**Table 31-2. XBARB signal output assignment  
(continued)**

| XBARB Output | Assigned Input |
|--------------|----------------|
| XBARB_OUT13  | AOI_IN13       |
| XBARB_OUT14  | AOI_IN14       |
| XBARB_OUT15  | AOI_IN15       |

## 31.2 Introduction

For a description of the general features and functionality of this module, refer to the [XBARA description](#).

## 31.3 Memory Map and Register Descriptions

This section provides information about the XBARB instance of the inter-peripheral crossbar switch. Refer to the [XBARA register details](#) for information about that instance of the module.

This XBAR module has only select registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR\_IN[\*]) is muxed to each mux output (XBAR\_OUT[\*]). There is one SELn field per mux and therefore one per XBAR\_OUT output. Crossbar output XBAR\_OUT[n] presents the value of XBAR\_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR\_IN and XBAR\_OUT are application specific and are described in the Chip Configuration details.

### XBARB memory map

| Absolute address (hex) | Register name                             | Width (in bits) | Access | Reset value | Section/ page              |
|------------------------|-------------------------------------------|-----------------|--------|-------------|----------------------------|
| 4005_A000              | Crossbar B Select Register 0 (XBARB_SEL0) | 16              | R/W    | 0000h       | <a href="#">31.3.1/672</a> |
| 4005_A002              | Crossbar B Select Register 1 (XBARB_SEL1) | 16              | R/W    | 0000h       | <a href="#">31.3.2/672</a> |
| 4005_A004              | Crossbar B Select Register 2 (XBARB_SEL2) | 16              | R/W    | 0000h       | <a href="#">31.3.3/673</a> |

# Chapter 32

## Multipurpose Clock Generator (MCG)

### 32.1 Chip-specific MCG information

#### 32.1.1 MCG oscillator clock input options

The MCG has multiple oscillator input clock sources. Within the context of the MCG these are all referred to as the external reference clock and selection is determined by MCG\_C7[OSCSSEL] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

**Table 32-1. MCG Oscillator Reference Options**

| MCG_C7[OSCSSEL] | MCG defined selection       | Chip clock                                                                                       |
|-----------------|-----------------------------|--------------------------------------------------------------------------------------------------|
| 00              | OSCCLK0 - System Oscillator | OSCCLK - System oscillator output. Derived from external crystal circuit or directly from EXTAL. |

See [Clock Distribution](#) for more details on these clocks.

### 32.2 Introduction

The multipurpose clock generator (MCG) module provides several clock source choices for the MCU.

The module contains a frequency-locked loop (FLL) and a phase-locked loop (PLL). The FLL is controllable by either an internal or an external reference clock. The PLL is controllable by the external reference clock. The module can select either an FLL or PLL

output clock, or a reference clock (internal or external) as a source for the MCU system clock. The MCG operates in conjunction with a crystal oscillator, which allows an external crystal, ceramic resonator, or another external clock source to produce the external reference clock.

### 32.2.1 Features

Key features of the MCG module are:

- Frequency-locked loop (FLL):
  - Digitally-controlled oscillator (DCO)
  - DCO frequency range is programmable for up to four different frequency ranges.
  - Option to program and maximize DCO output frequency for a low frequency external reference clock source.
  - Option to prevent FLL from resetting its current locked frequency when switching clock modes if FLL reference frequency is not changed.
  - Internal or external reference clock can be used as the FLL source.
  - Can be used as a clock source for other on-chip peripherals.
- Phase-locked loop (PLL):
  - Voltage-controlled oscillator (VCO)
  - External reference clock is used as the PLL source.
  - Modulo VCO frequency divider
  - Phase/Frequency detector
  - Integrated loop filter
  - Can be used as a clock source for other on-chip peripherals.
- Internal reference clock generator:
  - Slow clock with nine trim bits for accuracy
  - Fast clock with four trim bits
  - Can be used as source clock for the FLL. In FEI mode, only the slow Internal Reference Clock (IRC) can be used as the FLL source.

- Either the slow or the fast clock can be selected as the clock source for the MCU.
- Can be used as a clock source for other on-chip peripherals.
- Control signals for the MCG external reference low power oscillator clock generators are provided:
  - HGO, RANGE, EREFS
- External clock from the Crystal Oscillator :
  - Can be used as a source for the FLL and/or the PLL.
  - Can be selected as the clock source for the MCU.
- External clock monitor with reset and interrupt request capability to check for external clock failure when running in FBE, PEE, BLPE, or FEE modes
- Lock detector with interrupt request capability for use with the PLL
- Internal Reference Clocks Auto Trim Machine (ATM) capability using an external clock as a reference
- Reference dividers for both the FLL and the PLL are provided
- Reference dividers for the Fast Internal Reference Clock are provided
- 
- MCG FLL Clock (MCGFLLCLK) is provided as a clock source for other on-chip peripherals
- MCG Fixed Frequency Clock (MCGFFCLK) is provided as a clock source for other on-chip peripherals
- MCG Internal Reference Clock (MCGIRCLK) is provided as a clock source for other on-chip peripherals

This figure presents the block diagram of the MCG module.

**Figure 32-1. Multipurpose Clock Generator (MCG) block diagram**

### 32.2.2 Modes of Operation

The MCG has the following modes of operation: FEI, FEE, FBI, FBE, PBE, PEE, BLPI, BLPE, and Stop. For details, see [MCG modes of operation](#).

## 32.3 External Signal Description

There are no MCG signals that connect off chip.

## 32.4 Memory Map/Register Definition

This section includes the memory map and register definition.

The MCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus error. Read accesses may be performed in both supervisor and user mode.

**MCG memory map**

| SCTRIM | <p>Slow Internal Reference Clock Trim Setting</p> <p>SCTRIM<sup>1</sup> controls the slow internal reference clock frequency by controlling the slow internal reference clock period. The SCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period.</p> <p>An additional fine trim bit is available in C4 register as the SCFTRIM bit. Upon reset, this value is loaded with a factory trim value.</p> <p>If an SCTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register.</p> |

1. A value for SCTRIM is loaded during reset from a factory programmed location.

|                 | 0 DCO has a default range of 25%.<br>1 DCO is fine-tuned for maximum frequency with 32.768 kHz reference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |   |                   |      |            |
| 6–5<br>DRST_DRS | <b>DCO Range Select</b><br><br>The DRS bits select the frequency range for the FLL output, DCOOUT. When the LP bit is set, writes to the DRS bits are ignored. The DRST read field indicates the current frequency range for DCOOUT. The DRST field does not update immediately after a write to the DRS field due to internal synchronization between clock domains. See the DCO Frequency Range table for more details.<br><br>00 Encoding 0 — Low range (reset default).<br>01 Encoding 1 — Mid range.<br>10 Encoding 2 — Mid-high range.<br>11 Encoding 3 — High range. |   |                   |      |            |
| 4–1<br>FCTRIM   | <b>Fast Internal Reference Clock Trim Setting</b><br><br>FCTRIM <sup>1</sup> controls the fast internal reference clock frequency by controlling the fast internal reference clock period. The FCTRIM bits are binary weighted, that is, bit 1 adjusts twice as much as bit 0. Increasing the binary value increases the period, and decreasing the value decreases the period.<br><br>If an FCTRIM[3:0] value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this register.              |   |                   |      |            |
| 0<br>SCFTRIM    | <b>Slow Internal Reference Clock Fine Trim</b><br><br>SCFTRIM <sup>2</sup> controls the smallest adjustment of the slow internal reference clock frequency. Setting SCFTRIM increases the period and clearing SCFTRIM decreases the period by the smallest amount possible.<br><br>If an SCFTRIM value stored in nonvolatile memory is to be used, it is your responsibility to copy that value from the nonvolatile memory location to this bit.                                                                                                                           |   |                   |      |            |

1. A value for FCTRIM is loaded during reset from a factory programmed location.

2. A value for SCFTRIM is loaded during reset from a factory programmed location.

| 6<br>PLLCLKEN   | <p>PLL Clock Enable</p> <p>Enables PLL independent of PLLS and enables the PLL clock for use as MCGPLLCLK. (PRDIV needs to be programmed to the correct divider to generate a PLL reference clock in a valid reference range prior to setting the PLLCLKEN bit). Setting PLLCLKEN will enable the external oscillator if not already enabled. Whenever the PLL is being enabled by means of the PLLCLKEN bit, and the external oscillator is being used as the reference clock, the OSCINIT 0 bit should be checked to make sure it is set.</p> <p>0 MCGPLLCLK is inactive.<br/>1 MCGPLLCLK is active.</p>                                                                                                                  |       |               |     |   |     |   |     |   |     |   |     |   |     |   |     |   |     |   |
| 5<br>PLLSTEN    | <p>PLL Stop Enable</p> <p>Enables the PLL Clock during Normal Stop (In Low Power Stop mode, the PLL clock gets disabled even if PLLSTEN=1). All other power modes, PLLSTEN bit has no affect and does not enable the PLL Clock to run if it is written to 1.</p> <p>0 MCGPLLCLK and MCGPLLCLK2X are disabled in any of the Stop modes.<br/>1 MCGPLLCLK and MCGPLLCLK2X are enabled if system is in Normal Stop mode.</p>                                                                                                                                                                                                                                                                                                    |       |               |     |   |     |   |     |   |     |   |     |   |     |   |     |   |     |   |

| 6<br>PLLS                         | <p>PLL Select</p> <p>Controls whether the PLL or FLL output is selected as the MCG source when CLKS[1:0]=00. If the PLLS bit is cleared and PLLCLKEN 0 is not set, the PLL is disabled in all modes. If the PLLS is set, the FLL is disabled in all modes.</p> <p>0 FLL is selected.</p> <p>1 PLL is selected (PRDIV 0 need to be programmed to the correct divider to generate a PLL reference clock in the range of 8–16 MHz prior to setting the PLLS bit).</p>                                                                                                                                                                                                                                                                                                                                                                                                     |                                   |       |                 |  |       |                 |  |       |                 |  |  |      |                 |  |      |                 |  |      |                 |  |      |                 |       |    |  |       |    |  |       |    |  |       |    |       |    |  |       |    |  |       |    |  |       |    |
| 5<br>CME0                         | <p>Clock Monitor Enable</p> <p>Enables the loss of clock monitoring circuit for the OSC0 external reference mux select. The LOCRE0 bit will determine if a interrupt or a reset request is generated following a loss of OSC0 indication. The CME0 bit must only be set to a logic 1 when the MCG is in an operational mode that uses the external clock (FEE, FBE, PEE, PBE, or BLPE) . Whenever the CME0 bit is set to a logic 1, the value of the RANGE0 bits in the C2 register should not be changed. CME0 bit should be set to a logic 0 before the MCG enters any Stop mode. Otherwise, a reset request may occur while in Stop mode. CME0 should also be set to a logic 0 before entering VLPWR or VLPW power modes if the MCG is in BLPE mode.</p> <p>0 External clock monitor is disabled for OSC0.</p> <p>1 External clock monitor is enabled for OSC0.</p> |                                   |       |                 |  |       |                 |  |       |                 |  |  |      |                 |  |      |                 |  |      |                 |  |      |                 |       |    |  |       |    |  |       |    |  |       |    |       |    |  |       |    |  |       |    |  |       |    |
| VDIV                              | <p>VCO Divider</p> <p>Selects the amount to divide the VCO output of the PLL. The VDIV bits establish the multiplication factor (M) applied to the reference clock frequency. After the PLL is enabled (by setting either PLLCLKEN or PLLS), the VDIV value must not be changed when LOCK is zero.</p> <table><tr><th colspan="11">Table 32-3. | 7<br>LOLS0 | <p>Loss of Lock Status</p> <p>This bit is a sticky bit indicating the lock status for the PLL. LOLS is set if after acquiring lock, the PLL output frequency has fallen outside the lock exit frequency tolerance, <math>D_{unl}</math>. LOLIE determines whether an interrupt request is made when LOLS is set. LOLRE determines whether a reset request is made when LOLS is set. This bit is cleared by reset or by writing a logic 1 to it when set. Writing a logic 0 to this bit has no effect.</p> <p>0 PLL has not lost lock since LOLS 0 was last cleared.<br/>1 PLL has lost lock since LOLS 0 was last cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 6<br>LOCK0 | <p>Lock Status</p> <p>This bit indicates whether the PLL has acquired lock. Lock detection is disabled when not operating in either PBE or PEE mode unless PLLCLKEN=1 and the MCG is not configured in BLPI or BLPE mode. While the PLL clock is locking to the desired frequency, MCGPLLCLK and MCGPLLCLK2X will be gated off until the LOCK bit gets asserted. If the lock status bit is set, changing the value of the PRDIV[2:0] bits in the C5 register or the VDIV[4:0] bits in the C6 register causes the lock status bit to clear and stay cleared until the PLL has reacquired lock. Loss of PLL reference clock will also cause the LOCK bit to clear until PLL has reacquired lock. Entry into VLPS, or regular Stop with PLLSTEN=0 also causes the lock status bit to clear and stay cleared until the Stop mode is exited and the PLL has reacquired lock. Any time the PLL is enabled and the LOCK bit is cleared, the MCGPLLCLK and MCGPLLCLK2X will be gated off until the LOCK bit is asserted again.</p> <p>0 PLL is currently unlocked.<br/>1 PLL is currently locked.</p> |

## 32.5 Functional description

### 32.5.1 MCG mode state diagram

The nine states of the MCG are shown in the following figure and are described in [Table 32-4](#). The arrows indicate the permitted MCG mode transitions.

**Figure 32-2. MCG mode state diagram**

### NOTE

- During exits from VLPS when the MCG is in PEE mode, the MCG will reset to PBE clock mode and the C1[CLKS] and S[CLKST] will automatically be set to 2'b10.
- If entering Normal Stop mode when the MCG is in PEE mode with PLLSTEN=0, the MCG will reset to PBE clock mode and C1[CLKS] and S[CLKST] will automatically be set to 2'b10.

### 32.5.1.1 MCG modes of operation

The MCG operates in one of the following modes.

#### Note

The MCG restricts transitions between modes. For the permitted transitions, see [Figure 32-2](#).

**Table 32-4. MCG modes of operation**

| Mode                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FLL Engaged Internal (FEI)  | <p>FLL engaged internal (FEI) is the default mode of operation and is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 00 is written to C1[CLKS].</li> <li>• 1 is written to C1[IREFS].</li> <li>• 0 is written to C6[PLLS].</li> </ul> <p>In FEI mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the 32 kHz Internal Reference Clock (IRC). The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FEI mode, the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set .</p>                                                                                                                                                                                                                                                                                                                    |
| FLL Engaged External (FEE)  | <p>FLL engaged external (FEE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 00 is written to C1[CLKS].</li> <li>• 0 is written to C1[IREFS].</li> <li>• C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz</li> <li>• 0 is written to C6[PLLS].</li> </ul> <p>In FEE mode, MCGOUTCLK is derived from the FLL clock (DCOCLK) that is controlled by the external reference clock. The FLL loop will lock the DCO frequency to the FLL factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the external reference frequency, as specified by C1[FRDIV] and C2[RANGE]. See the C4[DMX32] bit description for more details. In FEE mode, the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set .</p>                                                                                                                                                                                             |
| FLL Bypassed Internal (FBI) | <p>FLL bypassed internal (FBI) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 01 is written to C1[CLKS].</li> <li>• 1 is written to C1[IREFS].</li> <li>• 0 is written to C6[PLLS]</li> <li>• 0 is written to C2[LP].</li> </ul> <p>In FBI mode, the MCGOUTCLK is derived either from the slow (32 kHz IRC) or fast (4 MHz IRC) internal reference clock, as selected by the C2[IRCS] bit. The FLL is operational but its output is not used. This mode is useful to allow the FLL to acquire its target frequency while the MCGOUTCLK is driven from the C2[IRCS] selected internal reference clock. The FLL clock (DCOCLK) is controlled by the slow internal reference clock, and the DCO clock frequency locks to a multiplication factor, as selected by C4[DRST_DRS] and C4[DMX32] bits, times the internal reference frequency. See the C4[DMX32] bit description for more details. In FBI mode, the PLL is disabled in a low-power state unless C5[PLLCLKEN] is set .</p> |
| FLL Bypassed External (FBE) | <p>FLL bypassed external (FBE) mode is entered when all the following conditions occur:</p> <ul style="list-style-type: none"> <li>• 10 is written to C1[CLKS].</li> <li>• 0 is written to C1[IREFS].</li> <li>• C1[FRDIV] must be written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz.</li> <li>• 0 is written to C6[PLLS].</li> <li>• 0 is written to C2[LP].</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 32-4. MCG modes of operation (continued)**

| Mode | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stop | <p>Entered whenever the MCU enters a Stop state. The power modes are chip specific. For power mode assignments, see the chapter that describes how modules are configured and MCG behavior during Stop recovery. Entering Stop mode, the FLL is disabled, and all MCG clock signals are static except in the following case:</p> <p>MCGPLLCLK is active in Normal Stop mode when PLLSTEN=1</p> <p>MCGIRCLK is active in Normal Stop mode when all the following conditions become true:</p> <ul style="list-style-type: none"> <li>• C1[IRCLKEN] = 1</li> <li>• C1[IREFSTEN] = 1</li> </ul> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• In VLPS Stop Mode, the MCGIRCLK can be programmed to stay enabled and continue running if C1[IRCLKEN] = 1, C1[IREFSTEN]=1, and Fast IRC clock is selected (C2[IRCS] = 1)</li> </ul> <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>• When entering Low Power Stop mode (VLPS) from PEE mode, on exit the MCG clock mode is forced to PBE clock mode. C1[CLKS] and S[CLKST] will be configured to 2'b10 if entering from PEE mode or to 2'b01 if entering from PEI mode, C5[PLLSTEN0] will be force to 1'b0 and S[LOCK] bit will be cleared without setting S[LOLS].</li> <li>• When entering Normal Stop mode from PEE mode and if C5[PLLSTEN]=0, on exit the MCG clock mode is forced to PBE mode, the C1[CLKS] and S[CLKST] will be configured to 2'b10 and S[LOCK] bit will clear without setting S[LOLS]. If C5[PLLSTEN]=1, the S[LOCK] bit will not get cleared and on exit the MCG will continue to run in PEE mode.</li> </ul> |

1. **Caution:** If entering VLPR mode, MCG has to be configured and enter BLPE mode or BLPI mode with the Fast IRC clock selected (C2[IRCS]=1). After it enters VLPR mode, writes to any of the MCG control registers that can cause an MCG clock mode switch to a non low power clock mode must be avoided.

