    |    |    |       |    |    |    |                 |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|-----|----|----|----|----------|----|----|----|-------|----|----|----|-----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27  | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19    | 18 | 17 | 16 | 15              | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Version             |    |    |    | IHL |    |    |    | TOS      |    |    |    |       |    |    |    | Length          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Fragment ID         |    |    |    |     |    |    |    |          |    |    |    | Flags |    |    |    | Fragment offset |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| TTL                 |    |    |    |     |    |    |    | Protocol |    |    |    |       |    |    |    | Header checksum |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Source address      |    |    |    |     |    |    |    |          |    |    |    |       |    |    |    |                 |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |     |    |    |    |          |    |    |    |       |    |    |    |                 |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Options             |    |    |    |     |    |    |    |          |    |    |    |       |    |    |    |                 |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 51-7. IPv4 header fields**

| Field name                          | Description                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Version                             | 4-bit IP version information. 0x4 for IPv4 frames.                                                                                                           |
| IHL                                 | 4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5. |
| TOS                                 | Type of service/DiffServ field.                                                                                                                              |
| Length                              | Total length of the datagram in bytes, including all octets of header and payload.                                                                           |
| Fragment ID, flags, fragment offset | Fields used for IP fragmentation.                                                                                                                            |
| TTL                                 | Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.                                                         |
| Protocol                            | Identifier of protocol that follows in the datagram.                                                                                                         |
| Header checksum                     | Checksum of IP header. For computational purposes, this field's value is zero.                                                                               |
| Source address                      | Source IP address.                                                                                                                                           |
| Destination address                 | Destination IP address.                                                                                                                                      |

### 51.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or ICMP).

Functional description

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

Figure 51-4. IPv6 header format

Table 51-8. IPv6 header fields

| Field name          | Description                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| Version             | 4-bit IP version information. 0x6 for all IPv6 frames.                                                                    |
| Traffic class       | 8-bit field defining the traffic class.                                                                                   |
| Flow label          | 20-bit flow label identifying frames of the same flow.                                                                    |
| Payload length      | 16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.                         |
| Next header         | Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header. |
| Hop limit           | Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.   |
| Source address      | 128-bit IPv6 source address.                                                                                              |
| Destination address | 128-bit IPv6 destination address.                                                                                         |

51.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 51-9. ICMP header format

|                   |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Type              |    |    |    |    |    |    |    | Code |    |    |    |    |    |    |    | Checksum |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| ICMP message data |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 51-10. IP header fields**

| Field name | Description                                                      |
|------------|------------------------------------------------------------------|
| Type       | 8-bit type information                                           |
| Code       | 8-bit code that is related to the message type                   |
| Checksum   | 16-bit one's complement checksum over the complete ICMP datagram |

### 51.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 51-11. UDP header format**

|             |             |             |             |                  |           |         |         |
|-------------|-------------|-------------|-------------|------------------|-----------|---------|---------|
| 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 16 | 15 14 13 12      | 11 10 9 8 | 7 6 5 4 | 3 2 1 0 |
| Source port |             |             |             | Destination port |           |         |         |
| Length      |             |             |             | Checksum         |           |         |         |

**Table 51-12. UDP header fields**

| Field name       | Description                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------|
| Source port      | Source application port                                                                                          |
| Destination port | Destination application port                                                                                     |
| Length           | Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8) |
| Checksum         | Checksum over the complete datagram and some IP header information                                               |

### 51.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 51-13. TCP header format**

|             |             |             |             |                  |           |         |         |
|-------------|-------------|-------------|-------------|------------------|-----------|---------|---------|
| 31 30 29 28 | 27 26 25 24 | 23 22 21 20 | 19 18 17 16 | 15 14 13 12      | 11 10 9 8 | 7 6 5 4 | 3 2 1 0 |
| Source port |             |             |             | Destination port |           |         |         |

*Table continues on the next page...*

**Table 51-13. TCP header format (continued)**

|                        |          |       |                |
|------------------------|----------|-------|----------------|
| Sequence number        |          |       |                |
| Acknowledgement number |          |       |                |
| Offset                 | Reserved | Flags | Window         |
| Checksum               |          |       | Urgent pointer |
| Options                |          |       |                |

**Table 51-14. TCP header fields**

| Field name       | Description                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------|
| Source port      | Source application port                                                                                         |
| Destination port | Destination application port                                                                                    |
| Sequence number  | Transmit sequence number                                                                                        |
| Ack. number      | Receive sequence number                                                                                         |
| Offset           | Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5 |
| Flags            | URG, ACK, PSH, RST, SYN, FIN flags                                                                              |
| Window           | TCP receive window size information                                                                             |
| Checksum         | Checksum over the complete datagram (TCP header and data) and IP header information                             |
| Options          | Additional 32-bit words for protocol options                                                                    |

### 51.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 51.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 51.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 51-15 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 51-15. UDP/IP multicast domains**

| Name                | IP Address  | MAC Address mapping |
|---------------------|-------------|---------------------|
| DefaultPTPdomain    | 224.0.1.129 | 01-00-5E-00-01-81   |
| AlternatePTPdomain1 | 224.0.1.130 | 01-00-5E-00-01-82   |
| AlternatePTPdomain2 | 224.0.1.131 | 01-00-5E-00-01-83   |
| AlternatePTPdomain3 | 224.0.1.132 | 01-00-5E-00-01-84   |

**Table 51-16. UDP port numbers**

| Message type | UDP port | Note                                                        |
|--------------|----------|-------------------------------------------------------------|
| Event        | 319      | Used for SYNC and DELAY_REQUEST messages                    |
| General      | 320      | All other messages (for example, follow-up, delay-response) |

### 51.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 51-17. PTPv2 multicast domains**

| Name                | MAC address       |
|---------------------|-------------------|
| Normal messages     | 01-1B-19-00-00-00 |
| Peer delay messages | 01-80-C2-00-00-0E |

### 51.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

## Functional description

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

### 51.6.3.2.1 PTPv1 header

**Table 51-18. Common PTPv1 message header**

| Offset | Octets | Bits                          |   |   |   |   |   |   |   |
|--------|--------|-------------------------------|---|---|---|---|---|---|---|
|        |        | 7                             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0      | 2      | versionPTP = 0x0001           |   |   |   |   |   |   |   |
| 2      | 2      | versionNetwork                |   |   |   |   |   |   |   |
| 4      | 16     | subdomain                     |   |   |   |   |   |   |   |
| 20     | 1      | messageType                   |   |   |   |   |   |   |   |
| 21     | 1      | sourceCommunicationTechnology |   |   |   |   |   |   |   |
| 22     | 6      | sourceUuid                    |   |   |   |   |   |   |   |
| 28     | 2      | sourcePortId                  |   |   |   |   |   |   |   |
| 30     | 2      | sequenceId                    |   |   |   |   |   |   |   |
| 32     | 1      | control                       |   |   |   |   |   |   |   |
| 33     | 1      | 0x00                          |   |   |   |   |   |   |   |
| 34     | 2      | flags                         |   |   |   |   |   |   |   |
| 36     | 4      | reserved                      |   |   |   |   |   |   |   |

The type of message is encoded in the messageType and control fields as shown in [Table 51-19](#) :

**Table 51-19. PTPv1 message type identification**

| messageType | control | Message Name | Message         |
|-------------|---------|--------------|-----------------|
| 0x01        | 0x0     | SYNC         | Event message   |
| 0x01        | 0x1     | DELAY_REQ    | Event message   |
| 0x02        | 0x2     | FOLLOW_UP    | General message |
| 0x02        | 0x3     | DELAY_RESP   | General message |
| 0x02        | 0x4     | MANAGEMENT   | General message |
| other       | other   | —            | Reserved        |

The field sequenceId is used to non-ambiguously identify a message.

### 51.6.3.2.2 PTPv2 header

**Table 51-20. Common PTPv2 message header**

| Offset | Octets | Bits                   |   |   |   |                  |   |   |   |
|--------|--------|------------------------|---|---|---|------------------|---|---|---|
|        |        | 7                      | 6 | 5 | 4 | 3                | 2 | 1 | 0 |
| 0      | 1      | transportSpecific      |   |   |   | messageId        |   |   |   |
| 1      | 1      | reserved               |   |   |   | versionPTP = 0x2 |   |   |   |
| 2      | 2      | messageLength          |   |   |   |                  |   |   |   |
| 4      | 1      | domainNumber           |   |   |   |                  |   |   |   |
| 5      | 1      | reserved               |   |   |   |                  |   |   |   |
| 6      | 2      | flags                  |   |   |   |                  |   |   |   |
| 8      | 8      | correctionField        |   |   |   |                  |   |   |   |
| 16     | 4      | reserved               |   |   |   |                  |   |   |   |
| 20     | 10     | sourcePortIdentity     |   |   |   |                  |   |   |   |
| 30     | 2      | sequenceId             |   |   |   |                  |   |   |   |
| 32     | 1      | control                |   |   |   |                  |   |   |   |
| 33     | 1      | logMeanMessageInterval |   |   |   |                  |   |   |   |

The type of message is encoded in the field messageId as follows:

**Table 51-21. PTPv2 message type identification**

| messageId | Message name         | Message         |
|-----------|----------------------|-----------------|
| 0x0       | SYNC                 | Event message   |
| 0x1       | DELAY_REQ            | Event message   |
| 0x2       | PATH_DELAY_REQ       | Event message   |
| 0x3       | PATH_DELAY_RESP      | Event message   |
| 0x4–0x7   | —                    | Reserved        |
| 0x8       | FOLLOW_UP            | General message |
| 0x9       | DELAY_RESP           | General message |
| 0xa       | PATH_DELAY_FOLLOW_UP | General message |
| 0xb       | ANNOUNCE             | General message |
| 0xc       | SIGNALING            | General message |
| 0xd       | MANAGEMENT           | General message |

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO\_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 51-22. PTPv2 message flags field definitions**

| Bit | Name             | Description                                                                         |
|-----|------------------|-------------------------------------------------------------------------------------|
| 0   | ALTERNATE_MASTER | See IEEE 1588 Clause 17.4                                                           |
| 1   | TWO_STEP         | 1 Two-step clock<br>0 One-step clock                                                |
| 2   | UNICAST          | 1 Transport layer address uses a unicast destination address<br>0 Multicast is used |
| 3   | —                | Reserved                                                                            |
| 4   | —                | Reserved                                                                            |
| 5   | Profile specific |                                                                                     |
| 6   | Profile specific |                                                                                     |
| 7   | —                | Reserved                                                                            |

### 51.6.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

Figure 51-5. MAC receive flow

#### 51.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

#### 51.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

### 51.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

#### 51.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ( $\text{RCR}[\text{PROM}] = 1$ ) no address checking is performed and all unicast frames are accepted.

#### 51.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in  $\text{ENETn\_GAUR/GALR}$  (group address hash match) or  $\text{ENETn\_IAUR/IALR}$  (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects  $\text{ENETn\_GAUR}$  (msb = 1) or  $\text{ENETn\_GALR}$  (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

$$\bullet \text{ FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

If Promiscuous mode is enabled ( $\text{ENETn\_RCR}[\text{PROM}] = 1$ ) all unicast and multicast frames are accepted regardless of  $\text{ENETn\_GAUR/GALR}$  and  $\text{ENETn\_IAUR/IALR}$  settings.

#### 51.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if  $\text{BC\_REJ}$  is cleared or  $\text{ENETn\_RCR}[\text{PROM}]$  is set. If  $\text{PROM}$  is cleared when  $\text{ENETn\_RCR}[\text{BC\_REJ}]$  is set, all broadcast frames are rejected.

**Table 51-23. Broadcast address reject programming**

| PROM | BC_REJ | Broadcast frames |
|------|--------|------------------|
| 0    | 0      | Accepted         |
| 0    | 1      | Rejected         |
| 1    | 0      | Accepted         |
| 1    | 1      | Accepted         |

#### 51.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes,  $\text{RxBD}[\text{M}]$  indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled ( $\text{RCR}[\text{PROM}] = 1$ ), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when  $\text{BC\_REJ}$  is set
- A unicast is received that does not match either:

- Node address (PALR[PADDR1] and PAUR[PADDR2])
- Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 51.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 51.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET $n$ \_FTRL[TRUNC\_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

#### 51.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

### 51.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if `ENETn_RCR[FCE]` is cleared and are forwarded to the client interface when `ENETn_RCR[PAUFWD]` is set.

### 51.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if `ENETn_RCR[CRCFWD]` is cleared and `ENETn_RCR[PADEN]` is set.

When `CRCFWD` is set (regardless of `PADEN`), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $$\text{FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}, x^{30}, \dots, x^1, x^0$ .

If a CRC error is detected, the frame is marked invalid and `RxBD[CR]` is set.

### 51.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENETn_RCR[PADEN]`.

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the

padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

### **51.6.5 MAC transmit**

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if `ENETn_TCR[TFC_PAUSE]` is set with `ENETn_OPD[PAUSE_DUR]` set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if `TFC_PAUSE` is set with `PAUSE_DUR` cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 51-6. Frame transmit overview**

### 51.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

### 51.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET $n$ \_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET $n$ \_TCR[ADDINS] = 0)

### 51.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

#### 51.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in `ENETn_TIPG`) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

#### 51.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets `TxBD[LCE]`.

**Figure 51-7. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

### warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

## 51.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

### 51.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

Optionally and independent of `ENETn_RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

### 51.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET $n$ \_TCR[TFC\_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC\_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET $n$ \_OPD[PAUSE\_DUR].

**Figure 51-8. Pause frame generation overview**

#### Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

## 51.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

### 51.6.7.1 Sleep mode

To put the MAC in Sleep mode, set `ENET $n$ _ECR[SLEEP]`. At the same time `ENET $n$ _ECR[MAGICEN]` should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the `ENET $n$ _ECR` register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

### 51.6.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in `PADDR1/2`

When a magic packet is detected, `EIR[WAKEUP]` is set and none of the statistic registers are incremented.

### 51.6.7.3 Wakeup

When a magic packet is detected, indicated by  $\text{ENET}_n\text{EIR}[\text{WAKEUP}]$ ,  $\text{ENET}_n\text{ECR}[\text{SLEEP}]$  should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks  $\text{ENET}_n\text{ECR}[\text{MAGICEN}]$ , disabling magic packet detection.

## 51.6.8 IP accelerator functions

The following sections describe the IP accelerator functions.

### 51.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 51-24. IPv4 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15             | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    | Protocol |    |    |    |    |    |    |    | TCP/UDP length |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 51-25. IPv6 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-------------|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7           | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| TCP/UDP length      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | Next header |   |   |   |   |   |   |   |

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 51.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 51.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET $n$ \_TACC and ENET $n$ \_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 51-26](#).

**Table 51-26. 64-bit interface data structure with SHIFT16 enabled**

|    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |
|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|
| 63 | 56 | 55 | 48 | 47 | 40 | 39 | 32 | 31 | 24 | 23 | 16 | 15 | 8 | 7 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|

*Table continues on the next page...*

**Table 51-26. 64-bit interface data structure with SHIFT16 enabled (continued)**

|         |         |         |         |        |        |           |           |
|---------|---------|---------|---------|--------|--------|-----------|-----------|
| Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 | Any value | Any value |
| Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 | Byte 7    | Byte 6    |
| ...     |         |         |         |        |        |           |           |

### 51.6.8.3.1 Receive processing

When `ENETn_RACC[SHIFT16]` is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

#### Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

### 51.6.8.3.2 Transmit processing

When `ENETn_TACC[SHIFT16]` is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

### 51.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (`ENETn_RSFL` cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than `MAX_FL`
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (`RX_ERR` asserted during reception)

- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENETn\_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### **51.6.8.5 IPv4 fragments**

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBDFRAG) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBDPayload checksum].

#### **Note**

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### **51.6.8.6 IPv6 support**

The following sections describe the IPv6 support.

### 51.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

### 51.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

## 51.6.9 Resets and stop controls

The following sections describe the resets and stop controls.

### 51.6.9.1 Hardware reset

To reset the Ethernet module, set ENET $n$ \_ECR[RESET].

### 51.6.9.2 Soft reset

When `ENET $n$ _ECR[ETHER_EN]` is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

### 51.6.9.3 Hardware freeze

When the processor enters debug mode and `ECR[DBGEN]` is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

### 51.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing `ETHER_EN` is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

#### 51.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

#### 51.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

### **Note**

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

#### **51.6.9.4.3 Graceful stop interrupt (GRA)**

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

## 51.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

Figure 51-9. IEEE 1588 functions overview

### 51.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 51.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

**Figure 51-10. Adjustable timer implementation detail**

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in  $\text{ENET}_n\text{\_ATINC}$ . The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in  $\text{ENET}_n\text{\_ATPER}$ , defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(\text{Current} + \text{Inc} - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in  $\text{ENET}_n\text{\_ATCOR}$ , it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in  $\text{ENET}_n\text{\_ATINC}$ . To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode ( $\text{ENET}_n\text{\_ATCR}[\text{SLAVE}] = 1$ ), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set `ENETn_ATINC[INC]` to the value of the master, since it is used for internal comparisons.

### 51.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENETn_ATSTMP`. `ENETn_EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENETn_EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENETn_ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

### 51.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

### 51.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

### 51.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

#### 51.6.10.5.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

#### 51.6.10.5.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

#### 51.6.10.5.3 DMA requests

A DMA request can be enabled by setting  $TCSR_n[TDRE]$ . The corresponding DMA request is generated when the  $TCSR_n[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSR_n[TF]$  flag is cleared.

### 51.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

### 51.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

**Table 51-27. Receive FIFO thresholds definition**

| Register                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENET $n$ _RSFL<br>[RX_SECTION_F<br>ULL]  | <p>When the FIFO level reaches the ENET<math>n</math>_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET<math>n</math>_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET<math>n</math>_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET<math>n</math>_RSFL (cut-through operation) it should be greater than ENET<math>n</math>_RAEM.</p> |
| ENET $n$ _RAEM<br>[RX_ALMOST_E<br>MPTY]  | <p>When the FIFO level reaches the ENET<math>n</math>_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET<math>n</math>_RAEM to a minimum of six.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ENET $n$ _RAFL<br>[RX_ALMOST_F<br>ULL]   | <p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET<math>n</math>_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p> <p>The corresponding error status is set when the frame is delivered to the application.</p> <p>Set ENET<math>n</math>_RAFL to a minimum of 4.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ENET $n$ _RSEM<br>[RX_SECTION_E<br>MPTY] | <p>When the FIFO level reaches the ENET<math>n</math>_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client.</p> <p>When the FIFO level goes below the value programmed in ENET<math>n</math>_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client.</p> <p>Clearing ENET<math>n</math>_RSEM disables any pause frame generation.</p>                                                                                                                                                                                                                                                                                                    |

**Figure 51-11. Receive FIFO overview**

### 51.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

**Table 51-28. Transmit FIFO thresholds definition**

| Register                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENET $n$ _TAEM<br>[TX_ALMOST_EMPTY]  | When the FIFO level reaches the ENET $n$ _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication.<br><br>Set ENET $n$ _TAEM to a minimum of 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENET $n$ _TAFL<br>[TX_ALMOST_FULL]   | When the FIFO level approaches the maximum, so that there is no more space for at least ENET $n$ _TAFL number of words, the MAC deasserts its control signal to the application.<br><br>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.<br><br>Set ENET $n$ _TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion. |
| ENET $n$ _TSEM<br>[TX_SECTION_EMPTY] | When the FIFO level reaches the ENET $n$ _TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.<br><br>When ENET $n$ _TSEM is 0, the signal is never deasserted.                                                                                                                                                                                                                                                                                                                                    |
| ENET $n$ _TFWR                       | When the FIFO level reaches the ENET $n$ _TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 51-28. Transmit FIFO thresholds definition**

| Register | Description                                                                                                                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | <p>If a complete frame has a size smaller than the <math>ENETn\_TFWR</math> threshold, the MAC also transmits the frame to the line.</p> <p>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.</p> |

**Figure 51-12. Transmit FIFO overview**

### 51.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the  $ENETn\_RCR$  register fields found here.

The core implements external and internal loopback options, which are controlled by the following  $ENETn\_RCR$  register fields:

**Table 51-29. Loopback options**

| Register field | Description                                                                                                                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOOP           | <p>Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.</p> <p>In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))</p> |

Figure 51-13. Loopback options

51.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENETn\_ECR[1588EN].

NOTE

- The legacy buffer descriptor tables show the byte order for little-endian chips. DBSWP must be set to 1 after reset to enable little-endian mode.

51.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 51-33 contains the descriptions for each field.

Table 51-30. Legacy FEC receive buffer descriptor (RxBD)

|            | Byte 1                                 |     |    |     |    |    |   |   | Byte 0 |    |    |    |   |    |    |    |
|------------|----------------------------------------|-----|----|-----|----|----|---|---|--------|----|----|----|---|----|----|----|
|            | 15                                     | 14  | 13 | 12  | 11 | 10 | 9 | 8 | 7      | 6  | 5  | 4  | 3 | 2  | 1  | 0  |
| Offset + 0 | Data length                            |     |    |     |    |    |   |   |        |    |    |    |   |    |    |    |

| Offset + 6 | Tx Data Buffer Pointer — high halfword |     |    |     |    |    |                  |   |        |   |   |   |   |   |   |   |

1. This field is not supported by the uDMA.

## 51.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET<sub>n</sub>\_ECR[1588EN].

### NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. [DBSWP](#) must be set to 1 after reset to enable little-endian mode.

### 51.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 51-33](#) contains the descriptions for each field.

**Table 51-32. Enhanced uDMA receive buffer descriptor (RxBD)**

|            | Byte 1                                 |     |    |     |    |    |   |   | Byte 0 |    |    |    |   |    |    |    |
|------------|----------------------------------------|-----|----|-----|----|----|---|---|--------|----|----|----|---|----|----|----|
|            | 15                                     | 14  | 13 | 12  | 11 | 10 | 9 | 8 | 7      | 6  | 5  | 4  | 3 | 2  | 1  | 0  |

|------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 0 | 15–0<br>Data Length | Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.                                                                                                                                                                                                        |
| Offset + 2 | 15<br>E             | Empty. Written by the MAC (= 0) and user (= 1).<br>0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required.<br>1 The data buffer associated with this BD is empty, or reception is currently in progress.                                                                                                                                     |
| Offset + 2 | 14<br>RO1           | Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.                                                                                                                                                                                                                                                                                                                    |
| Offset + 2 | 13<br>W             | Wrap. **Table 51-33. Receive buffer descriptor field definitions (continued)**

| Word       | Field                                  | Description                                                                                                                                                                                                                                                                                                                             |
|------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |                                        | The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.                                                                                                                                                                                                                              |
| Offset + 2 | 7<br>BC                                | Set if the DA is broadcast (FFFF_FFFF_FFFF).                                                                                                                                                                                                                                                                                            |
| Offset + 2 | 6<br>MC                                | Set if the DA is multicast and not BC.                                                                                                                                                                                                                                                                                                  |
| Offset + 2 | 5<br>LG                                | Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.                                                                                        |
| Offset + 2 | 4<br>NO                                | Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set. |
| Offset + 2 | 3                                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 2 | 2<br>CR                                | Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.                                                                                                                                                   |
| Offset + 2 | 1<br>OV                                | Overflow. Written by the MAC. A receive FIFO overflow occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.                                                                                        |
| Offset + 2 | 0<br>TR                                | Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.                                                                                                                                           |
| Offset + 4 | 15–0<br>Data buffer<br>pointer low     | Receive data buffer pointer, low halfword                                                                                                                                                                                                                                                                                               |
| Offset + 6 | 15–0<br>Data buffer<br>pointer<br>high | Receive data buffer pointer, high halfword <sup>1</sup>                                                                                                                                                                                                                                                                                 |
| Offset + 8 | 15–13<br>VPCP                          | VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.                                   |
| Offset + 8 | 12–6                                   | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 8 | 5<br>ICE                               | IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.                    |
| Offset + 8 | 4<br>PCR                               | Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.                                                                    |
| Offset + 8 | 3                                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 8 | 2<br>VLAN                              | VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.                                                                                                                                                                         |

**Table 51-33. Receive buffer descriptor field definitions (continued)**

| Word        | Field                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 8  | 1<br>IPV6                | IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + 8  | 0<br>FRAG                | IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Offset + A  | 15<br>ME                 | MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Offset + A  | 14–11                    | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + A  | 10<br>PE                 | PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + A  | 9<br>CE                  | Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Offset + A  | 8<br>UC                  | Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Offset + A  | 7<br>INT                 | Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb</i> / <i>dma_int_rxfevent</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Offset + A  | 6–0                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + C  | 15–0<br>Payload checksum | Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + E  | 15–11<br>Header length   | Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> This field is only valid if the L field is set. |
| Offset + E  | 10–8                     | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + E  | 7–0<br>Protocol type     | Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 51-33. Receive buffer descriptor field definitions (continued)**

| Word                            | Field          | Description                |
|---------------------------------|----------------|----------------------------|
|                                 | 1588 timestamp |                            |
| Offset + 18<br>—<br>Offset + 1E | 15–0           | Reserved, must be cleared. |

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

## 51.6.14.2 Enhanced transmit buffer descriptor

| Offset + 2 | 8–0                                 | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                             |
| Offset + 4 | 15–0<br>Data buffer<br>pointer low  | Tx data buffer pointer, low halfword                                                                                                                                                                                                                                                                                                                                                                                                   |
| Offset + 6 | 15–0<br>Data buffer<br>pointer high | Tx data buffer pointer, high halfword. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 8. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller.                                                                                                                                                         |
| Offset + 8 | 15<br>TXE                           | Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.                                                                                                                             |
| Offset + 8 | 14                                  | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                             |
| Offset + 8 | 13<br>UE                            | Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.                                                                                                                                                                                                                                                       |
| Offset + 8 | 12<br>EE                            | Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.                                                                                                                                                                                                                                         |

**Table 51-35. Enhanced transmit buffer descriptor field definitions (continued)**

| Word                    | Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 8              | 11<br>FE       | Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.                                                                                                                                                                                                                          |
| Offset + 8              | 10<br>LCE      | Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.                                                                                                                                                                                                                                    |
| Offset + 8              | 9<br>OE        | Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.                                                                                                                                                                                                                                 |
| Offset + 8              | 8<br>TSE       | Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.                                                                                                                                                                                                                                       |
| Offset + 8              | 7–0            | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + A              | 15             | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + A              | 14<br>INT      | Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.                                                                                                                                                                                                                                   |
| Offset + A              | 13<br>TS       | Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.                                                                                                                                                                      |
| Offset + A              | 12<br>PINS     | Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame. |
| Offset + A              | 11<br>IINS     | Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.          |
| Offset + A              | 10–0           | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + C              | 15–0           | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |

## 51.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

### 51.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 51-36. FIFO interface data structure**

|        | 63      | 56 55   | 48 47   | 40 39   | 32 31   | 24 23   | 16 15  | 8 7    | 0 |
|--------|---------|---------|---------|---------|---------|---------|--------|--------|---|
| Word 0 | Byte 7  | Byte 6  | Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 |   |
| Word 1 | Byte 15 | Byte 14 | Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 |   |
| ...    | ...     |         |         |         |         |         |        |        |   |

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

### Note

On transmit, if ENET $n$ \_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET $n$ \_PAUR and ENET $n$ \_PALR registers.

**Table 51-37. FIFO interface frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–13       | Length/type field       |
| 14–N        | Payload data            |

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 51-38. FIFO interface VLAN frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–15       | VLAN tag and info       |
| 16–17       | Length/type field       |
| 18–N        | Payload data            |

### Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

## 51.6.15.2 Data structure examples

Figure 51-14. Normal Ethernet frame 64-bit mapping example

Figure 51-15. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 51.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxB[ME] is also set with the last data of the frame.

## 51.6.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

### 51.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in Figure 51-16) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 51-16. Transmit FIFO underflow protection

### 51.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

#### Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $n$ \_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

### 51.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 51-17. Receive FIFO overflow protection

### 51.6.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

| Ethernet speed mode | Ethernet bus clock | Minimum ENET system clock |
|---------------------|--------------------|---------------------------|
| 10 Mbit/s           | 2.5 MHz            | 5 MHz                     |
| 100 Mbit/s          | 25.0 MHz           | 50 MHz                    |

### 51.6.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

#### 51.6.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 51-39. MDIO clause 22 frame structure**

| ST | OP | PHYADR | REGADR | TA | DATA |
|----|----|--------|--------|----|------|
|----|----|--------|--------|----|------|

**Table 51-40. MDIO frame field descriptions**

| Field          | Description                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| ST<br>(2 bits) | Start indication field, programmed with ENET <sub>n</sub> _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22). |
| OP             | Opcode defines type of operation. Programmed with ENET <sub>n</sub> _MMFR[OP].                                     |

*Table continues on the next page...*

**Table 51-40. MDIO frame field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (2 bits)           | 01 Write operation<br>10 Read operation                                                                                                                                                                                                                                        |
| PHYADR<br>(5 bits) | Five-bit PHY device address, programmed with ENET $n$ _MMFR[PA]. Up to 32 devices can be addressed.                                                                                                                                                                            |
| REGADR<br>(5 bits) | Five-bit register address, programmed with ENET $n$ _MMFR[RA]. Each PHY can implement up to 32 registers.                                                                                                                                                                      |
| TA<br>(2 bits)     | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| Data<br>(16 bits)  | Data, set by ENET $n$ _MMFR[DATA]. Written to or read from the PHY                                                                                                                                                                                                             |

### 51.6.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 51-41. MDIO clause 45 frame structure**

| ST | OP | PRTAD | DEVAD | TA | ADDR/DATA |
|----|----|-------|-------|----|-----------|
|----|----|-------|-------|----|-----------|

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 51-42. MDIO clause 45 frame field descriptions**

| Field | Description                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------|
| ST    | Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames. |

*Table continues on the next page...*

**Table 51-42. MDIO clause 45 frame field descriptions (continued)**

| Field     | Description                                                                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OP        | Opcode defines if a read or write operation is performed and is programmed with ENET $n$ _MMFR[OP]. See <a href="#">Table 51-43</a> for more information.<br>00 Address write<br>01 Write operation<br>10 Read inc. operation<br>11 Read operation                             |
| PRTAD     | The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.                                                                                                                                                   |
| DEVAD     | Device address. Up to 32 devices can be addressed (within a port).                                                                                                                                                                                                             |
| TA        | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| ADDR/DATA | 16-bit address (for address write) or data, set by ENET $n$ _MMFR[DATA], written to or read from the PHY.                                                                                                                                                                      |

**Table 51-43. MDIO Clause 45 Transactions**

| Transaction Type | Description                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address          | A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.                                             |
| Write            | Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.                                                                                                                                             |
| Read             | Data is read from the register identified by the device-internal address.                                                                                                                                                                                        |
| Read inc.        | Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around). |

### 51.6.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET $n$ \_MSCR[MII\_SPEED].

### 51.6.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

Figure 51-18. MDIO access overview

## 51.6.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

| Mode              | ECR[SPEED] | RCR[RMII_10T] | RCR[RMII_MODE] |
|-------------------|------------|---------------|----------------|
| MII - 10 Mbit/s   | 0          | —             | 0              |
| MII - 100 Mbit/s  | 0          | —             | 0              |
| RMII - 10 Mbit/s  | 0          | 1             | 1              |
| RMII - 100 Mbit/s | 0          | 0             | 1              |

### 51.6.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

### 51.6.19.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 51-22. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBDF[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 51-23. MII transmit operation — errored frame**

### 51.6.19.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

Figure 51-24. MII transmit operation — transmission with collision

### 51.6.19.3 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

Figure 51-25. MII receive operation

## Functional description

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

**Figure 51-26. MII receive operation — errored frame**

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

## Chapter 52

# Inter-Integrated Circuit (I2C)

## 52.1 Chip-specific I2C information

### 52.1.1 Number of I2C modules

This device has two I<sup>2</sup>C modules.