## NOTE

For the chip-specific modes of operation, see the power management chapter of this MCU.

### 32.5.1.2 MCG mode switching

C1[IREFS] can be changed at any time, but the actual switch to the newly selected reference clocks is shown by S[IREFST]. When switching between engaged internal and engaged external modes, the FLL will begin locking again after the switch is completed.

C1[CLKS] can also be changed at any time, but the actual switch to the newly selected clock is shown by S[CLKST]. If the newly selected clock is not available, the previous clock will remain selected.

The C4[DRST\_DRS] write bits can be changed at any time except when C2[LP] bit is 1. If C4[DRST\_DRS] write bits are changed while in FLL engaged internal (FEI) or FLL engaged external (FEE) mode, the MCGOUTCLK switches to the new selected DCO

range within three clocks of the selected DCO clock. After switching to the new DCO (indicated by the updated C4[DRST\_DRS] read bits), the FLL remains unlocked for several reference cycles. The FLL lock time is provided in the device data sheet as  $t_{fll\_acquire}$ .

### 32.5.2 Low-power bit usage

C2[LP] is provided to allow the FLL or PLL to be disabled and thus conserve power when these systems are not being used. C4[DRST\_DRS] can not be written while C2[LP] is 1. However, in some applications, it may be desirable to enable the FLL or PLL and allow it to lock for maximum accuracy before switching to an engaged mode. Do this by writing 0 to C2[LP].

### 32.5.3 MCG Internal Reference Clocks

This module supports two internal reference clocks with nominal frequencies of 32 kHz (slow IRC) and 4 MHz (fast IRC). The fast IRC frequency can be divided down by programming of the FCRDIV to produce a frequency range of 32 kHz to 4 MHz.

#### 32.5.3.1 MCG Internal Reference Clock

The MCG Internal Reference Clock (MCGIRCLK) provides a clock source for other on-chip peripherals and is enabled when C1[IRCLKEN]=1. When enabled, MCGIRCLK is driven by either the fast internal reference clock (4 MHz IRC which can be divided down by the FRDIV factors) or the slow internal reference clock (32 kHz IRC). The IRCS clock frequency can be re-targeted by trimming the period of its IRCS selected internal reference clock. This can be done by writing a new trim value to the C3[SCTRIM]:C4[SCFTRIM] bits when the slow IRC clock is selected or by writing a new trim value to C4[FCTRIM]:C2[FCFTRIM] when the fast IRC clock is selected. The internal reference clock period is proportional to the trim value written. C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) and C4[FCTRIM]:C2[FCFTRIM] (if C2[IRCS]=1) bits affect the MCGOUTCLK frequency if the MCG is in FBI or BLPI modes. C3[SCTRIM]:C4[SCFTRIM] (if C2[IRCS]=0) bits also affect the MCGOUTCLK frequency if the MCG is in FEI mode.

Additionally, this clock can be enabled in Stop mode by setting C1[IRCLKEN] and C1[IREFSTEN], otherwise this clock is disabled in Stop mode.

### 32.5.4 External Reference Clock

The MCG module can support an external reference clock in all modes. See the device datasheet for external reference frequency range. When C1[IREFS] is set, the external reference clock will not be used by the FLL or PLL. In these modes, the frequency can be equal to the maximum frequency the chip-level timing specifications will support.

If any of the CME bits are asserted the slow internal reference clock is enabled along with the enabled external clock monitor. For the case when C6[CME0]=1, a loss of clock is detected if the OSC0 external reference falls below a minimum frequency ( $f_{loc\_high}$  or  $f_{loc\_low}$  depending on C2[RANGE0]).

#### NOTE

All clock monitors must be disabled before entering these low-power modes: Stop, VLPS, VLPR, VLPW, and VLLSx.

On detecting a loss-of-clock event, the MCU generates a system reset if the respective LOCRE bit is set. Otherwise the MCG sets the respective LOCS bit and the MCG generates a LOCS interrupt request. In the case where a OSC loss of clock is detected, the PLL LOCK status bit is cleared.

### 32.5.5 MCG Fixed Frequency Clock

The MCG Fixed Frequency Clock (MCGFFCLK) provides a fixed frequency clock source for other on-chip peripherals; see the block diagram. This clock is driven by either the slow clock from the internal reference clock generator or the external reference clock from the Crystal Oscillator, divided by the FLL reference clock divider. The source of MCGFFCLK is selected by C1[IREFS].

This clock is synchronized to the peripheral bus clock and is valid only when its frequency is not more than 1/8 of the MCGOUTCLK frequency. When it is not valid, it is disabled and held high. The MCGFFCLK is not available when the MCG is in BLPI mode. This clock is also disabled in Stop mode. The FLL reference clock must be set within the valid frequency range for the MCGFFCLK.

### 32.5.6 MCG PLL clock

The MCG PLL available depending on the device's configuration of the MCG module. For more details, see the clock distribution chapter of this MCU. The MCGPLLCLK is prevented from coming out of the MCG until it is enabled and S[LOCK0] is set.

### 32.5.7 MCG Auto TRIM (ATM)

The MCG Auto Trim (ATM) is a MCG feature that when enabled, it configures the MCG hardware to automatically trim the MCG Internal Reference Clocks using an external clock as a reference. The selection between which MCG IRC clock gets tested and enabled is controlled by the ATC[ATMS] control bit (ATC[ATMS]=0 selects the 32 kHz IRC and ATC[ATMS]=1 selects the 4 MHz IRC). If 4 MHz IRC is selected for the ATM, a divide by 128 is enabled to divide down the 4 MHz IRC to a range of 31.250 kHz.

When MCG ATM is enabled by writing ATC[ATME] bit to 1, The ATM machine will start auto trimming the selected IRC clock. During the autotrim process, ATC[ATME] will remain asserted and will deassert after ATM is completed or an abort occurs. The MCG ATM is aborted if a write to any of the following control registers is detected : C1, C3, C4, or ATC or if Stop mode is entered. If an abort occurs, ATC[ATMF] fail flag is asserted.

The ATM machine uses the bus clock as the external reference clock to perform the IRC auto-trim. Therefore, it is required that the MCG is configured in a clock mode where the reference clock used to generate the system clock is the external reference clock such as FBE clock mode. The MCG must not be configured in a clock mode where selected IRC ATM clock is used to generate the system clock. The bus clock is also required to be running with in the range of 8–16 MHz.

To perform the ATM on the selected IRC, the ATM machine uses the successive approximation technique to adjust the IRC trim bits to generate the desired IRC trimmed frequency. The ATM SARs each of the ATM IRC trim bits starting with the MSB. For each trim bit test, the ATM uses a pulse that is generated by the ATM selected IRC clock to enable a counter that counts number of ATM external clocks. At end of each trim bit, the ATM external counter value is compared to the ATCV[15:0] register value. Based on the comparison result, the ATM trim bit under test will get cleared or stay asserted. This is done until all trim bits have been tested by ATM SAR machine.

Before the ATM can be enabled, the ATM expected count needs to be derived and stored into the ATCV register. The ATCV expected count is derived based on the required target Internal Reference Clock (IRC) frequency, and the frequency of the external reference clock using the following formula:

$$\text{ATCV Expected Count Value} = 21 * (\text{Fe} / \text{Fr})$$

- Fr = Target Internal Reference Clock (IRC) Trimmed Frequency
- Fe = External Clock Frequency

If the auto trim is being performed on the 4 MHz IRC, the calculated expected count value must be multiplied by 128 before storing it in the ATCV register. Therefore, the ATCV Expected Count Value for trimming the 4 MHz IRC is calculated using the following formula.

$$\text{Expected Count Value} = (\text{Fe}/\text{Fr}) * 21 * (128)$$

## 32.6 Initialization / Application information

This section describes how to initialize and configure the MCG module in an application.

The following sections include examples on how to initialize the MCG and properly switch between the various available modes.

### 32.6.1 MCG module initialization sequence

The MCG comes out of reset configured for FEI mode.

The internal reference will stabilize in  $t_{\text{irefstb}}$  microseconds before the FLL can acquire lock. As soon as the internal reference is stable, the FLL will acquire lock in  $t_{\text{fll\_acquire}}$  milliseconds.

#### 32.6.1.1 Initializing the MCG

Because the MCG comes out of reset in FEI mode, the only MCG modes that can be directly switched to upon reset are FEE, FBE, and FBI modes (see [Figure 32-2](#)). Reaching any of the other modes requires first configuring the MCG for one of these three intermediate modes. Care must be taken to check relevant status bits in the MCG status register reflecting all configuration changes within each mode.

To change from FEI mode to FEE or FBE modes, follow this procedure:

1. Enable the external clock source by setting the appropriate bits in C2 register.
2. Write to C1 register to select the clock mode.
  - If entering FEE mode, set C1[FRDIV] appropriately, clear C1[IREFS] bit to switch to the external reference, and leave C1[CLKS] at 2'b00 so that the output of the FLL is selected as the system clock source.

- If entering FBE, clear C1[IREFS] to switch to the external reference and change C1[CLKS] to 2'b10 so that the external reference clock is selected as the system clock source. The C1[FRDIV] bits should also be set appropriately here according to the external reference frequency to keep the FLL reference clock in the range of 31.25 kHz to 39.0625 kHz. Although the FLL is bypassed, it is still on in FBE mode.
  - The internal reference can optionally be kept running by setting C1[IRCLKEN]. This is useful if the application will switch back and forth between internal and external modes. For minimum power consumption, leave the internal reference disabled while in an external clock mode.
3. Once the proper configuration bits have been set, wait for the affected bits in the MCG status register to be changed appropriately, reflecting that the MCG has moved into the proper mode.
    - If the MCG is in FEE, FBE, PEE, PBE, or BLPE mode, and C2[EREFS] was also set in step 1, wait here for S[OSCINIT0] bit to become set indicating that the external clock source has finished its initialization cycles and stabilized.
    - If in FEE mode, check to make sure S[IREFST] is cleared before moving on.
    - If in FBE mode, check to make sure S[IREFST] is cleared and S[CLKST] bits have changed to 2'b10 indicating the external reference clock has been appropriately selected. Although the FLL is bypassed, it is still on in FBE mode.
  4. Write to the C4 register to determine the DCO output (MCGFLLCLK) frequency range.
    - By default, with C4[DMX32] cleared to 0, the FLL multiplier for the DCO output is 640. For greater flexibility, if a mid-low-range FLL multiplier of 1280 is desired instead, set C4[DRST\_DRS] bits to 2'b01 for a DCO output frequency of 40 MHz. If a mid high-range FLL multiplier of 1920 is desired instead, set the C4[DRST\_DRS] bits to 2'b10 for a DCO output frequency of 60 MHz. If a high-range FLL multiplier of 2560 is desired instead, set the C4[DRST\_DRS] bits to 2'b11 for a DCO output frequency of 80 MHz.
    - When using a 32.768 kHz external reference, if the maximum low-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b00 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 732 will be 24 MHz.

- When using a 32.768 kHz external reference, if the maximum mid-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b01 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 1464 will be 48 MHz.
  - When using a 32.768 kHz external reference, if the maximum mid high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b10 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2197 will be 72 MHz.
  - When using a 32.768 kHz external reference, if the maximum high-range DCO frequency that can be achieved with a 32.768 kHz reference is desired, set C4[DRST\_DRS] bits to 2'b11 and set C4[DMX32] bit to 1. The resulting DCO output (MCGOUTCLK) frequency with the new multiplier of 2929 will be 96 MHz.
5. Wait for the FLL lock time to guarantee FLL is running at new C4[DRST\_DRS] and C4[DMX32] programmed frequency.

To change from FEI clock mode to FBI clock mode, follow this procedure:

1. Change C1[CLKS] bits in C1 register to 2'b01 so that the internal reference clock is selected as the system clock source.
2. Wait for S[CLKST] bits in the MCG status register to change to 2'b01, indicating that the internal reference clock has been appropriately selected.
3. Write to the C2 register to determine the IRCS output (IRCSCLK) frequency range.
  - By default, with C2[IRCS] cleared to 0, the IRCS selected output clock is the slow internal reference clock (32 kHz IRC). If the faster IRC is desired, set C2[IRCS] to 1 for a IRCS clock derived from the 4 MHz IRC source.

### 32.6.2 Using a 32.768 kHz reference

In FEE and FBE modes, if using a 32.768 kHz external reference, at the default FLL multiplication factor of 640, the DCO output (MCGFLLCLK) frequency is 20.97 MHz at low-range.

If C4[DRST\_DRS] bits are set to 2'b01, the multiplication factor is doubled to 1280, and the resulting DCO output frequency is 41.94 MHz at mid-low-range. If C4[DRST\_DRS] bits are set to 2'b10, the multiplication factor is set to 1920, and the resulting DCO output frequency is 62.91 MHz at mid high-range. If C4[DRST\_DRS] bits are set to 2'b11, the multiplication factor is set to 2560, and the resulting DCO output frequency is 83.89 MHz at high-range.

In FBI and FEI modes, setting C4[DMX32] bit is not recommended. If the internal reference is trimmed to a frequency above 32.768 kHz, the greater FLL multiplication factor could potentially push the microcontroller system clock out of specification and damage the part.

### 32.6.3 MCG mode switching

When switching between operational modes of the MCG, certain configuration bits must be changed in order to properly move from one mode to another.

Each time any of these bits are changed (C6[PLLS], C1[IREFS], C1[CLKS], C2[IRCS], or C2[EREFS], the corresponding bits in the MCG status register (PLLST, IREFST, CLKST, IRCST, or OSCINIT) must be checked before moving on in the application software.

Additionally, care must be taken to ensure that the reference clock divider (C1[FRDIV]) is set properly for the mode being switched to.

In FBE, FEE, FBI, and FEI modes, at any time, the application can switch the FLL multiplication factor between 640, 1280, 1920, and 2560 with C4[DRST\_DRS] bits. Writes to C4[DRST\_DRS] bits will be ignored if C2[LP]=1.

The table below shows MCGOUTCLK frequency calculations using C1[FRDIV], C5[PRDIV0], and C6[VDIV0] settings for each clock mode.

**Table 32-5. MCGOUTCLK Frequency Calculation Options**

| Clock Mode                  | $f_{\text{MCGOUTCLK}}^1$                    | Note                                                                              |
|-----------------------------|---------------------------------------------|-----------------------------------------------------------------------------------|
| FEI (FLL engaged internal)  | $f_{\text{int}} \times F$                   | Typical $f_{\text{MCGOUTCLK}} = 21$ MHz immediately after reset.                  |
| FEE (FLL engaged external)  | $(f_{\text{ext}} / \text{FLL\_R}) \times F$ | $f_{\text{ext}} / \text{FLL\_R}$ must be in the range of 31.25 kHz to 39.0625 kHz |
| FBE (FLL bypassed external) | OSCCLK                                      | OSCCLK / FLL_R must be in the range of 31.25 kHz to 39.0625 kHz                   |
| FBI (FLL bypassed internal) | MCGIRCLK                                    | Selectable between slow and fast IRC                                              |
| PEE (PLL engaged external)  | $(\text{OSCCLK} / \text{PLL\_R}) \times M$  | OSCCLK / PLL_R must be in the range of                                            |

*Table continues on the next page...*

**Table 32-5. MCGOUTCLK Frequency Calculation Options  
(continued)**

| Clock Mode                         | $f_{\text{MCGOUTCLK}}^1$ | Note                                   |
|------------------------------------|--------------------------|----------------------------------------|
| PBE (PLL bypassed external)        | OSCCLK                   | OSCCLK / PLL_R must be in the range of |
| BLPI (Bypassed low power internal) | MCGIRCLK                 | Selectable between slow and fast IRC   |
| BLPE (Bypassed low power external) | OSCCLK                   |                                        |

1. FLL\_R is the reference divider selected by the C1[FRDIV] bits, F is the FLL factor selected by C4[DRST\_DRS] and C4[DMX32] bits, PLL\_R is the reference divider selected by C5[PRDIV0] bits, and M is the multiplier selected by C6[VDIV0] bits.

This section will include several mode switching examples, using an MHz external crystal. If using an external clock source less than MHz, the MCG must not be configured for any of the PLL modes (PEE and PBE).

### 32.6.3.1 Example 2: Moving from PEE to BLPI mode: MCGOUTCLK frequency =32 kHz

In this example, the MCG will move through the proper operational modes from PEE mode with a MHz crystal configured for a MHz MCGOUTCLK frequency (see previous example) to BLPI mode with a 32 kHz MCGOUTCLK frequency. First, the code sequence will be described. Then there is a flowchart that illustrates the sequence.

1. First, PEE must transition to PBE mode:
  - a. C1 =
    - C1[CLKS] set to 2'b10 to switch the system clock source to the external reference clock.
  - b. Loop until S[CLKST] are 2'b10, indicating that the external reference clock is selected to feed MCGOUTCLK.
2. Then, PBE must transition either directly to FBE mode or first through BLPE mode and then to FBE mode:
  - a. BLPE: If a transition through BLPE mode is desired, first set C2[LP] to 1.
  - b. BLPE/FBE: C6 = 0x00
    - C6[PLLS] clear to 0 to select the FLL. At this time, with C1[FRDIV] value of 3'b, the FLL divider is set to , resulting in a reference frequency of = 31.25 kHz. If C1[FRDIV] was not previously set to (necessary to achieve required 31.25–39.06 kHz FLL reference frequency with an MHz external

source frequency), it must be changed prior to clearing C6[PLLS] bit. In BLPE mode, changing this bit only prepares the MCG for FLL usage in FBE mode. With C6[PLLS] = 0, the C6[VDIV] value does not matter.

- c. BLPE: If transitioning through BLPE mode, clear C2[LP] to 0 here to switch to FBE mode.
- d. FBE: Loop until S[PLLST] is cleared, indicating that the current source for the PLLS clock is the FLL.

3. Next, FBE mode transitions into FBI mode:

- a. C1 =
  - C1[CLKS] set to 2'b01 to switch the system clock to the internal reference clock.
  - C1[IREFS] set to 1 to select the internal reference clock as the reference clock source.
  - C1[FRDIV] remain unchanged because the reference divider does not affect the internal reference.
- b. Loop until S[IREFST] is 1, indicating the internal reference clock has been selected as the reference clock source.
- c. Loop until S[CLKST] are 2'b01, indicating that the internal reference clock is selected to feed MCGOUTCLK.

4. Lastly, FBI transitions into BLPI mode.

- a. C2 =
  - C2[LP] is 1
  - C2[RANGE], C2[HGO], C2[EREFS], C1[IRCLKEN], and C1[IREFSTEN] bits are ignored when the C1[IREFS] bit is set. They can remain set, or be cleared at this point.

**Figure 32-3. Flowchart of PEE to BLPI mode transition using an MHz crystal**

## Chapter 33

# Oscillator (OSC)

### 33.1 Chip-specific OSC information

#### 33.1.1 OSC modes of operation with MCG

The MCG's C2 register bits configure the oscillator frequency range. See the OSC and MCG chapters for more details.

### 33.2 Introduction

The OSC module is a crystal oscillator. The module, in conjunction with an external crystal or resonator, generates a reference clock for the MCU.

### 33.3 Features and Modes

Key features of the module are listed here.

- Supports 32 kHz crystals (Low Range mode)
- Supports 3–8 MHz, 8–32 MHz crystals and resonators (High Range mode)
- Automatic Gain Control (AGC) to optimize power consumption in high frequency ranges 3–8 MHz, 8–32 MHz using low-power mode
- High gain option in frequency ranges: 32 kHz, 3–8 MHz, and 8–32 MHz
- Voltage and frequency filtering to guarantee clock frequency and stability
- Optionally external input bypass clock from EXTAL signal directly

## Block Diagram

- One clock for MCU clock system
- Two clocks for on-chip peripherals that can work in Stop modes

[Functional Description](#) describes the module's operation in more detail.

### 33.4 Block Diagram

The OSC module uses a crystal or resonator to generate three filtered oscillator clock signals. Three clocks are output from OSC module: OSCCLK for MCU system, OSCERCLK for on-chip peripherals, and . The OSCCLK can only work in run mode. OSCERCLK and can work in low power modes. For the clock source assignments, refer to the clock distribution information of this MCU.

Refer to the chip configuration details for the external reference clock source in this MCU.

The figure found here shows the block diagram of the OSC module.

**Figure 33-1. OSC Module Block Diagram**

## 33.5 OSC Signal Descriptions

The table found here shows the user-accessible signals available for the OSC module.

Refer to signal multiplexing information for this MCU for more details.

**Table 33-1. OSC Signal Descriptions**

| Signal | Description                     | I/O |
|--------|---------------------------------|-----|
| EXTAL  | External clock/Oscillator input | I   |
| XTAL   | Oscillator output               | O   |

## 33.6 External Crystal / Resonator Connections

The connections for a crystal/resonator frequency reference are shown in the figures found here.

When using low-frequency, low-power mode, the only external component is the crystal or ceramic resonator itself. In the other oscillator modes, load capacitors ( $C_x$ ,  $C_y$ ) and feedback resistor ( $R_F$ ) are required. The following table shows all possible connections.

**Table 33-2. External Crystal/Resonator Connections**

| Oscillator Mode                      | Connections                            |
|--------------------------------------|----------------------------------------|
| Low-frequency (32 kHz), low-power    | Connection 1 <sup>1</sup>              |
| Low-frequency (32 kHz), high-gain    | Connection 2/Connection 3 <sup>2</sup> |
| High-frequency (3~32 MHz), low-power | Connection 3 <sup>1</sup>              |
| High-frequency (3~32 MHz), high-gain | Connection 3                           |

1. With the low-power mode, the oscillator has the internal feedback resistor  $R_F$ . Therefore, the feedback resistor must not be externally with the Connection 3.
2. When the load capacitors ( $C_x$ ,  $C_y$ ) are greater than 30 pF, use Connection 3.

**Figure 33-2. Crystal/Ceramic Resonator Connections - Connection 1**

**Figure 33-3. Crystal/Ceramic Resonator Connections - Connection 2**

### NOTE

Connection 1 and Connection 2 should use internal capacitors as the load of the oscillator by configuring the CR[SCxP] bits.

**Figure 33-4. Crystal/Ceramic Resonator Connections - Connection 3**

## 33.7 External Clock Connections

In external clock mode, the pins can be connected as shown in the figure found [here](#).

### NOTE

XTAL can be used as a GPIO when the GPIO alternate function is configured for it.

Figure 33-5. External Clock Connections

## 33.8 Memory Map/Register Definitions

Some oscillator module register bits are typically incorporated into other peripherals such as MCG or SIM.

### 33.8.1 OSC Memory Map/Register Definition

OSC memory map

| Absolute address (hex) | Register name                  | Width (in bits) | Access | Reset value | Section/ page                |
|------------------------|--------------------------------|-----------------|--------|-------------|------------------------------|
| 4006_5000              | OSC Control Register (OSC0_CR) | 8               | R/W    | 00h         | <a href="#">33.8.1.1/711</a> |
| 4006_5002              | OSC_DIV (OSC0_OSC_DIV)         | 8               | R/W    | 00h         | <a href="#">33.8.1.2/713</a> |

#### 33.8.1.1 OSC Control Register (OSCx\_CR)

##### NOTE

After OSC is enabled and starts generating the clocks, the configurations such as low power and frequency range, must not be changed.

Address: 4006\_5000h base + 0h offset = 4006\_5000h

| Bit   | 7       | 6 | 5        | 4 | 3    | 2    | 1    | 0     |

## 33.9 Functional Description

Functional details of the module can be found [here](#).

### 33.9.1 OSC module states

The states of the OSC module are shown in the following figure. The states and their transitions between each other are described in this section.

Figure 33-6. OSC Module state diagram

**NOTE**

XTL\_CLK is the clock generated internally from OSC circuits.

**33.9.1.1 Off**

The OSC enters the Off state when the system does not require OSC clocks. Upon entering this state, XTL\_CLK is static unless OSC is configured to select the clock from the EXTAL pad by clearing the external reference clock selection bit. For details regarding the external reference clock source in this MCU, refer to the chip configuration details. The EXTAL and XTAL pins are also decoupled from all other oscillator circuitry in this state. The OSC module circuitry is configured to draw minimal current.

### 33.9.1.2 Oscillator startup

The OSC enters startup state when it is configured to generate clocks (internally the OSC\_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit. In this state, the OSC module is enabled and oscillations are starting up, but have not yet stabilized. When the oscillation amplitude becomes large enough to pass through the input buffer, XTL\_CLK begins clocking the counter. When the counter reaches 4096 cycles of XTL\_CLK, the oscillator is considered stable and XTL\_CLK is passed to the output clock OSC\_CLK\_OUT.

### 33.9.1.3 Oscillator Stable

The OSC enters stable state when it is configured to generate clocks (internally the OSC\_EN transitions high) using the internal oscillator circuits by setting the external reference clock selection bit and the counter reaches 4096 cycles of XTL\_CLK (when CNT\_DONE\_4096 is high). In this state, the OSC module is producing a stable output clock on OSC\_CLK\_OUT. Its frequency is determined by the external components being used.

### 33.9.1.4 External Clock mode

The OSC enters external clock state when it is enabled and external reference clock selection bit is cleared. For details regarding external reference clock source in this MCU, see the chip configuration details. In this state, the OSC module is set to buffer (with hysteresis) a clock from EXTAL onto the OSC\_CLK\_OUT. Its frequency is determined by the external clock being supplied.

## 33.9.2 OSC module modes

The OSC is a pierce-type oscillator that supports external crystals or resonators operating over the frequency ranges shown in [Table 33-3](#). These modes assume the following conditions: OSC is enabled to generate clocks (OSC\_EN=1), configured to generate clocks internally (MCG\_C2[EREFS] = 1), and some or one of the other peripherals (MCG, Timer, and so on) is configured to use the oscillator output clock (OSC\_CLK\_OUT).

**Table 33-3. Oscillator modes**

| Mode                     | Frequency Range                                              |
|--------------------------|--------------------------------------------------------------|
| Low-frequency, high-gain | $f_{osc\_lo}$ (32.768 kHz) up to $f_{osc\_lo}$ (39.0625 kHz) |

*Table continues on the next page...*

**Table 33-3. Oscillator modes (continued)**

| Mode                            | Frequency Range                                          |
|---------------------------------|----------------------------------------------------------|
| High-frequency mode1, high-gain | $f_{osc\_hi\_1}$ (3 MHz) up to $f_{osc\_hi\_1}$ (8 MHz)  |
| High-frequency mode1, low-power |                                                          |
| High-frequency mode2, high-gain | $f_{osc\_hi\_2}$ (8 MHz) up to $f_{osc\_hi\_2}$ (32 MHz) |
| High-frequency mode2, low-power |                                                          |

**NOTE**

For information about low power modes of operation used in this chip and their alignment with some OSC modes, see the chip's Power Management details.

**33.9.2.1 Low-Frequency, High-Gain Mode**

In Low-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes.

The oscillator input buffer in this mode is single-ended. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used.

**33.9.2.2 Low-Frequency, Low-Power Mode**

In low-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels. In this mode, the internal capacitors could be used, the internal feedback resistor is connected, and no external resistor should be used.

In this mode, the amplifier inputs, gain-control input, and input buffer input are all capacitively coupled for leakage tolerance (not sensitive to the DC level of EXTAL).

Also in this mode, all external components except for the resonator itself are integrated, which includes the load capacitors and feedback resistor that biases EXTAL.

### 33.9.2.3 High-Frequency, High-Gain Mode

In high-frequency, high-gain mode, the oscillator uses a simple inverter-style amplifier. The gain is set to achieve rail-to-rail oscillation amplitudes. This mode provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

### 33.9.2.4 High-Frequency, Low-Power Mode

In high-frequency, low-power mode, the oscillator uses a gain control loop to minimize power consumption. As the oscillation amplitude increases, the amplifier current is reduced. This continues until a desired amplitude is achieved at steady-state. In this mode, no external resistor should be used.

The oscillator input buffer in this mode is differential. It provides low pass frequency filtering as well as hysteresis for voltage filtering and converts the output to logic levels.

## 33.9.3 Counter

The oscillator output clock (OSC\_CLK\_OUT) is gated off until the counter has detected 4096 cycles of its input clock (XTL\_CLK). After 4096 cycles are completed, the counter passes XTL\_CLK onto OSC\_CLK\_OUT. This counting timeout is used to guarantee output clock stability.

## 33.9.4 Reference clock pin requirements

The OSC module requires use of both the EXTAL and XTAL pins to generate an output clock in Oscillator mode, but requires only the EXTAL pin in External clock mode. The EXTAL and XTAL pins are available for I/O. For the implementation of these pins on this device, refer to the Signal Multiplexing chapter.

## 33.10 Reset

There is no reset state associated with the OSC module. The counter logic is reset when the OSC is not configured to generate clocks.

There are no sources of reset requests for the OSC module.

## 33.11 Low power modes operation

When the MCU enters Stop modes, the OSC is functional depending on CR[ERCLKEN] and CR[EREFSETN] bit settings. If both these bits are set, the OSC is in operation.

After waking up from Very Low Leakage Stop (VLLSx) modes, all OSC register bits are reset and initialization is required through software.

## 33.12 Interrupts

The OSC module does not generate any interrupts.

## Chapter 34

# Flash Memory Controller (FMC)

### 34.1 Chip-specific FMC information

#### 34.1.1 Number of masters

The Flash Memory Controller supports up to eight crossbar switch masters. However, this device has a different number of crossbar switch masters. See [Chip-specific AXBS information](#) for details on the master port assignments.

#### 34.1.2 PFB1CR register

The FMC connects to one bank (called bank 0) of 256-bit flash. PFB0CR register controls this bank. The PFB1CR register is not available on this device.

### 34.2 Introduction

The Flash Memory Controller (FMC) is a memory acceleration unit that provides an interface between the device and the nonvolatile memory.

#### 34.2.1 Overview

The Flash Memory Controller manages the interface between the device and the flash memory. The FMC receives status information detailing the configuration of the memory and uses this information to ensure a proper interface. The following table shows the supported read/write operations.

## Modes of operation

| Flash memory type    | Read                                    | Write          |
|----------------------|-----------------------------------------|----------------|
| Program flash memory | 8-bit, 16-bit, 32-bit, and 64-bit reads | — <sup>1</sup> |

1. A write operation to program flash memory results in a bus error.

In addition, for bank 0, the FMC provides a mechanism for accelerating the interface between the device and the flash memory. A 256-bit speculation buffer can prefetch the next 256-bit flash memory location.

### 34.2.2 Features

The FMC's features include:

- Interface between the device and the flash memory:
  - 8-bit, 16-bit, 32-bit, and 64-bit read operations to program flash memory.
  - For bank 0: Read accesses to consecutive 64-bit spaces in memory return the 2nd, 3rd, and 4th read data with no wait states. The memory returns 256 bits via the 64-bit bus access.
  - Crossbar master access protection for setting no access, read-only access, write-only access, or read/write access for each crossbar master.
- For bank 0: Acceleration of data transfer from program flash memory to the device:
  - 256-bit prefetch speculation buffer with controls for instruction/data access per master
  - Invalidation control for the speculation buffer

## 34.3 Modes of operation

The FMC only operates when a bus master accesses the flash memory.

For any device power mode where the flash memory cannot be accessed, the FMC is disabled.

## 34.4 External signal description

The FMC has no external signals.

## 34.5 Memory map and register descriptions

The programming model consists of the FMC control registers.

### NOTE

Program the registers only while the flash controller is idle (for example, execute from RAM). Changing configuration settings while a flash access is in progress can lead to non-deterministic behavior. Whenever flash memory is modified, the Flash speculation buffer should be cleared (see PFB0CR[S\_INV], Invalidate Prefetch Speculation Buffer bit).

**Table 34-1. FMC register access**

| Registers                           | Read access                                  |         | Write access                         |         |
|-------------------------------------|----------------------------------------------|---------|--------------------------------------|---------|
|                                     | Mode                                         | Length  | Mode                                 | Length  |
| Control registers:<br>PFAPR, PFB0CR | Supervisor (privileged)<br>mode or user mode | 32 bits | Supervisor (privileged)<br>mode only | 32 bits |

### NOTE

Accesses to unimplemented registers within the FMC's 4 KB address space return a bus error.

### FMC memory map

## 34.6 Functional description

The FMC is a flash acceleration unit with flexible buffers for user configuration. Besides managing the interface between the device and the flash memory, the FMC can be used to restrict access from crossbar switch masters. Whenever a hit occurs for the prefetch speculation buffer, the requested data is transferred within a single system clock.

### 34.6.1 Default configuration

Upon system reset, the FMC is configured to enable speculation on transfers from the flash memory:

- The Cortex-M7, Debugger, and DMA have read access to the flash.
- Prefetch support for data and instructions is enabled for these masters.

### 34.6.2 Configuration options

Though the default configuration provides a high degree of flash acceleration, advanced users may desire to customize the FMC buffer configurations to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory is being accessed. Instead, change the control registers with a routine executing from RAM in supervisor mode.