## 52.2 Introduction

The inter-integrated circuit (I<sup>2</sup>C, I2C, or IIC) module provides a method of communication between a number of devices.

The interface is designed to operate up to 100 kbit/s with maximum bus loading and timing. The I2C device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF. The I2C module also complies with the *System Management Bus (SMBus) Specification, version 2*.

### 52.2.1 Features

The I2C module has the following features:

- Compatible with *The I<sup>2</sup>C-Bus Specification*
- Multimaster operation
- Software programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven byte-by-byte data transfer

- Arbitration-lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- START and STOP signal generation and detection
- Repeated START signal generation and detection
- Acknowledge bit generation and detection
- Bus busy detection
- General call recognition
- 10-bit address extension
- Support for *System Management Bus (SMBus) Specification, version 2*
- Programmable input glitch filter
- Low power mode wakeup on slave address match
- Range slave address support
- DMA support

## **52.2.2 Modes of operation**

The I2C module's operation in various low power modes is as follows:

- Run mode: This is the basic mode of operation. To conserve power in this mode, disable the module.
- Wait mode: The module continues to operate when the core is in Wait mode and can provide a wakeup interrupt.
- Stop mode: The module is inactive in Stop mode for reduced power consumption, except that address matching is enabled in Stop mode. The STOP instruction does not affect the I2C module's register states.

## **52.2.3 Block diagram**

The following figure is a functional block diagram of the I2C module.

Figure 52-1. I2C Functional block diagram

### 52.3 I<sup>2</sup>C signal descriptions

The signal properties of I<sup>2</sup>C are shown in the table found here.

Table 52-1. I<sup>2</sup>C signal descriptions

| Signal | Description                                                     | I/O |
|--------|-----------------------------------------------------------------|-----|
| SCL    | Bidirectional serial clock line of the I <sup>2</sup> C system. | I/O |
| SDA    | Bidirectional serial data line of the I <sup>2</sup> C system.  | I/O |

## 52.4 Memory map/register definition

This section describes in detail all I2C registers accessible to the end user.

### I2C memory map

| Absolute address (hex) | Register name                                            | Width (in bits) | Access | Reset value | Section/ page                |
|------------------------|----------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 4006_6000              | I2C Address Register 1 (I2C0_A1)                         | 8               | R/W    | 00h         | <a href="#">52.4.1/1615</a>  |
| 4006_6001              | I2C Frequency Divider register (I2C0_F)                  | 8               | R/W    | 00h         | <a href="#">52.4.2/1615</a>  |
| 4006_6002              | I2C Control Register 1 (I2C0_C1)                         | 8               | R/W    | 00h         | <a href="#">52.4.3/1616</a>  |
| 4006_6003              | I2C Status register (I2C0_S)                             | 8               | R/W    | 80h         | <a href="#">52.4.4/1618</a>  |
| 4006_6004              | I2C Data I/O register (I2C0_D)                           | 8               | R/W    | 00h         | <a href="#">52.4.5/1620</a>  |
| 4006_6005              | I2C Control Register 2 (I2C0_C2)                         | 8               | R/W    | 00h         | <a href="#">52.4.6/1620</a>  |
| 4006_6006              | I2C Programmable Input Glitch Filter Register (I2C0_FLT) | 8               | R/W    | 00h         | <a href="#">52.4.7/1621</a>  |
| 4006_6007              | I2C Range Address register (I2C0_RA)                     | 8               | R/W    | 00h         | <a href="#">52.4.8/1623</a>  |
| 4006_6008              | I2C SMBus Control and Status register (I2C0_SMB)         | 8               | R/W    | 00h         | <a href="#">52.4.9/1623</a>  |
| 4006_6009              | I2C Address Register 2 (I2C0_A2)                         | 8               | R/W    | C2h         | <a href="#">52.4.10/1625</a> |
| 4006_600A              | I2C SCL Low Timeout Register High (I2C0_SLTH)            | 8               | R/W    | 00h         | <a href="#">52.4.11/1625</a> |
| 4006_600B              | I2C SCL Low Timeout Register Low (I2C0_SLTL)             | 8               | R/W    | 00h         | <a href="#">52.4.12/1626</a> |
| 4006_7000              | I2C Address Register 1 (I2C1_A1)                         | 8               | R/W    | 00h         | <a href="#">52.4.1/1615</a>  |

| 4006_700B              | I2C SCL Low Timeout Register Low (I2C1_SLTL)             | 8               | R/W    | 00h         | <a href="#">52.4.12/1626</a> |

### 52.4.1 I2C Address Register 1 (I2Cx\_A1)

This register contains the slave address to be used by the I2C module.

Address: Base address + 0h offset

|       |         |   |   |   |   |   |   |   |
|-------|---------|---|---|---|---|---|---|---|
| Bit   | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Read  | AD[7:1] |   |   |   |   |   |   | 0 |
| Write |         |   |   |   |   |   |   | 0 |
| Reset | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

#### I2Cx\_A1 field descriptions

| Field          | Description                                                                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–1<br>AD[7:1] | Address<br><br>Contains the primary slave address used by the I2C module when it is addressed as a slave. This field is used in the 7-bit address scheme and the lower seven bits in the 10-bit address scheme. |
| 0<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                         |

### 52.4.2 I2C Frequency Divider register (I2Cx\_F)

Address: Base address + 1h offset

|       |      |   |   |     |   |   |   |   |
|-------|------|---|---|-----|---|---|---|---|
| Bit   | 7    | 6 | 5 | 4   | 3 | 2 | 1 | 0 |
| Read  | MULT |   |   | ICR |   |   |   |   |
| Write |      |   |   |     |   |   |   |   |

| 5<br>MST   | Master Mode Select<br><br>When MST is changed from 0 to 1, a START signal is generated on the bus and master mode is selected. When this bit changes from 1 to 0, a STOP signal is generated and the mode of operation changes from master to slave.<br><br>0 Slave mode<br>1 Master mode                                                                                                                                                                                                                                                                                        |
| 4<br>TX    | Transmit Mode Select<br><br>Selects the direction of master and slave transfers. In master mode this bit must be set according to the type of transfer required. Therefore, for address cycles, this bit is always set. When addressed as a slave this bit must be set by software according to the SRW bit in the status register.<br><br>0 Receive<br>1 Transmit                                                                                                                                                                                                               |
| 3<br>TXAK  | Transmit Acknowledge Enable<br><br>Specifies the value driven onto the SDA during data acknowledge cycles for both master and slave receivers. The value of SMB[FAK] affects NACK/ACK generation.<br><br><b>NOTE:</b> SCL is held low until TXAK is written.<br><br>0 An acknowledge signal is sent to the bus on the following receiving byte (if FACK is cleared) or the current receiving byte (if FACK is set).<br>1 No acknowledge signal is sent to the bus on the following receiving data byte (if FACK is cleared) or the current receiving data byte (if FACK is set). |
| 2<br>RSTA  | Repeat START<br><br>Writing 1 to this bit generates a repeated START condition provided it is the current master. This bit will always be read as 0. Attempting a repeat at the wrong time results in loss of arbitration.                                                                                                                                                                                                                                                                                                                                                       |
| 1<br>WUEN  | Wakeup Enable<br><br>The I2C module can wake the MCU from low power mode with no peripheral bus running when slave address matching occurs.<br><br>0 Normal operation. No interrupt generated when address matching in low power mode.<br>1 Enables the wakeup function in low power mode.                                                                                                                                                                                                                                                                                       |
| 0<br>DMAEN | DMA Enable<br><br>Enables or disables the DMA function.<br><br>0 All DMA signalling disabled.<br>1 DMA transfer is enabled. While SMB[FAK] = 0, the following conditions trigger the DMA request: <ul style="list-style-type: none"> <li>• a data byte is received, and either address or data is transmitted. (ACK/NACK is automatic)</li> <li>• the first byte received matches the A1 register or is a general call address.</li> </ul>                                                                                                                                       |

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>If any address matching occurs, S[IAAS] and S[TCF] are set. If the direction of transfer is known from master to slave, then it is not required to check S[SRW]. With this assumption, DMA can also be used in this case. In other cases, if the master reads data from the slave, then it is required to rewrite the C1 register operation. With this assumption, DMA cannot be used.</p> <p>When FACK = 1, an address or a data byte is transmitted.</p> |

**52.4.4 I2C Status register (I2Cx\_S)**

Address: Base address + 3h offset

|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA  | <p>Data</p> <p>In master transmit mode, when data is written to this register, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates receiving of the next byte of data.</p> <p><b>NOTE:</b> When making the transition out of master receive mode, switch the I2C mode before reading the Data register to prevent an inadvertent initiation of a master receive data transfer.</p> <p>In slave mode, the same functions are available after an address match occurs.</p> <p>The C1[TX] bit must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For example, if the I2C module is configured for master transmit but a master receive is desired, reading the Data register does not initiate the receive.</p> <p>Reading the Data register returns the last byte received while the I2C module is configured in master receive or slave receive mode. The Data register does not reflect every byte that is transmitted on the I2C bus, and neither can software verify that a byte has been written to the Data register correctly by reading it back.</p> <p>In master transmit mode, the first byte of data written to the Data register following assertion of MST (start bit) or assertion of RSTA (repeated start bit) is used for the address transfer and must consist of the calling address (in bits 7-1) concatenated with the required R/W bit (in position bit 0).</p> |

|             | <p>The following scenario explains the holdoff functionality:</p> <ol style="list-style-type: none"> <li>1. The I2C module is configured for a basic transfer, and the SHEN bit is set to 1.</li> <li>2. A transfer begins.</li> <li>3. The MCU signals the I2C module to enter stop mode.</li> <li>4. The byte currently being transferred, including both address and data, completes its transfer.</li> <li>5. The I2C slave or master acknowledges that the in-transfer byte completed its transfer and acknowledges the request to enter stop mode.</li> <li>6. After receiving the I2C module's acknowledgment of the request to enter stop mode, the MCU determines whether to shut off the I2C module's clock.</li> </ol> <p>If the SHEN bit is set to 1 and the I2C module is in an idle or disabled state when the MCU signals to enter stop mode, the module immediately acknowledges the request to enter stop mode.</p> <p>If SHEN is cleared to 0 and the overall data transmission or reception that was suspended by stop mode entry was incomplete: To resume the overall transmission or reception after the MCU exits stop mode, software must reinitialize the transfer by resending the address of the slave.</p> <p>If the I2C Control Register 1's IICIE bit was set to 1 before the MCU entered stop mode, system software will receive the interrupt triggered by the I2C Status Register's TCF bit after the MCU wakes from the stop mode.</p> <p>0 Stop holdoff is disabled. The MCU's entry to stop mode is not gated.<br/>1 Stop holdoff is enabled.</p> |
| 6<br>STOPF  | <p>I2C Bus Stop Detect Flag</p> <p>Hardware sets this bit when the I2C bus's stop status is detected. The STOPF bit must be cleared by writing 1 to it.</p> <p><b>NOTE:</b> The stop flag is only for the matched slave devices, therefore the master will not respond for it.</p> <p>0 No stop happens on I2C bus<br/>1 Stop detected on I2C bus</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 5<br>SSIE   | <p>I2C Bus Stop or Start Interrupt Enable</p> <p>This bit enables the interrupt for I2C bus stop or start detection.</p> <p><b>NOTE:</b> To clear the I2C bus stop or start detection interrupt: In the interrupt service routine, first clear the STOPF or STARTF bit by writing 1 to it, and then clear the IICIF bit in the status register. If this sequence is reversed, the IICIF bit is asserted again.</p> <p>0 Stop or start detection interrupt is disabled<br/>1 Stop or start detection interrupt is enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–1<br>RAD    | Range Slave Address<br>This field contains the slave address to be used by the I2C module. The field is used in the 7-bit address scheme. If I2C_C2[RMEN] is set to 1, any nonzero value write enables this register. This register value can be considered as a maximum boundary in the range matching mode. |
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                       |

**52.4.9 I2C SMBus Control and Status register (I2Cx\_SMB)****NOTE**

When the SCL and SDA signals are held high for a length of time greater than the high timeout period, the SHTF1 flag sets. Before reaching this threshold, while the system is detecting how long these signals are being held high, a master assumes that the bus is free. However, the SHTF1 bit is set to 1 in the bus transmission process with the idle bus state.

**NOTE**

When the TCKSEL bit is set, there is no need to monitor the SHTF1 bit because the bus speed is too high to match the protocol of SMBus.

## Memory map/register definition

52.5 Functional description

This section provides a comprehensive functional description of the I2C module.

52.5.1 I2C protocol

The I2C bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfers.

All devices connected to it must have open drain or open collector outputs. A logic AND function is exercised on both lines with external pull-up resistors. The value of these resistors depends on the system.

Normally, a standard instance of communication is composed of four parts:

- 1. START signal
- 2. Slave address transmission
- 3. Data transfer
- 4. STOP signal

The STOP signal should not be confused with the CPU STOP instruction. The following figure illustrates I2C bus system communication.

Figure 52-2. I2C bus transmission signals

### 52.5.1.1 START signal

The bus is free when no master device is engaging the bus (both SCL and SDA are high). When the bus is free, a master may initiate communication by sending a START signal. A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer—each data transfer might contain several bytes of data—and brings all slaves out of their idle states.

### 52.5.1.2 Slave address transmission

Immediately after the START signal, the first byte of a data transfer is the slave address transmitted by the master. This address is a 7-bit calling address followed by an  $R/\overline{W}$  bit. The  $R/\overline{W}$  bit tells the slave the desired direction of data transfer.

- 1 = Read transfer: The slave transmits data to the master
- 0 = Write transfer: The master transmits data to the slave

Only the slave with a calling address that matches the one transmitted by the master responds by sending an acknowledge bit. The slave sends the acknowledge bit by pulling SDA low at the ninth clock.

No two slaves in the system can have the same address. If the I2C module is the master, it must not transmit an address that is equal to its own slave address. The I2C module cannot be master and slave at the same time. However, if arbitration is lost during an address cycle, the I2C module reverts to slave mode and operates correctly even if it is being addressed by another master.

### **52.5.1.3 Data transfers**

When successful slave addressing is achieved, data transfer can proceed on a byte-by-byte basis in the direction specified by the  $\overline{R/W}$  bit sent by the calling master.

All transfers that follow an address cycle are referred to as data transfers, even if they carry subaddress information for the slave device.

Each data byte is 8 bits long. Data may be changed only while SCL is low. Data must be held stable while SCL is high. There is one clock pulse on SCL for each data bit, and the MSB is transferred first. Each data byte is followed by a ninth (acknowledge) bit, which is signaled from the receiving device by pulling SDA low at the ninth clock. In summary, one complete data transfer needs nine clock pulses.

If the slave receiver does not acknowledge the master in the ninth bit, the slave must leave SDA high. The master interprets the failed acknowledgement as an unsuccessful data transfer.

If the master receiver does not acknowledge the slave transmitter after a data byte transmission, the slave interprets it as an end to data transfer and releases the SDA line.

In the case of a failed acknowledgement by either the slave or master, the data transfer is aborted and the master does one of two things:

- Relinquishes the bus by generating a STOP signal.
- Commences a new call by generating a repeated START signal.

### **52.5.1.4 STOP signal**

The master can terminate the communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is asserted.

The master can generate a STOP signal even if the slave has generated an acknowledgement, at which point the slave must release the bus.

### 52.5.1.5 Repeated START signal

The master may generate a START signal followed by a calling command without generating a STOP signal first. This action is called a repeated START. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

### 52.5.1.6 Arbitration procedure

The I2C bus is a true multimaster bus that allows more than one master to be connected on it.

If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock. The bus clock's low period is equal to the longest clock low period, and the high period is equal to the shortest one among the masters.

The relative priority of the contending masters is determined by a data arbitration procedure. A bus master loses arbitration if it transmits logic level 1 while another master transmits logic level 0. The losing masters immediately switch to slave receive mode and stop driving SDA output. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets a status bit to indicate the loss of arbitration.

### 52.5.1.7 Clock synchronization

Because wire AND logic is performed on SCL, a high-to-low transition on SCL affects all devices connected on the bus. The devices start counting their low period and, after a device's clock has gone low, that device holds SCL low until the clock reaches its high state. However, the change of low to high in this device clock might not change the state of SCL if another device clock is still within its low period. Therefore, the synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time; see the following diagram. When all applicable devices have counted off their low period, the synchronized clock SCL is released and pulled high. Afterward there is no difference between the device clocks and the state of SCL, and all devices start counting their high periods. The first device to complete its high period pulls SCL low again.

**Figure 52-3. I2C clock synchronization**

### 52.5.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. A slave device may hold SCL low after completing a single byte transfer (9 bits). In this case, it halts the bus clock and forces the master clock into wait states until the slave releases SCL.

### 52.5.1.9 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master drives SCL low, a slave can drive SCL low for the required period and then release it. If the slave's SCL low period is greater than the master's SCL low period, the resulting SCL bus signal's low period is stretched. In other words, the SCL bus signal's low period is increased to be the same length as the slave's SCL low period.

### 52.5.1.10 I2C divider and hold values

#### NOTE

For some cases on some devices, the SCL divider value may vary by  $\pm 2$  or  $\pm 4$  when ICR's value ranges from 00h to 0Fh. These potentially varying SCL divider values are highlighted in the following table. For the actual SCL divider values for your device, see the chip-specific details about the I2C module.

Table 52-2. I2C divider and hold values

| ICR (hex) | SCL divider | SDA hold value | SCL hold (start) value | SCL hold (stop) value | ICR (hex) | SCL divider (clocks) | SDA hold (clocks) | SCL hold (start) value | SCL hold (stop) value |
|-----------|-------------|----------------|------------------------|-----------------------|-----------|----------------------|-------------------|------------------------|-----------------------|
| 00        | 20          | 7              | 6                      | 11                    | 20        | 160                  | 17                | 78                     | 81                    |

### 52.5.2 10-bit address

For 10-bit addressing, 0x11110 is used for the first 5 bits of the first address byte. Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing.

#### 52.5.2.1 Master-transmitter addresses a slave-receiver

The transfer direction is not changed. When a 10-bit address follows a START condition, each slave compares the first 7 bits of the first byte of the slave address (11110XX) with its own address and tests whether the eighth bit ( $R/\overline{W}$  direction bit) is 0. It is possible that more than one device finds a match and generates an acknowledge (A1). Each slave that finds a match compares the 8 bits of the second byte of the slave address with its own address, but only one slave finds a match and generates an acknowledge (A2). The matching slave remains addressed by the master until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

**Table 52-3. Master-transmitter addresses slave-receiver with a 10-bit address**

|   |                                               |       |    |                                   |    |      |   |     |      |     |   |
|---|-----------------------------------------------|-------|----|-----------------------------------|----|------|---|-----|------|-----|---|
| S | Slave address first 7 bits 11110 + AD10 + AD9 | R/W 0 | A1 | Slave address second byte AD[8:1] | A2 | Data | A | ... | Data | A/A | P |
|---|-----------------------------------------------|-------|----|-----------------------------------|----|------|---|-----|------|-----|---|

After the master-transmitter has sent the first byte of the 10-bit address, the slave-receiver sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

#### 52.5.2.2 Master-receiver addresses a slave-transmitter

The transfer direction is changed after the second  $R/\overline{W}$  bit. Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated START condition (Sr), a matching slave remembers that it was addressed before. This slave then checks whether the first seven bits of the first byte of the slave address following Sr are the same as they were after the START condition (S), and it tests whether the eighth ( $R/\overline{W}$ ) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a STOP condition (P) or a repeated START condition (Sr) followed by a different slave address.

After a repeated START condition (Sr), all other slave devices also compare the first seven bits of the first byte of the slave address with their own addresses and test the eighth ( $R/\overline{W}$ ) bit. However, none of them are addressed because  $R/\overline{W} = 1$  (for 10-bit devices), or the 11110XX slave address (for 7-bit devices) does not match.

**Table 52-4. Master-receiver addresses a slave-transmitter with a 10-bit address**

|   |                                                  |                        |    |                                      |    |    |                                                  |                        |    |      |   |     |      |   |   |
|---|--------------------------------------------------|------------------------|----|--------------------------------------|----|----|--------------------------------------------------|------------------------|----|------|---|-----|------|---|---|
| S | Slave address first 7 bits<br>11110 + AD10 + AD9 | R/ $\overline{W}$<br>0 | A1 | Slave address second byte<br>AD[8:1] | A2 | Sr | Slave address first 7 bits<br>11110 + AD10 + AD9 | R/ $\overline{W}$<br>1 | A3 | Data | A | ... | Data | A | P |
|---|--------------------------------------------------|------------------------|----|--------------------------------------|----|----|--------------------------------------------------|------------------------|----|------|---|-----|------|---|---|

After the master-receiver has sent the first byte of the 10-bit address, the slave-transmitter sees an I2C interrupt. User software must ensure that for this interrupt, the contents of the Data register are ignored and not treated as valid data.

### 52.5.3 Address matching

All received addresses can be requested in 7-bit or 10-bit address format.

- AD[7:1] in Address Register 1, which contains the I2C primary slave address, always participates in the address matching process. It provides a 7-bit address.
- If the ADEXT bit is set, AD[10:8] in Control Register 2 participates in the address matching process. It extends the I2C primary slave address to a 10-bit address.

Additional conditions that affect address matching include:

- If the GCAEN bit is set, general call participates the address matching process.
- If the ALERTEN bit is set, alert response participates the address matching process.
- If the SIICAEN bit is set, Address Register 2 participates in the address matching process.
- If the RMEN bit is set, when the Range Address register is programmed to a nonzero value, any address within the range of values of Address Register 1 (excluded) and the Range Address register (included) participates in the address matching process. The Range Address register must be programmed to a value greater than the value of Address Register 1.

When the I2C module responds to one of these addresses, it acts as a slave-receiver and the IAAS bit is set after the address cycle. Software must read the Data register after the first byte transfer to determine that the address is matched.

## 52.5.4 System management bus specification

SMBus provides a control bus for system and power management related tasks. A system can use SMBus to pass messages to and from devices instead of tripping individual control lines.

Removing the individual control lines reduces pin count. Accepting messages ensures future expandability. With the system management bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status.

### 52.5.4.1 Timeouts

The  $T_{\text{TIMEOUT,MIN}}$  parameter allows a master or slave to conclude that a defective device is holding the clock low indefinitely or a master is intentionally trying to drive devices off the bus. The slave device must release the bus (stop driving the bus and let SCL and SDA float high) when it detects any single clock held low longer than  $T_{\text{TIMEOUT,MIN}}$ . Devices that have detected this condition must reset their communication and be able to receive a new START condition within the timeframe of  $T_{\text{TIMEOUT,MAX}}$ .

SMBus defines a clock low timeout,  $T_{\text{TIMEOUT}}$ , of 35 ms, specifies  $T_{\text{LOW:SEXT}}$  as the cumulative clock low extend time for a slave device, and specifies  $T_{\text{LOW:MEXT}}$  as the cumulative clock low extend time for a master device.

#### 52.5.4.1.1 SCL low timeout

If the SCL line is held low by a slave device on the bus, no further communication is possible. Furthermore, the master cannot force the SCL line high to correct the error condition. To solve this problem, the SMBus protocol specifies that devices participating in a transfer must detect any clock cycle held low longer than a timeout value condition. Devices that have detected the timeout condition must reset the communication. When the I2C module is an active master, if it detects that SMBCLK low has exceeded the value of  $T_{\text{TIMEOUT,MIN}}$ , it must generate a stop condition within or after the current data byte in the transfer process. When the I2C module is a slave, if it detects the  $T_{\text{TIMEOUT,MIN}}$  condition, it resets its communication and is then able to receive a new START condition.

### 52.5.4.1.2 SCL high timeout

When the I2C module has determined that the SMBCLK and SMBDAT signals have been high for at least  $T_{\text{HIGH:MAX}}$ , it assumes that the bus is idle.

A HIGH timeout occurs after a START condition appears on the bus but before a STOP condition appears on the bus. Any master detecting this scenario can assume the bus is free when either of the following occurs:

- SHTF1 rises.
- The BUSY bit is high and SHTF1 is high.

When the SMBDAT signal is low and the SMBCLK signal is high for a period of time, another kind of timeout occurs. The time period must be defined in software. SHTF2 is used as the flag when the time limit is reached. This flag is also an interrupt resource, so it triggers IICIF.

### 52.5.4.1.3 CSMBCLK TIMEOUT MEXT and CSMBCLK TIMEOUT SEXT

The following figure illustrates the definition of the timeout intervals  $T_{\text{LOW:SEXT}}$  and  $T_{\text{LOW:MEXT}}$ . When in master mode, the I2C module must not cumulatively extend its clock cycles for a period greater than  $T_{\text{LOW:MEXT}}$  within a byte, where each byte is defined as START-to-ACK, ACK-to-ACK, or ACK-to-STOP. When CSMBCLK TIMEOUT MEXT occurs, SMBus MEXT rises and also triggers the SLTF.

**Figure 52-4. Timeout measurement intervals**

A master is allowed to abort the transaction in progress to any slave that violates the  $T_{\text{LOW:SEXT}}$  or  $T_{\text{TIMEOUT,MIN}}$  specifications. To abort the transaction, the master issues a STOP condition at the conclusion of the byte transfer in progress. When a slave, the I2C module must not cumulatively extend its clock cycles for a period greater than  $T_{\text{LOW:SEXT}}$  during any message from the initial START to the STOP. When CSMBCLK TIMEOUT SEXT occurs, SEXT rises and also triggers SLTF.

**NOTE**

CSMBCLK TIMEOUT SEXT and CSMBCLK TIMEOUT MEXT are optional functions that are implemented in the second step.

**52.5.4.2 FAST ACK and NACK**

To improve reliability and communication robustness, implementation of packet error checking (PEC) by SMBus devices is optional for SMBus devices but required for devices participating in and only during the address resolution protocol (ARP) process. The PEC is a CRC-8 error checking byte, calculated on all the message bytes. The PEC is appended to the message by the device that supplied the last data byte. If the PEC is present but not correct, a NACK is issued by the receiver. Otherwise an ACK is issued. To calculate the CRC-8 by software, this module can hold the SCL line low after receiving the eighth SCL (8th bit) if this byte is a data byte. So software can determine whether an ACK or NACK should be sent to the bus by setting or clearing the TXAK bit if the FACK (fast ACK/NACK enable) bit is enabled.

SMBus requires a device always to acknowledge its own address, as a mechanism to detect the presence of a removable device (such as a battery or docking station) on the bus. In addition to indicating a slave device busy condition, SMBus uses the NACK mechanism to indicate the reception of an invalid command or invalid data. Because such a condition may occur on the last byte of the transfer, SMBus devices are required to have the ability to generate the not acknowledge after the transfer of each byte and before the completion of the transaction. This requirement is important because SMBus does not provide any other resend signaling. This difference in the use of the NACK signaling has implications on the specific implementation of the SMBus port, especially in devices that handle critical system data such as the SMBus host and the SBS components.

**NOTE**

In the last byte of master receive slave transmit mode, the master must send a NACK to the bus, so FACK must be switched off before the last byte transmits.

**52.5.5 Resets**

The I2C module is disabled after a reset. The I2C module cannot cause a core reset.

## 52.5.6 Interrupts

The I2C module generates an interrupt when any of the events in the table found here occur, provided that the IICIE bit is set.

The interrupt is driven by the IICIF bit (of the I2C Status Register) and masked with the IICIE bit (of the I2C Control Register 1). The IICIF bit must be cleared (by software) by writing 1 to it in the interrupt routine. The SMBus timeouts interrupt is driven by SLTF and masked with the IICIE bit. The SLTF bit must be cleared by software by writing 1 to it in the interrupt routine. You can determine the interrupt type by reading the Status Register.

### NOTE

In master receive mode, the FACK bit must be set to zero before the last byte transfer.

**Table 52-5. Interrupt summary**

| Interrupt source                     | Status | Flag  | Local enable    |
|--------------------------------------|--------|-------|-----------------|
| Complete 1-byte transfer             | TCF    | IICIF | IICIE           |
| Match of received calling address    | IAAS   | IICIF | IICIE           |
| Arbitration lost                     | ARBL   | IICIF | IICIE           |
| I <sup>2</sup> C bus stop detection  | STOPF  | IICIF | IICIE & SSIE    |
| I <sup>2</sup> C bus start detection | STARTF | IICIF | IICIE & SSIE    |
| SMBus SCL low timeout                | SLTF   | IICIF | IICIE           |
| SMBus SCL high SDA low timeout       | SHTF2  | IICIF | IICIE & SHTF2IE |
| Wakeup from stop or wait mode        | IAAS   | IICIF | IICIE & WUEN    |

### 52.5.6.1 Byte transfer interrupt

The Transfer Complete Flag (TCF) bit is set at the falling edge of the ninth clock to indicate the completion of a byte and acknowledgement transfer. When FACK is enabled, TCF is then set at the falling edge of eighth clock to indicate the completion of byte.

### 52.5.6.2 Address detect interrupt

When the calling address matches the programmed slave address (I2C Address Register) or when the GCAEN bit is set and a general call is received, the IAAS bit in the Status Register is set. The CPU is interrupted, provided the IICIE bit is set. The CPU must check the SRW bit and set its Tx mode accordingly.

### 52.5.6.3 Stop Detect Interrupt

When the stop status is detected on the I<sup>2</sup>C bus, the STOPF bit is set to 1. The CPU is interrupted, provided the IICIE and SSIE bits are both set to 1.

### 52.5.6.4 Exit from low-power/stop modes

The slave receive input detect circuit and address matching feature are still active on low power modes (wait and stop). An asynchronous input matching slave address or general call address brings the CPU out of low power/stop mode if the interrupt is not masked. Therefore, TCF and IAAS both can trigger this interrupt.

### 52.5.6.5 Arbitration lost interrupt

The I2C is a true multimaster bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, the relative priority of the contending masters is determined by a data arbitration procedure. The I2C module asserts the arbitration-lost interrupt when it loses the data arbitration process and the ARBL bit in the Status Register is set.

Arbitration is lost in the following circumstances:

1. SDA is sampled as low when the master drives high during an address or data transmit cycle.
2. SDA is sampled as low when the master drives high during the acknowledge bit of a data receive cycle.
3. A START cycle is attempted when the bus is busy.
4. A repeated START cycle is requested in slave mode.
5. A STOP condition is detected when the master did not request it.

The ARBL bit must be cleared (by software) by writing 1 to it.

### 52.5.6.6 Timeout interrupt in SMBus

When the IICIE bit is set, the I2C module asserts a timeout interrupt (outputs SLTF and SHTF2) upon detection of any of the mentioned timeout conditions, with one exception. The SCL high and SDA high TIMEOUT mechanism must not be used to influence the timeout interrupt output, because this timeout indicates an idle condition on the bus. SHTF1 rises when it matches the SCL high and SDA high TIMEOUT and falls automatically just to indicate the bus status. The SHTF2's timeout period is the same as that of SHTF1, which is short compared to that of SLTF, so another control bit, SHTF2IE, is added to enable or disable it.

### 52.5.7 Programmable input glitch filter

An I2C glitch filter has been added outside legacy I2C modules but within the I2C package. This filter can absorb glitches on the I2C clock and data lines for the I2C module.

The width of the glitch to absorb can be specified in terms of the number of (half) I2C module clock cycles. A single Programmable Input Glitch Filter control register is provided. Effectively, any down-up-down or up-down-up transition on the data line that occurs within the number of clock cycles programmed in this register is ignored by the I2C module. The programmer must specify the size of the glitch (in terms of I2C module clock cycles) for the filter to absorb and not pass.

Figure 52-5. Programmable input glitch filter diagram

### 52.5.8 Address matching wake-up

When a primary, range, or general call address match occurs when the I2C module is in slave receive mode, the MCU wakes from a low power mode where no peripheral bus is running.

Data sent on the bus that is the same as a target device address might also wake the target MCU.

After the address matching IAAS bit is set, an interrupt is sent at the end of address matching to wake the core. The IAAS bit must be cleared after the clock recovery.

### **NOTE**

After the system recovers and is in Run mode, restart the I2C module if it is needed to transfer packets. To avoid I2C transfer problems resulting from the situation, firmware should prevent the MCU execution of a STOP instruction when the I2C module is in the middle of a transfer unless the Stop mode holdoff feature is used during this period (set FLT[SHEN] to 1).

## **52.5.9 DMA support**

If the DMAEN bit is cleared and the IICIE bit is set, an interrupt condition generates an interrupt request.

If the DMAEN bit is set and the IICIE bit is set, an interrupt condition generates a DMA request instead. DMA requests are generated by the transfer complete flag (TCF).

If the DMAEN bit is set, only the TCF initiates a DMA request. All other events generate CPU interrupts.

### **NOTE**

Before the last byte of master receive mode, TXAK must be set to send a NACK after the last byte's transfer. Therefore, the DMA must be disabled before the last byte's transfer.

### **NOTE**

In 10-bit address mode transmission, the addresses to send occupy 2–3 bytes. During this transfer period, the DMA must be disabled because the C1 register is written to send a repeat start or to change the transfer direction.

## **52.6 Initialization/application information**

### **Module Initialization (Slave)**

1. Write: Control Register 2
  - to enable or disable general call
  - to select 10-bit or 7-bit addressing mode
2. Write: Address Register 1 to set the slave address

3. Write: Control Register 1 to enable the I2C module and interrupts
4. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
5. Initialize RAM variables used to achieve the routine shown in the following figure

#### Module Initialization (Master)

1. Write: Frequency Divider register to set the I2C baud rate (see example in description of [ICR](#))
2. Write: Control Register 1 to enable the I2C module and interrupts
3. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
4. Initialize RAM variables used to achieve the routine shown in the following figure
5. Write: Control Register 1 to enable TX
6. Write: Control Register 1 to enable MST (master mode)
7. Write: Data register with the address of the target slave (the LSB of this byte determines whether the communication is master receive or transmit)

The routine shown in the following figure encompasses both master and slave I2C operations. For slave operation, an incoming I2C message that contains the proper address begins I2C communication. For master operation, communication must be initiated by writing the Data register. An example of an I2C driver which implements many of the steps described here is available in [AN4342: Using the Inter-Integrated Circuit on ColdFire+ and Kinetis](#) .

## Notes:

1. If general call is enabled, check to determine if the received address is a general call address (0x00).  
If the received address is a general call address, the general call must be handled by user software.
2. When 10-bit addressing addresses a slave, the slave sees an interrupt following the first byte of the extended address.  
Ensure that for this interrupt, the contents of the Data register are ignored and not treated as a valid data transfer.

Figure 52-6. Typical I2C interrupt routine

## Notes:

1. If general call or SIICAEN is enabled, check to determine if the received address is a general call address (0x00) or an SMBus device default address. In either case, they must be handled by user software.
2. In receive mode, one bit time delay may be needed before the first and second data reading, to wait for the possible longest time period (in worst case) of the 9th SCL cycle.
3. This read is a dummy read in order to reset the SMBus receiver state machine.

Figure 52-7. Typical I2C SMBus interrupt routine

# Chapter 53

## Universal Asynchronous Receiver/Transmitter (UART) / FlexSCI

### 53.1 Chip-specific UART information

#### 53.1.1 UART configuration

This chip contains six UART modules.

1. Standard features of all UARTs:
  - RS-485 support
  - Hardware flow control (RTS/CTS)
  - 9-bit UART to support address mark with parity
  - MSB/LSB configuration on data
2. All UARTs are clocked from the fast peripheral clock. The maximum baud rate is 1/16 of related source clock frequency.
3. IrDA is available on all UARTs
4. UART0 and UART1 contains the standard features plus ISO7816
5. UART0 and UART1 contain 8-entry transmit and 8-entry receive FIFOs
6. All other UARTs contain a 1-entry transmit and 1-entry receive FIFOs

#### 53.1.2 UART signals

| Signal            | I/O    | Connected to                                                      |
|-------------------|--------|-------------------------------------------------------------------|
| UART0             |        |                                                                   |
| Receive complete  | Output | DMA_MUX0 source 2                                                 |
| Transmit complete | Output | DMA_MUX0 source 3                                                 |
| UART0RXSRC        | Input  | UART0_RX pin or CMP0_OUT or CMP1_OUT                              |
| UART0TXSRC        | Input  | UART0_TX pin or UART0_TX pin modulated with FTM1 channel 0 output |
| UART1             |        |                                                                   |

*Table continues on the next page...*

## Chip-specific UART information

| Signal            | I/O    | Connected to                                                      |
|-------------------|--------|-------------------------------------------------------------------|
| Receive complete  | Output | DMA_MUX0 source 4                                                 |
| Transmit complete | Output | DMA_MUX0 source 5                                                 |

| Receive complete  | Output | DMA_MUX1 source 54                                                |
| Transmit complete | Output | DMA_MUX1 source 55                                                |
| UART1RXSRC        | Input  | UART4_RX pin                                                      |
| UART1TXSRC        | Input  | UART4_TX pin                                                      |
| <b>UART5</b>      |        |                                                                   |
| Receive complete  | Output | DMA_MUX1 source 56                                                |
| Transmit complete | Output | DMA_MUX1 source 57                                                |
| UART1RXSRC        | Input  | UART5_RX pin                                                      |
| UART1TXSRC        | Input  | UART5_TX pin                                                      |

### 53.1.3 UART wakeup

The UART can be configured to generate an interrupt/wakeup on the first active edge that it receives.

### 53.1.4 UART interrupts

The UART has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request:

The status interrupt combines the following interrupt sources:

| Source                   | UART 0 | UART 1 | UART 2 | UART 3 | UART 4 | UART 5 |
|--------------------------|--------|--------|--------|--------|--------|--------|
| Transmit data empty      | x      | x      | x      | x      | x      | x      |
| Transmit complete        | x      | x      | x      | x      | x      | x      |
| Idle line                | x      | x      | x      | x      | x      | x      |
| Receive data full        | x      | x      | x      | x      | x      | x      |
| LIN break detect         | x      | x      | x      | x      | x      | x      |
| RxD pin active edge      | x      | x      | x      | x      | x      | x      |
| Initial character detect | x      | x      | —      | —      | —      | —      |

The error interrupt combines the following interrupt sources:

| Source                         | UART 0 | UART 1 | UART 2 | UART 3 | UART 4 | UART 5 |
|--------------------------------|--------|--------|--------|--------|--------|--------|
| Receiver overrun               | x      | x      | x      | x      | x      | x      |
| Noise flag                     | x      | x      | x      | x      | x      | x      |
| Framing error                  | x      | x      | x      | x      | x      | x      |
| Parity error                   | x      | x      | x      | x      | x      | x      |
| Transmitter buffer overflow    | x      | x      | x      | x      | x      | x      |
| Receiver buffer overflow       | x      | x      | x      | x      | x      | x      |
| Receiver buffer underflow      | x      | x      | x      | x      | x      | x      |
| Transmit threshold (ISO7816)   | x      | x      | —      | —      | —      | —      |
| Receiver threshold (ISO7816)   | x      | x      | —      | —      | —      | —      |
| Wait timer (ISO7816)           | x      | x      | —      | —      | —      | —      |
| Character wait timer (ISO7816) | x      | x      | —      | —      | —      | —      |
| Block wait timer (ISO7816)     | x      | x      | —      | —      | —      | —      |
| Guard time violation (ISO7816) | x      | x      | —      | —      | —      | —      |
| ATR duration timer (ISO7816)   | x      | x      | —      | —      | —      | —      |

## 53.2 Introduction

The UART allows asynchronous serial communication with peripheral devices and CPUs.

### 53.2.1 Features

The UART includes the following features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
- 13-bit baud rate selection with /32 fractional divide, based on the module clock frequency
- Programmable 8-bit or 9-bit data format
- Programmable 1 or 2 stop bits in a data frame.
- Separately enabled transmitter and receiver
- Programmable transmitter output polarity
- Programmable receive input polarity
- Up to 16-bit break character transmission.
- 11-bit break character detection option
- Independent FIFO structure for transmit and receive
- Two receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
- Address match feature in the receiver to reduce address mark wakeup ISR overhead
- Ability to select MSB or LSB to be first bit on wire
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals

- Support for ISO 7816 protocol to interface with SIM cards and smart cards
  - Support for T=0 and T=1 protocols
  - Automatic retransmission of NACK'd packets with programmable retry threshold
  - Support for 11 and 12 ETU transfers
  - Detection of initial packet and automated transfer parameter programming
  - Interrupt-driven operation with seven ISO-7816 specific interrupts:
    - Wait time violated
    - Character wait time violated
    - Block wait time violated
    - Initial frame detected
    - Transmit error threshold exceeded
    - Receive error threshold exceeded
    - Guard time violated
- Interrupt-driven operation with flags, not specific to ISO-7816 support
  - Transmitter data buffer at or below watermark
  - Transmission complete
  - Receiver data buffer at or above watermark
  - Idle receiver input
  - Receiver data buffer overrun
  - Receiver data buffer underflow
  - Transmit data buffer overflow
  - Noise error
  - Framing error
  - Parity error
  - Active edge on receive pin
  - LIN break detect

- Receiver framing error detection
- Hardware parity generation and checking
- 1/16 bit-time noise detection
- DMA interface

## **53.2.2 Modes of operation**

The UART functions in the same way in all the normal modes.

It has the following low power modes:

- Wait mode
- Stop mode

### **53.2.2.1 Run mode**

This is the normal mode of operation.

### **53.2.2.2 Wait mode**

UART operation in the Wait mode depends on the state of the C1[UARTSWAI] field.

- If C1[UARTSWAI] is cleared, and the CPU is in Wait mode, the UART operates normally.
- If C1[UARTSWAI] is set, and the CPU is in Wait mode, the UART clock generation ceases and the UART module enters a power conservation state.

C1[UARTSWAI] does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

Setting C1[UARTSWAI] does not affect the state of the C2[RE] or C2[TE].

If C1[UARTSWAI] is set, any ongoing transmission or reception stops at the Wait mode entry. The transmission or reception resumes when either an internal or external interrupt brings the CPU out of Wait mode. Bringing the CPU out of Wait mode by reset aborts any ongoing transmission or reception and resets the UART.

### 53.2.2.3 Stop mode

The UART is inactive during Stop mode for reduced power consumption. The STOP instruction does not affect the UART register states, but the UART module clock is disabled. The UART operation resumes after an external interrupt brings the CPU out of Stop mode. Bringing the CPU out of Stop mode by reset aborts any ongoing transmission or reception and resets the UART. Entering or leaving Stop mode does not initiate any power down or power up procedures for the ISO-7816 smartcard interface.

## 53.3 UART signal descriptions

The UART signals are shown in the following table.

**Table 53-1. UART signal descriptions**

| Signal | Description     | I/O |
|--------|-----------------|-----|
| CTS    | Clear to send   | I   |
| RTS    | Request to send | O   |
| RXD    | Receive data    | I   |
| TXD    | Transmit data   | O   |

### 53.3.1 Detailed signal descriptions

The detailed signal descriptions of the UART are shown in the following table.

**Table 53-2. UART—Detailed signal descriptions**

| Signal | I/O | Description                                                                                                                                                                                                                                                                                |
|--------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CTS    | I   | Clear to send. Indicates whether the UART can start transmitting data when flow control is enabled.                                                                                                                                                                                        |
|        |     | <b>State meaning</b><br>Asserted—Data transmission can start.<br>Negated—Data transmission cannot start.                                                                                                                                                                                   |
|        |     | <b>Timing</b><br>Assertion—When transmitting device's $\overline{\text{RTS}}$ asserts.<br>Negation—When transmitting device's $\overline{\text{RTS}}$ deasserts.                                                                                                                           |
| RTS    | O   | Request to send. When driven by the receiver, indicates whether the UART is ready to receive data. When driven by the transmitter, can enable an external transceiver during transmission.                                                                                                 |
|        |     | <b>State meaning</b><br>Asserted—When driven by the receiver, ready to receive data. When driven by the transmitter, enable the external transmitter.<br>Negated—When driven by the receiver, not ready to receive data. When driven by the transmitter, disable the external transmitter. |

*Table continues on the next page...*

**Table 53-2. UART—Detailed signal descriptions (continued)**

| Signal | I/O | Description          |                                                                                                                                                                                          |
|--------|-----|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        |     | <b>Timing</b>        | Assertion—Can occur at any time; can assert asynchronously to the other input signals.<br>Negation—Can occur at any time; can deassert asynchronously to the other input signals.        |
| RXD    | I   |                      | Receive data. Serial data input to receiver.                                                                                                                                             |
|        |     | <b>State meaning</b> | Whether RXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.                                                                       |
|        |     | <b>Timing</b>        | Sampled at a frequency determined by the module clock divided by the baud rate.                                                                                                          |
| TXD    | O   |                      | Transmit data. Serial data output from transmitter.                                                                                                                                      |
|        |     | <b>State meaning</b> | Whether TXD is interpreted as a 1 or 0 depends on the bit encoding method along with other configuration settings.                                                                       |
|        |     | <b>Timing</b>        | Driven at the beginning or within a bit time according to the bit encoding method along with other configuration settings. Otherwise, transmissions are independent of reception timing. |

## 53.4 Memory map and registers

This section provides a detailed description of all memory and registers.

Accessing reserved addresses within the memory map results in a transfer error. None of the contents of the implemented addresses are modified as a result of that access.

Only byte accesses are supported.

### UART memory map

| Absolute address (hex) | Register name                              | Width (in bits) | Access | Reset value | Section/ page                |
|------------------------|--------------------------------------------|-----------------|--------|-------------|------------------------------|
| 4006_A000              | UART Baud Rate Registers: High (UART0_BDH) | 8               | R/W    | 00h         | <a href="#">53.4.1/1662</a>  |
| 4006_A001              | UART Baud Rate Registers: Low (UART0_BDL)  | 8               | R/W    | 04h         | <a href="#">53.4.2/1663</a>  |
| 4006_A002              | UART Control Register 1 (UART0_C1)         | 8               | R/W    | 00h         | <a href="#">53.4.3/1663</a>  |
| 4006_A003              | UART Control Register 2 (UART0_C2)         | 8               | R/W    | 00h         | <a href="#">53.4.4/1665</a>  |
| 4006_A004              | UART Status Register 1 (UART0_S1)          | 8               | R      | C0h         | <a href="#">53.4.5/1667</a>  |
| 4006_A005              | UART Status Register 2 (UART0_S2)          | 8               | R/W    | 00h         | <a href="#">53.4.6/1670</a>  |
| 4006_A006              | UART Control Register 3 (UART0_C3)         | 8               | R/W    | 00h         | <a href="#">53.4.7/1672</a>  |
| 4006_A007              | UART Data Register (UART0_D)               | 8               | R/W    | 00h         | <a href="#">53.4.8/1673</a>  |

### 53.4.1 UART Baud Rate Registers: High (UARTx\_BDH)

This register, along with the BDL register, controls the prescale divisor for UART baud rate generation. To update the 13-bit baud rate setting (SBR[12:0]), first write to BDH to buffer the high half of the new value and then write to BDL. The working value in BDH does not change until BDL is written.

BDL is reset to a nonzero value, but after reset, the baud rate generator remains disabled until the first time the receiver or transmitter is enabled, that is, when C2[RE] or C2[TE] is set.

Address: Base address + 0h offset

| Bit   | 7      | 6       | 5    | 4   | 3 | 2 | 1 | 0 |
|-------|--------|---------|------|-----|---|---|---|---|
| Read  | LBKDIE | RXEDGIE | SBNS | SBR |   |   |   |   |
| Write |        |         |      |     |   |   |   |   |
| Reset | 0      | 0       | 0    | 0   | 0 | 0 | 0 | 0 |

|               | 0 Normal operation.<br>1 Loop mode where transmitter output is internally connected to receiver input. The receiver input is determined by RSRC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6<br>UARTSWAI | UART Stops in Wait Mode<br>0 UART clock continues to run in Wait mode.<br>1 UART clock freezes while CPU is in Wait mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 5<br>RSRC     | Receiver Source Select<br>This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.<br>0 Selects internal loop back mode. The receiver input is internally connected to transmitter output.<br>1 Single wire UART mode where the receiver input is connected to the transmit pin input signal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 4<br>M        | 9-bit or 8-bit Mode Select<br>This field must be set when C7816[ISO_7816E] is set/enabled.<br>0 Normal—start + 8 data bits (MSB/LSB first as determined by MSBF) + stop.<br>1 Use—start + 9 data bits (MSB/LSB first as determined by MSBF) + stop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3<br>WAKE     | Receiver Wakeup Method Select<br>Determines which condition wakes the UART: <ul style="list-style-type: none"> <li>Address mark in the most significant bit position of a received data character, or</li> <li>An idle condition on the receive pin input signal.</li> </ul> 0 Idle line wakeup.<br>1 Address mark wakeup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2<br>ILT      | Idle Line Type Select<br>Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.<br><b>NOTE:</b> <ul style="list-style-type: none"> <li>In case the UART is programmed with ILT = 1, a logic of 1'b0 is automatically shifted after a received stop bit, therefore resetting the idle count.</li> <li>In case the UART is programmed for IDLE line wakeup (RWU = 1 and WAKE = 0), ILT has no effect on when the receiver starts counting logic 1s as idle character bits. In idle line wakeup, an idle character is recognized at anytime the receiver sees 10, 11, or 12 1s depending on the M, PE, and C4[M10] fields.</li> </ul> 0 Idle character bit count starts after start bit.<br>1 Idle character bit count starts after stop bit. |
| 1<br>PE       | Parity Enable<br>Enables the parity function. When parity is enabled, parity function inserts a parity bit in the bit position immediately preceding the stop bit. This field must be set when C7816[ISO_7816E] is set/enabled.<br>0 Parity function disabled.<br>1 Parity function enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|          | 0 IDLE interrupt requests disabled.<br>1 IDLE interrupt requests enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3<br>TE  | <b>Transmitter Enable</b><br><br>Enables the UART transmitter. TE can be used to queue an idle preamble by clearing and then setting TE. When C7816[ISO_7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block has been transmitted. This condition is detected when TL7816[TLEN] = 0 and four additional characters are transmitted.<br><br>0 Transmitter off.<br>1 Transmitter on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 2<br>RE  | <b>Receiver Enable</b><br><br>Enables the UART receiver.<br><br>0 Receiver off.<br>1 Receiver on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 1<br>RWU | <b>Receiver Wakeup Control</b><br><br>This field can be set to place the UART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when C1[WAKE] is clear or an address match when C1[WAKE] is set. This field must be cleared when C7816[ISO_7816E] is set.<br><br><b>NOTE:</b> RWU must be set only with C1[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by S2[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the UART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to reasserted.<br><br>0 Normal operation.<br>1 RWU enables the wakeup function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU. |
| 0<br>SBK | <b>Send Break</b><br><br>Toggling SBK sends one break character from the following: See <a href="#">Transmitting break characters</a> for the number of logic 0s for the different configurations. Toggling implies clearing the SBK field before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send complete break characters (10, 11, or 12 bits, or 13 or 14 bits). Ensure that C2[TE] is asserted at least 1 clock before assertion of this bit. <ul style="list-style-type: none"> <li>• 10, 11, or 12 logic 0s if S2[BRK13] is cleared</li> <li>• 13 or 14 logic 0s if S2[BRK13] is set.</li> </ul> This field must be cleared when C7816[ISO_7816E] is set.<br><br>0 Normal transmitter operation.<br>1 Queue break characters to be sent.                                                                                                                    |

### 53.4.5 UART Status Register 1 (UARTx\_S1)

The S1 register provides inputs to the MCU for generation of UART interrupts or DMA requests. This register can also be polled by the MCU to check the status of its fields. To clear a flag, the status register should be read followed by a read or write to D register, depending on the interrupt flag type. Other instructions can be executed between the two steps as long the handling of I/O is not compromised, but the order of operations is important for flag clearing. When a flag is configured to trigger a DMA request, assertion of the associated DMA done signal from the DMA controller clears the flag.

#### NOTE

- If the condition that results in the assertion of the flag, interrupt, or DMA request is not resolved prior to clearing the flag, the flag, and interrupt/DMA request, reasserts. For example, if the DMA or interrupt service routine fails to write sufficient data to the transmit buffer to raise it above the watermark level, the flag reasserts and generates another interrupt or DMA request.
- Reading an empty data register to clear one of the flags of the S1 register causes the FIFO pointers to become misaligned. A receive FIFO flush reinitializes the pointers. A better way to prevent this situation is to always leave one byte in FIFO and this byte will be read eventually in clearing the flag bit.

Address: Base address + 4h offset

| Bit   | 7    | 6  | 5    | 4    | 3  | 2  | 1  | 0  |
|-------|------|----|------|------|----|----|----|----|
| Read  | TDRE | TC | RDRF | IDLE | OR | NF | FE | PF |
| Write |      |    |      |      |    |    |    |    |
| Reset | 1    | 1  | 0    | 0    | 0  | 0  | 0  | 0  |

#### UARTx\_S1 field descriptions

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>TDRE | <p>Transmit Data Register Empty Flag</p> <p>TDRE will set when the number of datawords in the transmit buffer (D and C3[T8]) is equal to or less than the number indicated by TWFIPO[TXWATER]. A character that is in the process of being transmitted is not included in the count. To clear TDRE, read S1 when TDRE is set and then write to the UART data register (D). For more efficient interrupt servicing, all data except the final value to be written to the buffer must be written to D/C3[T8]. Then S1 can be read before writing the final data value, resulting in the clearing of the TDRE flag. This is more efficient because the TDRE reasserts until the watermark has been exceeded. So, attempting to clear the TDRE with every write will be ineffective until sufficient data has been written.</p> |

## UARTx\_S1 field descriptions (continued)

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>0 The amount of data in the transmit buffer is greater than the value indicated by TWFIPO[TXWATER].</p> <p>1 The amount of data in the transmit buffer is less than or equal to the value indicated by TWFIPO[TXWATER] at some point in time since the flag has been cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 6<br>TC   | <p>Transmit Complete Flag</p> <p>TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by reading S1 with TC set and then doing one of the following: When C7816[ISO_7816E] is set/enabled, this field is set after any NACK signal has been received, but prior to any corresponding guard times expiring.</p> <ul style="list-style-type: none"> <li>• Writing to D to transmit new data.</li> <li>• Queuing a preamble by clearing and then setting C2[TE].</li> <li>• Queuing a break character by writing 1 to SBK in C2.</li> </ul> <p>0 Transmitter active (sending data, a preamble, or a break).</p> <p>1 Transmitter idle (transmission activity complete).</p>                                                                                                                                                                                                                                                                                                                       |
| 5<br>RDRF | <p>Receive Data Register Full Flag</p> <p>RDRF is set when the number of datawords in the receive buffer is equal to or more than the number indicated by RWFIFO[RXWATER]. A dataword that is in the process of being received is not included in the count. To clear RDRF, read S1 when RDRF is set and then read D. For more efficient interrupt and DMA operation, read all data except the final value from the buffer, using D/C3[T8]/ED. Then read S1 and the final data value, resulting in the clearing of the RDRF flag. Even if RDRF is set, data will continue to be received until an overrun condition occurs. RDRF is prevented from setting while S2[LBKDE] is set. Additionally, when S2[LBKDE] is set, the received datawords are stored in the receive buffer but over-write each other.</p> <p>0 The number of datawords in the receive buffer is less than the number indicated by RXWATER.</p> <p>1 The number of datawords in the receive buffer is equal to or greater than the number indicated by RXWATER at some point in time since this flag was last cleared.</p>                                              |
| 4<br>IDLE | <p>Idle Line Flag</p> <p>After the IDLE flag is cleared, a frame must be received (although not necessarily stored in the data buffer, for example if C2[RWU] is set), or a LIN break character must set the S2[LBKDIF] flag before an idle condition can set the IDLE flag. To clear IDLE, read UART status S1 with IDLE set and then read D. IDLE is set when either of the following appear on the receiver input:</p> <ul style="list-style-type: none"> <li>• 10 consecutive logic 1s if C1[M] = 0</li> <li>• 11 consecutive logic 1s if C1[M] = 1 and C4[M10] = 0</li> <li>• 12 consecutive logic 1s if C1[M] = 1, C4[M10] = 1, and C1[PE] = 1</li> </ul> <p>Idle detection is not supported when 7816E is set/enabled and hence this flag is ignored.</p> <p><b>NOTE:</b> When RWU is set and WAKE is cleared, an idle line condition sets the IDLE flag if RWUID is set, else the IDLE flag does not become set.</p> <p>0 Receiver input is either active now or has never become active since the IDLE flag was last cleared.</p> <p>1 Receiver input has become idle or the flag has not been cleared since it last asserted.</p> |
| 3<br>OR   | <p>Receiver Overrun Flag</p> <p>OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the UART data registers is not affected. If the OR flag is set, no data is stored in the data buffer even if sufficient room exists. Additionally, while the OR flag is set, the RDRF and IDLE flags are blocked from asserting, that is, transition from an inactive to an active state. To clear OR, read S1 when OR is set and then read D. See functional description for more details regarding the operation of</p>                                                                                                                                                                                                                                                                                                                |

**UARTx\_S1 field descriptions (continued)**

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | <p>the OR bit. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if S2[LBKDIF] is not cleared before the next data character is received. In 7816 mode, it is possible to configure a NACK to be returned by programming C7816[ONACK].</p> <p>0 No overrun has occurred since the last time the flag was cleared.</p> <p>1 Overrun has occurred or the overrun flag has not been cleared since the last overrun occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2<br>NF | <p>Noise Flag</p> <p>NF is set when the UART detects noise on the receiver input. NF does not become set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). When NF is set, it indicates only that a dataword has been received with noise since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has noise or that there is only one dataword in the buffer that was received with noise unless the receive buffer has a depth of one. To clear NF, read S1 and then read D.</p> <p>0 No noise detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1 then there may be data in the receiver buffer that was received with noise.</p> <p>1 At least one dataword was received with noise detected since the last time the flag was cleared.</p>                                                                                                                                                                                                                                              |
| 1<br>FE | <p>Framing Error Flag</p> <p>FE is set when a logic 0 is accepted as the stop bit. When BDH[SBNS] is set, then FE will set when a logic 0 is accepted for either of the two stop bits. FE does not set in the case of an overrun or while the LIN break detect feature is enabled (S2[LBKDE] = 1). FE inhibits further data reception until it is cleared. To clear FE, read S1 with FE set and then read D. The last data in the receive buffer represents the data that was received with the frame error enabled. Framing errors are not supported when 7816E is set/enabled. However, if this flag is set, data is still not received in 7816 mode.</p> <p>0 No framing error detected.</p> <p>1 Framing error.</p>                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0<br>PF | <p>Parity Error Flag</p> <p>PF is set when PE is set and the parity of the received data does not match its parity bit. The PF is not set in the case of an overrun condition. When PF is set, it indicates only that a dataword was received with parity error since the last time it was cleared. There is no guarantee that the first dataword read from the receive buffer has a parity error or that there is only one dataword in the buffer that was received with a parity error, unless the receive buffer has a depth of one. To clear PF, read S1 and then read D., S2[LBKDE] is disabled. Within the receive buffer structure the received dataword is tagged if it is received with a parity error. This information is available by reading the ED register prior to reading the D register.</p> <p>0 No parity error detected since the last time this flag was cleared. If the receive buffer has a depth greater than 1, then there may be data in the receive buffer what was received with a parity error.</p> <p>1 At least one dataword was received with a parity error since the last time this flag was cleared.</p> |

### 53.4.6 UART Status Register 2 (UARTx\_S2)

The S2 register provides inputs to the MCU for generation of UART interrupts or DMA requests. Also, this register can be polled by the MCU to check the status of these bits. This register can be read or written at any time, with the exception of the MSBF and RXINV bits, which should be changed by the user only between transmit and receive packets.