The FMC's buffering controls allow the tuning of resources to suit particular applications' needs. The FMC Flash Bank 0 Control Register controls enable prefetching per access type (instruction fetch or data reference).

As an application example: if both instruction fetches and data references are accessing flash memory, then speculation can be enabled or disabled for either type of access.

### 34.6.3 Speculative reads

The FMC has a single buffer that reads ahead to the next word in the flash memory if there is an idle cycle. Speculative prefetching is programmable for each bank for instruction and/or data accesses using the B0DPE and B0IPE fields of PFB0CR. Because many code accesses are sequential, using the speculative prefetch buffer improves performance in most cases.

When speculative reads are enabled, the FMC immediately requests the next sequential address after a read completes. By requesting the next word immediately, speculative reads can help to reduce or even eliminate wait states when accessing sequential code and/or data.

For example, consider the following scenario:

- Assume a system with a 4:1 core-to-flash clock ratio and with speculative reads enabled.
- The core requests 8 sequential double-words in back-to-back requests, meaning there are no core cycle delays except for stalls waiting for flash memory data to be returned.
- None of the data is already stored in the speculation buffer.

In this scenario, the sequence of events for accessing the 8 double-words is:

1. The 1st double-word read requires 4 - 7 core clocks. See [Wait states](#) for more information.
2. Due to the 256-bit data bus of the flash memory, the 2nd double-word read takes only 1 core clock, because the data is already available inside the FMC. For the same reason, the 3rd and 4th double-word reads each take only 1 core clock.
3. Accessing the 5th double-word requires 1 core clock cycle. The flash memory read itself takes 4 clocks, but the access starts immediately after the 1st read. As a result, 3 clocks for this access overlap with the 2nd, 3rd, and 4th double-word reads from the core.
4. Reading the 6th, 7th, and 8th double-words takes only 1 clock each because the data is already available inside the FMC.

## 34.7 Initialization and application information

- The FMC does not require user initialization.
- Flash acceleration features are enabled by default for masters enabled at reset.
- The FMC has no visibility into flash memory erase and program cycles, because the Flash Memory module manages them directly.

# Chapter 35

## Flash Memory Module (FTFE)

### 35.1 Introduction

The FTFE module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- Programming acceleration RAM to speed flash programming

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The FTFE module includes a memory controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

#### CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased with security disabled. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0') states. Therefore, it is recommended that each flash block or sector be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

## 35.1.1 Features

The FTFE module includes the following features.

### NOTE

See the chip-specific information section for the exact amount of flash memory available on your device.

### 35.1.1.1 Program Flash Memory Features

- Sector size of 8 Kbytes
- Program flash protection scheme prevents accidental program or erase of stored data
- Automated, built-in, program and erase algorithms with verify
- Section programming for faster bulk programming times

### 35.1.1.2 Programming Acceleration RAM features

- RAM to support section programming

### 35.1.1.3 Other FTFE module features

- Internal high-voltage supply generator for flash memory program and erase operations
- Optional interrupt generation upon flash command completion
- Supports MCU security mechanisms which prevent unauthorized access to the flash memory contents

## 35.1.2 Block diagram

The block diagram of the FTFE module is shown in the following figure.

Figure 35-1. FTFE block diagram

### 35.1.3 Glossary

**Command write sequence** — A series of MCU writes to the Flash FCCOB register group that initiates and controls the execution of Flash algorithms that are built into the FTFE module.

**Endurance** — The number of times that a flash memory location can be erased and reprogrammed.

**FCCOB (Flash Common Command Object)** — A group of flash registers that are used to pass command, address, data, and any associated parameters to the memory controller in the FTFE module.

**Flash block** — A macro within the FTFE module which provides the nonvolatile memory storage.

**FTFE Module** — All flash blocks plus a flash management unit providing high-level control and an interface to MCU buses.

**IFR** — Nonvolatile information register found in each flash block, separate from the main memory array.

**NVM** — Nonvolatile memory. A memory technology that maintains stored data during power-off. The flash array is an NVM using NOR-type flash memory technology.

**NVM Normal Mode** — An NVM mode that provides basic user access to FTFE resources. The CPU or other bus masters initiate flash program and erase operations (or other flash commands) using writes to the FCCOB register group in the FTFE module.

**NVM Special Mode** — An NVM mode enabling external, off-chip access to the memory resources in the FTFE module. A reduced flash command set is available when the MCU is secured. See the Chip Configuration details for information on when this mode is used.

**Quad-Phrase** — 256 bits of data with an aligned quad-phrase having byte-address[4:0] = 00000.

**Phrase** — 64 bits of data with an aligned phrase having byte-address[2:0] = 000.

**Longword** — 32 bits of data with an aligned longword having byte-address[1:0] = 00.

**Word** — 16 bits of data with an aligned word having byte-address[0] = 0.

**Program flash** — The program flash memory provides nonvolatile storage for vectors and code store.

**Program flash sector** — The smallest portion of the program flash memory (consecutive addresses) that can be erased.

**Retention** — The length of time that data can be kept in the NVM without experiencing errors upon readout. Since erased (1) states are subject to degradation just like programmed (0) states, the data retention limit may be reached from the last erase operation (not from the programming time).

**Section program buffer** — Lower quarter of the programming acceleration RAM allocated for storing large amounts of data for programming via the Program Section command.

**Secure** — An MCU state conveyed to the FTFE module as described in the Chip Configuration details for this device. In the secure state, reading and changing NVM contents is restricted.

## 35.2 External signal description

The FTFE module contains no signals that connect off-chip.

## 35.3 Memory map and registers

This section describes the memory map and registers for the FTFE module. Data read from unimplemented memory space in the FTFE module is undefined. Writes to unimplemented or reserved memory space (registers) in the FTFE module are ignored.

### 35.3.1 Flash configuration field description

The program flash memory contains a 16-byte flash configuration field that stores default protection settings (loaded on reset) and security information that allows the MCU to restrict access to the FTFE module.

#### NOTE

The flash configuration field offset addresses are relative byte addresses. Check your device specific memory map for the location of the program flash memory.

| Flash Configuration Field Offset Address | Size (Bytes) | Field Description                                                                                                                                       |

### 35.3.2 Program flash 0 IFR map

The program flash 0 IFR is a 1 Kbyte nonvolatile information memory that can be read freely, but the user has no erase and limited program capabilities (see the Read Once, Program Once, and Read Resource commands in [Read Once Command](#), [Program Once command](#) and [Read Resource Command](#)). The contents of the program flash 0 IFR are summarized in the following table and further described in the subsequent paragraphs.

The program flash 0 IFR is located within the program flash 0 memory block.

| Address Range | Size (Bytes) | Field Description  |
|---------------|--------------|--------------------|
| 0x000 – 0x3BF | 960          | Reserved           |
| 0x3C0 – 0x3FF | 64           | Program Once Field |

### 35.3.2.1 Program Once field

The Program Once field in the program flash 0 IFR provides 64 bytes of user data storage separate from the program flash 0 main array. The user can program the Program Once field one time only as there is no program flash IFR erase mechanism available to the user. The Program Once field can be read any number of times. This section of the program flash 0 IFR is accessed in 8 byte records using the Read Once and Program Once commands (see [Read Once Command](#) and [Program Once command](#)).

### 35.3.3 Register descriptions

The FTFE module contains a set of memory-mapped control and status registers.

#### NOTE

While a command is running (FSTAT[CCIF]=0), register writes are not accepted to any register except FCNFG and FSTAT. The no-write rule is relaxed during the start-up reset sequence, prior to the initial rise of CCIF. During this initialization period the user may write any register. All register writes are also disabled (except for registers FCNFG and FSTAT) whenever an erase suspend request is active (FCNFG[ERSSUSP]=1).

**35.3.3.1 Flash Status Register (FTFE\_FSTAT)**

The FSTAT register reports the operational status of the FTFE module.

The CCIF, RDCOLERR, ACCERR, and FPVIOL bits are readable and writable. The MGSTAT0 bit is read only. The unassigned bits read 0 and are not writable.

**NOTE**

When set, the Access Error (ACCERR) and Flash Protection Violation (FPVIOL) bits in this register prevent the launch of

any more commands until the flag is cleared (by writing a one to it).

Address: 4002\_0000h base + 0h offset = 4002\_0000h

| Bit   | 7    | 6        | 5      | 4      | 3 | 2 | 1 | 0       |
|-------|------|----------|--------|--------|---|---|---|---------|
| Read  | CCIF | RDCOLERR | ACCERR | FPVIOL | 0 |   |   | MGSTAT0 |
| Write | w1c  | w1c      | w1c    | w1c    |   |   |   |         |
| Reset | 0    | 0        | 0      | 0      | 0 | 0 | 0 | 0       |

### FTFE\_FSTAT field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>CCIF       | <p>Command Complete Interrupt Flag</p> <p>The CCIF flag indicates that a FTFE command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a command, and CCIF stays low until command completion or command violation.</p> <p>The CCIF bit is reset to 0 but is set to 1 by the memory controller at the end of the reset initialization sequence. Depending on how quickly the read occurs after reset release, the user may or may not see the 0 hardware reset value.</p> <p>0 FTFE command in progress<br/>1 FTFE command has completed</p> |
| 6<br>RDCOLERR   | <p>FTFE Read Collision Error Flag</p> <p>The RDCOLERR error bit indicates that the MCU attempted a read from an FTFE resource that was being manipulated by an FTFE command (CCIF=0). Any simultaneous access is detected as a collision error by the block arbitration logic. The read data in this case cannot be guaranteed. The RDCOLERR bit is cleared by writing a 1 to it. Writing a 0 to RDCOLERR has no effect.</p> <p>0 No collision error detected<br/>1 Collision error detected</p>                                                                     |
| 5<br>ACCERR     | <p>Flash Access Error Flag</p> <p>The ACCERR error bit indicates an illegal access has occurred to an FTFE resource caused by a violation of the command write sequence or issuing an illegal FTFE command. While ACCERR is set, the CCIF flag cannot be cleared to launch a command. The ACCERR bit is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR bit has no effect.</p> <p>0 No access error detected<br/>1 Access error detected</p>                                                                                           |
| 4<br>FPVIOL     | <p>Flash Protection Violation Flag</p> <p>The FPVIOL error bit indicates an attempt was made to program or erase an address in a protected area of program flash memory during a command write sequence. While FPVIOL is set, the CCIF flag cannot be cleared to launch a command. The FPVIOL bit is cleared by writing a 1 to FPVIOL while CCIF is set. Writing a 0 to the FPVIOL bit has no effect.</p> <p>0 No protection violation detected<br/>1 Protection violation detected</p>                                                                              |
| 3–1<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0<br>MGSTAT0    | Memory Controller Command Completion Status Flag                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Table continues on the next page...

**FTFE\_FSTAT field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>The MGSTAT0 status flag is set if an error is detected during execution of an FTFE command or during the flash reset sequence. As a status flag, this bit cannot (and need not) be cleared by the user like the other error flags in this register.</p> <p>The value of the MGSTAT0 bit for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the previous result is discarded and any previous error is cleared.</p> |

**35.3.3.2 Flash Configuration Register (FTFE\_FCNFG)**

This register provides information on the current functional state of the FTFE module.

The erase control bits (ERSAREQ and ERSSUSP) have write restrictions. RAMRDY is a read-only status bit while PFLSH and EEERDY are reserved bits.

Address: 4002\_0000h base + 1h offset = 4002\_0001h

| Bit   | 7    | 6        | 5       | 4       | 3     | 2      | 1      | 0 |
|-------|------|----------|---------|---------|-------|--------|--------|---|
| Read  | CCIE | RDCOLLIE | ERSAREQ | ERSSUSP | PFLSH | RAMRDY | EEERDY |   |
| Write |      |          |         |         |       |        |        |   |

## 35.3.3.3 Flash Security Register (FTFE\_FSEC)

This read-only register holds all bits associated with the security of the MCU and FTFE module.

During the reset sequence, the register is loaded with the contents of the flash security byte in the Flash Configuration Field located in program flash memory. The Flash basis for the values is signified by X in the reset value.

Address: 4002\_0000h base + 2h offset = 4002\_0002h

**35.3.3.4 Flash Option Register (FTFE\_FOPT)**

The flash option register allows the MCU to customize its operations by examining the state of these read-only bits, which are loaded from NVM at reset. The function of the bits is defined in the device's Chip Configuration details.

All bits in the register are read-only.

Memory map and registers

During the reset sequence, the register is loaded from the flash nonvolatile option byte in the Flash Configuration Field located in program flash memory. The flash basis for the values is signified by X in the reset value.

Address: 4002\_0000h base + 3h offset = 4002\_0003h

- \* Notes:
- x = Undefined at reset.

35.3.3.5 Flash Common Command Object Registers (FTFE\_FCCOBn)

The FCCOB register group provides 12 bytes for command codes and parameters. The individual bytes within the set append a 0-B hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOBB.

Address: 4002\_0000h base + 4h offset + (1d × i), where i=0d to 11d

| CCOBn | The FCCOB register provides a command code and relevant parameters to the memory controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command's execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes.<br><br>Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1 by the memory controller. |

**FTFE\_FCCOB $n$  field descriptions (continued)**

| Field                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                           |                                          |   |                                             |   |                       |   |                      |   |                     |   |             |   |             |   |             |   |             |   |             |   |             |   |             |   |             |

|                           | <p>The following table shows a generic FTFE command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific FTFE command, typically an address and/or data values.</p> <p><b>NOTE:</b> The command parameter table is written in terms of FCCOB Number (which is equivalent to the byte number). This number is a reference to the FCCOB register name and is not the register address.</p> <table> <tr> <th>FCCOB Number<sup>1</sup></th><th>Typical Command Parameter Contents [7:0]</th></tr> <tr> <td>0</td><td>FCMD (a code that defines the FTFE command)</td></tr> <tr> <td>1</td><td>Flash address [23:16]</td></tr> <tr> <td>2</td><td>Flash address [15:8]</td></tr> <tr> <td>3</td><td>Flash address [7:0]</td></tr> <tr> <td>4</td><td>Data Byte 0</td></tr> <tr> <td>5</td><td>Data Byte 1</td></tr> <tr> <td>6</td><td>Data Byte 2</td></tr> <tr> <td>7</td><td>Data Byte 3</td></tr> <tr> <td>8</td><td>Data Byte 4</td></tr> <tr> <td>9</td><td>Data Byte 5</td></tr> <tr> <td>A</td><td>Data Byte 6</td></tr> <tr> <td>B</td><td>Data Byte 7</td></tr> </table> <p><b>FCCOB Endianness and Multi-Byte Access:</b></p> <p>The FCCOB register group uses a big endian addressing convention. For all command parameter fields larger than 1 byte, the most significant data resides in the lowest FCCOB register number. The FCCOB register group may be read and written as individual bytes, aligned words (2 bytes) or aligned longwords (4 bytes).</p> | FCCOB Number <sup>1</sup> | Typical Command Parameter Contents [7:0] | 0 | FCMD (a code that defines the FTFE command) | 1 | Flash address [23:16] | 2 | Flash address [15:8] | 3 | Flash address [7:0] | 4 | Data Byte 0 | 5 | Data Byte 1 | 6 | Data Byte 2 | 7 | Data Byte 3 | 8 | Data Byte 4 | 9 | Data Byte 5 | A | Data Byte 6 | B | Data Byte 7 |

1. Refers to FCCOB register name, not register address

**35.3.3.6 Program Flash Protection Registers (FTFE\_FPROT $n$ )**

The FPROT registers define which program flash regions are protected from program and erase operations. Protected flash regions cannot have their content changed; that is, these regions cannot be programmed and cannot be erased by any FTFE command.

Unprotected regions can be changed by program and erase operations.

The four FPROT registers allow up to 32 protectable regions of equal memory size.

| Program flash protection register | Program flash protection bits |
|-----------------------------------|-------------------------------|
| FPROT0                            | PROT[31:24]                   |
| FPROT1                            | PROT[23:16]                   |

*Table continues on the next page...*

| Program flash protection register | Program flash protection bits |
|-----------------------------------|-------------------------------|
| FPROT2                            | PROT[15:8]                    |
| FPROT3                            | PROT[7:0]                     |

During the reset sequence, the FPROT registers are loaded with the contents of the program flash protection bytes in the Flash Configuration Field as indicated in the following table.

| Program flash protection register | Flash Configuration Field offset address |
|-----------------------------------|------------------------------------------|
| FPROT0                            | 0x000B                                   |
| FPROT1                            | 0x000A                                   |
| FPROT2                            | 0x0009                                   |
| FPROT3                            | 0x0008                                   |

To change the program flash protection that is loaded during the reset sequence, unprotect the sector of program flash memory that contains the Flash Configuration Field. Then, reprogram the program flash protection byte.

Address: 4002\_0000h base + 10h offset + (1d × i), where i=0d to 3d

| Write |    |    |    |    |    |    |    |    |
| Reset | x* | x* | x* | x* | x* | x* | x* | x* |

\* Notes:

- x = Undefined at reset.

### FTFE\_FPROT<sub>n</sub> field descriptions

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROT  | <p>Program Flash Region Protect</p> <p>Each program flash region can be protected from program and erase operations by setting the associated PROT bit to the protected state.</p> <p><b>In NVM Normal mode:</b> The protection can only be increased, meaning that currently unprotected memory can be protected, but currently protected memory cannot be unprotected. Since unprotected regions are marked with a 1 and protected regions use a 0, only writes changing 1s to 0s are accepted. This 1-to-0 transition check is performed on a bit-by-bit basis. Those FPROT bits with 1-to-0 transitions are accepted while all bits with 0-to-1 transitions are ignored.</p> <p><b>In NVM Special mode:</b> All bits of FPROT are writable without restriction. Unprotected areas can be protected and protected areas can be unprotected.</p> <p><b>Restriction:</b> The user must never write to any FPROT register while a command is running (CCIF=0). Trying to alter data in any protected area in the program flash memory results in a protection violation error and sets the FSTAT[FPVIOL] bit. A full block erase of a program flash block is not possible if it contains any protected region.</p> |

FTFE\_FPROTn field descriptions (continued)

| Field | Description                           |
|-------|---------------------------------------|
| 0     | Program flash region is protected.    |
| 1     | Program flash region is not protected |

35.4 Functional Description

The following sections describe functional details of the FTFE module.

35.4.1 Flash Protection

Individual regions within the flash memory can be protected from program and erase operations. Protection is controlled by the following registers:

- FPROTn — Four registers protect 32 regions of the program flash memory as shown in the following figure

Figure 35-2. Program flash protection

NOTE

Flash protection features are discussed further in [AN4507: Using the Kinetis Security and Flash Protection Features](#) . Some features described in the application note may not be available on this device.

## 35.4.2 Interrupts

The FTFE module can generate interrupt requests to the MCU upon the occurrence of various FTFE events. These interrupt events and their associated status and control bits are shown in the following table.

**Table 35-1. FTFE Interrupt Sources**

| FTFE Event                | Readable Status Bit | Interrupt Enable Bit |
|---------------------------|---------------------|----------------------|
| FTFE Command Complete     | FSTAT[CCIF]         | FCNFG[CCIE]          |
| FTFE Read Collision Error | FSTAT[RDCOLERR]     | FCNFG[RDCOLLIE]      |

### Note

Vector addresses and their relative interrupt priority are determined at the MCU level.

## 35.4.3 Flash Operation in Low-Power Modes

### 35.4.3.1 Wait Mode

When the MCU enters wait mode, the FTFE module is not affected. The FTFE module can recover the MCU from wait via the command complete interrupt (see [Interrupts](#)).

### 35.4.3.2 Stop Mode

When the MCU requests stop mode, if an FTFE command is active (CCIF = 0) the command execution completes before the MCU is allowed to enter stop mode.

### CAUTION

The MCU should never enter stop mode while any FTFE command is running (CCIF = 0).

### NOTE

While the MCU is in very-low-power modes (VLPR, VLPW, VLPS), the FTFE module does not accept flash commands.

### 35.4.4 Functional modes of operation

The FTFE module has two operating modes: NVM Normal and NVM Special. The operating mode affects the command set availability (see [Table 35-2](#)). Refer to the Chip Configuration details of this device for how to activate each mode.

### 35.4.5 Flash memory reads and ignored writes

The FTFE module requires only the flash address to execute a flash memory read. MCU read access is available to all flash memory.

The MCU must not read from the flash memory while commands are running (as evidenced by CCIF=0) on that block. Read data cannot be guaranteed from a flash block while any command is processing within that block. The block arbitration logic detects any simultaneous access and reports this as a read collision error (see the FSTAT[RDCOLERR] bit).

### 35.4.6 Flash Program and Erase

All flash functions except read require the user to setup and launch an FTFE command through a series of peripheral bus writes. The user cannot initiate any further FTFE commands until notified that the current command has completed. The FTFE command structure and operation are detailed in [FTFE Command Operations](#).

### 35.4.7 FTFE Command Operations

FTFE command operations are typically used to modify flash memory contents. The next sections describe:

- The command write sequence used to set FTFE command parameters and launch execution
- A description of all FTFE commands available

### 35.4.7.1 Command Write Sequence

FTFE commands are specified using a command write sequence illustrated in [Figure 35-3](#). The FTFE module performs various checks on the command (FCCOB) content and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR and FPVIOL bits in the FSTAT register must be zero and the CCIF flag must read 1 to verify that any previous command has completed. If CCIF is zero, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

Attempts to launch an FTFE command in VLP mode will be ignored.

#### 35.4.7.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the desired FTFE command. The individual registers that make up the FCCOB data set can be written in any order.

#### 35.4.7.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The CCIF flag remains zero until the FTFE command completes.

The FSTAT register contains a blocking mechanism, which prevents a new command from launching (can't clear CCIF) if the previous command resulted in an access error (FSTAT[ACCERR]=1) or a protection violation (FSTAT[FPVIOL]=1). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write clears the error flags, the second write clears CCIF.

#### 35.4.7.1.3 Command Execution and Error Reporting

The command processing has several steps:

1. The FTFE reads the command code and performs a series of parameter checks and protection checks, if applicable, which are unique to each command.

If the parameter check fails, the FSTAT[ACCERR] (access error) flag is set. ACCERR reports invalid instruction codes and out-of bounds addresses. Usually, access errors suggest that the command was not set-up with valid parameters in the FCCOB register group.

Program and erase commands also check the address to determine if the operation is requested to execute on protected areas. If the protection check fails, the FSTAT[FPVIOL] (protection error) flag is set.

Command processing never proceeds to execution when the parameter or protection step fails. Instead, command processing is terminated after setting the FSTAT[CCIF] bit.

2. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to erase verify, may occur during the execution phase. Run-time errors are reported in the FSTAT[MGSTAT0] bit. A command may have access errors, protection errors, and run-time errors, but the run-time errors are not seen until all access and protection errors have been corrected.
3. Command execution results, if applicable, are reported back to the user via the FCCOB and FSTAT registers.
4. The FTFE sets the FSTAT[CCIF] bit signifying that the command has completed.

The flow for a generic command write sequence is illustrated in the following figure.

**Figure 35-3. Generic Flash Command Write Sequence Flowchart**

### 35.4.7.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

| FCMD | Command         | Program flash 0 | Function                                                                                  |
|------|-----------------|-----------------|-------------------------------------------------------------------------------------------|
| 0x01 | Read 1s Section | x               | Verify that a given number of program flash locations from a starting address are erased. |

*Table continues on the next page...*

| FCMD | Command                    | Program flash 0 | Function                                                                                                                                                              |
|------|----------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x02 | Program Check              | x               | Tests previously-programmed phrases at margin read levels.                                                                                                            |
| 0x03 | Read Resource              | IFR,ID          | Read 8 bytes from program flash IFR or version ID.                                                                                                                    |
| 0x07 | Program Phrase             | x               | Program 8 bytes in a program flash block.                                                                                                                             |
| 0x09 | Erase Flash Sector         | x               | Erase all bytes in a program flash sector.                                                                                                                            |
| 0x0B | Program Section            | x               | Program data from the Section Program Buffer to a program flash block.                                                                                                |
| 0x40 | Read 1s All Blocks         | x               | Verify that all program flash blocks are erased then release MCU security.                                                                                            |
| 0x41 | Read Once                  | IFR             | Read 8 bytes of a dedicated 64 byte field in the program flash 0 IFR.                                                                                                 |
| 0x43 | Program Once               | IFR             | One-time program of 8 bytes of a dedicated 64-byte field in the program flash 0 IFR.                                                                                  |
| 0x44 | Erase All Blocks           | x               | Erase all program flash blocks. Then, verify-erase and release MCU security.<br><br><b>NOTE:</b> An erase is only possible when all memory locations are unprotected. |
| 0x45 | Verify Backdoor Access Key | x               | Release MCU security after comparing a set of user-supplied security keys to those stored in the program flash.                                                       |
| 0x49 | Erase All Blocks Unsecure  | x               | Erase all program flash blocks. Then, verify-erase, program the security byte to the unsecure state, and release MCU security.                                        |

### 35.4.7.3 Flash commands by mode

The following table shows the flash commands that can be executed in each flash operating mode.

**Table 35-2. Flash commands by mode**

| FCMD | Command                    | NVM Normal |        |         | NVM Special |        |         |
|------|----------------------------|------------|--------|---------|-------------|--------|---------|
|      |                            | Unsecure   | Secure | MEEN=10 | Unsecure    | Secure | MEEN=10 |
| 0x01 | Read 1s Section            | x          | x      | x       | x           | —      | —       |
| 0x02 | Program Check              | x          | x      | x       | x           | —      | —       |
| 0x03 | Read Resource              | x          | x      | x       | x           | —      | —       |
| 0x07 | Program Phrase             | x          | x      | x       | x           | —      | —       |
| 0x09 | Erase Flash Sector         | x          | x      | x       | x           | —      | —       |
| 0x0B | Program Section            | x          | x      | x       | x           | —      | —       |
| 0x40 | Read 1s All Blocks         | x          | x      | x       | x           | x      | —       |
| 0x41 | Read Once                  | x          | x      | x       | x           | —      | —       |
| 0x43 | Program Once               | x          | x      | x       | x           | —      | —       |
| 0x44 | Erase All Blocks           | x          | x      | x       | x           | x      | —       |
| 0x45 | Verify Backdoor Access Key | x          | x      | x       | x           | —      | —       |
| 0x49 | Erase All Blocks Unsecure  | x          | x      | —       | x           | x      | —       |

### 35.4.8 Margin Read Commands

The Read-1s commands (Read 1s All Blocks/Read 1s Section) and the Program Check command have a margin choice parameter that allows the user to apply non-standard read reference levels to the program flash array reads performed by these commands. Using the preset 'user' and 'factory' margin levels, these commands perform their associated read operations at tighter tolerances than a 'normal' read. These non-standard read levels are applied only during the command execution. All simple (uncommanded) flash array reads to the MCU always use the standard, un-margined, read reference level.

Only the 'normal' read level should be employed during normal flash usage. The non-standard, 'user' and 'factory' margin levels should be employed only in special cases. They can be used during special diagnostic routines to gain confidence that the device is not suffering from the end-of-life data loss customary of flash memory devices.

Erased ('1') and programmed ('0') bit states can degrade due to elapsed time and data cycling (number of times a bit is erased and re-programmed). The lifetime of the erased states is relative to the last erase operation. The lifetime of the programmed states is measured from the last program time.

The 'user' and 'factory' levels become, in effect, a minimum safety margin; i.e. if the reads pass at the tighter tolerances of the 'user' and 'factory' margins, then the 'normal' reads have at least this much safety margin before they experience data loss.

The 'user' margin is a small delta to the normal read reference level. 'User' margin levels can be employed to check that flash memory contents have adequate margin for normal level read operations. If unexpected read results are encountered when checking flash memory contents at the 'user' margin levels, loss of information might soon occur during 'normal' readout.

The 'factory' margin is a bigger deviation from the norm, a more stringent read criteria that should only be attempted immediately (or very soon) after completion of an erase or program command, early in the cycling life. 'Factory' margin levels can be used to check that flash memory contents have adequate margin for long-term data retention at the normal level setting. If unexpected results are encountered when checking flash memory contents at 'factory' margin levels, the flash memory contents should be erased and reprogrammed.

### CAUTION

Factory margin levels must only be used during verify of the initial factory programming.

## 35.4.9 Flash command descriptions

This section describes all flash commands that can be launched by a command write sequence. The FTFE sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in a FCCOB field for the specific commands. Refer to the error handling table provided for each command.

Ensure that the ACCERR and FPVIOL bits in the FSTAT register are cleared prior to starting the command write sequence. As described in [Launch the Command by Clearing CCIF](#), a new command cannot be launched while these error flags are set.

Do not attempt to read a flash block while the FTFE is running a command (CCIF = 0) on that same block. The FTFE may return invalid data to the MCU with the collision error flag (FSTAT[RDCOLERR]) set.

### CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

### 35.4.9.1 Read 1s Section command

The Read 1s Section command checks if a section of program flash memory is erased to the specified read margin level. The Read 1s Section command defines the starting address and the number of quad-phrases to be verified.

**Table 35-3. Read 1s Section Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                                                     |
|--------------|--------------------------------------------------------------------------|
| 0            | 0x01 (RD1SEC)                                                            |
| 1            | Flash address [23:16] of the first quad-phrase to be verified            |
| 2            | Flash address [15:8] of the first quad-phrase to be verified             |
| 3            | Flash address [7:0] <sup>1</sup> of the first quad-phrase to be verified |
| 4            | Number of quad-phrases to be verified [15:8]                             |
| 5            | Number of quad-phrases to be verified [7:0]                              |
| 6            | Read-1 Margin Choice                                                     |

1. Must be 256-bit aligned (Flash address [4:0] = 00000).

Upon clearing CCIF to launch the Read 1s Section command, the FTFE sets the read margin for 1s according to [Table 35-4](#) and then reads all locations within the specified section of flash memory.

If the FTFE fails to read all 1s (i.e. the flash section is not erased), the FSTAT(MGSTAT0) bit is set. The CCIF flag sets after the Read 1s Section operation completes.

**Table 35-4. Margin Level Choices for Read 1s Section**

| Read Margin Choice | Margin Level Description                              |
|--------------------|-------------------------------------------------------|
| 0x00               | Use the 'normal' read level for 1s                    |
| 0x01               | Apply the 'User' margin to the normal read-1 level    |
| 0x02               | Apply the 'Factory' margin to the normal read-1 level |

**Table 35-5. Read 1s Section Command Error Handling**

| Error Condition                                      | Error Bit      |
|------------------------------------------------------|----------------|
| Command not available in current mode/security       | FSTAT[ACCERR]  |
| An invalid margin code is supplied                   | FSTAT[ACCERR]  |
| An invalid flash address is supplied                 | FSTAT[ACCERR]  |
| Flash address is not 256-bit aligned                 | FSTAT[ACCERR]  |
| The requested section crosses a flash block boundary | FSTAT[ACCERR]  |
| The requested number of quad-phrases is zero         | FSTAT[ACCERR]  |
| Read-1s fails                                        | FSTAT[MGSTAT0] |

### 35.4.9.2 Program Check command

The Program Check command tests a previously programmed program flash longword to see if it reads correctly at the specified margin level.

**Table 35-6. Program Check Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]             |
|--------------|----------------------------------|
| 0            | 0x02 (PGMCHK)                    |
| 1            | Flash address [23:16]            |
| 2            | Flash address [15:8]             |
| 3            | Flash address [7:0] <sup>1</sup> |
| 4            | Margin Choice                    |
| 8            | Byte 0 expected data             |
| 9            | Byte 1 expected data             |
| A            | Byte 2 expected data             |
| B            | Byte 3 expected data             |

1. Must be longword aligned (Flash address [1:0] = 00).

Upon clearing CCIF to launch the Program Check command, the FTFE sets the read margin for 1s based on the provided margin choice according to [Table 35-7](#). The Program Check operation then reads the specified longword, and compares the actual read data to the expected data provided by the FCCOB. If the comparison at margin-1 fails, the MGSTAT0 bit is set.

The FTFE will then set the read margin for 0s based on the provided margin choice. The Program Check operation will then read the specified longword and compare the actual read data to the expected data provided by the FCCOB. If the comparison at margin-0 fails, the MGSTAT0 bit will be set. The CCIF flag will set after the Program Check operation has completed.

The starting address must be longword aligned (the lowest two bits of the byte address must be 00):

- Byte 0 data is expected at the supplied 32-bit aligned address,
- Byte 1 data is expected at byte address specified + 0b01,
- Byte 2 data is expected at byte address specified + 0b10, and
- Byte 3 data is expected at byte address specified + 0b11.

#### NOTE

See the description of margin reads, [Margin Read Commands](#)

**Table 35-7. Margin Level Choices for Program Check**

| Read Margin Choice | Margin Level Description                          |
|--------------------|---------------------------------------------------|
| 0x01               | Read at 'User' margin-1 and 'User' margin-0       |
| 0x02               | Read at 'Factory' margin-1 and 'Factory' margin-0 |

**Table 35-8. Program Check Command Error Handling**

| Error Condition                                             | Error Bit      |
|-------------------------------------------------------------|----------------|
| Command not available in current mode/security              | FSTAT[ACCERR]  |
| An invalid flash address is supplied                        | FSTAT[ACCERR]  |
| Flash address is not longword aligned                       | FSTAT[ACCERR]  |
| An invalid margin choice is supplied                        | FSTAT[ACCERR]  |
| Either of the margin reads does not match the expected data | FSTAT[MGSTAT0] |

### 35.4.9.3 Read Resource Command

The Read Resource command is provided for the user to read data from special-purpose memory resources located within the Flash module. The special-purpose memory resources available include program flash IFR space, and the Version ID field. The Version ID field contains an 8 byte code that indicates a specific FTFE implementation.