Address: Base address + 5h offset

| Bit   | 7      | 6       | 5    | 4     | 3     | 2     | 1     | 0   |
|-------|--------|---------|------|-------|-------|-------|-------|-----|
| Read  | LBKDIF | RXEDGIF | MSBF | RXINV | RWUID | BRK13 | LBKDE | RAF |
| Write | w1c    | w1c     |      |       |       |       |       |     |

**UARTx\_S2 field descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>LBKDIF  | <p>LIN Break Detect Interrupt Flag</p> <p>LBKDIF is set when LBKDE is set and a LIN break character is detected on the receiver input. The LIN break characters are 11 consecutive logic 0s if C1[M] = 0 or 12 consecutive logic 0s if C1[M] = 1. LBKDIF is set after receiving the last LIN break character. LBKDIF is cleared by writing a 1 to it.</p> <p>0 No LIN break character detected.<br/>1 LIN break character detected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6<br>RXEDGIF | <p>RxD Pin Active Edge Interrupt Flag</p> <p>RXEDGIF is set when an active edge occurs on the RxD pin. The active edge is falling if RXINV = 0, and rising if RXINV=1. RXEDGIF is cleared by writing a 1 to it. See for additional details. <a href="#">RXEDGIF description</a></p> <p><b>NOTE:</b> The active edge is detected only in two wire mode and on receiving data coming from the RxD pin.</p> <p>0 No active edge on the receive pin has occurred.<br/>1 An active edge on the receive pin has occurred.</p>                                                                                                                                                                                                                                                                                                                                                 |
| 5<br>MSBF    | <p>Most Significant Bit First</p> <p>Setting this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p>0 LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.<br/>1 MSB (bit8, bit7 or bit6) is the first bit that is transmitted following the start bit, depending on the setting of C1[M] and C1[PE]. Further, the first bit received after the start bit is identified as bit8, bit7, or bit6, depending on the setting of C1[M] and C1[PE].</p> |
| 4<br>RXINV   | Receive Data Inversion                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## UARTx\_S2 field descriptions (continued)

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <p>Setting this field reverses the polarity of the received data input. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity. A zero is represented by a short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p><b>NOTE:</b> Setting RXINV inverts the RxD input for data bits, start and stop bits, break, and idle. When C7816[ISO7816E] is set/enabled, only the data bits and the parity bit are inverted.</p> <p>0 Receive data is not inverted.<br/>1 Receive data is inverted.</p> |
| 3<br>RWUID | <p>Receive Wakeup Idle Detect</p> <p>When RWU is set and WAKE is cleared, this field controls whether the idle character that wakes the receiver sets S1[IDLE]. This field must be cleared when C7816[ISO7816E] is set/enabled.</p> <p>0 S1[IDLE] is not set upon detection of an idle character.<br/>1 S1[IDLE] is set upon detection of an idle character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 2<br>BRK13 | <p>Break Transmit Character Length</p> <p>Determines whether the transmit break character is 10, 11, or 12 bits long, or 13 or 14 bits long. See for the length of the break character for the different configurations. The detection of a framing error is not affected by this field. <a href="#">Transmitting break characters</a></p> <p>0 Break character is 10, 11, or 12 bits long.<br/>1 Break character is 13 or 14 bits long.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 1<br>LBKDE | <p>LIN Break Detection Enable</p> <p>Enables the LIN Break detection feature. While LBKDE is set, S1[RDRF], S1[NF], S1[FE], and S1[PF] are prevented from setting. When LBKDE is set, see <a href="#">. Overrun operation</a>. LBKDE must be cleared when C7816[ISO7816E] is set.</p> <p>0 Break character detection is disabled.<br/>1 Break character is detected at length of 11 bit times if C1[M] = 0 or 12 bits time if C1[M] = 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0<br>RAF   | <p>Receiver Active Flag</p> <p>RAF is set when the UART receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character when C7816[ISO7816E] is cleared/disabled. When C7816[ISO7816E] is enabled, the RAF is cleared if the C7816[TTYE] = 0 expires or the C7816[TTYE] = 1 expires.</p> <p><b>NOTE:</b> In case C7816[ISO7816E] is set and C7816[TTYE] = 0, it is possible to configure the guard time to 12. However, if a NACK is required to be transmitted, the data transfer actually takes 13 ETU with the 13th ETU slot being an inactive buffer. Therefore, in this situation, the RAF may deassert one ETU prior to actually being inactive.</p> <p>0 UART receiver idle/inactive waiting for a start bit.<br/>1 UART receiver active, RxD input not idle.</p>                                                                         |

### 53.4.7 UART Control Register 3 (UARTx\_C3)

Writing R8 does not have any effect. TXDIR and TXINV can be changed only between transmit and receive packets.

Address: Base address + 6h offset

#### UARTx\_C3 field descriptions

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>R8    | <p>Received Bit 8</p> <p>R8 is the ninth data bit received when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1. The R8 value corresponds to the current data value in the UARTx_D register. To read the 9th bit, read the value of UARTx_C3[R8], then read the UARTx_D register.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6<br>T8    | <p>Transmit Bit 8</p> <p>T8 is the ninth data bit transmitted when the UART is configured for 9-bit data format, that is, if C1[M] = 1 or C4[M10] = 1.</p> <p><b>NOTE:</b> If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.</p> <p>To correctly transmit the 9th bit, write UARTx_C3[T8] to the desired value, then write the UARTx_D register with the remaining data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 5<br>TXDIR | <p>Transmitter Pin Data Direction in Single-Wire mode</p> <p>Determines whether the TXD pin is used as an input or output in the single-wire mode of operation. This field is relevant only to the single wire mode. When C7816[ISO7816E] is set/enabled and C7816[TTYTYPE] = 1, this field is automatically cleared after the requested block is transmitted. This condition is detected when TL7816[TLEN] = 0 and 4 additional characters are transmitted. Additionally, if C7816[ISO7816E] is set/enabled and C7816[TTYTYPE] = 0 and a NACK is being transmitted, the hardware automatically overrides this field as needed. In this situation, TXDIR does not reflect the temporary state associated with the NACK.</p> <p>0 TXD pin is an input in single wire mode.<br/>1 TXD pin is an output in single wire mode.</p>                                                                                                                                                                               |
| 4<br>TXINV | <p>Transmit Data Inversion.</p> <p>Setting this field reverses the polarity of the transmitted data output. In NRZ format, a one is represented by a mark and a zero is represented by a space for normal polarity, and the opposite for inverted polarity. In IrDA format, a zero is represented by short high pulse in the middle of a bit time remaining idle low for a one for normal polarity, and a zero is represented by short low pulse in the middle of a bit time remaining idle high for a one for inverted polarity. This field is automatically set when C7816[INIT] and C7816[ISO7816E] are enabled and an initial character is detected in T = 0 protocol mode.</p> <p><b>NOTE:</b> Setting TXINV inverts all transmitted values, including idle, break, start, and stop bits. In loop mode, if TXINV is set, the receiver gets the transmit inversion bit when RXINV is disabled. When C7816[ISO7816E] is set/enabled then only the transmitted data bits and parity bit are inverted.</p> |

**53.4.8 UART Data Register (UARTx\_D)**

This register is actually two separate registers. Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register.

**NOTE**

- In 8-bit or 9-bit data format, only UART data register (D) needs to be accessed to clear the S1[RDRF] bit (assuming receiver buffer level is less than RWFIFO[RXWATER]). The C3 register needs to be read, prior to the D register, only if the ninth bit of data needs to be captured. Similarly, the ED register needs to be read, prior to the D register, only if the additional flag data for the dataword needs to be captured.
- In the normal 8-bit mode (M bit cleared) if the parity is enabled, you get seven data bits and one parity bit. That one parity bit is loaded into the D register. So, for the data

bits, mask off the parity bit from the value you read out of this register.

- When transmitting in 9-bit data format and using 8-bit write instructions, write first to transmit bit 8 in UART control register 3 (C3[T8]), then D. A write to C3[T8] stores the data in a temporary register. If D register is written first, and then the new data on data bus is stored in D, the temporary value written by the last write to C3[T8] gets stored in the C3[T8] register.

|-------|--------------------------------------------------------------------------------------------------------------------------|
| RT    | Reads return the contents of the read-only receive data register and writes go to the write-only transmit data register. |

53.4.9 UART Match Address Registers 1 (UARTx\_MA1)

The MA1 and MA2 registers are compared to input data addresses when the most significant bit is set and the associated C4[MAEN] field is set. If a match occurs, the following data is transferred to the data register. If a match fails, the following data is discarded. These registers can be read and written at anytime.

Address: Base address + 8h offset

**53.4.13 UART Extended Data Register (UARTx\_ED)**

This register contains additional information flags that are stored with a received dataword. This register may be read at any time but contains valid data only if there is a dataword in the receive FIFO.

**NOTE**

- The data contained in this register represents additional information regarding the conditions on which a dataword was received. The importance of this data varies with the application, and in some cases maybe completely optional. These fields automatically update to reflect the conditions of the next dataword whenever D is read.
- If S1[NF] and S1[PF] have not been set since the last time the receive buffer was empty, the NOISY and PARITYE fields will be zero.

Address: Base address + Ch offset

## 53.4.14 UART Modem Register (UARTx\_MODEM)

The MODEM register controls options for setting the modem configuration.

**NOTE**

RXRTSE, TXRTSPOL, TXRTSE, and TXCTSE must all be cleared when C7816[ISO7816EN] is enabled. This will cause the RTS to deassert during ISO-7816 wait times. The ISO-7816 protocol does not use the RTS and CTS signals.

Address: Base address + Dh offset

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | 0 Transmitter RTS is active low.<br>1 Transmitter RTS is active high.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 1<br>TXRTSE | Transmitter request-to-send enable<br><br>Controls RTS before and after a transmission.<br><br>0 The transmitter has no effect on RTS.<br>1 When a character is placed into an empty transmitter data buffer , RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. (FIFO)<br><b>NOTE:</b> Ensure that C2[TE] is asserted before assertion of this bit.                                                            |
| 0<br>TXCTSE | Transmitter clear-to-send enable<br><br>TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.<br><br>0 CTS has no effect on the transmitter.<br>1 Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

**53.4.15 UART Infrared Register (UARTx\_IR)**

The IR register controls options for setting the infrared configuration.

Address: Base address + Eh offset

| 11    | 1/4.        |

**53.4.16 UART FIFO Parameters (UARTx\_PFIFO)**

This register provides the ability for the programmer to turn on and off FIFO functionality. It also provides the size of the FIFO that has been implemented. This register may be read at any time. This register must be written only when C2[RE] and C2[TE] are cleared/not set and when the data buffer/FIFO is empty.

Address: Base address + 10h offset

| Bit   | 7    | 6 | 5 | 4 | 3    | 2 | 1 | 0 |
|-------|------|---|---|---|------|---|---|---|
| Read  | TXFE |   |   |   | RXFE |   |   |   |
| Write |      |   |   |   |      |   |   |   |
| Reset | 0    | * | * | * | 0    | * | * | * |

\* Notes:

- TXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.
- RXFIFOSIZE field: The reset value depends on whether the specific UART instance supports the FIFO and on the size of that FIFO. See the Chip Configuration details for more information on the FIFO size supported for each UART instance.

**53.4.17 UART FIFO Control Register (UARTx\_CFIFO)**

This register provides the ability to program various control fields for FIFO operation. This register may be read or written at any time. Note that writing to TXFLUSH and RXFLUSH may result in data loss and requires careful action to prevent unintended/unpredictable behavior. Therefore, it is recommended that TE and RE be cleared prior to flushing the corresponding FIFO.

Address: Base address + 11h offset

53.4.19 UART FIFO Transmit Watermark (UARTx\_TWFIFO)

This register provides the ability to set a programmable threshold for notification of needing additional transmit data. This register may be read at any time but must be written only when C2[TE] is not set. Changing the value of the watermark will not clear the S1[TDRE] flag.

Address: Base address + 13h offset

UARTx\_TWFIFO field descriptions

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXWATER | <div>Transmit Watermark</div> <div>When the number of datawords in the transmit FIFO/buffer is equal to or less than the value in this register field, an interrupt via S1[TDRE] or a DMA request via C5[TDMAS] is generated as determined by C5[TDMAS] and C2[TIE]. For proper operation, the value in TXWATER must be set to be less than the size of the transmit buffer/FIFO size as indicated by PFIFO[TXFIFOSIZE] and PFIFO[TXFE].</div> |

53.4.20 UART FIFO Transmit Count (UARTx\_TCFIFO)

This is a read only register that indicates how many datawords are currently in the transmit buffer/FIFO. It may be read at any time.

Address: Base address + 14h offset

UARTx\_TCFIFO field descriptions

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXCOUNT | <div>Transmit Counter</div> <div>The value in this register indicates the number of datawords that are in the transmit FIFO/buffer. If a dataword is being transmitted, that is, in the transmit shift register, it is not included in the count. This value may be used in conjunction with PFIFO[TXFIFOSIZE] to calculate how much room is left in the transmit FIFO/buffer.</div> |

### 53.4.21 UART FIFO Receive Watermark (UARTx\_RWFIFO)

This register provides the ability to set a programmable threshold for notification of the need to remove data from the receiver FIFO/buffer. This register may be read at any time but must be written only when C2[RE] is not asserted. Changing the value in this register will not clear S1[RDRF].

Address: Base address + 15h offset

### 53.4.23 UART 7816 Control Register (UARTx\_C7816)

The C7816 register is the primary control register for ISO-7816 specific functionality. This register is specific to 7816 functionality and the values in this register have no effect on UART operation and should be ignored if ISO\_7816E is not set/enabled. This register may be read at any time but values must be changed only when ISO\_7816E is not set.

Address: Base address + 18h offset

| Bit   | 7 | 6 | 5 | 4     | 3     | 2    | 1       | 0         |
|-------|---|---|---|-------|-------|------|---------|-----------|
| Read  | 0 |   |   | ONACK | ANACK | INIT | TTYTYPE | ISO_7816E |
| Write |   |   |   |       |       |      |         |           |

| 7–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4<br>ONACK      | Generate NACK on Overflow<br><br>When this field is set, the receiver automatically generates a NACK response if a receive buffer overrun occurs, as indicated by S1[OR]. In many systems, this results in the transmitter resending the packet that overflowed until the retransmit threshold for that transmitter is reached. A NACK is generated only if TTYPE=0. This field operates independently of ANACK. See . <a href="#">Overrun NACK considerations</a><br><br>0 The received data does not generate a NACK when the receipt of the data results in an overflow event.<br>1 If the receiver buffer overflows, a NACK is automatically sent on a received character.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3<br>ANACK      | Generate NACK on Error<br><br>When this field is set, the receiver automatically generates a NACK response if a parity error occurs or if INIT is set and an invalid initial character is detected. A NACK is generated only if TTYPE = 0. If ANACK is set, the UART attempts to retransmit the data indefinitely. To stop retransmission attempts, clear C2[TE] or ISO_7816E and do not set until S1[TC] sets C2[TE] again.<br><br>0 No NACK is automatically generated.<br>1 A NACK is automatically generated if a parity error is detected or if an invalid initial character is detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2<br>INIT       | Detect Initial Character<br><br>When this field is set, all received characters are searched for a valid initial character. If an invalid initial character is identified, and ANACK is set, a NACK is sent. All received data is discarded and error flags blocked (S1[NF], S1[OR], S1[FE], S1[PF], IS7816[WT], IS7816[CWT], IS7816[BWT], IS7816[ADT], IS7816[GTV]) until a valid initial character is detected. Upon detecting a valid initial character, the configuration values S2[MSBF], C3[TXINV], and S2[RXINV] are automatically updated to reflect the initial character that was received. The actual INIT data value is not stored in the receive buffer. Additionally, upon detection of a valid initial character, IS7816[INITD] is set and an interrupt issued as programmed by IE7816[INITDE]. When a valid initial character is detected, INIT is automatically cleared. This Initial Character Detect feature is supported only in T = 0 protocol mode.<br><br>0 Normal operating mode. Receiver does not seek to identify initial character.<br>1 Receiver searches for initial character. |

**53.4.24 UART 7816 Interrupt Enable Register (UARTx\_IE7816)**

The IE7816 register controls which flags result in an interrupt being issued. This register is specific to 7816 functionality, the corresponding flags that drive the interrupts are not asserted when 7816E is not set/enabled. However, these flags may remain set if they are asserted while 7816E was set and not subsequently cleared. This register may be read or written to at any time.

**53.4.25 UART 7816 Interrupt Status Register (UARTx\_IS7816)**

The IS7816 register provides a mechanism to read and clear the interrupt flags. All flags/ interrupts are cleared by writing a 1 to the field location. Writing a 0 has no effect. All bits are "sticky", meaning they indicate that only the flag condition that occurred since the last time the bit was cleared, not that the condition currently exists. The status flags are set regardless of whether the corresponding field in the IE7816 is set or cleared. The IE7816 controls only if an interrupt is issued to the host processor. This register is specific to 7816 functionality and the values in this register have no affect on UART operation and should be ignored if 7816E is not set/enabled. This register may be read or written at anytime.

Address: Base address + 1Ah offset

| Bit   | 7   | 6   | 5   | 4     | 3   | 2   | 1   | 0   |

| 0<br>RXT | Receive Threshold Exceeded Interrupt<br><br>Indicates that there are more than ET7816[RXTHRESHOLD] consecutive NACKS generated in response to parity errors on received data. This flag requires ANACK to be set. Additionally, this flag asserts only when C7816[TTYPE] = 0. Clearing this field also resets the counter keeping track of consecutive NACKS. The UART will continue to attempt to receive data regardless of whether this flag is set. If 7816E is cleared/disabled, RE is cleared/disabled, C7816[TTYPE] = 1, or packet is received without needing to issue a NACK, the internal NACK detection counter is cleared and the count restarts from zero on the next transmitted NACK. This interrupt is cleared by writing 1.<br><br>0 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is less than or equal to the value in ET7816[RXTHRESHOLD].<br>1 The number of consecutive NACKS generated as a result of parity errors and buffer overruns is greater than the value in ET7816[RXTHRESHOLD]. |

**53.4.26 UART 7816 Wait Parameter Register (UARTx\_WP7816)**

The WP7816 register contains the WTX variable used in the generation of the block wait timer. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set.

Address: Base address + 1Bh offset

| GTFD  | FD Multiplier<br><br>Used as another multiplier in the calculation of BWT. This value represents a number between 1 and 255. The value of 0 is invalid. This value is not used in baud rate generation. See <a href="#">Wait time and guard time parameters</a> and <a href="#">Baud rate generation</a> . |

### 53.4.29 UART 7816 Error Threshold Register (UARTx\_ET7816)

The ET7816 register contains fields that determine the number of NACKs that must be received or transmitted before the host processor is notified. This register may be read at anytime. This register must be written to only when C7816[ISO\_7816E] is not set.

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–4<br>TXTHRESHOLD | <p>Transmit NACK Threshold</p> <p>The value written to this field indicates the maximum number of failed attempts (NACKs) a transmitted character can have before the host processor is notified. This field is meaningful only when C7816[TTYPE] = 0 and C7816[ANACK] = 1. The value read from this field represents the number of consecutive NACKs that have been received since the last successful transmission. This counter saturates at 4'hF and does not wrap around. Regardless of how many NACKs that are received, the UART continues to retransmit indefinitely. This flag only asserts when C7816[TTYPE] = 0. For additional information see the IS7816[TXT] field description.</p> <p>0 TXT asserts on the first NACK that is received.<br/>1 TXT asserts on the second NACK that is received.</p> |
| RXTHRESHOLD        | <p>Receive NACK Threshold</p> <p>The value written to this field indicates the maximum number of consecutive NACKs generated as a result of a parity error or receiver buffer overruns before the host processor is notified. After the counter exceeds that value in the field, the IS7816[RXT] is asserted. This field is meaningful only when C7816[TTYPE] = 0. The value read from this field represents the number of consecutive NACKs that have been transmitted since the last successful reception. This counter saturates at 4'hF and does not wrap around. Regardless of the number of NACKs sent, the UART continues to receive valid packets indefinitely. For additional information, see IS7816[RXT] field description.</p>                                                                        |

### 53.4.30 UART 7816 Transmit Length Register (UARTx\_TL7816)

The TL7816 register is used to indicate the number of characters contained in the block being transmitted. This register is used only when C7816[TTYPE] = 1. This register may be read at anytime. This register must be written only when C2[TE] is not enabled.

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TLEN  | <p>Transmit Length</p> <p>This value plus four indicates the number of characters contained in the block being transmitted. This register is automatically decremented by 1 for each character in the information field portion of the block. Additionally, this register is automatically decremented by 1 for the first character of a CRC in the epilogue field. Therefore, this register must be programmed with the number of bytes in the data packet if an LRC is being transmitted, and the number of bytes + 1 if a CRC is being transmitted. This register is not decremented for characters that are assumed to be part of the Prologue field, that is, the first three characters transmitted in a block, or the LRC or last CRC character in the Epilogue field, that is, the last character transmitted. This field must be programed or adjusted only when C2[TE] is cleared.</p> |

**53.4.31 UART 7816 ATR Duration Timer Register A (UARTx\_AP7816A\_T0)**

The AP7816A\_T0 register contains variables used in the generation of the ATR Duration Timer. This register may be read at any time. This register must be written to only when C7816[ISO\_7816E] is not set, except when writing 0 to clear the ADT Counter.

**NOTE**

The ADT Counter starts counting on detection of the complete TS Character. It must be noted that by this time, exactly 10 ETUs have elapsed since the start bit of the TS character. The user must take this into account while programming this register.

**53.5 Functional description**

This section provides a complete functional description of the UART block.

The UART allows full duplex, asynchronous, NRZ serial communication between the CPU and remote devices, including other CPUs. The UART transmitter and receiver operate independently, although they use the same baud rate generator. The CPU monitors the status of the UART, writes the data to be transmitted, and processes received data.

## 53.5.1 Transmitter

Figure 53-1. Transmitter Block Diagram

### 53.5.1.1 Transmitter character length

The UART transmitter can accommodate either 8, 9, or 10-bit data characters. The state of the C1[M] and C1[PE] bits and the C4[M10] bit determine the length of data characters. When transmitting 9-bit data, bit C3[T8] is the ninth bit (bit 8).

### 53.5.1.2 Transmission bit order

When S2[MSBF] is set, the UART automatically transmits the MSB of the data word as the first bit after the start bit. Similarly, the LSB of the data word is transmitted immediately preceding the parity bit, or the stop bit if parity is not enabled. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data written to D for transmission is completely independent of the S2[MSBF] setting.

### 53.5.1.3 Character transmission

To transmit data, the MCU writes the data bits to the UART transmit buffer using UART data registers C3[T8] and D. Data in the transmit buffer is then transferred to the transmitter shift register as needed. The transmit shift register then shifts a frame out through the transmit data output signal after it has prefaced it with any required start and stop bits. The UART data registers, C3[T8] and D, provide access to the transmit buffer structure.

The UART also sets a flag, the transmit data register empty flag S1[TDRE], and generates an interrupt or DMA request (C5[TDMAS]) whenever the number of datawords in the transmit buffer is equal to or less than the value indicated by TWFIFO[TXWATER]. The transmit driver routine may respond to this flag by writing additional datawords to the transmit buffer using C3[T8]/D as space permits.

See [Application information](#) for specific programing sequences.

Setting C2[TE] automatically loads the transmit shift register with the following preamble:

**Table 53-3. Transmit preamble length**

| BDH[SBNS] | C1[M] | C4[M10] | C1[PE] | Bits transmitted |
|-----------|-------|---------|--------|------------------|
| 0         | 0     | —       | —      | 10               |
| 1         | 0     | —       | —      | 11               |
| 0         | 1     | 0       | —      | 11               |
| 1         | 1     | 0       | —      | 12               |
| 0         | 1     | 1       | 1      | 12               |
| 1         | 1     | 1       | 1      | 13               |

After the preamble shifts out, control logic transfers the data from the D register into the transmit shift register. The transmitter automatically transmits the correct start bit and stop bit before and after the dataword. The number of stop bits transmitted after the dataword can be programmed using BDH[SBNS] field.

When C7816[ISO\_7816E] = 1, setting C2[TE] does not result in a preamble being generated. The transmitter starts transmitting as soon as the corresponding guard time expires. When C7816[TTYTYPE] = 0, the value in GT is used. When C7816[TTYTYPE] = 1, the value in BGT is used, because C2[TE] will remain asserted until the end of the block transfer. C2[TE] is automatically cleared when C7816[TTYTYPE] = 1 and the block being transmitted has completed. When C7816[TTYTYPE] = 0, the transmitter listens for a NACK indication. If no NACK is received, it is assumed that the character was correctly received. If a NACK is received, the transmitter resends the data, assuming that the number of retries for that character, that is, the number of NACKs received, is less than or equal to the value in ET7816[TXTHRESHOLD].

Hardware supports odd or even parity. When parity is enabled, the bit immediately preceding the stop bit is the parity bit.

When the transmit shift register is not transmitting a frame, the transmit data output signal goes to the idle condition, logic 1. If at any time software clears C2[TE], the transmitter enable signal goes low and the transmit signal goes idle.

If the software clears C2[TE] while a transmission is in progress, the character in the transmit shift register continues to shift out, provided S1[TC] was cleared during the data write sequence. To clear S1[TC], the S1 register must be read followed by a write to D register.

If S1[TC] is cleared during character transmission and C2[TE] is cleared, the transmission enable signal is deasserted at the completion of the current frame. Following this, the transmit data out signal enters the idle state even if there is data pending in the UART transmit data buffer. To ensure that all the data written in the FIFO is transmitted on the link before clearing C2[TE], wait for S1[TC] to set. Alternatively, the same can be achieved by setting TWFIFO[TXWATER] to 0x0 and waiting for S1[TDRE] to set.

#### 53.5.1.4 Transmitting break characters

Setting C2[SBK] loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on C1[M], C1[PE], S2[BRK13], BDH[SBNS] and C4[M10]. See the following table.

**Table 53-4. Transmit break character length**

| S2[BRK13] | BDH[SBNS] | C1[M] | C4[M10] | C1[PE] | Bits transmitted |
|-----------|-----------|-------|---------|--------|------------------|
| 0         | 0         | 0     | —       | —      | 10               |
| 0         | 1         | 0     | —       | —      | 11               |
| 0         | 0         | 1     | 0       | —      | 11               |

*Table continues on the next page...*

**Table 53-4. Transmit break character length (continued)**

| S2[BRK13] | BDH[SBNS] | C1[M] | C4[M10] | C1[PE] | Bits transmitted |
|-----------|-----------|-------|---------|--------|------------------|
| 0         | 1         | 1     | 0       | —      | 12               |
| 0         | 0         | 1     | 1       | 1      | 12               |
| 0         | 1         | 1     | 1       | 1      | 13               |
| 1         | 0         | 0     | —       | —      | 13               |
| 1         | 0         | 1     | —       | —      | 14               |
| 1         | 1         | 0     | —       | —      | 15               |
| 1         | 1         | 1     | —       | —      | 16               |

As long as C2[SBK] is set, the transmitter logic continuously loads break characters into the transmit shift register. After the software clears C2[SBK], the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character. Break bits are not supported when C7816[ISO\_7816E] is set/enabled.

### NOTE

When queuing a break character, it will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that, if data is queued in the data buffer to be transmitted, the break character preempts that queued data. The queued data is then transmitted after the break character is complete.

### 53.5.1.5 Idle characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on C1[M], C1[PE], BDH[SBNS] and C4[M10]. The preamble is a synchronizing idle character that begins the first transmission initiated after setting C2[TE]. When C7816[ISO\_7816E] is set/enabled, idle characters are not sent or detected. When data is not being transmitted, the data I/O line is in an inactive state.

If C2[TE] is cleared during a transmission, the transmit data output signal becomes idle after completion of the transmission in progress. Clearing and then setting C2[TE] during a transmission queues an idle character to be sent after the dataword currently being transmitted.

### Note

When queuing an idle character, the idle character will be transmitted following the completion of the data value currently being shifted out from the shift register. This means that if data

is queued in the data buffer to be transmitted, the idle character preempts that queued data. The queued data is then transmitted after the idle character is complete.

If C2[TE] is cleared and the transmission is completed, the UART is not the master of the TXD pin.

### 53.5.1.6 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS. If the clear-to-send operation is enabled, the character is transmitted when CTS is asserted. If CTS is deasserted in the middle of a transmission with characters remaining in the receiver data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS is reasserted.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS. Also, if the transmitter is forced to send a continuous low condition because it is sending a break character, the transmitter ignores the state of CTS regardless of whether the clear-to-send operation is enabled.

The transmitter's CTS signal can also be enabled even if the same UART receiver's RTS signal is disabled.

### 53.5.1.7 Transceiver driver enable

The transmitter can use RTS as an enable signal for the driver of an external transceiver. See [Transceiver driver enable using RTS](#) for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS asserts one bit time before the start bit is transmitted. RTS remains asserted for the whole time that the transmitter data buffer has any characters. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS signal asserts only when the transmitter is enabled. However, the transmitter's RTS signal is unaffected by its CTS signal. RTS will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

The following figure shows the functional timing information for the transmitter. Along with the actual character itself, TXD shows the start bit. The stop bit is also indicated, with a dashed line if necessary.

1. Cn = transmit characters

**Figure 53-2. Transmitter RTS and CTS timing diagram**

## 53.5.2 Receiver

Figure 53-3. UART receiver block diagram

### 53.5.2.1 Receiver character length

The UART receiver can accommodate 8-, 9-, or 10-bit data characters. The states of C1[M], C1[PE], BDH[SBNS] and C4[M10] determine the length of data characters. When receiving 9 or 10-bit data, C3[R8] is the ninth bit (bit 8).

### 53.5.2.2 Receiver bit ordering

When S2[MSBF] is set, the receiver operates such that the first bit received after the start bit is the MSB of the dataword. Similarly, the bit received immediately preceding the parity bit, or the stop bit if parity is not enabled, is treated as the LSB for the dataword. All necessary bit ordering is handled automatically by the module. Therefore, the format of the data read from receive data buffer is completely independent of S2[MSBF].

### 53.5.2.3 Character reception

During UART reception, the receive shift register shifts a frame in from the unsynchronized receiver input signal. After a complete frame shifts into the receive shift register, the data portion of the frame transfers to the UART receive buffer. Additionally, the noise and parity error flags that are calculated during the receive process are also captured in the UART receive buffer. The receive data buffer is accessible via the D and C3[T8] registers. Additional received information flags regarding the receive dataword can be read in ED register. S1[RDRF] is set if the number of resulting datawords in the receive buffer is equal to or greater than the number indicated by RWFIFO[RXWATER]. If the C2[RIE] is also set, RDRF generates an RDRF interrupt request. Alternatively, by programming C5[RDMAS], a DMA request can be generated.

When C7816[ISO\_7816E] is set/enabled and C7816[TTYPE] = 0, character reception operates slightly differently. Upon receipt of the parity bit, the validity of the parity bit is checked. If C7816[ANACK] is set and the parity check fails, or if INIT and the received character is not a valid initial character, then a NACK is sent by the receiver. If the number of consecutive receive errors exceeds the threshold set by ET7816[RXTHRESHOLD], then IS7816[RXT] is set and an interrupt generated if IE7816[RXTE] is set. If an error is detected due to parity or an invalid initial character, the data is not transferred from the receive shift register to the receive buffer. Instead, the data is overwritten by the next incoming data.

When the C7816[ISO\_7816E] is set/enabled, C7816[ONACK] is set/enabled, and the received character results in the receive buffer overflowing, a NACK is issued by the receiver. Additionally, S1[OR] is set and an interrupt is issued if required, and the data in the shift register is discarded.

### 53.5.2.4 Data sampling

The receiver samples the unsynchronized receiver input signal at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock (see the following figure) is re-synchronized:

- After every start bit.
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0).

Functional description

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

Figure 53-4. Receiver data sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7 when C7816[ISO\_7816E] is cleared/disabled and RT8, RT9 and RT10 when C7816[ISO\_7816E] is set/enabled. The following table summarizes the results of the start bit verification samples.

Table 53-5. Start bit verification

| RT3, RT5, and RT7 samples<br>RT8, RT9, RT10 samples when 7816E | Start bit verification | Noise flag |
|----------------------------------------------------------------|------------------------|------------|
| 000                                                            | Yes                    | 0          |
| 001                                                            | Yes                    | 1          |
| 010                                                            | Yes                    | 1          |
| 011                                                            | No                     | 0          |
| 100                                                            | Yes                    | 1          |
| 101                                                            | No                     | 0          |
| 110                                                            | No                     | 0          |
| 111                                                            | No                     | 0          |

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. The following table summarizes the results of the data bit samples.

**Table 53-6. Data bit recovery**

| RT8, RT9, and RT10 samples | Data bit determination | Noise flag |
|----------------------------|------------------------|------------|
| 000                        | 0                      | 0          |
| 001                        | 0                      | 1          |
| 010                        | 0                      | 1          |
| 011                        | 1                      | 1          |
| 100                        | 0                      | 1          |
| 101                        | 1                      | 1          |
| 110                        | 1                      | 1          |
| 111                        | 1                      | 0          |

**Note**

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (S1[NF]) is set and the receiver assumes that the bit is a start bit (logic 0). With the exception of when C7816[ISO\_7816E] is set/enabled, where the values of RT8, RT9 and RT10 exclusively determine if a start bit exists.

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. The following table summarizes the results of the stop bit samples. In the event that C7816[ISO\_7816E] is set/enabled and C7816[TTYPE] = 0, verification of a stop bit does not take place. Rather, starting with RT8 the receiver transmits a NACK as programmed until time RT9 of the following time period. Framing Error detection is not supported when C7816[ISO\_7816E] is set/enabled.

**Table 53-7. Stop bit recovery**

| RT8, RT9, and RT10 samples | Framing error flag | Noise flag |
|----------------------------|--------------------|------------|
| 000                        | 1                  | 0          |
| 001                        | 1                  | 1          |
| 010                        | 1                  | 1          |
| 011                        | 0                  | 1          |
| 100                        | 1                  | 1          |
| 101                        | 0                  | 1          |
| 110                        | 0                  | 1          |
| 111                        | 0                  | 0          |

In the following figure, the verification samples RT3 and RT5 determine that the first low detected was noise and not the beginning of a start bit. In this example  $C7816[ISO\_7816E] = 0$ . The RT clock is reset and the start bit search begins again. The noise flag is not set because the noise occurred before the start bit was found.

**Figure 53-5. Start bit search example 1 ( $C7816[ISO\_7816E] = 0$ )**

In the following figure, verification sample at RT3 is high. In this example  $C7816[ISO\_7816E] = 0$ . The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

**Figure 53-6. Start bit search example 2 ( $C7816[ISO\_7816E] = 0$ )**

In the following figure, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. In this example  $C7816[ISO\_7816E] = 0$ . The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the data samples RT8, RT9, and RT10 are within the bit time and data recovery is successful.

**Figure 53-7. Start bit search example 3 (C7816[ISO\_7816E] = 0)**

The following figure shows the effect of noise early in the start bit time. In this example C7816[ISO\_7816E] = 0. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

**Figure 53-8. Start bit search example 4 (C7816[ISO\_7816E] = 0)**

The following figure shows a burst of noise near the beginning of the start bit that resets the RT clock. In this example C7816[ISO\_7816E] = 0. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.

**Figure 53-9. Start bit search example 5 (C7816[ISO\_7816E] = 0)**

In the following figure, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. In this example C7816[ISO\_7816E] = 0. This sets the noise flag but does not reset the RT clock. In start bits only, the RT8, RT9, and RT10 data samples are ignored. In this example, if C7816[ISO\_7816E] = 1 then a start bit would not have been detected at all since at least two of the three samples (RT8, RT9, RT10) were high.

**Figure 53-10. Start bit search example 6**

### 53.5.2.5 Framing errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, S1[FE], if S2[LBKDE] is disabled. When S2[LBKDE] is disabled, a break character also sets the S1[FE] because a break character has no stop bit. S1[FE] is set at the same time that received data is placed in the receive data buffer. Framing errors are not supported when C7816[ISO7816E] is set/enabled. However, if S1[FE] is set, data will not be received when C7816[ISO7816E] is set.

### 53.5.2.6 Receiving break characters

The UART recognizes a break character when a start bit is followed by eight, nine, or ten logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has these effects on UART registers:

- Sets the framing error flag, S1[FE].
- Writes an all 0 dataword to the data buffer, which may cause S1[RDRF] to set, depending on the watermark and number of values in the data buffer.
- May set the overrun flag, S1[OR], noise flag, S1[NF], parity error flag, S1[PE], or the receiver active flag, S2[RAF].

The detection threshold for a break character can be adjusted when using an internal oscillator in a LIN system by setting S2[LBKDE]. The UART break character detection threshold depends on C1[M], C1[PE], S2[LBKDE] and C4[M10]. See the following table.

**Table 53-8. Receive break character detection threshold**

| LBKDE | SBNS | M | M10 | PE | Threshold (bits) |
|-------|------|---|-----|----|------------------|
| 0     | 0    | 0 | —   | —  | 10               |
| 0     | 1    | 0 | —   | —  | 11               |
| 0     | 0    | 1 | 0   | —  | 11               |
| 0     | 1    | 1 | 0   | —  | 12               |
| 0     | 0    | 1 | 1   | 1  | 12               |
| 0     | 1    | 1 | 1   | 1  | 13               |
| 1     | —    | 0 | —   | —  | 11               |
| 1     | —    | 1 | —   | —  | 12               |

While S2[LBKDE] is set, it will have these effects on the UART registers:

- Prevents S1[RDRF], S1[FE], S1[NF], and S1[PF] from being set. However, if they are already set, they will remain set.
- Sets the LIN break detect interrupt flag, S2[LBKDIF], if a LIN break character is received.

Break characters are not detected or supported when C7816[ISO\_7816E] is set/enabled.

### 53.5.2.7 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS.

- RTS remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See [Transceiver driver enable using RTS](#) for more details.
- If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS if the number of characters in the receiver data register is equal to or greater than receiver data buffer's watermark, RWFIFO[RXWATER].
- The receiver asserts RTS when the number of characters in the receiver data register is less than the watermark. It is not affected if RDRF is asserted.
- Even if RTS is deasserted, the receiver continues to receive characters until the receiver data buffer is full or is overrun.
- If the receiver request-to-send functionality is disabled, the receiver RTS remains deasserted.

The following figure shows receiver hardware flow control functional timing. Along with the actual character itself, RXD shows the start bit. The stop bit can also indicated, with a dashed line, if necessary. The watermark is set to 2.

**Figure 53-11. Receiver hardware flow control timing diagram**

### 53.5.2.8 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a 16-RT clock counter that filters noise and indicates when a 1 is received.

#### 53.5.2.8.1 Start bit detection

When S2[RXINV] is cleared, the first rising edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

#### 53.5.2.8.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one RT clocks can be undetected by it regardless of whether it is seen in the first or second half of the count.

#### 53.5.2.8.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

#### 53.5.2.8.4 High-bit detection

At 16-RT clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to [Low-bit detection](#). The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.

### 53.5.2.9 Baud rate tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error will occur if the

RT8, RT9, and RT10 samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RT8, RT9, and RT10 stop bit samples are a logic 0.

As the receiver samples an incoming frame, it resynchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

### 53.5.2.9.1 Slow data tolerance

The following figure shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

**Figure 53-12. Slow data**

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 53-12](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 147 RT cycles (9 bit times  $\times$  16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((154 - 147) \div 154) \times 100 = 4.54\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 53-12](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 163 RT cycles (10 bit times  $\times$  16 RT cycles + 3 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((170 - 163) \div 170) \times 100 = 4.12\%$$

### 53.5.2.9.2 Fast data tolerance

The following figure shows how much a fast received frame can be misaligned. The fast stop bit ends at RT10 instead of RT16 but is still sampled at RT8, RT9, and RT10.

**Figure 53-13. Fast data**

For an 8-bit data character, data sampling of the stop bit takes the receiver 154 RT cycles (9 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 53-13](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 160 RT cycles (10 bit times  $\times$  16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((154 - 160) \div 154) \times 100 = 3.90\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 170 RT cycles (10 bit times  $\times$  16 RT cycles + 10 RT cycles).

With the misaligned character shown in the [Figure 53-13](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 176 RT cycles (11 bit times  $\times$  16 RT cycles).

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((170 - 176) \div 170) \times 100 = 3.53\%$$

### 53.5.2.10 Receiver wakeup

C1[WAKE] determines how the UART is brought out of the standby state to process an incoming message. C1[WAKE] enables either idle line wakeup or address mark wakeup.

Receiver wakeup is not supported when C7816[ISO\_7816E] is set/enabled because multi-receiver systems are not allowed.

### 53.5.2.10.1 Idle input line wakeup (C1[WAKE] = 0)

In this wakeup method, an idle condition on the unsynchronized receiver input signal clears C2[RWU] and wakes the UART. The initial frame or frames of every message contain addressing information. All receivers evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another idle character appears on the unsynchronized receiver input signal.

Idle line wakeup requires that messages be separated by at least one idle character and that no message contains idle characters.

When C2[RWU] is 1 and S2[RWUID] is 0, the idle character that wakes the receiver does not set S1[IDLE] or the receive data register full flag, S1[RDRF]. The receiver wakes and waits for the first data character of the next message which is stored in the receive data buffer. When S2[RWUID] and C2[RWU] are set and C1[WAKE] is cleared, any idle condition sets S1[IDLE] and generates an interrupt if enabled.

Idle input line wakeup is not supported when C7816[ISO\_7816E] is set/enabled.

### 53.5.2.10.2 Address mark wakeup (C1[WAKE] = 1)

In this wakeup method, a logic 1 in the bit position immediately preceding the stop bit of a frame clears C2[RWU] and wakes the UART. A logic 1 in the bit position immediately preceding the stop bit marks a frame as an address frame that contains addressing information. All receivers evaluate the addressing information, and the receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its C2[RWU] and return to the standby state. C2[RWU] remains set and the receiver remains in standby until another address frame appears on the unsynchronized receiver input signal.

A logic 1 in the bit position immediately preceding the stop bit clears the receiver's C2[RWU] after the stop bit is received and places the received data into the receiver data buffer. Note that if Match Address operation is enabled i.e. C4[MAEN1] or C4[MAEN2] is set, then received frame is transferred to receive buffer only if the comparison matches.

Address mark wakeup allows messages to contain idle characters but requires that the bit position immediately preceding the stop bit be reserved for use in address frames.

If module is in standby mode and nothing triggers to wake the UART, no error flag is set even if an invalid error condition is detected on the receiving data line.

Address mark wakeup is not supported when C7816[ISO\_7816E] is set/enabled.

### 53.5.2.10.3 Match address operation

Match address operation is enabled when C4[MAEN1] or C4[MAEN2] is set. In this function, a frame received by the RX pin with a logic 1 in the bit position of the address mark is considered an address and is compared with the associated MA1 or MA2 register. The frame is transferred to the receive buffer, and S1[RDRF] is set, only if the comparison matches. All subsequent frames received with a logic 0 in the bit position of the address mark are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs, then no transfer is made to the receive data buffer, and all following frames with logic 0 in the bit position of the address mark are also discarded. If both C4[MAEN1] and C4[MAEN2] are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Match address operation functions in the same way for both MA1 and MA2 registers. Note that the position of the address mark is the same as the Parity Bit when parity is enabled for 8 bit and 9 bit data formats.

- If only one of C4[MAEN1] and C4[MAEN2] is asserted, a marked address is compared only with the associated match register and data is transferred to the receive data buffer only on a match.
- If C4[MAEN1] and C4[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either register.

Address match operation is not supported when C7816[ISO\_7816E] is set/enabled.

### 53.5.3 Baud rate generation

A 13-bit modulus counter and a 5-bit fractional fine-adjust counter in the baud rate generator derive the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to SBR[12:0] determines the module clock divisor. The SBR bits are in the UART baud rate registers, BDH and BDL. The baud rate clock is synchronized with the module clock and drives the receiver. The fractional fine-adjust counter adds fractional delays to the baud rate clock to allow fine trimming of the baud rate to match the system baud rate. The transmitter is driven by the baud rate clock divided by 16. The receiver has an acquisition rate of 16 samples per bit time.

Baud rate generation is subject to two sources of error:

## Functional description

- Integer division of the module clock may not give the exact target frequency. This error can be reduced with the fine-adjust counter.
- Synchronization with the module clock can cause phase shift.

The [Table 53-9](#) lists the available baud divisor fine adjust values.

$$\text{UART baud rate} = \text{UART module clock} / (16 \times (\text{SBR}[12:0] + \text{BRFD}))$$

The following table lists some examples of achieving target baud rates with a module clock frequency of 10.2 MHz, with and without fractional fine adjustment.

**Table 53-9. Baud rates (example: module clock = 10.2 MHz)**

| Bits<br>SBR<br>(decimal) | Bits<br>BRFA | BRFD value    | Receiver<br>clock (Hz) | Transmitter<br>clock (Hz) | Target Baud<br>rate | Error<br>(%) |
|--------------------------|--------------|---------------|------------------------|---------------------------|---------------------|--------------|
| 17                       | 00000        | 0             | 600,000.0              | 37,500.0                  | 38,400              | 2.3          |
| 16                       | 10011        | 19/32=0.59375 | 614,689.3              | 38,418.08                 | 38,400              | 0.047        |
| 33                       | 00000        | 0             | 309,090.9              | 19,318.2                  | 19,200              | 0.62         |
| 33                       | 00110        | 6/32=0.1875   | 307,344.6              | 19,209.04                 | 19,200              | 0.047        |
| 66                       | 00000        | 0             | 154,545.5              | 9659.1                    | 9600                | 0.62         |
| 133                      | 00000        | 0             | 76,691.7               | 4793.2                    | 4800                | 0.14         |
| 266                      | 00000        | 0             | 38,345.9               | 2396.6                    | 2400                | 0.14         |
| 531                      | 00000        | 0             | 19,209.0               | 1200.6                    | 1200                | 0.11         |
| 1062                     | 00000        | 0             | 9604.5                 | 600.3                     | 600                 | 0.05         |
| 2125                     | 00000        | 0             | 4800.0                 | 300.0                     | 300                 | 0.00         |
| 4250                     | 00000        | 0             | 2400.0                 | 150.0                     | 150                 | 0.00         |
| 5795                     | 00000        | 0             | 1760.1                 | 110.0                     | 110                 | 0.00         |

**Table 53-10. Baud rate fine adjust**

| BRFA      | Baud Rate Fractional Divisor (BRFD) |
|-----------|-------------------------------------|

### 53.5.4 Data format (non ISO-7816)

Each data character is contained in a frame that includes a start bit and a stop bit. The rest of the data format depends upon C1[M], C1[PE], S2[MSBF], BDH[SBNS] and C4[M10].

#### 53.5.4.1 Eight-bit configuration

Clearing C1[M] configures the UART for 8-bit data characters, that is, eight bits are memory mapped in D. A frame with eight data bits has a total of 10 bits (This becomes 11 bits if BDH[SBNS] = 1). The most significant bit of the eight data bits can be used as an address mark to wake the receiver. If the most significant bit is used in this way, then it serves as an address or data indication, leaving the remaining seven bits as actual data. When C1[PE] is set, the eighth data bit is automatically calculated as the parity bit. See the following table.

**Table 53-11. Configuration of 8-bit data format**

| UART_C1[PE] | Start bit | Data bits | Address bits   | Parity bits | Stop bit |
|-------------|-----------|-----------|----------------|-------------|----------|
| 0           | 1         | 8         | 0              | 0           | 1        |
| 0           | 1         | 7         | 1 <sup>1</sup> | 0           | 1        |
| 1           | 1         | 7         | 0              | 1           | 1        |

1. The address bit identifies the frame as an address character. See [Receiver wakeup](#).

### NOTE

In the last column of the above table, the number of stop bits become 2 when BDH[SBNS] is set.

## 53.5.4.2 Nine-bit configuration

When C1[M] is set and C4[M10] is cleared and BDH[SBNS] is cleared, the UART is configured for 9-bit data characters. If C1[PE] is enabled, the ninth bit is either C3[T8/R8] or the internally generated parity bit. This results in a frame consisting of a total of 11 bits. In the event that the ninth data bit is selected to be C3[T8], it will remain unchanged after transmission and can be used repeatedly without rewriting it, unless the value needs to be changed. This feature may be useful when the ninth data bit is being used as an address mark.

When C1[M] and C4[M10] are set and BDH[SBNS] is cleared, the UART is configured for 9-bit data characters, but the frame consists of a total of 12 bits. The 12 bits include the start and stop bits, the 9 data character bits, and a tenth internal data bit. Note that if C4[M10] is set, C1[PE] must also be set. In this case, the tenth bit is the internally generated parity bit. The ninth bit can either be used as an address mark or a ninth data bit.

See the following table.

**Table 53-12. Configuration of 9-bit data formats**

| C1[PE] | UC1[M] | C1[M10] | Start bit                                   | Data bits | Address bits   | Parity bits | Stop bit |
|--------|--------|---------|---------------------------------------------|-----------|----------------|-------------|----------|
| 0      | 0      | 0       | See <a href="#">Eight-bit configuration</a> |           |                |             |          |
| 0      | 0      | 1       | Invalid configuration                       |           |                |             |          |
| 0      | 1      | 0       | 1                                           | 9         | 0              | 0           | 1        |
| 0      | 1      | 0       | 1                                           | 8         | 1 <sup>1</sup> | 0           | 1        |
| 0      | 1      | 1       | Invalid Configuration                       |           |                |             |          |
| 1      | 0      | 0       | See <a href="#">Eight-bit configuration</a> |           |                |             |          |

Table continues on the next page...

**Table 53-12. Configuration of 9-bit data formats (continued)**

| C1[PE] | UC1[M] | C1[M10] | Start bit             | Data bits | Address bits   | Parity bits | Stop bit |
|--------|--------|---------|-----------------------|-----------|----------------|-------------|----------|
| 1      | 0      | 1       | Invalid Configuration |           |                |             |          |
| 1      | 1      | 0       | 1                     | 8         | 0              | 1           | 1        |
| 1      | 1      | 1       | 1                     | 9         | 0              | 1           | 1        |
| 1      | 1      | 1       | 1                     | 8         | 1 <sup>1</sup> | 1           | 1        |

1. The address bit identifies the frame as an address character.

### NOTE

In the last column of the above table, the number of stop bits become 2 when BDH[SBNS] is set.

### Note

Unless in 9-bit mode with M10 set, do not use address mark wakeup with parity enabled.

## 53.5.4.3 Timing examples

Timing examples of these configurations in the NRZ mark/space data format are illustrated in the following figures. The timing examples show all of the configurations in the following sub-sections along with the LSB and MSB first variations. This section explains the data formats available assuming single stop bit mode is selected.

### 53.5.4.3.1 Eight-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

**Figure 53-14. Eight bits of data with LSB first****Figure 53-15. Eight bits of data with MSB first**

### 53.5.4.3.2 Eight-bit format with parity enabled

**Figure 53-16. Seven bits of data with LSB first and parity**

**Figure 53-17. Seven bits of data with MSB first and parity**

### 53.5.4.3.3 Nine-bit format with parity disabled

The most significant bit can be used for address mark wakeup.

**Figure 53-18. Nine bits of data with LSB first**

**Figure 53-19. Nine bits of data with MSB first**

### 53.5.4.3.4 Nine-bit format with parity enabled

**Figure 53-20. Eight bits of data with LSB first and parity**

**Figure 53-21. Eight bits of data with MSB first and parity**

### 53.5.4.3.5 Non-memory mapped tenth bit for parity

The most significant memory-mapped bit can be used for address mark wakeup.

**Figure 53-22. Nine bits of data with LSB first and parity**

**Figure 53-23. Nine bits of data with MSB first and parity**

### 53.5.5 Single-wire operation

Normally, the UART uses two pins for transmitting and receiving. In single wire operation, the RXD pin is disconnected from the UART and the UART implements a half-duplex serial connection. The UART uses the TXD pin for both receiving and transmitting.

**Figure 53-24. Single-wire operation (C1[LOOPS] = 1, C1[RSRC] = 1)**

Enable single wire operation by setting C1[LOOPS] and the receiver source field, C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Setting C1[RSRC] connects the receiver input to the output of the TXD pin driver. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO\_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

### 53.5.6 Loop operation

In loop operation, the transmitter output goes to the receiver input. The unsynchronized receiver input signal is disconnected from the UART.

**Figure 53-25. Loop operation (C1[LOOPS] = 1, C1[RSRC] = 0)**

Enable loop operation by setting C1[LOOPS] and clearing C1[RSRC]. Setting C1[LOOPS] disables the path from the unsynchronized receiver input signal to the receiver. Clearing C1[RSRC] connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (C2[TE] = 1 and C2[RE] = 1). When C7816[ISO\_7816EN] is set, it is not required that both C2[TE] and C2[RE] are set.

### 53.5.7 ISO-7816/smartcard support

The UART provides mechanisms to support the ISO-7816 protocol that is commonly used to interface with smartcards. The ISO-7816 protocol is an NRZ, single wire, half-duplex interface. The TxD pin is used in open-drain mode because the data signal is used for both transmitting and receiving. There are multiple subprotocols within the ISO-7816 standard. The UART supports both  $T = 0$  and  $T = 1$  protocols. The module also provides for automated initial character detection and configuration, which allows for support of both direct convention and inverse convention data formats. A variety of interrupts specific to 7816 are provided in addition to the general interrupts to assist software. Additionally, the module is able to provide automated NACK responses and has programmed automated retransmission of failed packets. An assortment of programmable timeouts and guard band times are also supported.

The term elemental time unit (ETU) is frequently used in the context of ISO-7816. This concept is used to relate the frequency that the system (UART) is running at and the frequency that data is being transmitted and received. One ETU represents the time it takes to transmit or receive a single bit. For example, a standard 7816 packet, excluding any guard time or NACK elements is 10 ETUs (start bit, 8 data bits, and a parity bit). Guard times and wait times are also measured in ETUs.,

#### NOTE

The ISO-7816 specification may have certain configuration options that are reserved. To maintain maximum flexibility to support future 7816 enhancements or devices that may not strictly conform to the specification, the UART does not prevent those options being used. Further, the UART may provide configuration options that exceed the flexibility of options explicitly allowed by the 7816 specification. Failure to correctly configure the UART may result in unexpected behavior or incompatibility with the ISO-7816 specification.

#### 53.5.7.1 Initial characters

In ISO-7816 with  $T = 0$  mode, the UART can be configured to use C7816[INIT] to detect the next valid initial character, referred to by the ISO-7816 specifically as a TS character. When the initial character is detected, the UART provides the host processor with an interrupt if IE7816[INITDE] is set. Additionally, the UART will alter S2[MSBF],

C3[TXINV], and S2[RXINV] automatically, based on the initial character. The corresponding initial character and resulting register settings are listed in the following table.

**Table 53-13. Initial character automated settings**

| Initial character (bit 1-10)       | Initial character (hex) | MSBF | TXINV | RXINV |
|------------------------------------|-------------------------|------|-------|-------|
| LHHL LLL LLH<br>inverse convention | 3F                      | 1    | 1     | 1     |
| LHHL HHH LLH<br>direct convention  | 3B                      | 0    | 0     | 0     |

S2[MSBF], C3[TXINV], and S2[RXINV] must be reset to their default values before C7816[INIT] is set. Once C7816[INIT] is set, the receiver searches all received data for the first valid initial character. Detecting a Direct Convention Initial Character will cause no change to S2[MSBF], C3[TXINV], and S2[RXINV], while detecting an Inverse Convention Initial Character will cause these fields to set automatically. All data received, which is not a valid initial character, is ignored and all flags resulting from the invalid data are blocked from asserting. If C7816[ANACK] is set, a NACK is returned for invalid received initial characters and an RXT interrupt is generated as programmed.

### 53.5.7.2 Protocol T = 0

When T = 0 protocol is selected, a relatively complex error detection scheme is used. Data characters are formatted as illustrated in the following figure. This scheme is also used for answer to reset and Peripheral Pin Select (PPS) formats.

**Figure 53-26. ISO-7816 T = 0 data format**

As with other protocols supported by the UART, the data character includes a start bit. However, in this case, there are two stop bits rather than the typical single stop bit. In addition to a standard even parity check, the receiver has the ability to generate and return a NACK during the second half of the first stop bit period. The NACK must be at least

one time period (ETU) in length and no more than two time periods (ETU) in length. The transmitter must wait for at least two time units (ETU) after detection of the error signal before attempting to retransmit the character.

It is assumed that the UART and the device (smartcard) know in advance which device is receiving and which is transmitting. No special mechanism is supplied by the UART to control receive and transmit in the mode other than C2[TE] and C2[RE]. Initial Character Detect feature is also supported in this mode.

### 53.5.7.3 Protocol T = 1

When T = 1 protocol is selected, the NACK error detection scheme is not used. Rather, the parity bit is used on a character basis and a CRC or LRC is used on the block basis, that is, for each group of characters. In this mode, the data format allows for a single stop bit although additional inactive bit periods may be present between the stop bit and the next start bit. Data characters are formatted as illustrated in the following figure.

**Figure 53-27. ISO 7816 T=1 data format**

The smallest data unit that is transferred is a block. A block is made up of several data characters and may vary in size depending on the block type. The UART does not provide a mechanism to decode the block type. As part of the block, an LRC or CRC is included. The UART does not calculate the CRC or LRC for transmitted blocks, nor does it verify the validity of the CRC or LRC for received blocks. The 7816 protocol requires that the initiator and the smartcard (device) takes alternate turns in transmitting and receiving blocks. When the UART detects that the last character in a block has been transmitted it will automatically clear C2[TE], C3[TXDIR] and enter receive mode. Therefore, the software must program the transmit buffer with the next data to be transmitted and then enable C2[TE] and set C3[TXDIR], once the software has determined that the last character of the received block has been received. The UART detects that the last character of the transmit block has been sent when TL7816[TLEN] = 0 and four additional characters have been sent. The four additional characters are made up of three prior to TL7816[TLEN] decrementing (prologue) and one after TL7816[TLEN] = 0, the final character of the epilogue.

### 53.5.7.4 Wait time and guard time parameters

The ISO-7816 specification defines several wait time and guard time parameters. The UART allows for flexible configuration and violation detection of these settings. On reset, the wait time (IS7816[WT]) defaults to 9600 ETUs and guard time (GT) to 12 ETUs. These values are controlled by parameters in the WP7816, WN7816, and WF7816 registers. Additionally, the value of C7816[TTYTYPE] also factors into the calculation. The formulae used to calculate the number ETUs for each wait time and guard time value are shown in [Table 53-14](#).

Wait time (WT) is defined as the maximum allowable time between the leading edge of a character transmitted by the smartcard device and the leading edge of the previous character that was transmitted by the UART or the device. Similarly, character wait time (CWT) is defined as the maximum allowable time between the leading edge of two characters within the same block. Block wait time (BWT) is defined as the maximum time between the leading edge character of the last block received by the smartcard device and the leading edge of the first character transmitted by the smartcard device.

Guard time (GT) is defined as the minimum allowable time between the leading edge of two consecutive characters. Character guard time (CGT) is the minimum allowable time between the leading edges of two consecutive characters in the same direction, that is, transmission or reception. Block guard time (BGT) is the minimum allowable time between the leading edges of two consecutive characters in opposite directions, that is, transmission then reception or reception then transmission.

The GT and WT counters reset whenever C7816[TTYTYPE] = 1 or C7816[ISO\_7816E] = 0 or a new dataword start bit has been received or transmitted as specified by the counter descriptions. The CWT, CGT, BWT, BGT counters reset whenever C7816[TTYTYPE] = 0 or C7816[ISO\_7816E] = 0 or a new dataword start bit is received or transmitted as specified by the counter descriptions. When C7816[TTYTYPE] = 1, some of the counter values require an assumption regarding the first data transferred when the UART first starts. This assumption is required when the 7816E is disabled, when transition from C7816[TTYTYPE] = 0 to C7816[TTYTYPE] = 1 or when coming out of reset. In this case, it is assumed that the previous non-existent transfer was a received transfer.

The UART will automatically handle GT, CGT, and BGT such that the UART will not send a packet before the corresponding guard time expiring.

**Table 53-14. Wait and guard time calculations**

| Parameter                 | Reset value<br>[ETU] | C7816[TTYTYPE] = 0<br>[ETU] | C7816[TTYTYPE] = 1<br>[ETU] |
|---------------------------|----------------------|-----------------------------|-----------------------------|
| Wait time (WT)            | 9600                 | $WI \times 480$             | Not used                    |
| Character wait time (CWT) | Not used             | Not used                    | $2^{(CWI1)} + CWI2$         |

| Block guard time (BGT)     | Not used             | Not used                                                                   | $16 + BGI$                                                                 |

**NOTE**

- User must ensure that the Character Wait time (CWT) programmed using the formula above is atleast 12. Values smaller than 12 are invalid and will lead to unexpected CWT interrupts.
- The 16 bit Wait Time integer WI is formed by concatenation of {WP7816A\_T0[WI\_H], WP7816B\_T0[WI\_L]}.
- The 16 bit Block Wait Time integer BWI is formed by concatenation of {WP7816A\_T1[BWI\_H], WP7816B\_T1[BWI\_L]}.

**53.5.7.5 ATR Duration Time Counter**

The ISO-7816 specification defines a specific time (in etus) within which the terminal must receive the ATR (Answer to Reset), failing which the terminal must abort the card session by initiating the deactivation sequence.

UART supports this in hardware via the ATR Duration Time (ATD) Counter which can be programmed using AP7816a\_T0 and AP7816b\_T0 registers. The value loaded into the ADT (ATR Duration Time) counter is given by the concatenation of the register fields as shown;  $ADT = \{AP7816a\_T0[ADTI\_H], AP7816a\_T0[ADTI\_L]\}$ . This counter begins to count on detection of the TS character which is detected when IS7816[INITD] flag is

set. Once the ATR process is completed, the ATD Counter must be disabled by writing 0 to AP7816x\_T0 registers, in order to prevent the false occurrence of the ATD Duration Time interrupt IS7816[ATD]. Note that this feature is only supported in T = 0 mode.