**Table 35-9. Read Resource Command FCCOB Requirements**

| FCCOB Number    | FCCOB contents [7:0]                                    |
|-----------------|---------------------------------------------------------|
| 0               | 0x03 (RDRSRC)                                           |
| 1               | Flash address [23:16]                                   |
| 2               | Flash address [15:8]                                    |
| 3               | Flash address [7:0] <sup>1</sup>                        |
| 4               | Resource select code (see <a href="#">Table 35-10</a> ) |
| Returned values |                                                         |
| 4               | Read Data [64:56]                                       |
| 5               | Read Data [55:48]                                       |
| 6               | Read Data [47:40]                                       |
| 7               | Read Data [39:32]                                       |
| 8               | Read Data [31:24]                                       |
| 9               | Read Data [23:16]                                       |
| A               | Read Data [15:8]                                        |
| B               | Read Data [7:0]                                         |

1. Must be 64-bit aligned (Flash address [2:0] = 000).

**Table 35-10. Read Resource Select Codes**

| Resource Select Code | Description         | Resource Size | Local Address Range   |
|----------------------|---------------------|---------------|-----------------------|
| 0x00                 | Program Flash 0 IFR | 1024 Bytes    | 0x00_0000 - 0x00_03FF |
| 0x01                 | Version ID          | 8 Bytes       | 0x00_0008 - 0x00_000F |

After clearing CCIF to launch the Read Resource command, eight consecutive bytes are read from the selected resource at the provided relative address and stored in the FCCOB register. The CCIF flag will set after the Read Resource operation has completed. The Read Resource command exits with an access error if an invalid resource code is provided or if the address for the applicable area is out-of-range.

**Table 35-11. Read Resource Command Error Handling**

| Error Condition                                          | Error Bit     |
|----------------------------------------------------------|---------------|
| Command not available in current mode/security           | FSTAT[ACCERR] |
| An invalid resource code is entered                      | FSTAT[ACCERR] |
| Flash address is out-of-range for the targeted resource. | FSTAT[ACCERR] |
| Flash address is not 64-bit aligned                      | FSTAT[ACCERR] |

#### 35.4.9.4 Program Phrase command

The Program Phrase command programs eight previously-erased bytes in the program flash memory using an embedded algorithm.

#### CAUTION

A Flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a Flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

**Table 35-12. Program Phrase Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]             |
|--------------|----------------------------------|
| 0            | 0x07 (PGM8)                      |
| 1            | Flash address [23:16]            |
| 2            | Flash address [15:8]             |
| 3            | Flash address [7:0] <sup>1</sup> |
| 4            | Byte 0 program value             |
| 5            | Byte 1 program value             |

*Table continues on the next page...*

**Table 35-12. Program Phrase Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB Contents [7:0] |
|--------------|----------------------|
| 6            | Byte 2 program value |
| 7            | Byte 3 program value |
| 8            | Byte 4 program value |
| 9            | Byte 5 program value |
| A            | Byte 6 program value |
| B            | Byte 7 program value |

1. Must be 64-bit aligned (Flash address [2:0] = 000)

Upon clearing CCIF to launch the Program Phrase command, the FTFE programs the data bytes into the flash using the supplied address. The protection status is always checked. The targeted flash locations must be currently unprotected (see the description of the FPROT registers) to permit execution of the Program Phrase operation.

The programming operation is unidirectional. It can only move NVM bits from the erased state ('1') to the programmed state ('0'). Erased bits that fail to program to the '0' state are flagged as errors in MGSTAT0. The CCIF flag is set after the Program Phrase operation completes.

The starting address must be 64-bit aligned (flash address [2:0] = 000):

- Byte 0 data is written to the starting address ('start'),
- Byte 1 data is programmed to byte address start+0b01,
- Byte 2 data is programmed to byte address start+0b10, and
- Byte 3 data is programmed to byte address start+0b11, etc.

**Table 35-13. Program Phrase Command Error Handling**

| Error Condition                                               | Error Bit      |
|---------------------------------------------------------------|----------------|
| Command not available in current mode/security                | FSTAT[ACCERR]  |
| An invalid flash address is supplied                          | FSTAT[ACCERR]  |
| Flash address is not 64-bit aligned                           | FSTAT[ACCERR]  |
| Flash address points to a protected area                      | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation. | FSTAT[MGSTAT0] |

### 35.4.9.5 Erase Flash Sector command

The Erase Flash Sector operation erases all addresses in a flash sector.

**Table 35-14. Erase Flash Sector Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                                              |
|--------------|-------------------------------------------------------------------|
| 0            | 0x09 (ERSSCR)                                                     |
| 1            | Flash address [23:16] in the flash sector to be erased            |
| 2            | Flash address [15:8] in the flash sector to be erased             |
| 3            | Flash address [7:0] <sup>1</sup> in the flash sector to be erased |

1. Must be 256-bit aligned (Flash address [4:0] = 00000).

After clearing CCIF to launch the Erase Flash Sector command, the FTFE erases the selected program flash sector and then verifies that it is erased. The Erase Flash Sector command aborts if the selected sector is protected (see the description of the FPROT registers). If the erase-verify fails the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase Flash Sector operation completes. The Erase Flash Sector command is suspendable (see the FCNFG[ERSSUSP] bit and [Figure 35-4](#)).

**Table 35-15. Erase Flash Sector Command Error Handling**

| Error Condition                                                           | Error Bit      |
|---------------------------------------------------------------------------|----------------|
| Command not available in current mode/security                            | FSTAT[ACCERR]  |
| An invalid Flash address is supplied                                      | FSTAT[ACCERR]  |
| Flash address is not 256-bit aligned                                      | FSTAT[ACCERR]  |
| The selected program flash sector is protected                            | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation <sup>1</sup> | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s Section command to verify all bits are erased.

### 35.4.9.5.1 Suspending an Erase Flash Sector Operation

To suspend an Erase Flash Sector operation set the FCNFG[ERSSUSP] bit when CCIF, ACCERR, and FPVIOL are clear and the CCOB command field holds the code for the Erase Flash Sector command. During the Erase Flash Sector operation (see [Erase Flash Sector command](#)), the flash samples the state of the ERSSUSP bit at convenient points. If the FTFE detects that the ERSSUSP bit is set, the Erase Flash Sector operation is suspended and the FTFE sets CCIF. While ERSSUSP is set, all writes to flash registers are ignored except for writes to the FSTAT and FCNFG registers.

If an Erase Flash Sector operation effectively completes before the FTFE detects that a suspend request has been made, the FTFE clears the ERSSUSP bit prior to setting CCIF. When an Erase Flash Sector operation has been successfully suspended, the FTFE sets CCIF and leaves the ERSSUSP bit set. While CCIF is set, the ERSSUSP bit can only be cleared to prevent the withdrawal of a suspend request before the FTFE has acknowledged it.

### 35.4.9.5.2 Resuming a Suspended Erase Flash Sector Operation

If the ERSSUSP bit is still set when CCIF is cleared to launch the next command, the previous Erase Flash Sector operation resumes. The FTFE acknowledges the request to resume a suspended operation by clearing the ERSSUSP bit. A new suspend request can then be made by setting ERSSUSP. A single Erase Flash Sector operation can be suspended and resumed multiple times.

There is a minimum elapsed time limit of 4.3 msec between the request to resume the Erase Flash Sector operation (CCIF is cleared) and the request to suspend the operation again (ERSSUSP is set). This minimum time period is required to ensure that the Erase Flash Sector operation will eventually complete. If the minimum period is continually violated, i.e. the suspend requests come repeatedly and too quickly, no forward progress is made by the Erase Flash Sector algorithm. The resume/suspend sequence runs indefinitely without completing the erase.

### 35.4.9.5.3 Aborting a Suspended Erase Flash Sector Operation

The user may choose to abort a suspended Erase Flash Sector operation by clearing the ERSSUSP bit prior to clearing CCIF for the next command launch. When a suspended operation is aborted, the FTFE starts the new command using the new FCCOB contents.

#### Note

Aborting the erase leaves the bitcells in an indeterminate, partially-erased state. Data in this sector is not reliable until a new erase command fully completes.

The following figure shows how to suspend and resume the Erase Flash Sector operation.

### 35.4.9.6 Program Section command

The Program Section operation programs the data found in the section program buffer to previously erased locations in the flash memory using an embedded algorithm. Data is preloaded into the section program buffer (see [Flash sector programming](#)).

The section program buffer is limited to the lower quarter of the programming acceleration RAM (relative byte addresses 0x0000-0x03FF - be sure to check your device specific memory map for the location of the programming acceleration RAM). Data written to the remainder of the programming acceleration RAM is ignored and may be overwritten during Program Section command execution.

#### CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash memory location is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

**Table 35-16. Program Section Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                     |
|--------------|------------------------------------------|
| 0            | 0x0B (PGMSEC)                            |
| 1            | Flash address [23:16]                    |
| 2            | Flash address [15:8]                     |
| 3            | Flash address [7:0] <sup>1</sup>         |
| 4            | Number of quad-phrases to program [15:8] |
| 5            | Number of quad-phrases to program [7:0]  |

1. Must be 256-bit aligned (Flash address [4:0] = 00000).

After clearing CCIF to launch the Program Section command, the FTFE will block access to the programming acceleration RAM and program the data residing in the Section Program Buffer into the flash memory starting at the flash address provided.

The starting address must be unprotected (see the description of the FPROT registers) to permit execution of the Program Section operation. Programming, which is not allowed to cross a flash sector boundary, continues until all requested quad-phrases have been programmed.

After the Program Section operation has completed, the CCIF flag will set. The contents of the Section Program Buffer are not changed by the Program Section operation.

**Table 35-17. Program Section Command Error Handling**

| Error Condition                                                                                                                               | Error Bit      |
|-----------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Command not available in current mode/security                                                                                                | FSTAT[ACCERR]  |
| An invalid flash address is supplied                                                                                                          | FSTAT[ACCERR]  |
| Flash address is not 256-bit aligned                                                                                                          | FSTAT[ACCERR]  |
| The requested section crosses a program flash sector boundary                                                                                 | FSTAT[ACCERR]  |
| The requested number of quad-words is zero                                                                                                    | FSTAT[ACCERR]  |
| The space required to store data for the requested number of quad-words is more than one quarter the size of the programming acceleration RAM | FSTAT[ACCERR]  |
| The flash address falls in a protected area                                                                                                   | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation                                                                                  | FSTAT[MGSTAT0] |

### 35.4.9.6.1 Flash sector programming

The process of programming an entire flash sector using the Program Section command is as follows:

1. Launch the Erase Flash Sector command to erase the flash sector to be programmed.
2. Beginning with the starting address of the programming acceleration RAM, sequentially write enough data to the RAM to fill an entire flash sector, or as much data is allowed due to RAM size versus flash sector size. This area of the RAM serves as the section program buffer. The section program buffer can be written to while the operation launched in step 1 is executing, i.e. while CCIF = 0.
3. Execute the Program Section command to program the contents of the section program buffer into the selected flash sector.
4. Repeat steps 2 through 3 to complete the entire flash sector, if necessary.
5. To program additional flash sectors, repeat steps 1 through 4.

### 35.4.9.7 Read 1s All Blocks Command

The Read 1s All Blocks command checks if the program flash blocks have been erased to the specified read margin level, if applicable, and releases security if the readout passes, i.e. all data reads as '1'.

**Table 35-18. Read 1s All Blocks Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|--------------|----------------------|
| 0            | 0x40 (RD1ALL)        |
| 1            | Read-1 Margin Choice |

After clearing CCIF to launch the Read 1s All Blocks command, the FTFE :

## Functional Description

- sets the read margin for 1s according to [Table 35-19](#),
- checks the contents of the program flash are in the erased state.

If the FTFE confirms that these memory resources are erased, security is released by setting the FSEC[SEC] field to the unsecure state. The security byte in the flash configuration field (see [Flash configuration field description](#)) remains unaffected by the Read 1s All Blocks command. If the read fails, i.e. all flash memory resources are not in the fully erased state, the FSTAT[MGSTAT0] bit is set.

The EEERDY and RAMRDY bits are clear during the Read 1s All Blocks operation and are restored at the end of the Read 1s All Blocks operation.

The CCIF flag sets after the Read 1s All Blocks operation has completed.

**Table 35-19. Margin Level Choices for Read 1s All Blocks**

| Read Margin Choice | Margin Level Description                              |
|--------------------|-------------------------------------------------------|
| 0x00               | Use the 'normal' read level for 1s                    |
| 0x01               | Apply the 'User' margin to the normal read-1 level    |
| 0x02               | Apply the 'Factory' margin to the normal read-1 level |

**Table 35-20. Read 1s All Blocks Command Error Handling**

| Error Condition                                | Error Bit      |
|------------------------------------------------|----------------|
| Command not available in current mode/security | FSTAT[ACCERR]  |
| An invalid margin choice is specified          | FSTAT[ACCERR]  |
| Read-1s fails                                  | FSTAT[MGSTAT0] |

### 35.4.9.8 Read Once Command

The Read Once command provides read access to a reserved 64-byte field located in the program flash 0 IFR (see [Program flash 0 IFR map](#) and [Program Once field](#)). Access to the Program Once field is via 8 records, each 8 bytes long. The Program Once field is programmed using the Program Once command described in [Program Once command](#).

**Table 35-21. Read Once Command FCCOB Requirements**

| FCCOB Number    | FCCOB Contents [7:0]                    |
|-----------------|-----------------------------------------|
| 0               | 0x41 (RDONCE)                           |
| 1               | Program Once record index (0x00 - 0x07) |
| Returned Values |                                         |
| 4               | Program Once byte 0 value               |
| 5               | Program Once byte 1 value               |

*Table continues on the next page...*

**Table 35-21. Read Once Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB Contents [7:0]      |
|--------------|---------------------------|
| 6            | Program Once byte 2 value |
| 7            | Program Once byte 3 value |
| 8            | Program Once byte 4 value |
| 9            | Program Once byte 5 value |
| A            | Program Once byte 6 value |
| B            | Program Once byte 7 value |

After clearing CCIF to launch the Read Once command, an 8-byte Program Once record is read from the program flash IFR and stored in the FCCOB register. The CCIF flag is set after the Read Once operation completes. Valid record index values for the Read Once command range from 0x00 to 0x07. During execution of the Read Once command, any attempt to read addresses within the program flash block containing this 64-byte field returns invalid data. The Read Once command can be executed any number of times.

**Table 35-22. Read Once Command Error Handling**

| Error Condition                                | Error Bit     |
|------------------------------------------------|---------------|
| Command not available in current mode/security | FSTAT[ACCERR] |
| An invalid record index is supplied            | FSTAT[ACCERR] |

### 35.4.9.9 Program Once command

The Program Once command enables programming to a reserved 64-byte field in the program flash 0 IFR (see [Program flash 0 IFR map](#) and [Program Once field](#)). Access to the Program Once field is via 8 records, each 8 bytes long. The Program Once field can be read using the Read Once command (see [Read Once Command](#)) or using the Read Resource command (see [Read Resource Command](#)). Each Program Once record can be programmed only once since the program flash 0 IFR cannot be erased.

**Table 35-23. Program Once Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0]                    |
|--------------|-----------------------------------------|
| 0            | 0x43 (PGMONCE)                          |
| 1            | Program Once record index (0x00 - 0x07) |
| 2            | Not Used                                |
| 3            | Not Used                                |
| 4            | Program Once Byte 0 value               |
| 5            | Program Once Byte 1 value               |

*Table continues on the next page...*

**Table 35-23. Program Once Command FCCOB Requirements (continued)**

| FCCOB Number | FCCOB Contents [7:0]      |
|--------------|---------------------------|
| 6            | Program Once Byte 2 value |
| 7            | Program Once Byte 3 value |
| 8            | Program Once Byte 4 value |
| 9            | Program Once Byte 5 value |
| A            | Program Once Byte 6 value |
| B            | Program Once Byte 7 value |

After clearing CCIF to launch the Program Once command, the FTFE first verifies that the selected record is erased. If erased, then the selected record is programmed using the values provided. The Program Once command also verifies that the programmed values read back correctly. The CCIF flag is set after the Program Once operation has completed.

The reserved program flash 0 IFR location accessed by the Program Once command cannot be erased and any attempt to program one of these records when the existing value is not Fs (erased) is not allowed. Valid record index values for the Program Once command range from 0x00 to 0x07. During execution of the Program Once command, any attempt to read addresses within program flash 0 returns invalid data.

**Table 35-24. Program Once Command Error Handling**

| Error Condition                                                                     | Error Bit      |
|-------------------------------------------------------------------------------------|----------------|
| Command not available in current mode/security                                      | FSTAT[ACCERR]  |
| An invalid record index is supplied                                                 | FSTAT[ACCERR]  |
| The requested record has already been programmed to a non-erased value <sup>1</sup> | FSTAT[ACCERR]  |
| Any errors have been encountered during the verify operation.                       | FSTAT[MGSTAT0] |

1. If a Program Once record is initially programmed to 0xFFFF\_FFFF\_FFFF\_FFFF, the Program Once command is allowed to execute again on that same record.

### 35.4.9.10 Erase All Blocks Command

The Erase All Blocks operation erases all flash memory, verifies all memory contents, and releases MCU security.

**Table 35-25. Erase All Blocks Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|--------------|----------------------|
| 0            | 0x44 (ERSALL)        |

After clearing CCIF to launch the Erase All Blocks command, the FTFE erases all program flash memory, then verifies that all are erased.

If the FTFE verifies that all flash memories were properly erased, security is released by setting the FSEC[SEC] field to the unsecure state and the FCNFG[RAMRDY] bit is set. The Erase All Blocks command aborts if any flash region is protected. The security byte and all other contents of the flash configuration field (see [Flash configuration field description](#)) are erased by the Erase All Blocks command. If the erase-verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Blocks operation completes.