### NOTE

The ADT counter starts counting on detection of the complete TS Character. It must be noted that by this time, exactly 10 ETUs have elapsed since the start bit of the TS character. The user must take this into account while programming AP7816a\_T0 and AP7816b\_T0 registers.

#### 53.5.7.6 Baud rate generation

The value in WF7816[GTFD] does not impact the clock frequency. SBR and BRFD are used to generate the clock frequency. This clock frequency is used by the UART only and is not seen by the smartcard device. The transmitter clocks operates at 1/16 the frequency of the receive clock so that the receiver is able to sample the received value 16 times during the ETU.

#### 53.5.7.7 UART restrictions in ISO-7816 operation

Due to the flexibility of the UART module, there are several features and interrupts that are not supported while running in ISO-7816 mode. These restrictions are documented within the register field definitions.

### 53.5.8 Infrared interface

The UART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the UART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This design covers data rates only between 2.4 kbits/s and 115.2 kbits/s.

The UART has an infrared transmit encoder and receive decoder. The UART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the MCU. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the UART.

The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active low pulses.

The infrared submodule receives its clock sources from the UART. One of these two clocks are selected in the infrared submodule to generate either 3/16, 1/16, 1/32, or 1/4 narrow pulses during transmission.

### **53.5.8.1 Infrared transmit encoder**

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a zero bit and no pulse for a one bit. The narrow pulse is sent in the middle of the bit with a duration of 1/32, 1/16, 3/16, or 1/4 of a bit time. A narrow high pulse is transmitted for a zero bit when C3[TXINV] is cleared, while a narrow low pulse is transmitted for a zero bit when C3[TXINV] is set.

### **53.5.8.2 Infrared receive decoder**

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each zero received and no pulse is expected for each one received. A narrow high pulse is expected for a zero bit when S2[RXINV] is cleared, while a narrow low pulse is expected for a zero bit when S2[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

## **53.6 Reset**

All registers reset to a particular value are indicated in [Memory map and registers](#).

## **53.7 System level interrupt sources**

There are several interrupt signals that are sent from the UART. The following table lists the interrupt sources generated by the UART. The local enables for the UART interrupt sources are described in this table. Details regarding the individual operation of each interrupt are contained under various sub-sections of [Memory map and registers](#).

However, [RXEDGIF description](#) also outlines additional details regarding the RXEDGIF interrupt because of its complexity of operation. Any of the UART interrupt requests listed in the table can be used to bring the CPU out of Wait mode.

**Table 53-15. UART interrupt sources**

| Interrupt Source | Flag    | Local enable | DMA select    |
|------------------|---------|--------------|---------------|
| Transmitter      | TDRE    | TIE          | TDMA5 = 0     |
| Transmitter      | TC      | TCIE         | -             |
| Receiver         | IDLE    | ILIE         | -             |
| Receiver         | RDRF    | RIE          | RDMA5 = 0     |
| Receiver         | LBKDIF  | LBKDIE       | LBKD DMA5 = 0 |
| Receiver         | RXEDGIF | RXEDGIE      | -             |
| Receiver         | OR      | ORIE         | -             |
| Receiver         | NF      | NEIE         | -             |
| Receiver         | FE      | FEIE         | -             |
| Receiver         | PF      | PEIE         | -             |
| Receiver         | RXUF    | RXUFE        | -             |
| Transmitter      | TXOF    | TXOFE        | -             |
| Receiver         | WT      | WTWE         | -             |
| Receiver         | CWT     | CWTE         | -             |
| Receiver         | BWT     | BWTE         | -             |
| Receiver         | INITD   | INITDE       | -             |
| Receiver         | TXT     | TXTE         | -             |
| Receiver         | RXT     | RXTE         | -             |
| Receiver         | GTV     | GTVE         | -             |

### 53.7.1 RXEDGIF description

S2[RXEDGIF] is set when an active edge is detected on the RxD pin. Therefore, the active edge can be detected only when in two wire mode. A RXEDGIF interrupt is generated only when S2[RXEDGIF] is set. If RXEDGIE is not enabled before S2[RXEDGIF] is set, an interrupt is not generated.

#### 53.7.1.1 RxD edge detect sensitivity

Edge sensitivity can be software programmed to be either falling or rising. The polarity of the edge sensitivity is selected using S2[RXINV]. To detect the falling edge, S2[RXINV] is programmed to 0. To detect the rising edge, S2[RXINV] is programmed to 1.

Synchronizing logic is used prior to detect edges. Prior to detecting an edge, the receive data on RxD input must be at the deasserted logic level. A falling edge is detected when the RxD input signal is seen as a logic 1 (the deasserted level) during one module clock

cycle, and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input is seen as a logic 0 during one module clock cycle and then a logic 1 during the next cycle.

### 53.7.1.2 Clearing RXEDGIF interrupt request

Writing a logic 1 to S2[RXEDGIF] immediately clears the RXEDGIF interrupt request even if the RxD input remains asserted. S2[RXEDGIF] remains set if another active edge is detected on RxD while attempting to clear S2[RXEDGIF] by writing a 1 to it.

### 53.7.1.3 Exit from low-power modes

The receive input active edge detect circuit is still active on low power modes (Wait and Stop). An active edge on the receive input brings the CPU out of low power mode if the interrupt is not masked (S2[RXEDGIF] = 1).

## 53.8 DMA operation

In the transmitter, S1[TDRE] can be configured to assert a DMA transfer request. In the receiver, S1[RDRF], and S2[LBKDIF] can be configured to assert a DMA transfer request. The following table shows the configuration field settings required to configure each flag for DMA operation.

**Table 53-16. DMA configuration**

| Flag   | Request enable bit | DMA select bit |
|--------|--------------------|----------------|
| TDRE   | TIE = 1            | TDMAS = 1      |
| RDRF   | RIE = 1            | RDMAS = 1      |
| LBKDIF | LBKDIE = 1         | LBKDDMAS = 1   |

When a flag is configured for a DMA request, its associated DMA request is asserted when the flag is set. When S1[RDRF] is configured as a DMA request, the clearing mechanism of reading S1, followed by reading D, does not clear the associated flag. The DMA request remains asserted until an indication is received that the DMA transactions are done. When this indication is received, the flag bit and the associated DMA request is cleared. If the DMA operation failed to remove the situation that caused the DMA request, another request is issued.

## 53.9 Application information

This section describes the UART application information.

### 53.9.1 Transmit/receive data buffer operation

The UART has independent receive and transmit buffers. The size of these buffers may vary depending on the implementation of the module. The implemented size of the buffers is a fixed constant via PFIFO[TXFIFOSIZE] and PFIFO[RXFIFOSIZE]. Additionally, legacy support is provided that allows for the FIFO structure to operate as a depth of one. This is the default/reset behavior of the module and can be adjusted using the PFIFO[RXFE] and PFIFO[TXFE] bits. Individual watermark levels are also provided for transmit and receive.

There are multiple ways to ensure that a data block, which is a set of characters, has completed transmission. These methods include:

1. Set TXFIFO[TXWATER] to 0. TDRE asserts when there is no further data in the transmit buffer. Alternatively the S1[TC] flag can be used to indicate when the transmit shift register is also empty.
2. Poll TCFIFO[TXCOUNT]. Assuming that only data for a data block has been put into the data buffer, when TCFIFO[TXCOUNT] = 0, all data has been transmitted or is in the process of transmission.
3. S1[TC] can be monitored. When S1[TC] asserts, it indicates that all data has been transmitted and there is no data currently being transmitted in the shift register.

### 53.9.2 ISO-7816 initialization sequence

This section outlines how to program the UART for ISO-7816 operation. Elements such as procedures to power up or power down the smartcard, and when to take those actions, are beyond the scope of this description. To set up the UART for ISO-7816 operation:

1. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL. According to the 7816 specification the initial (default) baud rating setting should be  $F_i = 372$  and  $D_i = 1$  and a maximum frequency of 5 MHz. In other words, the BDH,

BDL, and C4 registers should be programmed such that the transmission frequency provided to the smartcard device must be 1/372th of the clock and must not exceed 5 MHz.

2. Write to set BDH[LBKDIE] = 0.
3. Write to C1 to configure word length, parity, and other configuration fields (LOOPS, RSRC) and set C1[M] = 1, C1[PE] = 1, and C1[PT] = 0.
4. Write to set S2[RWUID] = 0 and S2[LBKDE] = 0.
5. Write to set MODEM[RXRTSE] = 0, MODEM[TXRTSPOL] = 0, MODEM[TXRTSE] = 0, and MODEM[TXCTSE] = 0.
6. Write to set up interrupt enable fields desired (C3[ORIE], C3[NEIE], C3[PEIE], and C3[FEIE])
7. Write to set C4[MAEN1] = 0 and C4[MAEN2] = 0.
8. Write to C5 register and configure DMA control register fields as desired for application.
9. Write to set C7816[INIT] = 1, C7816[ TTYPE] = 0, and C7816[ISO\_7816E] = 1. Program C7816[ONACK] and C7816[ANACK] as desired.
10. Write to IE7816 to set interrupt enable parameters as desired.
11. Write to ET7816 and set as desired.
12. Write to set C2[ILIE] = 0, C2[RE] = 1, C2[TE] = 1, C2[RWU] = 0, and C2[SBK] = 0. Set up interrupt enables C2[TIE], C2[TCIE], and C2[RIE] as desired.

At this time, the UART will start listening for an initial character. After being identified, it will automatically adjust S2[MSBF], C3[TXINV], and S2[RXINV]. The software must then receive and process an answer to reset. Upon processing the answer to reset, the software must write to set C2[RE] = 0 and C2[TE] = 0. The software should then adjust 7816 specific and UART generic parameters to match and configure data that was received during the answer on reset period. After the new settings have been programmed, including the new baud rate and C7816[TTYPE], C2[RE] and C2[TE] can be reenabled as required.

### 53.9.2.1 Transmission procedure for (C7816[TTYPE] = 0)

When the protocol selected is C7816[TTYPE] = 0, it is assumed that the software has a prior knowledge of who should be transmitting and receiving. Therefore, no mechanism is provided for automated transmission/receipt control. The software must monitor

S1[TDRE], or configure for an interrupt, and provide additional data for transmission, as appropriate. Additionally, software should set C2[TE] = 1 and control TXDIR whenever it is the UART's turn to transmit information. For ease of monitoring, it is suggested that only data be transmitted until the next receiver/transmit switchover is loaded into the transmit FIFO/buffer.

### 53.9.2.2 Transmission procedure for (C7816[TTYPE] = 1)

When the protocol selected is C7816[TTYPE] = 1, data is transferred in blocks. Before starting a transmission, the software must write the size, in number of bytes, for the Information Field portion of the block into TLEN. If a CRC is being transmitted for the block, the value in TLEN must be one more than the size of the information field. The software must then set C2[TE] = 1 and C2[RE] = 1. The software must then monitor S1[TDRE]/interrupt and write the prologue, information, and epilogue field to the transmit buffer. TLEN automatically decrements, except for prologue bytes and the final epilogue byte. When the final epilogue byte has been transmitted, the UART automatically clears C2[TE] and C3[TXDIR] to 0, and the UART automatically starts capturing the response to the block that was transmitted. After the software has detected the receipt of the response, the transmission process must be repeated as needed with sufficient urgency to ensure that the block wait time and character wait times are not violated.

### 53.9.3 Initialization sequence (non ISO-7816)

To initiate a UART transmission:

1. Configure the UART.
  - a. Select a baud rate. Write this value to the UART baud registers (BDH/L) to begin the baud rate generator. Remember that the baud rate generator is disabled when the baud rate is zero. Writing to the BDH has no effect without also writing to BDL.
  - b. Write to C1 to configure word length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, and PT). Write to C4, MA1, and MA2 to configure.
  - c. Enable the transmitter, interrupts, receiver, and wakeup as required, by writing to C2 (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK), S2 (MSBF and BRK13), and C3 (ORIE, NEIE, PEIE, and FEIE). A preamble or idle character is then shifted out of the transmitter shift register.

2. Transmit procedure for each byte.
  - a. Monitor S1[TDRE] by reading S1 or responding to the TDRE interrupt. The amount of free space in the transmit buffer directly using TCFIFO[TXCOUNT] can also be monitored.
  - b. If the TDRE flag is set, or there is space in the transmit buffer, write the data to be transmitted to (C3[T8]/D). A new transmission will not result until data exists in the transmit buffer.
3. Repeat step 2 for each subsequent transmission.

### Note

During normal operation, S1[TDRE] is set when the shift register is loaded with the next data to be transmitted from the transmit buffer and the number of datawords contained in the transmit buffer is less than or equal to the value in TWFIFO[TXWATER]. This occurs 9/16ths of a bit time after the start of the stop bit of the previous frame.

To separate messages with preambles with minimum idle line time, use this sequence between messages.

1. Write the last dataword of the first message to C3[T8]/D.
2. Wait for S1[TDRE] to go high with TWFIFO[TXWATER] = 0, indicating the transfer of the last frame to the transmit shift register.
3. Queue a preamble by clearing and then setting C2[TE].
4. Write the first and subsequent datawords of the second message to C3[T8]/D.

## 53.9.4 Overrun (OR) flag implications

To be flexible, the overrun flag (OR) operates slightly differently depending on the mode of operation. There may be implications that need to be carefully considered. This section clarifies the behavior and the resulting implications. Regardless of mode, if a dataword is received while S1[OR] is set, S1[RDRF] and S1[IDLE] are blocked from asserting. If S1[RDRF] or S1[IDLE] were previously asserted, they will remain asserted until cleared.

### 53.9.4.1 Overrun operation

The assertion of S1[OR] indicates that a significant event has occurred. The assertion indicates that received data has been lost because there was a lack of room to store it in the data buffer. Therefore, while S1[OR] is set, no further data is stored in the data buffer until S1[OR] is cleared. This ensures that the application will be able to handle the overrun condition.

In most applications, because the total amount of lost data is known, the application will attempt to return the system to a known state. Before S1[OR] is cleared, all received data will be dropped. For this, the software does the following.

1. Remove data from the receive data buffer. This could be done by reading data from the data buffer and processing it if the data in the FIFO was still valuable when the overrun event occurred, or using CFIFO[RXFLUSH] to clear the buffer.
2. Clear S1[OR]. Note that if data was cleared using CFIFO[RXFLUSH], then clearing S1[OR] will result in SFIFO[RXUF] asserting. This is because the only way to clear S1[OR] requires reading additional information from the FIFO. Care should be taken to disable the SFIFO[RXUF] interrupt prior to clearing the OR flag and then clearing SFIFO[RXUF] after the OR flag has been cleared.

Note that, in some applications, if an overrun event is responded to fast enough, the lost data can be recovered. For example, when C7816[ISO\_7816E] is asserted, C7816[TTYTYPE]=1 and C7816[ONACK] = 1, the application may reasonably be able to determine whether the lost data will be resent by the device. In this scenario, flushing the receiver data buffer may not be required. Rather, if S1[OR] is cleared, the lost data may be resent and therefore may be recoverable.

When LIN break detect (LBKDE) is asserted, S1[OR] has significantly different behavior than in other modes. S1[OR] will be set, regardless of how much space is actually available in the data buffer, if a LIN break character has been detected and the corresponding flag, S2[LBKDIF], is not cleared before the first data character is received after S2[LBKDIF] asserted. This behavior is intended to allow the software sufficient time to read the LIN break character from the data buffer to ensure that a break character was actually detected. The checking of the break character was used on some older implementations and is therefore supported for legacy reasons. Applications that do not require this checking can simply clear S2[LBKDIF] without checking the stored value to ensure it is a break character.

### 53.9.5 Overrun NACK considerations

When C7816[ISO\_7816E] is enabled and C7816[TTYTYPE] = 0, the retransmission feature of the 7816 protocol can be used to help avoid lost data when the data buffer overflows. Using C7816[ONACK], the module can be programmed to issue a NACK on an overflow event. Assuming that the smartcard device has implemented retransmission, the lost data will be retransmitted. While useful, there is a programming implication that may require special consideration. The need to transmit a NACK must be determined and committed to prior to the dataword being fully received. While the NACK is being received, it is possible that the application code will read the data buffer such that sufficient room will be made to store the dataword that is being NACKed. Even if room has been made in the data buffer after the transmission of a NACK is completed, the received data will always be discarded as a result of an overflow and the ET7816[RXTHRESHOLD] value will be incremented by one. However, if sufficient space now exists to write the received data which was NACK'ed, S1[OR] will be blocked and kept from asserting.

### 53.9.6 Match address registers

The two match address registers allow a second match address function for a broadcast or general call address to the serial bus, as an example.

### 53.9.7 Modem feature

This section describes the modem features.

#### 53.9.7.1 Ready-to-receive using RTS

To help to stop overrun of the receiver data buffer, the RTS signal can be used by the receiver to indicate to another UART that it is ready to receive data. The other UART can send the data when its CTS signal is asserted. This handshaking conforms to the TIA-232-E standard. A transceiver is necessary if the required voltage levels of the communication link do not match the voltage levels of the UART's RTS and CTS signals.

Figure 53-28. Ready-to-receive

The transmitter's CTS signal can be used for hardware flow control whether its RTS signal is used for hardware flow control, transceiver driver enable, or not at all.

### 53.9.7.2 Transceiver driver enable using RTS

RS-485 is a multiple drop communication protocol in which the UART transceiver's driver is 3-stated unless the UART is driving. The RTS signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS can be matched to the polarity of the transceiver's driver enable signal. See the following figure.

Figure 53-29. Transceiver driver enable using RTS

In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS\_B to both DE and RE\_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the UART in single wire mode, freeing the RXD pin for other uses.

### 53.9.8 IrDA minimum pulse width

The IrDA specifies a minimum pulse width of 1.6  $\mu$ s. The UART hardware does not include a mechanism to restrict/force the pulse width to be greater than or equal to 1.6  $\mu$ s. However, configuring the baud rate to 115.2 kbit/s and the narrow pulse width to 3/16 of a bit time results in a pulse width of 1.6  $\mu$ s.

### 53.9.9 Clearing 7816 wait timer (WT, BWT, CWT) interrupts

The 7816 wait timer interrupts associated with IS7816[WT], IS7816[BWT], and IS7816[CWT] will automatically reassert if they are cleared and the wait time is still violated. This behavior is similar to most of the other interrupts on the UART. In most cases, if the condition that caused the interrupt to trigger still exists when the interrupt is cleared, then the interrupt will reassert. For example, consider the following scenario:

1. IS7816[WT] is programmed to assert after 9600 cycles of unresponsiveness.
2. The 9600 cycles pass without a response resulting in the WT interrupt asserting.
3. The IS7816[WT] is cleared at cycle 9700 by the interrupt service routine.
4. After the WT interrupt has been cleared, the smartcard remains unresponsive. At cycle 9701 the WT interrupt will be reasserted.

If the intent of clearing the interrupt is such that it does not reassert, the interrupt service routine must remove or clear the condition that originally caused the interrupt to assert prior to clearing the interrupt. There are multiple ways that this can be accomplished, including ensuring that an event that results in the wait timer resetting occurs, such as, the transmission of another packet.

### 53.9.10 Legacy and reverse compatibility considerations

Recent versions of the UART have added several new features. Whenever reasonably possible, reverse compatibility was maintained. However, in some cases this was either not feasible or the behavior was deemed as not intended. This section describes several differences to legacy operation that resulted from these recent enhancements. If application code from previous versions is used, it must be reviewed and modified to take the following items into account. Depending on the application code, additional items that are not listed here may also need to be considered.

1. Various reserved registers and register bits are used, such as, MSFB and M10.
2. This module now generates an error when invalid address spaces are used.
3. While documentation indicated otherwise, in some cases it was possible for S1[IDLE] to assert even if S1[OR] was set.
4. S1[OR] will be set only if the data buffer (FIFO) does not have sufficient room. Previously, the data buffer was always a fixed size of one and the S1[OR] flag would set so long as S1[RDRF] was set even if there was room in the data buffer. While the clearing mechanism has remained the same for S1[RDRF], keeping the OR flag assertion tied to the RDRF event rather than the data buffer being full would have greatly reduced the usefulness of the buffer when its size is larger than one.

5. Previously, when C2[RWU] was set (and WAKE = 0), the IDLE flag could reassert up to every bit period causing an interrupt and requiring the host processor to reassert C2[RWU]. This behavior has been modified. Now, when C2[RWU] is set (and WAKE = 0), at least one non-idle bit must be detected before an idle can be detected.

## Chapter 54

# Flex Controller Area Network (FlexCAN)

### 54.1 Chip-specific FlexCAN information

#### 54.1.1 Instantiation information

This device contains three FlexCAN modules.

#### 54.1.2 FlexCAN glitch filter

This chip supports wakeup from the FlexCAN module's Stop and Doze mode through a CAN wakeup interrupt. Any recessive to dominant transition on the CAN bus (CAN\_RX) can wake the chip from Stop or Doze mode. An optional glitch filter is connected on CAN\_RX to the interrupt generation logic path.

The glitch filter provides the following functionality:

- Filtering out of unwanted noise on the CAN bus
- Selection of the wakeup source, either from the filtered or unfiltered CAN bus
- Routing of the wakeup source to either the synchronous (Doze) or asynchronous (Stop) wakeup path within the FlexCAN module

The reference clock for the glitch filter is a 4 MHz clock derived from the MCGIRCLK. The MCGIRCLK must be configured to be 4 MHz and must remain on if the user wants a low power wakeup through the glitch filter. The glitch filter counts 11 cycles of the 4 MHz clock before recognizing it as a valid recessive to dominant transition.

#### 54.1.3 FlexCAN Supervisor Mode

The module's MCR[SUPV] field configures the FlexCAN to be in either Supervisor or User Mode. On this chip:

- MCR[SUPV] is always 1: the FlexCAN is in Supervisor Mode.
- Writes to MCR[SUPV] have no effect.

## 54.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

**Figure 54-1. FlexCAN block diagram**

## 54.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN 2.0 version B protocol, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

## 54.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing

- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 16 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity
- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames

- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version

### 54.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ\_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Doze mode:

This low power mode is entered when the DOZE bit in MCR is asserted and Doze mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Doze mode, the module requests to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. Exit from this mode happens when the DOZE bit in MCR is negated, when the chip is removed from Doze mode, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See [Doze mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See [Stop mode](#) for more information.

## 54.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 54-1. FlexCAN signal descriptions**

| Signal | Description      | I/O    |
|--------|------------------|--------|
| CAN Rx | CAN Receive Pin  | Input  |
| CAN Tx | CAN Transmit Pin | Output |

### 54.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 54.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 54.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

### 54.4.1 FlexCAN memory mapping

The memory map for the FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of [Table 54-2](#).

**Table 54-2. Register access and reset information**

| Register                                | Access type | Affected by hard reset | Affected by soft reset |
|-----------------------------------------|-------------|------------------------|------------------------|
| Module Configuration Register (CAN_MCR) | S           | Yes                    | Yes                    |

*Table continues on the next page...*

**Table 54-2. Register access and reset information (continued)**

| Register                                         | Access type | Affected by hard reset | Affected by soft reset |
|--------------------------------------------------|-------------|------------------------|------------------------|
| Control 1 register (CAN_CTRL1)                   | S/U         | Yes                    | No                     |
| Free Running Timer register (CAN_TIMER)          | S/U         | Yes                    | Yes                    |
| Rx Mailboxes Global Mask register (CAN_RXMGMASK) | S/U         | No                     | No                     |
| Rx Buffer 14 Mask register (CAN_RX14MASK)        | S/U         | No                     | No                     |
| Rx Buffer 15 Mask register (CAN_RX15MASK)        | S/U         | No                     | No                     |
| Error Counter Register (CAN_ECR)                 | S/U         | Yes                    | Yes                    |
| Error and Status 1 Register (CAN_ESR1)           | S/U         | Yes                    | Yes                    |
| Interrupt Masks 1 register (CAN_IMASK1)          | S/U         | Yes                    | Yes                    |
| Interrupt Flags 1 register (CAN_IFLAG1)          | S/U         | Yes                    | Yes                    |
| Control 2 Register (CAN_CTRL2)                   | S/U         | Yes                    | No                     |
| Error and Status 2 Register (CAN_ESR2)           | S/U         | Yes                    | Yes                    |
| CRC Register (CAN_CRCCR)                         | S/U         | Yes                    | Yes                    |
| Rx FIFO Global Mask register (CAN_RXFGMASK)      | S/U         | No                     | No                     |
| Rx FIFO Information Register (CAN_RXFIR)         | S/U         | No                     | No                     |
| CAN Bit Timing Register (CAN_CBT)                | S/U         | Yes                    | No                     |
| Message buffers                                  | S/U         | No                     | No                     |
| Rx Individual Mask Registers                     | S/U         | No                     | No                     |

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

The table below shows the FlexCAN memory map.

The address range from offset 0x80 to 0x17F allocates the sixteen 128-bit Message Buffers (MBs).

The memory maps for the message buffers are in [FlexCAN message buffer memory map](#).

#### CAN memory map

| Absolute address (hex) | Register name                                     | Width (in bits) | Access | Reset value                 | Section/page                |
|------------------------|---------------------------------------------------|-----------------|--------|-----------------------------|-----------------------------|
| 4002_4000              | Module Configuration Register (CAN0_MCR)          | 32              | R/W    | <a href="#">See section</a> | <a href="#">54.4.2/1755</a> |

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>MDIS | <p>Module Disable</p> <p>This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This bit is not affected by soft reset.</p> <p>0 Enable the FlexCAN module.<br/>1 Disable the FlexCAN module.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 30<br>FRZ  | <p>Freeze Enable</p> <p>The FRZ bit specifies the FlexCAN behavior when the HALT bit in the CAN_MCR Register is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.</p> <p>0 Not enabled to enter Freeze mode.<br/>1 Enabled to enter Freeze mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                      |
| 29<br>RFEN | <p>Rx FIFO Enable</p> <p>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CAN_CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see <a href="#">Arbitration and matching timing</a>). This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p>0 Rx FIFO not enabled.<br/>1 Rx FIFO enabled.</p> |
| 28<br>HALT | Halt FlexCAN                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p>Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and the Control Registers CAN_CTRL1 and CAN_CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode.</p> <p>0 No Freeze mode request.<br/>1 Enters Freeze mode if the FRZ bit is asserted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 27<br>NOTRDY  | <p>FlexCAN Not Ready</p> <p>This read-only bit indicates that FlexCAN is either in Disable mode, Doze mode, Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes. This bit is not affected by soft reset.</p> <p>0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode.<br/>1 FlexCAN module is either in Disable mode, Doze mode, Stop mode or Freeze mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 26<br>WAKMSK  | <p>Wake Up Interrupt Mask</p> <p>This bit enables the Wake Up Interrupt generation under Self Wake Up mechanism.</p> <p>0 Wake Up Interrupt is disabled.<br/>1 Wake Up Interrupt is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 25<br>SOFTRST | <p>Soft Reset</p> <p>When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers.</p> <p>The SOFTRST bit can be asserted directly by the CPU when it writes to the MCR Register, but it is also asserted when global soft reset is requested at chip level. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.</p> <p>Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset.</p> <p>0 No reset request.<br/>1 Resets the registers affected by soft reset.</p>            |
| 24<br>FRZACK  | <p>Freeze Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode". This bit is not affected by soft reset.</p> <p><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN not in Freeze mode, prescaler running.<br/>1 FlexCAN in Freeze mode, prescaler stopped.</p> |
| 23<br>SUPV    | <p>Supervisor Mode</p> <p>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <p>the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses.</p> <p>1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.</p>                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 22<br>SLFWAK | <p>Self Wake Up</p> <p>This bit enables the Self Wake Up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for wake up event, that is, a recessive-to-dominant transition.</p> <p>If a wake up event is detected during Doze mode, FlexCAN requests to resume its clocks and, if enabled to do so, generates a Wake Up interrupt to the CPU.</p> <p>If a wake up event is detected during Stop mode, then FlexCAN generates, if enabled to do so, a Wake Up interrupt to the CPU so that it can exit Stop mode globally and FlexCAN can request to resume the clocks.</p> <p>When FlexCAN is in a low-power mode other than Disable mode, this bit cannot be written as it is blocked by hardware.</p> <p>0 FlexCAN Self Wake Up feature is disabled.</p> <p>1 FlexCAN Self Wake Up feature is enabled.</p> |
| 21<br>WRNEN  | <p>Warning Interrupt Enable</p> <p>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p>0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.</p> <p>1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.</p>                                                                                                                                                                                                                 |
| 20<br>LPMACK | <p>Low-Power Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset.</p> <p><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN is not in a low-power mode.</p> <p>1 FlexCAN is in a low-power mode.</p>                                                                                                                                                                                           |
| 19<br>WAKSRC | <p>Wake Up Source</p> <p>This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wake up. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus.</p> <p>1 FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 18<br>DOZE   | <p>Doze Mode Enable</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**CANx\_MCR field descriptions (continued)**

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p>This bit defines whether FlexCAN is allowed to enter low-power mode when Doze mode is requested at chip level. This bit is automatically reset when FlexCAN wakes up from Doze mode upon detecting activity on the CAN bus (self wake-up enabled).</p> <p>0 FlexCAN is not enabled to enter low-power mode when Doze mode is requested.<br/> 1 FlexCAN is enabled to enter low-power mode when Doze mode is requested.</p>                                                                                                                                                                                     |
| 17<br>SRXDIS   | <p>Self Reception Disable</p> <p>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Self reception enabled.<br/> 1 Self reception disabled.</p>                                                        |
| 16<br>IRMQ     | <p>Individual Rx Masking And Queue Enable</p> <p>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with CAN_RXMGMASK, CAN_RX14MASK, CAN_RX15MASK and CAN_RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p>0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.<br/> 1 Individual Rx masking and queue feature are enabled.</p>                             |
| 15<br>DMA      | <p>DMA Enable</p> <p>The DMA Enable bit controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, consequently the bit CAN_MCR[RFEN] must be asserted. When DMA and RFEN are set, the CAN_IFLAG1[BUF5I] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes.</p> <p>0 DMA feature for RX FIFO disabled.<br/> 1 DMA feature for RX FIFO enabled.</p>                                                                                                                   |
| 14<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 13<br>LPRIOEN  | <p>Local Priority Enable</p> <p>This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Local Priority disabled.<br/> 1 Local Priority enabled.</p> |
| 12<br>AEN      | <p>Abort Enable</p> <p>When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p>                                                                                                                                                                                                                                                                                    |

| 9–8<br>IDAM    | <p>ID Acceptance Mode</p> <p>This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>00 Format A: One full ID (standard and extended) per ID Filter Table element.<br/>01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element.<br/>10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element.<br/>11 Format D: All frames rejected.</p>                                                                                                                                                                                                                                                 |
| 7<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| MAXMB          | <p>Number Of The Last Message Buffer</p> <p>This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Number of the last MB = MAXMB</p> <p><b>NOTE:</b> MAXMB must be programmed with a value smaller than or equal to the number of available Message Buffers.</p> <p>Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by RFFN bit in CAN_CTRL2 register. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see <a href="#">Arbitration and matching timing</a>).</p> |

**54.4.3 Control 1 register (CANx\_CTRL1)**

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

The CAN bit timing variables (PRES DIV, PROPSEG, PSEG1, PSEG2 and RJW) can also be configured in CAN\_CBT register, which extends the range of all these variables. If CAN\_CBT[BTF] is set, PRES DIV, PROPSEG, PSEG1, PSEG2 and RJW fields of CAN\_CTRL1 become read only.

The contents of this register are not affected by soft reset.

### NOTE

The CAN bit variables in CAN\_CTRL1 and in CAN\_CBT are stored in the same register.

Address: Base address + 4h offset

### CANx\_CTRL1 field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–24<br>PRES DIV | <p>Prescaler Division Factor</p> <p>This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Sclock frequency = PE clock frequency / (PRES DIV + 1)</p> |
| 23–22<br>RJW      | <p>Resync Jump Width</p> <p>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p>                                                                                                                                                                                                                                                                                  |

| 13<br>CLKSRC   | <p>CAN Engine Clock Source</p> <p>This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclock). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See <a href="#">Protocol timing</a>".</p> <p>0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock.<br/>1 The CAN engine clock source is the peripheral clock.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| 12<br>LPB      | <p>Loop Back Mode</p> <p>This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node.</p> <p>In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> In this mode, the CAN_MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message.</p> <p>0 Loop Back disabled.<br/>1 Loop Back enabled.</p> |
| 11<br>TWRNMSK  | Tx Warning Interrupt Mask                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 8<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 7<br>SMP      | <p>CAN Bit Sampling</p> <p>This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> For proper operation, to assert SMP it is necessary to guarantee a minimum value of 2 TQs in CAN_CTRL1[PSEG1] (or CAN_CBT[EPSEG1]).</p> <p>0 Just one sample is used to determine the bit value.<br/>1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 6<br>BOFFREC  | <p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p>0 Automatic recovering from Bus Off state enabled.<br/>1 Automatic recovering from Bus Off state disabled.</p> |
| 5<br>TSYN     | <p>Timer Sync</p> <p>This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special "SYNC" message, that is, global network time. If the RFEN bit in CAN_MCR is set (Rx FIFO enabled), the first available Mailbox, according to CAN_CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| 4<br>LBUF | Lowest Buffer Transmitted First<br><br>This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the CAN_MCR[LPRIOEN] bit does not affect the priority arbitration. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.<br><br>0 Buffer with highest priority is transmitted first.<br>1 Lowest number buffer is transmitted first.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 3<br>LOM  | Listen-Only Mode<br><br>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in CAN_ECR register are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (RXERRCNT) in CAN_ECR register, as if it was trying to acknowledge the message.<br><br>Listen-Only mode is acknowledged by the state of CAN_ESR1[FLTCONF] field indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge.<br><br>This bit can be written in Freeze mode only because it is blocked by hardware in other modes.<br><br>0 Listen-Only mode is deactivated.<br>1 FlexCAN module operates in Listen-Only mode. |
| PROPSEG   | Propagation Segment<br><br>This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br>$\text{Propagation Segment Time} = (\text{PROPSEG} + 1) \times \text{Time-Quanta}$ .<br>$\text{Time-Quantum} = \text{one Sclock period}$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**54.4.4 Free Running Timer (CANx\_TIMER)**

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CAN\_CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CAN\_CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure, see Section "Mailbox Lock Mechanism".

## 54.4.5 Rx Mailboxes Global Mask Register (CANx\_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the CAN\_MCR[IRMQ] bit is negated, RXMGMASK is always in effect (the bits in the MG field will mask the Mailbox filter bits).
- When the CAN\_MCR[IRMQ] bit is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the Mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

| MG                    | <p>Rx Mailboxes Global Mask Bits</p> <p>These bits mask the Mailbox filter bits. Note that the alignment with the ID word of the Mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the Mailbox. The following table shows in detail which MG bits mask each Mailbox filter field.</p> <table><tr><th rowspan="2">SMB[RTR] <sup>1</sup></th><th rowspan="2">CAN_CTRL2[RRS]</th><th rowspan="2">CAN_CTRL2[EACEN]</th><th colspan="4">Mailbox filter fields</th></tr><tr><th>MB[RTR]</th><th>MB[IDE]</th><th>MB[ID]</th><th>Reserved</th></tr><tr><td>0</td><td>-</td><td>0</td><td>note <sup>2</sup></td><td>note <sup>3</sup></td><td>MG[28:0]</td><td>MG[31:29]</td></tr><tr><td>0</td><td>-</td><td>1</td><td>MG[31]</td><td>MG[30]</td><td>MG[28:0]</td><td>MG[29]</td></tr><tr><td>1</td><td>0</td><td>-</td><td>-</td><td>-</td><td>-</td><td>MG[31:0]</td></tr><tr><td>1</td><td>1</td><td>0</td><td>-</td><td>-</td><td>MG[28:0]</td><td>MG[31:29]</td></tr><tr><td>1</td><td>1</td><td>1</td><td>MG[31]</td><td>MG[30]</td><td>MG[28:0]</td><td>MG[29]</td></tr></table> <p>0 The corresponding bit in the filter is "don't care."<br/>1 The corresponding bit in the filter is checked.</p> | SMB[RTR] <sup>1</sup> | CAN_CTRL2[RRS]    | CAN_CTRL2[EACEN]  | Mailbox filter fields |                       |  |  | MB[RTR] | MB[IDE] | MB[ID] | Reserved | 0 | - | 0 | note <sup>2</sup> | note <sup>3</sup> | MG[28:0] | MG[31:29] | 0 | - | 1 | MG[31] | MG[30] | MG[28:0] | MG[29] | 1 | 0 | - | - | - | - | MG[31:0] | 1 | 1 | 0 | - | - | MG[28:0] | MG[31:29] | 1 | 1 | 1 | MG[31] | MG[30] | MG[28:0] | MG[29] |

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN\_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

### 54.4.6 Rx 14 Mask register (CANx\_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the CAN\_MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: Base address + 14h offset

**54.4.7 Rx 15 Mask register (CANx\_RX15MASK)**

This register is located in RAM.

RX15MASK is provided for legacy application support. When the CAN\_MCR[IRMQ] bit is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of Message Buffer 15.

This register can be programmed only while the module is in Freeze mode because it is blocked by hardware in other modes.

**54.4.8 Error Counter (CANx\_ECR)**

This register has two 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)

The Fault Confinement State (FLTCONF field in Error and Status Register 1 - CAN\_ESR1) is updated based on TXERRCNT and RXERRCNT counters. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect "Error Passive" state.
- If the FlexCAN state is "Error Passive", and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect "Error Active" state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect "Bus Off" state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in "Bus Off" state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be "Error Active" and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to "Error Passive" state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the "Bus Off" state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to "Error Active" state.

**54.4.9 Error and Status 1 register (CANx\_ESR1)**

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device and it is the source of some interrupts to the CPU.

The reported error conditions are BIT1ERR, BIT0ERR, ACKKERR, CRCERR, FRMERR and STFERR.

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative in case more error events happen in the next frames while the CPU does not attempt to read this register.

TXWRN, RXWRN, IDLE, TX, FLTCONF, RX and SYNCH are status bits.

BOFFINT, BOFFDONEINT, ERRINT, WAKINT, TWRNINT and RWRNINT are interrupt bits. It is recommended the CPU to use the following procedure when servicing interrupt requests generated by these bits:

- Read this register to capture all error condition and status bits. This action clear the respective bits that were set since the last read access.
- Write 1 to clear the interrupt bit that has triggered the interrupt request.
- Write 1 to clear the ERR\_OVR bit if it is set.

Memory map/register definition

Starting from all error flags cleared, a first error event sets the ERRINT (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU to serve the interrupt request, the ERR\_OVR bit is set to indicate that errors from different frames had accumulated.

| SYNCH | IDLE | TX | RX | FlexCAN State               |

| 19<br>BOFFDONEINT | Bus Off Done Interrupt<br><br>This bit is set when the Tx Error Counter (TXERRCNT) has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If the corresponding mask bit in the Control 2 Register (BOFFDONEMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.<br><br>0    No such occurrence.<br>1    FlexCAN module has completed Bus Off process.                                                                                                                                                                                                                                                                                    |
| 18<br>SYNCH       | CAN Synchronization Status<br><br>This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description.<br><br>0    FlexCAN is not synchronized to the CAN bus.<br>1    FlexCAN is synchronized to the CAN bus.                                                                                                                                                                                                                                                                                                                                                                                    |
| 17<br>TWRNINT     | Tx Warning Interrupt Flag<br><br>If the WRNEN bit in CAN_MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode.<br><br>0    No such occurrence.<br>1    The Tx error counter transitioned from less than 96 to greater than or equal to 96. |
| 16<br>RWRNINT     | Rx Warning Interrupt Flag<br><br>If the WRNEN bit in CAN_MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode.<br><br>0    No such occurrence.<br>1    The Rx error counter transitioned from less than 96 to greater than or equal to 96.                                                 |
| 15<br>BIT1ERR     | Bit1 Error<br><br>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.<br><br><b>NOTE:</b> This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.<br><br>0    No such occurrence.<br>1    At least one bit sent as recessive is received as dominant.                                                                                                                                                                                                                                                                                                                                                     |

**CANx\_ESR1 field descriptions (continued)**

| Field | Description                                                               |
|-------|---------------------------------------------------------------------------|
| 0     | No such occurrence.                                                       |
| 1     | Indicates a recessive to dominant transition was received on the CAN bus. |

**54.4.10 Interrupt Masks 1 register (CANx\_IMASK1)**

This register allows any number of a range of the 16 Message Buffer Interrupts to be enabled or disabled for MB15 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN\_IFLAG1 bit is set.

| BUF31TO0M | <p>Buffer MB<sub>i</sub> Mask</p> <p>Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0.</p> <p><b>NOTE:</b> Setting or clearing a bit in the CAN_IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set.</p> <p>0 The corresponding buffer Interrupt is disabled.</p> <p>1 The corresponding buffer Interrupt is enabled.</p> |

**54.4.11 Interrupt Flags 1 register (CANx\_IFLAG1)**

This register defines the flags for the 16 Message Buffer interrupts for MB15 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN\_IFLAG1 bit. If the corresponding CAN\_IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit CAN\_MCR[RFEN] is set and the bit CAN\_MCR[DMA] is negated, the function of the 8 least significant interrupt flags changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling the CAN\_MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the CAN\_MCR[RFEN] bit is negated, the FIFO flags must be cleared. The same care must be taken when an CAN\_CTRL2[RFFN] value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

When both the CAN\_MCR[RFEN] and CAN\_MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as, BUF4I to BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit CAN\_MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling the bit CAN\_MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. When the bit CAN\_MCR[DMA] is negated, the FIFO must be empty.

Before updating CAN\_MCR[MAXMB] field, CPU must service the CAN\_IFLAG1 bits whose MB value is greater than the CAN\_MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

| 7<br>BUF7I        | <p>Buffer MB7 Interrupt Or "Rx FIFO Overflow"</p> <p>When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes.</p> <p>The BUF7I flag represents "Rx FIFO Overflow" when CAN_MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox.</p> <p>0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1<br/>1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1</p>                                                                                                                                                                                                                   |
| 6<br>BUF6I        | <p>Buffer MB6 Interrupt Or "Rx FIFO Warning"</p> <p>When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6.</p> <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes.</p> <p>The BUF6I flag represents "Rx FIFO Warning" when CAN_MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4.</p> <p>0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1<br/>1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1</p> |

**CANx\_IFLAG1 field descriptions (continued)**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p><b>NOTE:</b> This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by CPU writes. When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I.</p> <p>0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1</p> <p>1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled.</p>                                                                                           |
| 4–1<br>BUF4TO1I | <p>Buffer MB<sub>i</sub> Interrupt Or "reserved"</p> <p>When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1.</p> <p><b>NOTE:</b> These flags are cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes.</p> <p>The BUF4TO1I flags are reserved when CAN_MCR[RFEN] is set.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.</p> <p>1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p>                                                                                                                                                                                                                                                     |
| 0<br>BUF0I      | <p>Buffer MB0 Interrupt Or Clear FIFO bit</p> <p>When the RFEN bit in MCR is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0. If the Rx FIFO is enabled, this bit is used to trigger the clear FIFO operation. This operation empties FIFO contents. Before performing this operation the CPU must service all FIFO related IFLAGS. When the bit MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently abort the DMA request. The clear FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze Mode and is blocked by hardware in other conditions.</p> <p>0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0.</p> <p>1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.</p> |

**54.4.12 Control 2 register (CANx\_CTRL2)**

This register complements Control1 Register providing control bits for memory write access in Freeze Mode, for extending FIFO filter quantity, and for adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

| 22–16<br>LPTM     | Lowest Priority Tx Mailbox<br><br>If CAN_ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the CAN_ESR2[IMB] bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CAN_CTRL1[LBUF] bit value. If CAN_CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CAN_CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number. |

| 14<br>VPS      | <p>Valid Priority Status</p> <p>This bit indicates whether CAN_ESR2[IMB] and CAN_ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox.</p> <p><b>NOTE:</b> CAN_ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When CAN_MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with CAN_IFLAG set is blocked.</p> <p>0 Contents of IMB and LPTM are invalid.<br/>1 Contents of IMB and LPTM are valid.</p> |
| 13<br>IMB      | <p>Inactive Mailbox</p> <p>If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases:</p> <ul style="list-style-type: none"> <li>• During arbitration, if an CAN_ESR2[LPTM] is found and it is inactive.</li> <li>• If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully.</li> </ul> <p>This bit is cleared in all start of arbitration (see Section "Arbitration process").</p> <p><b>NOTE:</b> CAN_ESR2[LPTM] mechanism have the following behavior: if an MB is successfully transmitted and CAN_ESR2[IMB]=0 (no inactive Mailbox), then CAN_ESR2[VPS] and CAN_ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into CAN_ESR2[LPTM].</p> <p>0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox.<br/>1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.</p>                       |
| Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

54.4.14 CRC Register (CANx\_CRCR)

This register provides information about the CRC of transmitted messages. This register is updated at the same time the Tx Interrupt Flag is asserted.

54.4.15 Rx FIFO Global Mask register (CANx\_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CAN\_CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

## Memory map/register definition

1. If CAN\_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN\_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

## 54.4.16 Rx FIFO Information Register (CANx\_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

### CANx\_RXFIR field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–9<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                     |
| IDHIT            | Identifier Acceptance Filter Hit Indicator<br><br>This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the CAN_IFLAG1[BUF5] is asserted. |

### 54.4.17 CAN Bit Timing Register (CANx\_CBT)

This register is an alternative way to store the CAN bit timing variables described in CAN\_CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW bit fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

#### NOTE

The CAN bit variables in CAN\_CTRL1 and in CAN\_CBT are stored in the same register.

Address: Base address + 50h offset

**CANx\_CBT field descriptions (continued)**

| Field  | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | <p>This 5-bit field defines the length of Phase Segment 1 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta.</p> <p>Time-Quantum = one Sclock period.</p>                                 |
| EPSEG2 | <p>Extended Phase Segment 2</p> <p>This 5-bit field defines the length of Phase Segment 2 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta.</p> <p>Time-Quantum = one Sclock period.</p> |

**54.4.18 Rx Individual Mask Registers (CANx\_RXIMRn)**

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CAN\_MCR[RFEN] bit is negated), an individual mask is provided for each available Rx Mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CAN\_MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID Filter Table Element on a one-to-one correspondence depending on the setting of CAN\_CTRL2[RFFN] (see [Rx FIFO](#)).

CAN\_RXIMR0 stores the individual mask associated to either MB0 or ID Filter Table Element 0, CAN\_RXIMR1 stores the individual mask associated to either MB1 or ID Filter Table Element 1 and so on.

CAN\_RXIMR registers can only be accessed by the CPU while the module is in Freeze mode, otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

Address: Base address + 880h offset + (4d × i), where i=0d to 15d

**54.4.70 Message buffer structure**

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x17F is used by the mailboxes.

**CODE - Message Buffer Code**

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 54-4](#) and [Table 54-5](#). See [Functional description](#) for additional information.

**Table 54-4. Message buffer code for Rx buffers**

| CODE description                                              | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment                                                                                                                                                                                                                                                                                               |

Table 54-4. Message buffer code for Rx buffers (continued)

| CODE description                                                                                                                   | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|------------------|-------------------------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                    |                                  | No               | OVERRUN                                         | -                | If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See <a href="#">Matching process</a> for details about overrun behavior.                                                                                                                                    |
| 0b1010: RANSWER <sup>4</sup> - A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return. | RANSWER                          | -                | TANSWER(0b1110)                                 | 0                | A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See <a href="#">Matching process</a> for details. If CAN_CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received. |
|                                                                                                                                    |                                  | -                | -                                               | 1                | This code is ignored during matching and arbitration process. See <a href="#">Matching process</a> for details.                                                                                                                                                                                                                                                   |
| CODE[0]=1: BUSY - FlexCAN is updating the contents of the MB. The CPU must not access the MB.                                      | BUSY <sup>5</sup>                | -                | FULL                                            | -                | Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.                                                                                                                                                                                                                                               |
|                                                                                                                                    |                                  | -                | OVERRUN                                         | -                |                                                                                                                                                                                                                                                                                                                                                                   |

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.

2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.

3. Remote Request Stored bit, see "Control 2 Register (CAN\_CTRL2)" for details.

4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 54-5. Message buffer code for Tx buffers**

| CODE Description                                                                  | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 0b1100: DATA - MB is a Tx Data Frame (MB RTR must be 0)                           | DATA                    | 0      | INACTIVE                              | Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0b1100: REMOTE - MB is a Tx Remote Request Frame (MB RTR must be 1)               | REMOTE                  | 1      | EMPTY                                 | Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0b1110: TANSWER - MB is a Tx Response Frame from an incoming Remote Request Frame | TANSWER                 | -      | RANSWER                               | This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details. |

**SRR** - Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

### **IDE** - ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

### **RTR** - Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 54-4](#), [Table 54-5](#), and the description of the RRS bit in Control 2 Register (CAN\_CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

### **DLC** - Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see [Table 54-3](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 54-6](#)).

### **TIME STAMP** - Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

### **PRIO** - Local priority

This 3-bit field is used only when LPRIO\_EN bit is set in CAN\_MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

### ID - Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

### DATA BYTE 0 to 7 - Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

**Table 54-6. DATA BYTEs validity**

| DLC        | Valid DATA BYTEs |
|------------|------------------|
| 0          | none             |
| 1          | DATA BYTE 0      |
| 2          | DATA BYTE 0 to 1 |
| 3          | DATA BYTE 0 to 2 |
| 4          | DATA BYTE 0 to 3 |
| 5          | DATA BYTE 0 to 4 |
| 6          | DATA BYTE 0 to 5 |
| 7          | DATA BYTE 0 to 6 |
| 8 or above | DATA BYTE 0 to 7 |

### 54.4.71 Rx FIFO structure

When the CAN\_MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x17C (normally occupied by MBs 6–15) depending on the CAN\_CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 40 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 54-7. Rx FIFO structure**

|       | 31                                | 28                          | 24 | 23 | 22          | 21  | 20  | 19  | 18 | 17          | 16 | 15         | 8           | 7 | 0 |             |  |
|-------|-----------------------------------|-----------------------------|----|----|-------------|-----|-----|-----|----|-------------|----|------------|-------------|---|---|-------------|--|
| 0x80  | IDHIT                             |                             |    |    | SRR         | IDE | RTR | DLC |    |             |    | TIME STAMP |             |   |   |             |  |
| 0x84  |                                   | ID standard                 |    |    |             |     |     |     |    | ID extended |    |            |             |   |   |             |  |
| 0x88  | Data byte 0                       |                             |    |    | Data byte 1 |     |     |     |    |             |    |            | Data byte 2 |   |   | Data byte 3 |  |
| 0x8C  | Data byte 4                       |                             |    |    | Data byte 5 |     |     |     |    |             |    |            | Data byte 6 |   |   | Data byte 7 |  |
| 0x90  | Reserved                          |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| to    |                                   |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0xDC  |                                   |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0xE0  | ID filter table element 0         |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0xE4  | ID filter table element 1         |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0xE8  | ID filter table elements 2 to 125 |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| to    |                                   |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0x2D4 |                                   |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0x2D8 | ID filter table element 126       |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
| 0x2DC | ID filter table element 127       |                             |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |
|       |                                   | = Unimplemented or reserved |    |    |             |     |     |     |    |             |    |            |             |   |   |             |  |

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the CAN\_MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

**Table 54-8. ID table structure**

| Format | 31  | 30  | 29                                           | 24 | 23 | 16 | 15 | 14  | 13  | 8       | 7 | 1 | 0 |
|--------|-----|-----|----------------------------------------------|----|----|----|----|-----|-----|---------|---|---|---|
| A      | RTR | IDE | RXIDA<br>(standard = 29–19, extended = 29–1) |    |    |    |    |     |     |         |   |   |   |
| B      | RTR | IDE | RXIDB_0                                      |    |    |    |    | RTR | IDE | RXIDB_1 |   |   |   |

*Table continues on the next page...*

**Table 54-8. ID table structure (continued)**

|   |                              |  |                                      |                             |  |                                    |
|---|------------------------------|--|--------------------------------------|-----------------------------|--|------------------------------------|
| C |                              |  | (standard = 29–19, extended = 29–16) |                             |  | (standard = 13–3, extended = 13–0) |
|   | RXIDC_0<br>(std/ext = 31–24) |  | RXIDC_1<br>(std/ext = 23–16)         | RXIDC_2<br>(std/ext = 15–8) |  | RXIDC_3<br>(std/ext = 7–0)         |
|   | = Unimplemented or Reserved  |  |                                      |                             |  |                                    |

**RTR** — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

**IDE** — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

**RXIDA** — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

**RXIDB\_0, RXIDB\_1** — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

**RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

**IDHIT** — Identifier Acceptance Filter Hit Indicator

This 9-bit field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. See [Rx FIFO](#) for more information.

## 54.5 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements.

Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 54-4](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 54-5](#)).

### 54.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the CAN\_IFLAG register or by the interrupt request if enabled by the respective IMASK bit. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)). If backwards compatibility is

desired (CAN\_MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).

3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority.

At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 54-4](#) and [Table 54-5](#) in [Message buffer structure](#)).

When the Abort feature is enabled (CAN\_MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

## 54.5.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CAN\_CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.

- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CAN\_CTRL1[LBUF] and CAN\_MCR[LPRIOEN] bits settings.

#### **54.5.2.1 Lowest-number Mailbox first**

If CAN\_CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. CAN\_MCR[LPRIOEN] bit has no effect when CAN\_CTRL1[LBUF] is asserted.

#### **54.5.2.2 Highest-priority Mailbox first**

If CAN\_CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on CAN\_MCR[LPRIOEN] bit setting.

### 54.5.2.2.1 Local Priority disabled

If CAN\_MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

**Table 54-9. Composition of the arbitration value when Local Priority is disabled**

| Format             | Mailbox Arbitration Value (32 bits) |             |             |                             |             |
|--------------------|-------------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | Standard ID (11 bits)               | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | Extended ID[28:18] (11 bits)        | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

### 54.5.2.2.2 Local Priority enabled

If Local Priority is desired CAN\_MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 54-10. Composition of the arbitration value when Local Priority is enabled**

| Format             | Mailbox Arbitration Value (35 bits) |                              |             |             |                             |             |
|--------------------|-------------------------------------|------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | PRIO (3 bits)                       | Standard ID (11 bits)        | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | PRIO (3 bits)                       | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 54.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if the AEN bit in CAN\_MCR register is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame.  
CAN\_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX\_ERR\_CNT=124 to 128. CAN\_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer

- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 54.5.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most for Classical CAN message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 54-4](#) and [Table 54-5](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should poll for frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 54-4](#). If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

### **CAUTION**

*In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. When CAN\_MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx Mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when CAN\_MCR[SRXDIS] bit is deasserted, FlexCAN can receive frames transmitted by itself if there exists a matching Rx Mailbox.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the BUF5I bit "Frames available in Rx FIFO" bit in the CAN\_IFLAG1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional: needed only if a mask was used)
3. Read the Data field
4. Read the CAN\_RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to CAN\_IFLAG1[BUF5I] bit (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry)

When CAN\_MCR[DMA] is asserted, upon receiving a frame in FIFO, CAN\_IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see [Rx FIFO under DMA Operation](#)). The CAN\_IMASK1 bits in Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 0x80 address, optional)
2. Read the ID field (read 0x84 address, optional)
3. Read all Data Bytes (start read at 0x88 address, optional)
4. Read the last Data Bytes (read 0x8C address is mandatory)

### 54.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. The matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame

- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

**Table 54-11. Matching architecture**

| Structure         | SMB[RTR] | CTRL2[RRS] | CTRL2[EAC EN] | MB[IDE]          | MB[RTR]             | MB[ID <sup>1</sup> ] | MB[CODE]                 |
|-------------------|----------|------------|---------------|------------------|---------------------|----------------------|--------------------------|
| Mailbox           | 0        | -          | 0             | cmp <sup>2</sup> | no_cmp <sup>3</sup> | cmp_msk <sup>4</sup> | EMPTY or FULL or OVERRUN |
| Mailbox           | 0        | -          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 0          | -             | cmp              | no_cmp              | cmp                  | RANSWER                  |
| Mailbox           | 1        | 1          | 0             | cmp              | no_cmp              | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 1          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| FIFO <sup>5</sup> | -        | -          | -             | cmp_msk          | cmp_msk             | cmp_msk              | -                        |

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no\_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp\_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY

- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the CAN\_MCR[IRMQ] bit. If it is negated, the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CAN\_CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless of the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found, then the matching winner determination is conditioned by the CAN\_MCR[IRMQ] bit:
  - If CAN\_MCR[IRMQ] bit is negated, the matching winner is the first matched Mailbox
  - If CAN\_MCR[IRMQ] bit is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

**Table 54-12. Matching possibilities and resulting reception structures**

| RFEN                                                               | IRMQ | MRP            | Matched in MB     | Matched in FIFO      | Reception structure | Description                             |
|--------------------------------------------------------------------|------|----------------|-------------------|----------------------|---------------------|-----------------------------------------|
| <b>No FIFO, only MB, match is always MB first</b>                  |      |                |                   |                      |                     |                                         |
| 0                                                                  | 0    | X <sup>1</sup> | None <sup>2</sup> | - <sup>3</sup>       | None                | Frame lost by no match                  |
| 0                                                                  | 0    | X              | Free <sup>4</sup> | -                    | FirstMB             |                                         |
| 0                                                                  | 1    | X              | None              | -                    | None                | Frame lost by no match                  |

| 1                                                                  | 0    | 1              | Free              | X                    | FirstMB             |                                         |
| 1                                                                  | 0    | 1              | NotFree           | X                    | FirtsMb             | Overrun                                 |
| <b>FIFO enabled, Queue enabled</b>                                 |      |                |                   |                      |                     |                                         |
| 1                                                                  | 1    | 0              | X                 | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 0              | None              | Full                 | None                | Frame lost by FIFO full (FIFO Overflow) |
| 1                                                                  | 1    | 0              | Free              | Full                 | FirstMB             |                                         |
| 1                                                                  | 1    | 0              | NotFree           | Full                 | LastMb              | Overrun                                 |
| 1                                                                  | 1    | 1              | None              | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 1              | Free              | X                    | FirstMB             |                                         |
| 1                                                                  | 1    | 1              | NotFree           | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 1              | NotFree           | Full                 | LastMb              | Overrun                                 |

1. This is a don't care condition.

2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).

3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CAN\_CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. See the description of the Rx Individual Mask Registers (CAN\_RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (CAN\_RXFGMASK, CAN\_RXMGMASK, CAN\_RX14MASK and CAN\_RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the CAN\_MCR Register is negated.

## 54.5.5 Move process

There are two types of move process: move-in and move-out.

### 54.5.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CAN\_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (CAN\_MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined to the Rx FIFO.
2. Read DATA0-3 and DATA4-7 words from the Rx SMB.
3. Write DATA0-3 and DATA4-7 words to the Rx Mailbox
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx Mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

#### 54.5.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

#### 54.5.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

### 54.5.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- CAN\_MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters the BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.

- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

### 54.5.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instructions on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without setting the respective IFLAG

In order to perform a *safe inactivation* and avoid the above consequences for Tx Mailboxes, the CPU must use the Transmission Abort mechanism (see [Transmission abort mechanism](#)).

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

#### NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by

FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

### 54.5.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

#### NOTE

The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code different than INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

### Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (CAN\_TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)), and it takes place only when the module resumes to Normal or Freeze modes.

## 54.5.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CAN\_MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The CAN\_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the CAN\_RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the CAN\_RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the CAN\_IFLAG1[BUF5I] is asserted.

The CAN\_IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The CAN\_IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CAN\_CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

### **Note**

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the CAN\_RXFIR register. The CAN\_RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the CAN\_IFLAG1[BUF5I] flag is asserted. The CAN\_RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 16 elements of the filter table are individually affected by the Individual Mask Registers (CAN\_RXIMRx), according to the setting of CAN\_CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the CAN\_MCR[IRMQ] bit is negated, then the FIFO filter table is affected by CAN\_RXFGMASK.

### 54.5.7.1 Rx FIFO under DMA Operation

The receive-only FIFO can support DMA, this feature is enabled by asserting both the CAN\_MCR[RFEN] and CAN\_MCR[DMA] bits. The reset value of CAN\_MCR[DMA] bit is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a Message Buffer structure at the FIFO output port at the 0x80-0x8C address range.

When CAN\_MCR[DMA] is asserted the CPU must not access the FIFO output port address range. Before enabling the CAN\_MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. Otherwise, these IFLAGs may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling the CAN\_MCR[DMA], the CPU must perform a clear FIFO operation.

The CAN\_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO, consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the FIFO as a Message Buffer). The DMA reading process must end by reading address 0x8C, which clears the CAN\_IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the CAN\_RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, the CAN\_IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

#### NOTE

CAN\_RXFIR register contents cannot be read after DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080 (see [Rx FIFO structure](#)).

The CAN\_IFLAG1[BUF6I] and CAN\_IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Rx FIFO interruption and must not clear the related IFLAGs. In addition, the related IMASKs are not used to mask the generation of DMA requests.