**Table 35-26. Erase All Blocks Command Error Handling**

| Error Condition                                                           | Error Bit      |
|---------------------------------------------------------------------------|----------------|
| Command not available in current mode/security                            | FSTAT[ACCERR]  |
| Any region of the program flash memory is protected                       | FSTAT[FPVIOL]  |
| Any errors have been encountered during the verify operation <sup>1</sup> | FSTAT[MGSTAT0] |

1. User margin read may be run using the Read 1s All Blocks command to verify all bits are erased.

#### 35.4.9.10.1 Triggering an erase all external to the flash module

The functionality of the Erase All Blocks/Erase All Blocks Unsecure command is also available in an uncommanded fashion outside of the flash memory. Refer to the device's Chip Configuration details for information on this functionality.

Before invoking the external erase all function, the FCCOB0 register must not contain 0x44. When invoked, the erase-all function erases all program flash memory regardless of the state of the FSTAT[ACCERR and FPVIOL] flags or the protection settings. If the post-erase verify passes, the routine releases security by setting the FSEC[SEC] field register to the unsecure state and the FCNFG[RAMRDY] bit sets. The security byte in the Flash Configuration Field is also programmed to the unsecure state. The status of the erase-all request is reflected in the FCNFG[ERSAREQ] bit. The FCNFG[ERSAREQ] bit is cleared once the operation completes and the normal FSTAT error reporting, except FPVIOL, is available as described in [Erase All Blocks Command/Erase All Blocks Unsecure Command](#).

#### 35.4.9.11 Verify Backdoor Access Key command

The Verify Backdoor Access Key command only executes if the mode and security conditions are satisfied (see [Flash commands by mode](#)). Execution of the Verify Backdoor Access Key command is further qualified by the FSEC[KEYEN] bits. The Verify Backdoor Access Key command releases security if user-supplied keys in the

FCCOB match those stored in the Backdoor Comparison Key bytes of the Flash Configuration Field. The column labeled Flash Configuration Field offset address shows the location of the matching byte in the Flash Configuration Field.

**Table 35-27. Verify Backdoor Access Key Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] | Flash Configuration Field Offset Address |
|--------------|----------------------|------------------------------------------|
| 0            | 0x45 (VFYKEY)        |                                          |
| 1-3          | Not Used             |                                          |
| 4            | Key Byte 0           | 0x0_0003                                 |
| 5            | Key Byte 1           | 0x0_0002                                 |
| 6            | Key Byte 2           | 0x0_0001                                 |
| 7            | Key Byte 3           | 0x0_0000                                 |
| 8            | Key Byte 4           | 0x0_0007                                 |
| 9            | Key Byte 5           | 0x0_0006                                 |
| A            | Key Byte 6           | 0x0_0005                                 |
| B            | Key Byte 7           | 0x0_0004                                 |

After clearing CCIF to launch the Verify Backdoor Access Key command, the FTFE checks the FSEC[KEYEN] bits to verify that this command is enabled. If not enabled, the FTFE sets the FSTAT[ACCERR] bit and terminates. If the command is enabled, the FTFE compares the key provided in FCCOB to the backdoor comparison key in the Flash Configuration Field. If the backdoor keys match, the FSEC[SEC] field is changed to the unsecure state and security is released. If the backdoor keys do not match, security is not released and all future attempts to execute the Verify Backdoor Access Key command are immediately aborted and the FSTAT[ACCERR] bit is (again) set to 1 until a reset of the FTFE module occurs. If the entire 8-byte key is all zeros or all ones, the Verify Backdoor Access Key command fails with an access error. The CCIF flag is set after the Verify Backdoor Access Key operation completes.

**Table 35-28. Verify Backdoor Access Key Command Error Handling**

| Error Condition                                                                              | Error Bit     |
|----------------------------------------------------------------------------------------------|---------------|
| Command not available in current mode/security                                               | FSTAT[ACCERR] |
| The supplied key is all-0s or all-Fs                                                         | FSTAT[ACCERR] |
| An incorrect backdoor key is supplied                                                        | FSTAT[ACCERR] |
| Backdoor key access has not been enabled (see the description of the FSEC register)          | FSTAT[ACCERR] |
| This command is launched and the backdoor key has mismatched since the last power down reset | FSTAT[ACCERR] |

### 35.4.9.12 Erase All Blocks Unsecure Command

The Erase All Blocks Unsecure operation erases all flash memory, verifies all memory contents, programs the security byte in the Flash Configuration Field to the unsecure state, and releases MCU security.

**Table 35-29. Erase All Blocks Unsecure Command FCCOB Requirements**

| FCCOB Number | FCCOB Contents [7:0] |
|--------------|----------------------|
| 0            | 0x49 (ERSALLU)       |

After clearing CCIF to launch the Erase All Blocks Unsecure command, the FTFE erases all program flash memory, then verifies that all are erased.

If the FTFE verifies that all flash memories were properly erased, security is released by setting the FSEC[SEC] field to the unsecure state, the security byte (see [Flash configuration field description](#)) is programmed to the unsecure state by the Erase All Blocks Unsecure command, and the FCNFG[RAMRDY] bit is set. If the erase or program verify fails, the FSTAT[MGSTAT0] bit is set. The CCIF flag is set after the Erase All Blocks Unsecure operation completes.

**Table 35-30. Erase All Blocks Unsecure Command Error Handling**

| Error Condition                                                            | Error Bit      |
|----------------------------------------------------------------------------|----------------|
| Command not available in current mode/security                             | FSTAT[ACCERR]  |
| Any errors have been encountered during erase or program verify operations | FSTAT[MGSTAT0] |

## 35.4.10 Security

The FTFE module provides security information to the MCU based on contents of the FSEC security register. The MCU then limits access to FTFE resources as defined in the device's Chip Configuration details. During reset, the FTFE module initializes the FSEC register using data read from the security byte of the Flash Configuration Field (see [Flash configuration field description](#)).

The following fields are available in the FSEC register. Details of the settings are described in the FSEC register description.

Flash security features are discussed further in [AN4507: Using the Kinetis Security and Flash Protection Features](#). Some features described in the application note may not be available on this device.

**Table 35-31. FSEC fields**

| FSEC field | Description                   |
|------------|-------------------------------|
| KEYEN      | Backdoor Key Access           |
| MEEN       | Mass Erase Capability         |
| FSLACC     | Factory Security Level Access |
| SEC        | MCU security                  |

### 35.4.10.1 FTFE Access by Mode and Security

The following table summarizes how access to the FTFE module is affected by security and operating mode.

**Table 35-32. FTFE Access Summary**

| Operating Mode | MCU Security State |                                                                                       |
|----------------|--------------------|---------------------------------------------------------------------------------------|
|                | Unsecure           | Secure                                                                                |
| NVM Normal     | Full command set   |                                                                                       |
| NVM Special    | Full command set   | Only the Erase All Blocks, Erase All Blocks Unsecure and Read 1s All Blocks commands. |

### 35.4.10.2 Changing the Security State

The security state out of reset can be permanently changed by programming the security byte of the flash configuration field. This assumes that you are starting from a mode where the necessary program flash erase and program commands are available and that the region of the program flash containing the flash configuration field is unprotected. If the flash security byte is successfully programmed, its new value takes effect after the next MCU reset.

#### 35.4.10.2.1 Unsecuring the MCU Using Backdoor Key Access

The MCU can be unsecured by using the backdoor key access feature which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see [Flash configuration field description](#)). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see [Verify Backdoor Access Key command](#)) can be run which allows the user to present prospective keys for comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the MCU. The entire 8-byte key cannot be all 0s or all 1s, i.e.

0x0000\_0000\_0000\_0000 and 0xFFFF\_FFFF\_FFFF\_FFFF are not accepted by the Verify Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Verify Backdoor Access Key command](#)
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the MCU is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field ([Flash configuration field description](#)). After the next reset of the MCU, the security state of the FTFE module reverts back to the Flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may erase the sector containing the Flash Configuration Field and reprogram the flash security byte to the unsecure state and change the backdoor keys to any desired value.

### 35.4.10.3 Unsecuring the MCU Using Backdoor Key Access

The MCU can be unsecured by using the backdoor key access feature which requires knowledge of the contents of the 8-byte backdoor key value stored in the Flash Configuration Field (see [Flash configuration field description](#)). If the FSEC[KEYEN] bits are in the enabled state, the Verify Backdoor Access Key command (see [Verify Backdoor Access Key command](#)) can be run which allows the user to present prospective keys for

comparison to the stored keys. If the keys match, the FSEC[SEC] bits are changed to unsecure the MCU. The entire 8-byte key cannot be all 0s or all 1s, i.e. 0x0000\_0000\_0000\_0000 and 0xFFFF\_FFFF\_FFFF\_FFFF are not accepted by the Verify Backdoor Access Key command as valid comparison values. While the Verify Backdoor Access Key command is active, program flash memory is not available for read access and returns invalid data.

The user code stored in the program flash memory must have a method of receiving the backdoor keys from an external stimulus. This external stimulus would typically be through one of the on-chip serial ports.

If the KEYEN bits are in the enabled state, the MCU can be unsecured by the backdoor key access sequence described below:

1. Follow the command sequence for the Verify Backdoor Access Key command as explained in [Verify Backdoor Access Key command](#)
2. If the Verify Backdoor Access Key command is successful, the MCU is unsecured and the FSEC[SEC] bits are forced to the unsecure state

An illegal key provided to the Verify Backdoor Access Key command prohibits future use of the Verify Backdoor Access Key command. A reset of the MCU is the only method to re-enable the Verify Backdoor Access Key command when a comparison fails.

After the backdoor keys have been correctly matched, the MCU is unsecured by changing the FSEC[SEC] bits. A successful execution of the Verify Backdoor Access Key command changes the security in the FSEC register only. It does not alter the security byte or the keys stored in the Flash Configuration Field ([Flash configuration field description](#)). After the next reset of the MCU, the security state of the FTFE module reverts back to the Flash security byte in the Flash Configuration Field. The Verify Backdoor Access Key command sequence has no effect on the program and erase protections defined in the program flash protection registers.

If the backdoor keys successfully match, the unsecured MCU has full control of the contents of the Flash Configuration Field. The MCU may erase the sector containing the Flash Configuration Field and reprogram the flash security byte to the unsecure state and change the backdoor keys to any desired value.

## 35.5 Reset Sequence

On each system reset the FTFE module executes a sequence which establishes initial values for the flash block configuration parameters, FPROT, FOPT, and FSEC registers and the FCNFG[RAMRDY, EEERDY] bits.

CCIF is cleared throughout the reset sequence. The FTFE module holds off all CPU access for a portion of the reset sequence. Flash reads are possible when the hold is removed. Completion of the reset sequence is marked by setting CCIF which enables flash user commands.

If a reset occurs while any FTFE command is in progress, that command is immediately aborted. The state of the word being programmed or the sector/block being erased is not guaranteed. Commands and operations do not automatically resume after exiting reset.

## Chapter 36

# External Bus Interface (FlexBus)

### 36.1 Chip-specific Flexbus information

#### 36.1.1 FlexBus clocking

The system provides a dedicated clock source to the FlexBus module's external CLKOUT. Its clock frequency is derived from a divider of the MCGOUTCLK. See [Clock Distribution](#) for more details.

#### 36.1.2 FlexBus signal multiplexing

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals are controlled by the port control and FlexBus modules. The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals are available from the modules. The control signals are grouped as illustrated:

Figure 36-1. FlexBus control signal multiplexing

Therefore, use the CSPMCR and port control registers to configure which control signal is available on the external pin. All control signals, except for  $\overline{\text{FB\_TA}}$ , are assigned to the ALT8 function in the port control module. Since, unlike the other control signals,  $\overline{\text{FB\_TA}}$  is an input signal, it is assigned to the ALT9 function.

### 36.1.3 FlexBus CSCR0 reset value

On this device the CSCR0 resets to 0x003F\_FC00. Configure this register as needed before performing any FlexBus access.

### 36.1.4 FlexBus Security

When security is enabled on the device, FlexBus accesses may be restricted by configuring SIM\_SOPT2[FBSL]. See [System Integration Module \(SIM\)](#) for details.

### 36.1.5 FlexBus line transfers

Line transfers are not possible from the ARM Cortex-M7 core. Ignore any references to line transfers in the FlexBus chapter.

## 36.2 Introduction

This chapter describes external bus data transfer operations and error conditions. It describes transfers initiated by the core processor (or any other bus master) and includes detailed timing diagrams showing the interaction of signals in supported bus operations.

### 36.2.1 Definition

The FlexBus multifunction external bus interface controller is a hardware module that:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Can be directly connected to the following asynchronous or synchronous slave-only devices with little or no additional circuitry:

- External ROMs
- Flash memories
- Programmable logic devices
- Other simple target (slave) devices

### 36.2.2 Features

FlexBus offers the following features:

- Six independent, user-programmable chip-select signals ( $\overline{\text{FB\_CS5}}$  –  $\overline{\text{FB\_CS0}}$ )
- 8-bit, 16-bit, and 32-bit transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with respect to the assertion of a chip-select
- Programmable address-hold time with respect to the deassertion of a chip-select and transfer direction
- Extended address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

## 36.3 Signal descriptions

This table describes the external signals involved in data-transfer operations.

### NOTE

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

**Table 36-1. FlexBus signal descriptions**

| Signal           | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FB_AD31 - FB_AD0 | I/O | <p>This is the address and data bus, FB_AD.</p> <p>The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select.</p> <p>The full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0.</p> |

*Table continues on the next page...*

Table 36-1. FlexBus signal descriptions (continued)

| Signal                                                | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| FB_CS5–FB_CS0                                         | O   | General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| FB_BE_31_24<br>FB_BE_23_16<br>FB_BE_15_8<br>FB_BE_7_0 | O   | Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only.<br><br>For external SRAM or flash devices, the $\overline{\text{FB\_BE}}$ outputs should be connected to individual byte strobe signals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| FB_OE                                                 | O   | Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FB_R/W                                                | O   | Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W high) or a write operation (FB_R/W low).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FB_TS                                                 | O   | Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid.<br><br>An inverted $\overline{\text{FB\_TS}}$ is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus.<br><br>$\overline{\text{FB\_TS}}$ /FB_ALE is asserted for one bus clock cycle.<br><br>The chip can extend this signal until the first positive clock edge after $\overline{\text{FB\_CS}}$ asserts. See CSCR[EXTS] and <a href="#">Extended Transfer Start/Address Latch Enable</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| FB_ALE                                                | O   | Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| FB_TBST                                               | O   | Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size.<br><br><b>Note:</b> When a burst transfer is in progress ( $\overline{\text{FB\_TBST}} = 0\text{b}$ ), the transfer size is 16 bytes ( $\overline{\text{FB\_TSIZ1}}\text{--}\overline{\text{FB\_TSIZ0}} = 11\text{b}$ ), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FB_TA                                                 | I   | Transfer Acknowledge—Indicates that the external data transfer is complete. When $\overline{\text{FB\_TA}}$ is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When $\overline{\text{FB\_TA}}$ is asserted during a write transfer, the transfer is terminated.<br><br>If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives $\overline{\text{FB\_TA}}$ to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), $\overline{\text{FB\_TA}}$ is generated internally after a specified number of wait states, or the external memory or peripheral may assert external $\overline{\text{FB\_TA}}$ before the wait-state countdown to terminate the transfer early. The chip deasserts $\overline{\text{FB\_CS}}$ one cycle after the last $\overline{\text{FB\_TA}}$ is asserted. During read transfers, the external memory or peripheral must continue to drive data until $\overline{\text{FB\_TA}}$ is recognized. For write transfers, the chip continues driving data one clock cycle after $\overline{\text{FB\_CS}}$ is deasserted.<br><br>The number of wait states is determined by CSCR or the external $\overline{\text{FB\_TA}}$ input. If the external $\overline{\text{FB\_TA}}$ is used, the external memory or peripheral has complete control of the number of wait states.<br><br><b>Note:</b> External memory or peripherals should assert $\overline{\text{FB\_TA}}$ only while the FB_CS signal to the external memory or peripheral is asserted. |

**Table 36-1. FlexBus signal descriptions (continued)**

| Signal | I/O | Function                                                                                                                                                                                             |
|--------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        |     | The CSPMCR register controls muxing of FB_TA with other signals. When the CSPMCR register does not allow fb_ta control, auto-acknowledge must be used (CSCR[AA] = 1'b1); otherwise the bus may hang. |
| FB_CLK | O   | FlexBus Clock Output                                                                                                                                                                                 |

## 36.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

### Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations.