### 54.5.7.2 Clear FIFO Operation

When CAN\_MCR[RFEN] is asserted, the clear FIFO operation is a feature used to empty FIFO contents. With CAN\_MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes 1 in CAN\_IFLAG1[BUF0I]. This operation can only be performed in Freeze

Mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs, consequently the CPU must service all FIFO IFLAGs before execute the clear FIFO task.

When Rx FIFO is working with DMA, the clear FIFO operation clears the CAN\_IFLAG1[BUF5I] and the DMA request is canceled.

### CAUTION

*Clear FIFO operation does not clear IFLAGs, except when CAN\_MCR[DMA] is asserted, in this case only the CAN\_IFLAG1[BUF5I] is cleared.*

## 54.5.8 CAN protocol related features

This section describes the CAN protocol related features.

### 54.5.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by configuring the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

### 54.5.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

### 54.5.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The Free Running Timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 Register (CAN\_CTRL1).

### 54.5.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CAN\_CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (MDIS bit set in the Module Configuration Register).

**Figure 54-2. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control 1 Register (CAN\_CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW.

The CAN Bit Timing register (CAN\_CBT) extends the range of the CAN bit timing variables in CAN\_CTRL1.

The PRESDIV field (as well as its extended range EPRESDIV) defines the Prescaler Value (see the equation below) that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) \* T<sub>q</sub>

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

A bit time is subdivided into three segments<sup>1</sup> (see [Figure 54-3](#) and [Table 54-13](#)):

- **SYNC\_SEG:** This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- **Time Segment 1:** This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CAN\_CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta. When CAN\_CBT[BTF] bit is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CAN\_CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta.
- **Time Segment 2:** This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CAN\_CTRL1 Register (plus 1) to be 2 to 8 time quanta long. When CAN\_CBT[BTF] bit is asserted, FlexCAN uses EPSEG2 fields of CAN\_CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. The Time Segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

### NOTE

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an Information Processing Time (IPT) of 2, which is the value implemented in the FlexCAN module.

1. For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

**Figure 54-3. Segments within the bit time (example using CAN\_CTRL1 bit timing variables for Classical CAN format)**

**Table 54-13. Time segment syntax**

| Syntax         | Description                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| SYNC_SEG       | System expects transitions to occur on the bus during this period.                                                                             |
| TSEG1          | Corresponds to the sum of PROPSEG and PSEG1.                                                                                                   |
| TSEG2          | Corresponds to the PSEG2 value.                                                                                                                |
| Transmit Point | A node in transmit mode transfers a new value to the CAN bus at this point.                                                                    |
| Sample Point   | A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample. |

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) messages.

**Table 54-14. Bosch CAN 2.0B standard compliant bit time segment settings**

| Time segment 1 | Time segment 2 | Re-synchronization jump width |
|----------------|----------------|-------------------------------|
| 5 .. 10        | 2              | 1 .. 2                        |
| 4 .. 11        | 3              | 1 .. 3                        |
| 5 .. 12        | 4              | 1 .. 4                        |
| 6 .. 13        | 5              | 1 .. 4                        |
| 7 .. 14        | 6              | 1 .. 4                        |
| 8 .. 15        | 7              | 1 .. 4                        |
| 9 .. 16        | 8              | 1 .. 4                        |

### Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (e.g. estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRES DIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

where:

- NumClkBit is the number of peripheral clocks in one CAN bit;
- $f_{\text{CANCLK}}$  is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- $f_{\text{SYS}}$  is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CAN\_CTRL1[PSEG1] field;
- PSEG2 is the value in CAN\_CTRL1[PSEG2] field;
- PROPSEG is the value in CAN\_CTRL1[PROPSEG] field;
- PRES DIV is the value in CAN\_CTRL1[PRES DIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing Register (CAN\_CBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

#### 54.5.8.5 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

Figure 54-4. Matching and move-in time windows

**Figure 54-5. Arbitration and move-out time windows**

**Figure 54-6. Arbitration at the end of bus off and move-out time windows**

### NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

#### 54.5.8.6 Tx Arbitration start delay

The Tx Arbitration Start Delay (TASD) bit field in Control 2 register (CAN\_CTRL2[TASD]) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx Arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure Message Buffers (MBs) for transmission after the end of the internal Arbitration process, where FlexCAN finds the winner MB for transmission (see [Arbitration process](#)). If the Arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the Arbitration start point, as shown in the next figure, based on factors such as:

- The peripheral-to-oscillator clock ratio

- CAN bit timing variables that determine the CAN bit rate
- The number of Message Buffers (MBs) in use by the Matching and Arbitration processes.

**Figure 54-7. Optimal Tx Arbitration start point**

The duration of an Arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal Arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the Arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the Arbitration start is not delayed and more time is reserved for Arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for Arbitration. If too little time is reserved for Arbitration the FlexCAN may not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

$$\text{TASD} = 25 - \left( \frac{f_{\text{CANCLK}} \times [\text{MAXMB} + 3 - (\text{RFEN} \times 8) - (\text{RFEN} \times \text{RFFN} \times 2)] \times 2}{f_{\text{SYS}} \times [1 + (\text{PSEG1} + 1) + (\text{PSEG2} + 1) + (\text{PROPSEG} + 1)] \times (\text{PRES DIV} + 1)} \right)$$

where:

- MAXMB is the value in CAN\_CTRL1[MAXMB] field
- $f_{\text{CANCLK}}$  is the oscillator clock, in Hz
- $f_{\text{SYS}}$  is the peripheral clock, in Hz

- RFEN is the value in CAN\_CTRL1[RFEN] bit
- RFFN is the value in CAN\_CTRL2[RFFN] field
- PSEG1 is the value in CAN\_CTRL1[PSEG1] field
- PSEG2 is the value in CAN\_CTRL1[PSEG2] field
- PROPSEG is the value in CAN\_CTRL1[PROPSEG] field
- PRESDIV is the value in CAN\_CTRL1[PRESDIV] field

See also [Protocol timing](#) for more details.

### 54.5.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CAN\_CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

#### **NOTE**

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency can not be smaller than the oscillator clock frequency
- For 16 Mailboxes, the minimum number of peripheral clocks per CAN bit is 16

The minimum number of peripheral clocks per CAN bit determines the minimum peripheral clock frequency for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values contained in either the Control 1 Register (CAN\_CTRL1) or CAN Bit Time register (CAN\_CBT). The time quantum (Tq) is defined in [Protocol timing](#). The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

### 54.5.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

#### CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

#### 54.5.10.1 Freeze mode

This mode is requested either by the CPU through the assertion of the HALT bit in the CAN\_MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the CAN\_MCR Register and the module is not in a low-power mode.

The acknowledgement is obtained through the assertion by the FlexCAN of FRZ\_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in does not prevent going to Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities

- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT\_RDY and FRZ\_ACK bits in CAN\_MCR

After requesting Freeze mode, the user must wait for the FRZ\_ACK bit to be asserted in CAN\_MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CAN\_CTRL1[CLKSRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the CAN\_MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ\_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

### **54.5.10.2 Module Disable mode**

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the CAN\_MCR[MDIS] bit, and the acknowledgement is obtained through the assertion by the FlexCAN of the CAN\_MCR[LPMACK] bit. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in CAN\_MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

### 54.5.10.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, the DOZE bit in CAN\_MCR Register needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of the LPMACK bit in the same register. The CPU must only consider the FlexCAN in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit. If Doze Mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in CAN\_MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Doze Mode.

Exiting Doze mode is done in one of the following ways:

## Functional description

- CPU removing the Doze mode request
- CPU negating the DOZE bit of the CAN\_MCR Register
- Self Wake mechanism

In the Self Wake mechanism, if the SLFWAK bit in CAN\_MCR Register was set at the time FlexCAN entered Doze mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets the WAKINT bit in the ESR Register and, if enabled by the WAKMSK bit in CAN\_MCR, generates a Wake Up interrupt to the CPU. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wake-up from Doze mode.

**Table 54-15. Wake-up from Doze mode**

| SLFWAK | WAKINT | WAKMSK | FlexCAN clocks enabled | Wake-up interrupt generated |
|--------|--------|--------|------------------------|-----------------------------|
| 0      | -      | -      | No                     | No                          |
| 0      | -      | -      | No                     | No                          |
| 1      | 0      | 0      | No                     | No                          |
| 1      | 0      | 1      | No                     | No                          |
| 1      | 1      | 0      | Yes                    | No                          |
| 1      | 1      | 1      | Yes                    | Yes                         |

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line while in Doze Mode. See the WAKSRC bit in the description of the Module Configuration Register (CAN\_MCR). This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

### 54.5.10.4 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in CAN\_MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request. This can be as a result of the Self Wake mechanism.

In the Self Wake mechanism, if the SLFWAK bit in CAN\_MCR Register was set at the time FlexCAN entered Stop mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAKINT bit in the CAN\_ESR Register and, if enabled by the WAKMSK bit in CAN\_MCR, generates a Wake Up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK upon wake-up from Stop mode. Note that wake-up from Stop mode only works when both bits are asserted.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

**Table 54-16. Wake-up from Stop Mode**

| SLFWAK | WAKINT | WAKMSK | Chip clocks enabled | Wake-up interrupt generated |
|--------|--------|--------|---------------------|-----------------------------|
| 0      | -      | -      | No                  | No                          |
| 0      | -      | -      | No                  | No                          |
| 1      | 0      | 0      | No                  | No                          |

*Table continues on the next page...*

**Table 54-16. Wake-up from Stop Mode (continued)**

| SLFWAK | WAKINT | WAKMSK | Chip<br>clocks enabled | Wake-up interrupt<br>generated |
|--------|--------|--------|------------------------|--------------------------------|
| 1      | 0      | 1      | No                     | No                             |
| 1      | 1      | 0      | No                     | No                             |
| 1      | 1      | 1      | Yes                    | Yes                            |

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line while in Stop mode. See the WAKSRC bit in the description of the Module Configuration Register (CAN\_MCR). This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

### 54.5.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Wake Up, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the CAN\_IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

#### Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CAN\_MCR[RFEN] = 1) and DMA is disabled (CAN\_MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the CAN\_IFLAG1 register becomes the "FIFO Overflow" flag; bit 6 becomes the "FIFO Warning" flag, bit 5 becomes the "Frames Available in FIFO" flag and bits 4-0 are unused. See the description of the Interrupt Flags 1 Register (CAN\_IFLAG1) for more information.

If both Rx FIFO and DMA are enabled (`CAN_MCR[RFEN]` and `CAN_MCR[DMA] = 1`) the FlexCAN does not generate any FIFO interrupt. Bit 5 of the `CAN_IFLAG1` register still indicates "Frames Available in FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the `CAN_IFLAG` registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Bus Off Done, Error, Wake Up, Tx Warning and Rx Warning generate interrupts like the MB interrupt sources, and can be read from `CAN_ESR1` register. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the `CAN_CTRL1` Register; the Wake-Up interrupt mask bit is located in the `CAN_MCR`.

## 54.5.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If `MAXMB` in `CAN MCR` register is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, `CAN_CTRL2[RFFN]` is 0x0, and `CAN_MCR[MAXMB]` is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is

reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

## 54.6 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

### 54.6.1 FlexCAN initialization sequence

The FlexCAN module may be reset in three ways:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See [Table 54-2](#) to see what registers are affected by soft reset.
- Chip level soft reset, which has the same effect as the SOFTRST bit in MCR

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The CAN\_MCR[SOFTRST] bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected while the module is in Disable mode (see CAN\_CTRL1[CLKSRC] bit). After the clock source is selected and the module is enabled (CAN\_MCR[MDIS] bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in CAN\_MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the CAN\_MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode (see [Freeze mode](#)). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register (CAN\_MCR)
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - If Rx FIFO is enabled and DMA is required, set DMA bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control 1 Register (CAN\_CTRL1) and optionally the CAN Bit Timing Register (CAN\_CBT).
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, ERJW
  - Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers (CAN\_RXIMRn)
- Set required interrupt mask bits in the CAN\_IMASK Registers (for all MB interrupts), in CAN\_MCR Register for Wake-Up interrupt and in CAN\_CTRL1 / CAN\_CTRL2 Registers (for Bus Off and Error interrupts)
- Negate the HALT bit in CAN\_MCR

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

## Chapter 55

# General-Purpose Input/Output (GPIO)

### 55.1 Chip-specific GPIO information

#### 55.1.1 GPIO access protection

The GPIO module does not have access protection because it is not connected to a peripheral bridge slot.

#### 55.1.2 Number of GPIO signals

The number of GPIO signals available on the devices covered by this document are detailed in [Orderable part numbers](#).

Eight GPIO pins support a high drive capability - PTB0, PTB1, PTD4, PTD5, PTD6, PTD7, PTC3, and PTC4. All other GPIO support normal drive option only.

PTA4 includes a passive input filter that is enabled or disabled by PORTA\_PCR4[PFE] control. This reset default is to have this function disabled.

### 55.2 Introduction

The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

## 55.2.1 Features

Features of the GPIO module include:

- Port Data Input register visible in all digital pin-multiplexing modes
- Port Data Output register with corresponding set/clear/toggle registers
- Port Data Direction register

### NOTE

The GPIO module is clocked by system clock.

## 55.2.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

**Table 55-1. Modes of operation**

| Modes of operation | Description                        |
|--------------------|------------------------------------|
| Run                | The GPIO module operates normally. |
| Wait               | The GPIO module operates normally. |
| Stop               | The GPIO module is disabled.       |
| Debug              | The GPIO module operates normally. |

## 55.2.3 GPIO signal descriptions

**Table 55-2. GPIO signal descriptions**

| GPIO signal descriptions | Description                  | I/O |
|--------------------------|------------------------------|-----|
| PORTA31–PORTA0           | General-purpose input/output | I/O |
| PORTB31–PORTB0           | General-purpose input/output | I/O |
| PORTC31–PORTC0           | General-purpose input/output | I/O |
| PORTD31–PORTD0           | General-purpose input/output | I/O |
| PORTE31–PORTE0           | General-purpose input/output | I/O |

### NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

### 55.2.3.1 Detailed signal description

**Table 55-3. GPIO interface-detailed signal descriptions**

| Signal                                                                                 | I/O | Description                  |                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------------|-----|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

For input, it may occur at any time and input may be asserted asynchronously to the system clock. |

#### NOTE

Not all pins within each port are implemented on each device.  
See the chapter on signal multiplexing for the number of GPIO ports available in the device.

## 55.3 Memory map and register definition

Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

#### GPIO memory map

| Absolute address (hex) | Register name                           | Width (in bits) | Access                | Reset value | Section/page                |
|------------------------|-----------------------------------------|-----------------|-----------------------|-------------|-----------------------------|
| 400F_F000              | Port Data Output Register (GPIOA_PDOR)  | 32              | R/W                   | 0000_0000h  | <a href="#">55.3.1/1839</a> |
| 400F_F004              | Port Set Output Register (GPIOA_PSOR)   | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">55.3.2/1840</a> |
| 400F_F008              | Port Clear Output Register (GPIOA_PCOR) | 32              | W<br>(always reads 0) | 0000_0000h  | <a href="#">55.3.3/1840</a> |

**55.3.1 Port Data Output Register (GPIOx\_PDOR)**

This register configures the logic levels that are driven on each general-purpose output pins.

**NOTE**

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

Address: Base address + 0h offset

### 55.3.5 Port Data Input Register (GPIOx\_PDIR)

#### NOTE

Do not modify pin configuration registers associated with pins not available in your selected package. All unbonded pins not available in your package will default to DISABLE state for lowest power consumption.

## 55.4 Functional description

### 55.4.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The Port Data Input registers return the synchronized pin state after any enabled digital filter in the Port Control and Interrupt module. The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

### 55.4.2 General-purpose output

The logic state of each pin can be controlled via the port data output registers and port data direction registers, provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input/output.

|    |      |
|----|------|
| If | Then |
|----|------|

Table continues on the next page...

|                                                                                                            |                                                                                                                            |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| A pin is configured for the GPIO function and the corresponding port data direction register bit is clear. | The pin is configured as an input.                                                                                         |
| A pin is configured for the GPIO function and the corresponding port data direction register bit is set.   | The pin is configured as an output and the logic state of the pin is equal to the corresponding port data output register. |

To facilitate efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers exist to allow one or more outputs within one port to be set, cleared, or toggled from a single register write.

The corresponding Port Control and Interrupt module does not need to be enabled to update the state of the port data direction registers and port data output registers including the set/clear/toggle registers.

## Chapter 56

# JTAG Controller (JTAGC)

### 56.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

#### 56.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as [Register description](#) for more information about the JTAGC registers.

**Figure 56-1. JTAG (IEEE 1149.1) block diagram**

## 56.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 56-3](#) for a list of supported instructions.
- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

## 56.1.3 Modes of operation

The JTAGC block uses a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

### 56.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

### 56.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

### 56.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 56.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 56-1. JTAG signal properties**

| Name | I/O    | Function         | Reset State         | Pull |
|------|--------|------------------|---------------------|------|
| TCK  | Input  | Test Clock       | —                   | Down |
| TDI  | Input  | Test Data In     | —                   | Up   |
| TDO  | Output | Test Data Out    | High Z <sup>1</sup> | —    |
| TMS  | Input  | Test Mode Select | —                   | Up   |

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 56.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 56.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 56.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

### 56.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

## 56.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 56.3.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the

Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                  |   |   |   |
|--------|------------------|---|---|---|
|        | 3                | 2 | 1 | 0 |
| R      | 0                | 0 | 0 | 1 |
| W      | Instruction Code |   |   |   |
| Reset: | 0                | 0 | 0 | 1 |

**Figure 56-2. Instruction register**

### 56.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 56.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

|       |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |    |
|-------|----------------------------|----|----|----|----------------------------|----|----|----|----|----|----------------------------|----|----|----|----|----|
|       | 31                         | 30 | 29 | 28 | 27                         | 26 | 25 | 24 | 23 | 22 | 21                         | 20 | 19 | 18 | 17 | 16 |
| R     | Part Revision Number       |    |    |    | Design Center              |    |    |    |    |    | Part Identification Number |    |    |    |    |    |
| W     |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |    |
| Reset | PRN                        |    |    |    | DC                         |    |    |    |    |    | PIN                        |    |    |    |    |    |
|       | 15                         | 14 | 13 | 12 | 11                         | 10 | 9  | 8  | 7  | 6  | 5                          | 4  | 3  | 2  | 1  | 0  |
| R     | Part Identification Number |    |    |    | Manufacturer Identity Code |    |    |    |    |    |                            |    |    |    |    | 1  |
| W     |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |    |
| Reset | PIN (contd.)               |    |    |    | MIC                        |    |    |    |    |    |                            |    |    |    |    | 1  |

The following table describes the device identification register functions.

**Table 56-2. Device identification register field descriptions**

| Field     | Description                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------|
| PRN       | Part Revision Number. Contains the revision number of the part. Value is .                                                       |
| DC        | Design Center. Indicates the design center. Value is .                                                                           |
| PIN       | Part Identification Number. Contains the part number of the device. .                                                            |
| MIC       | Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.           |
| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1. |

### 56.3.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

## 56.4 Functional description

This section explains the JTAGC functional description.

### 56.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

### 56.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

**Figure 56-3. Shifting data through a register**

### 56.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 56-4. IEEE 1149.1-2001 TAP controller finite state machine**

### 56.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting the JTAGC enable to a logic 1 value.

### 56.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

### 56.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 56-3. 4-bit JTAG instructions**

| Instruction            | Code[3:0] | Instruction summary                                                                                                                                 |
|------------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| IDCODE                 | 0000      | Selects device identification register for shift                                                                                                    |
| SAMPLE/PRELOAD         | 0010      | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation                                       |
| SAMPLE                 | 0011      | Selects boundary scan register for shifting and sampling without disturbing functional operation                                                    |
| EXTEST                 | 0100      | Selects boundary scan register and applies preloaded values to output pins.<br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| Factory debug reserved | 0101      | Intended for factory debug only                                                                                                                     |
| Factory debug reserved | 0110      | Intended for factory debug only                                                                                                                     |
| Factory debug reserved | 0111      | Intended for factory debug only                                                                                                                     |
| ARM JTAG-DP Reserved   | 1000      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.                                           |
| HIGHZ                  | 1001      | Selects bypass register and three-states all output pins.<br><b>NOTE:</b> Execution of this instruction asserts functional reset.                   |
| ARM JTAG-DP Reserved   | 1010      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.                                           |

*Table continues on the next page...*

**Table 56-3. 4-bit JTAG instructions (continued)**

| Instruction          | Code[3:0] | Instruction summary                                                                                                                              |
|----------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| ARM JTAG-DP Reserved | 1011      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.                                        |
| CLAMP                | 1100      | Selects bypass register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| ARM JTAG-DP Reserved | 1110      | This instruction goes the ARM JTAG-DP controller. See the ARM JTAG-DP documentation for more information.                                        |
| BYPASS               | 1111      | Selects bypass register for data operations                                                                                                      |

#### 56.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

#### 56.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

### 56.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

### 56.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

### 56.4.4.5 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

### 56.4.4.6 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### 56.4.4.7 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

#### 56.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

### 56.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Place the JTAGC in reset through TAP controller state machine transitions controlled by TMS
2. Load the appropriate instruction for the test or action to be performed

## **Chapter 57**

### **Release Notes for Revision 4**

#### **57.1 General changes throughout document**

- No substantial content changes

#### **57.2 About This Document chapter changes**

- No substantial content changes

#### **57.3 Introduction chapter changes**

- No substantial content changes

#### **57.4 Core Overview changes**

- No substantial content changes

#### **57.5 Memories and Memory Interfaces changes**

- No substantial content changes

## 57.6 Memory Map changes

- No substantial content changes

## 57.7 Clock Distribution changes

- In section [Internal clocking requirements](#), changed maximum Fast Peripheral clock from 110 MHz to 120 MHz.

## 57.8 Reset and Boot chapter changes

- No substantial content changes

## 57.9 Power Management chapter changes

- No substantial content changes

## 57.10 Security chapter changes

- No substantial content changes

## 57.11 Debug chapter changes

- No substantial content changes

## 57.12 Signal Multiplexing and Signal Descriptions chapter changes

- No substantial content changes

## 57.13 PORT changes

### 57.13.1 Chip-specific PORT information changes

- No substantial content changes

### 57.13.2 PORT changes

- In the "Pin Control Register n (PORT\_PCRn)" section, clarified the last paragraph in the note.

## 57.14 SIM changes

No substantial content changes

## 57.15 Kinetis Flashloader changes

### 57.15.1 Chip-specific Kinetis Flashloader information changes

- No substantial content changes

### 57.15.2 Kinetis Flash Bootloader changes

- In "GetProperty command" section, added mentions of internal memory regions, and 2 footnotes.
- In FlashEraseAll command section, in "FlashEraseAll Command Packet Format" table, added MemoryID parameter to command packet parameters
- In "FillMemory command" section, corrected missing text for "Writing to flash requires the start address to be"
- In "Get/SetProperty Command Properties" section, table "Properties used by Get/SetProperty Commands, sorted by Value", updated the description of RAMStartAddress and RAMSizeInBytes properties.

## 57.16 RCM changes

- No substantial content changes

## 57.17 SMC changes

- No substantial content changes

## 57.18 MCM changes

- No substantial content changes

## 57.19 MSCM changes

- No substantial content changes

## 57.20 PMC changes

- No substantial content changes

## 57.21 LLWU changes

### 57.21.1 Chip-specific LLWU information changes

- No substantial content changes

### 57.21.2 LLWU changes

- No substantial content changes

## 57.22 AXBS changes

### 57.22.1 Chip-specific AXBS information changes

- No substantial content changes

### 57.22.2 Crossbar switch module changes

- [General operation](#) : Removed paragraph beginning with "A master is given control of the targeted slave..." and the following list, beginning with "A higher priority master has...".
- [Initialization/application information](#) :
  - Minor edit
  - Added note about configuration: other masters must be idle.
  - Added note about preventing reconfiguration.

## 57.23 AIPS-Lite changes

### 57.23.1 Chip-specific AIPS-Lite information changes

- No substantial content changes

### 57.23.2 AIPS module changes

- No substantial content changes

## 57.24 MPU changes

### 57.24.1 Chip-specific MPU information changes

- No substantial content changes

## 57.24.2 MPU module changes

- In [Memory map/register definition](#)
  - Reformatted paragraph about error-generating references into list, and added item to list: "Accesses in user mode"
  - Moved sentence to precede list of error-generating references: "The programming model can be accessed only in supervisor mode."
- Edited description of [Region Descriptor n, Word 2 \(MPU\\_RGDn\\_WORD2\)](#)
- In descriptions of following registers, changed SPERR to SPERRn:
  - [Error Address Register, slave port n \(MPU\\_EARn\)](#)
  - [Error Detail Register, slave port n \(MPU\\_EDRn\)](#)

## 57.25 BME configuration changes

- In topic [Introduction](#), removed reference to M2B.

## 57.26 DMAMUX changes

### 57.26.1 Chip-specific DMAMUX information changes

- No substantial content changes

### 57.26.2 DMAMUX module changes

- No substantial content changes

## 57.27 eDMA module changes

- [eDMA initialization](#) : In bullet beginning with "Enable any hardware service requests..." replaced "ERQH and ERQL registers" with "ERQ register."
- [Error Status Register \(DMA\\_ES\)](#) : In description, replaced "See the Error Reporting and Handling section" with "See [Fault reporting and handling](#)."

## 57.28 EWM changes

### 57.28.1 Chip-specific EWM information changes

- No substantial content changes

### 57.28.2 EWM changes

- Substantial changes throughout the chapter which include:
  - Changed the term "service" to "refresh" throughout the chapter to better explain the EWM refresh mechanism.
  - Updated the block diagram.
  - Updated the table "EWM refresh mechanism".
  - Editorial changes

## 57.29 WDOG changes

### 57.29.1 Chip-specific WDOG information changes

- No substantial content changes

### 57.29.2 WDOG changes

- No substantial content changes

## 57.30 AOI changes

### 57.30.1 Chip-specific AOI information changes

- No substantial content changes

## **57.30.2 AOI changes**

- No substantial content changes

## **57.31 XBARA changes**

### **57.31.1 Chip-specific XBARA information changes**

- No substantial content changes

### **57.31.2 XBARA changes**

- No substantial content changes

## **57.32 XBARB changes**

### **57.32.1 Chip-specific XBARB information changes**

- No substantial content changes

### **57.32.2 XBARB changes**

- No substantial content changes

## **57.33 MCG changes**

### **57.33.1 Chip-specific MCG information changes**

- No substantial content changes

## 57.33.2 MCG changes

- No substantial content changes

## 57.34 OSC changes

### 57.34.1 Chip-specific OSC information changes

- No substantial content changes

### 57.34.2 OSC changes

## 57.35 FMC changes

### 57.35.1 Chip-specific FMC information changes

- No substantial content changes

### 57.35.2 FMC changes

- No substantial content changes

## 57.36 FTFE changes

- No substantial content changes

## 57.37 FlexBus changes

### 57.37.1 Chip-specific FlexBus information changes

- No substantial content changes

### 57.37.2 FlexBus changes

- No substantial content changes

## 57.38 CRC changes

- No substantial content changes

## 57.39 MMCAU changes

- No substantial content changes

## 57.40 16-bit ADC changes

### 57.40.1 Chip-specific ADC information changes

- No substantial content changes

### 57.40.2 ADC changes

## 57.41 HSADC changes

### 57.41.1 Chip-specific HSADC information changes

- No substantial content changes

### 57.41.2 SAR ADC 12b5Msps changes

- No substantial content changes

## 57.42 CMP changes

### 57.42.1 Chip-specific CMP information changes

- Added [CMP voltage references](#)

### 57.42.2 CMP changes

- No substantial content changes

## 57.43 DAC changes

### 57.43.1 Chip-specific DAC information changes

- No substantial content changes

### 57.43.2 DAC changes

- No substantial content changes

## 57.44 FlexTimer changes

### 57.44.1 Chip-specific FlexTimer information changes

- No substantial content changes

### 57.44.2 FTM changes

- No substantial content changes

## 57.45 LPTMR changes

### 57.45.1 Chip-specific LPTMR information changes

- No substantial content changes

### 57.45.2 LPTMR changes

- No substantial content changes

## 57.46 PDB changes

### 57.46.1 Chip-specific PDB information changes

- No substantial content changes

### 57.46.2 PDB changes

- No substantial content changes

## 57.47 ENC changes

### 57.47.1 Chip-specific ENC information changes

- No substantial content changes

### 57.47.2 ENC changes

- No substantial content changes

## 57.48 eFlexPWM changes

### 57.48.1 Chip-specific eFlexPWM information changes

- No substantial content changes

### 57.48.2 eFlexPWM changes

- No substantial content changes

## 57.49 PIT changes

### 57.49.1 Chip-specific PIT information changes

- No substantial content changes

### 57.49.2 PIT module changes

- No substantial content changes

## 57.50 SPI changes

### 57.50.1 Chip-specific SPI information changes

- No substantial content changes

### 57.50.2 SPI module changes

- In [PCS0/SS—Peripheral Chip Select/Slave Select](#) - Added note.
- Deleted note from [SOUT—Serial Output](#).
- Clarified [Memory Map/Register Definition](#) introductory text by changing second sentence:
  - From: "Write access to the POPR and RXFRn also results in a transfer error."
  - To: "Any Write access to the POPR and RXFRn also results in a transfer error."
- In section, [PCS0/SS—Peripheral Chip Select/Slave Select](#) : Updated note.

## 57.51 ENET changes

### 57.51.1 Chip-specific ENET information changes

- No substantial content changes

### 57.51.2 ENET module changes

- In [Ethernet Control Register \(ENET\\_ECR\)](#), 20-bit Reserved field was divided into two fields and their corresponding description's were added.

## 57.52 I2C changes

### 57.52.1 Chip-specific I2C information changes

- No substantial content changes

## 57.52.2 I2C changes

- No substantial content changes

## 57.53 UART changes

### 57.53.1 Chip-specific UART information changes

- No substantial content changes

### 57.53.2 UART changes

- No substantial content changes

## 57.54 FlexCAN changes

### 57.54.1 Chip-specific FlexCAN information changes

- No substantial content changes

### 57.54.2 FlexCAN module changes

- No substantial content changes
- In [Control 2 register \(CAN\\_CTRL2\)](#), removed the reserved fields at CTRL2 positions 0 and 1 with RW access and consolidated them with the reserved field at 2-10 with ROZ access.
- In the introduction section of [Memory map/register definition](#), added text explaining that there is a separate message buffer memory map section, and added a link to that section.
- Table in [CAN\\_CTRL2\[RFFN\]](#) field description was modified to show only information for 16 message buffers.

## 57.55 GPIO changes

### 57.55.1 Chip-specific GPIO information changes

- No substantial content changes

### 57.55.2 GPIO changes

- No substantial content changes

## 57.56 JTAGC module changes

- No substantial content changes