### FB memory map

| Absolute address (hex) | Register name                           | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|-----------------------------------------|-----------------|--------|-------------|----------------------------|

| 0<br>V           | <p>Valid</p> <p>Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0, which acts as the global chip-select).</p> <p><b>NOTE:</b> At reset, <math>\overline{\text{FB\_CS0}}</math> will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.</p> <p>0 Chip-select is invalid.<br/> 1 Chip-select is valid.</p> |

### 36.4.3 Chip Select Control Register (FB\_CSCR<sub>n</sub>)

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

#### NOTE

To support the global chip-select ( $\overline{\text{FB\_CS0}}$ ), the CSCR0 reset values differ from the other CSCRs. The reset value of CSCR0 is as follows:

- Bits 31–24 are 0b
- Bit 23–3 are chip-dependent
- Bits 3–0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

Address: 4000\_C000h base + 8h offset + (12d × i), where i=0d to 5d

**FB\_CSCR<sub>n</sub> field descriptions (continued)**

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>Specifies if data on FB_AD appears left-aligned or right-aligned during the data phase of a FlexBus access.</p> <p>0 Not shifted. Data is left-aligned on FB_AD.<br/>1 Shifted. Data is right-aligned on FB_AD.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8<br>AA   | <p>Auto-Acknowledge Enable</p> <p>Asserts the internal transfer acknowledge for accesses specified by the chip-select address.</p> <p><b>NOTE:</b> If AA is 1b for a corresponding FB_CS<sub>n</sub> and the external system asserts an external <math>\overline{\text{FB\_TA}}</math> before the wait-state countdown asserts the internal FB_TA, the cycle is terminated. Burst cycles increment the address bus between each internal termination.</p> <p><b>NOTE:</b> This field must be 1b if CSPMCR disables FB_TA.</p> <p>0 Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally.<br/>1 Enabled. Internal transfer acknowledge is asserted as specified by WS.</p> |
| 7–6<br>PS | <p>Port Size</p> <p>Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles.</p> <p>00 32-bit port size. Valid data is sampled and driven on FB_D[31:0].<br/>01 8-bit port size. Valid data is sampled and driven on FB_D[31:24] when BLS is 0b, or FB_D[7:0] when BLS is 1b.<br/>1X 16-bit port size. Valid data is sampled and driven on FB_D[31:16] when BLS is 0b, or FB_D[15:0] when BLS is 1b.</p>                                                                                                                                                                                                 |
| 5<br>BEM  | <p>Byte-Enable Mode</p> <p>Specifies whether the corresponding <math>\overline{\text{FB\_BE}}</math> is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs.</p> <p>0 <math>\overline{\text{FB\_BE}}</math> is asserted for data write only.<br/>1 <math>\overline{\text{FB\_BE}}</math> is asserted for data read and write accesses.</p>                                                                                                                                                                                           |
| 4<br>BSTR | <p>Burst-Read Enable</p> <p>Specifies whether burst reads are enabled for memory associated with each chip select.</p> <p>0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads.<br/>1 Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports.</p>                                                                                                                                                                                |
| 3<br>BSTW | <p>Burst-Write Enable</p> <p>Specifies whether burst writes are enabled for memory associated with each chip select.</p> <p>0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes.<br/>1 Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.</p>                                                                                                                                                                                       |
| Reserved  | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 36.4.4 Chip Select port Multiplexing Control Register (FB\_CSPMCR)

Controls the multiplexing of the FlexBus signals.

#### NOTE

A bus error occurs when you do any of the following:

- Write to a reserved address
- Write to a reserved field in this register, or
- Access this register using a size other than 32 bits.

Address: 4000\_C000h base + 60h offset = 4000\_C060h

## 36.5 Functional description

### 36.5.1 Use cases

In general, FlexBus supports the following use cases, but note that your device may not support all of these use cases, because of limitations imposed by your specific package's pinouts:

- Multiplexed 32-bit address and 32-bit data
- Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)
- Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)
- Non-multiplexed 32-bit address and 32-bit data busses

#### NOTE

All use cases require signals to actually be available on the pins of your specific device package. Refer to your specific device's signal multiplexing table to verify the availability of specific signals for your device package.

## 36.5.2 Address comparison

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

| When the transfer address                            | Then FlexBus                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Matches one address register configuration           | Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR.<br><br>If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle. |
| Does not match an address register configuration     | Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.                                                                                                                                                                                   |
| Matches more than one address register configuration | Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.                                                                                                                                                                                   |

## 36.5.3 Address driven on address bus

FlexBus always drives a 32-bit address on the FB\_AD bus regardless of the external memory's or peripheral's address size.

## 36.5.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
  - FB\_AD from FB\_AD0 upward
- Data lines
  - If CSCR[BLS] = 0, FB\_AD from FB\_AD31 downward
  - If CSCR[BLS] = 1, FB\_AD from FB\_AD0 upward

## 36.5.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB\_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB\_AD16–FB\_AD1 and data15–data0 to FB\_AD31–FB\_AD16. See [Data-byte alignment and physical connections](#) for a graphical connection.

### 36.5.6 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB\_AD31–FB\_AD0 )
- Control signals ( $\overline{\text{FB\_TS}}/\overline{\text{FB\_ALE}}$ ,  $\overline{\text{FB\_TA}}$ ,  $\overline{\text{FB\_CS}}_n$ ,  $\overline{\text{FB\_OE}}$ ,  $\text{FB\_R}/\overline{\text{W}}$ ,  $\overline{\text{FB\_BE}}_n$ )
- Attribute signals ( $\overline{\text{FB\_TBST}}$  )

### 36.5.7 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB\_CLK):

- Address
- Write data
- $\overline{\text{FB\_TS}}/\overline{\text{FB\_ALE}}$
- $\overline{\text{FB\_CS}}_n$
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

### 36.5.8 Data-byte alignment and physical connections

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane FB\_AD31–FB\_AD24 ( $\overline{\text{FB\_BE}}_{31\_24}$ ). A 32-bit transfer through this 8-bit port takes four transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each four-byte lane.

**Figure 36-2. Connections for external memory port sizes (CSCRn[BLS] = 0)**

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

**Figure 36-3. Connections for external memory port sizes (CSCRn[BLS] = 1)**

### 36.5.9 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB\_AD31–FB\_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB\_AD31–FB\_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB\_AD31–FB\_AD0 lines not used for data.

#### 36.5.9.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

| Port size and phase |               | FB_AD   |         |         |     |
|---------------------|---------------|---------|---------|---------|-----|
|                     |               | 31–24   | 23–16   | 15–8    | 7–0 |
| 32-bit              | Address phase | Address |         |         |     |
|                     | Data phase    | Data    |         |         |     |
| 16-bit              | Address phase | Address |         |         |     |
|                     | Data phase    | Data    |         | Address |     |
| 8-bit               | Address phase | Address |         |         |     |
|                     | Data phase    | Data    | Address |         |     |

#### 36.5.9.2 FlexBus multiplexed operating modes for CSCRn[BLS]=1

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 1b.

| Port size and phase |               | FB_AD   |       |      |      |
|---------------------|---------------|---------|-------|------|------|
|                     |               | 31–24   | 23–16 | 15–8 | 7–0  |
| 32-bit              | Address phase | Address |       |      |      |
|                     | Data phase    | Data    |       |      |      |
| 16-bit              | Address phase | Address |       |      |      |
|                     | Data phase    | Address |       | Data |      |
| 8-bit               | Address phase | Address |       |      |      |
|                     | Data phase    | Address |       |      | Data |

### 36.5.10 Data transfer states

Basic data transfers occur in four clocks or states. (See [Figure 36-5](#) and [Figure 36-7](#) for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.

The states are described in this table.

| State | Cycle | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S0    | All   | The read or write cycle is initiated. On the rising clock edge, FlexBus: <ul style="list-style-type: none"> <li>Places a valid address on FB_ADn</li> <li>Asserts <math>\overline{\text{FB\_TS}}/\text{FB\_ALE}</math></li> <li>Drives FB_R/<math>\overline{\text{W}}</math> high for a read and low for a write</li> </ul>                                                                                                                                                                                                                                                                           |
| S1    | All   | FlexBus: <ul style="list-style-type: none"> <li>Negates <math>\overline{\text{FB\_TS}}/\text{FB\_ALE}</math> on the rising edge of FB_CLK</li> <li>Asserts FB_CS<sub>n</sub></li> <li>Drives the data on FB_AD31–FB_ADX for writes</li> <li>Tristates FB_AD31–FB_ADX for reads</li> <li>Continues to drive the address on FB_AD pins that are unused for data</li> </ul> <p>If the external memory or peripheral asserts <math>\overline{\text{FB\_TA}}</math>, then the process moves to S2. If <math>\overline{\text{FB\_TA}}</math> is not asserted internally or externally, then S1 repeats.</p> |
|       | Read  | The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with $\overline{\text{FB\_TA}}$ asserted.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| S2    | All   | For internal termination, FlexBus negates $\overline{\text{FB\_CS}}_n$ and the transfer is complete. For external termination, the external memory or peripheral negates $\overline{\text{FB\_TA}}$ , and FlexBus negates $\overline{\text{FB\_CS}}_n$ after the rising edge of FB_CLK at the end of S2.                                                                                                                                                                                                                                                                                              |
|       | Read  | FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge or continue to drive the data until the end of S3 or through any additional address hold cycles.                                                                                                                                                                                                                                                                                                                                                           |
| S3    | All   | FlexBus invalidates the address, data, and FB_R/ $\overline{\text{W}}$ on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 36.5.11 FlexBus Timing Examples

#### Note

The timing diagrams throughout this section use signal names that may not be included on your particular device. Ignore these extraneous signals.

#### Note

Throughout this section:

- FB\_D[X] indicates a 32-, 16-, or 8-bit wide data bus
- FB\_A[Y] indicates an address bus that can be 32, 24, or 16 bits wide.

#### 36.5.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device. The following figure shows a read cycle flowchart.

**Figure 36-4. Read Cycle Flowchart**

The read cycle timing diagram is shown in the following figure.

### Note

$\overline{\text{FB\_TA}}$  does not have to be driven by the external device for internally-terminated bus cycles.

### Note

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

**Figure 36-5. Basic Read-Bus Cycle**

### 36.5.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device. The following figure shows the write cycle flowchart.

**Figure 36-6. Write-Cycle Flowchart**

The following figure shows the write cycle timing diagram.

#### Note

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

Figure 36-7. Basic Write-Bus Cycle

### 36.5.11.3 Bus Cycle Sizing

This section shows timing diagrams for various port size scenarios.

#### 36.5.11.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The following figure illustrates the basic byte read transfer to an 8-bit device with no wait states:

- The address is driven on the full FB\_AD[31:0] bus in the first clock.

- The device tristates FB\_AD[31:24] on the second clock and continues to drive address on FB\_AD[23:0] throughout the bus cycle.
- The external device returns the read data on FB\_AD[31:24] and may tristate the data line or continue driving the data one clock after FB\_TA is sampled asserted.

**Figure 36-8. Single Byte-Read Transfer**

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB\_AD[31:24].

**Figure 36-9. Single Byte-Write Transfer**

### 36.5.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The following figure illustrates the basic word read transfer to a 16-bit device with no wait states.

- The address is driven on the full FB\_AD[31:8] bus in the first clock.
- The device tristates FB\_AD[31:16] on the second clock and continues to drive address on FB\_AD[15:0] throughout the bus cycle.
- The external device returns the read data on FB\_AD[31:16] and may tristate the data line or continue driving the data one clock after FB\_TA is sampled asserted.

**Figure 36-10. Single Word-Read Transfer**

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB\_AD[31:16].

### Figure 36-11. Single Word-Write Transfer

### 36.5.11.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The following figure depicts a longword read from a 32-bit device.

**Figure 36-12. Longword-Read Transfer**

The following figure illustrates the longword write to a 32-bit device.

Figure 36-13. Longword-Write Transfer

### 36.5.11.4 Timing Variations

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

#### 36.5.11.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the  $CSCR_n$  registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in [Figure 36-5](#) and [Figure 36-10](#)) with the default of no wait states respectively.

**Figure 36-14. Basic Read-Bus Cycle (No Wait States)**

**Figure 36-15. Basic Write-Bus Cycle (No Wait States)**

If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external  $\overline{\text{FB\_TA}}$  is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.

Figure 36-16. Read-Bus Cycle (One Wait State)

**Figure 36-17. Write-Bus Cycle (One Wait State)**

#### 36.5.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable ( $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$ ) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

**Figure 36-18. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)**

**Figure 36-19. Write-Bus Cycle with Two Clock Address Setup (No Wait States)**

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

**Figure 36-20. Read Cycle with Two-Clock Address Hold (No Wait States)**

**Figure 36-21. Write Cycle with Two-Clock Address Hold (No Wait States)**

The following figure shows a bus cycle using address setup, wait states, and address hold.

**Figure 36-22. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)**

## 36.5.12 Burst cycles

The chip can be programmed to initiate burst cycles if its transfer size exceeds the port size of the selected destination.

### 36.5.12.1 Enabling and inhibiting burst

The CSCRn registers enable bursting for reads, writes, or both.

Memory spaces can be declared burst-inhibited for reads and writes by writing 0b to the appropriate CSCRn[BSTR] and CSCRn[BSTW] fields.

### 36.5.12.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

| Port size PS[1:0] | Transfer size | Burst-inhibited: Number of transfers |
|-------------------|---------------|--------------------------------------|
|                   |               | Burst enabled: Number of beats       |
| 01b (8 bit)       | 16 bits       | 2                                    |
|                   | 32 bits       | 4                                    |
| 1Xb (16 bit)      | 32 bits       | 2                                    |
| 00b (32 bit)      | line          | 4                                    |

The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

### 36.5.12.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB\_AD[31:24].

#### Note

- In **non-multiplexed address/data mode**: the address on FB\_A increments only during internally-terminated burst cycles. The first address is driven throughout the entire burst for externally-terminated cycles.
- In **multiplexed address/data mode**: the address is driven on FB\_AD only during the first cycle for all terminated cycles. In other words, the lower address lines only increment during internally-terminated burst cycles (assuming that the lower address lines are being driven with the address during the data phase).

## 32-bit Read Burst from 8-bit port 2-1-1-1, with no Wait states

Figure 36-23. 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

## 36.5.12.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB\_AD[31:24].

**Note**

The first beat of any write burst cycle has at least one wait state. If the bus cycle is programmed for zero wait states (CSCR<sub>n</sub>[WS] = 0b), one wait state is added. Otherwise, the programmed number of wait states are used.

**Figure 36-24. 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)**

### 36.5.12.5 32-bit-read burst-inhibited from 8-bit port (no wait states)

The following figure shows a 32-bit read from an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

#### Note

There is an extra clock of address setup (AS) for each burst-inhibited transfer between states S0 and S1.

32-bit-read burst-inhibited to 8-bit port (no wait states)

### 36.5.12.6 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers.

**Figure 36-25. 32-bit-write burst-inhibited to 8-bit port (no wait states)**

### 36.5.12.7 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

#### Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSEN] = 1b) determines the number of wait states.

## 32-bit Read Burst from 8-bit port 3-2-2-2, with 1 wait state

Figure 36-26. 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

## 36.5.12.8 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.

**Figure 36-27. 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)**

### 36.5.12.9 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

#### Note

In non-multiplexed address/data mode, the address on FB\_A increments only during internally-terminated burst cycles (CSCRN[AA] = 1b). The attached device must be able to

account for this, or a wait state must be added. The first address is driven throughout the entire burst for externally-terminated cycles.

In multiplexed address/data mode, the address is driven on FB\_AD only during the first cycle for internally- and externally-terminated cycles.

32-bit Read Burst from 8-bit port 3-1-1-1, with Address Setup and Hold

Figure 36-28. 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

### 36.5.12.10 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.

**Figure 36-29. 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)**

### 36.5.13 Extended Transfer Start/Address Latch Enable

The  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal asserts for a single bus clock cycle. When  $\text{CSCR}_n[\text{EXTS}]$  is set, the  $\overline{\text{FB\_TS}}$ / $\overline{\text{FB\_ALE}}$  signal asserts and remain asserted until the first positive clock edge after  $\overline{\text{FB\_CS}}_n$  asserts. See the following figure.

#### NOTE

When EXTS is set,  $\text{CSCR}_n[\text{WS}]$  must be programmed to have at least one primary wait state.

**Figure 36-30. Read-Bus Cycle with CSCRn[EXTS] = 1 (One Wait State)**

### 36.5.14 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, then the transfer can be terminated by asserting  $\overline{\text{FB\_TA}}$ . If the processor must manage a bus error differently, then asserting an interrupt to the core along with  $\overline{\text{FB\_TA}}$  when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for  $\overline{\text{FB\_TA}}$ .

## **36.6 Initialization/Application Information**

### **36.6.1 Initializing a chip-select**

Before using any other chip select to take it out of global chip select mode, you must initialize CS0.

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

### **36.6.2 Reconfiguring a chip-select**

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

# Chapter 37

## Cyclic Redundancy Check (CRC)

### 37.1 Introduction

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

#### 37.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option to transpose input data or output data (the CRC result) bitwise or byte-wise.  
This option is required for certain CRC standards. A byte-wise transpose operation is not possible when accessing the CRC data register via 8-bit accesses. In this case, the user's software must perform the byte-wise transpose function.
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

#### 37.1.2 Block diagram

The following is a block diagram of the CRC.

### Figure 37-1. Programmable cyclic redundancy check (CRC) block diagram

### 37.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

### 37.1.3.1 Run mode

This is the basic mode of operation.

### 37.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

## 37.2 Memory map and register descriptions

## CRC memory map

| Absolute address (hex) | Register name                       | Width (in bits) | Access | Reset value | Section/ page              |
|------------------------|-------------------------------------|-----------------|--------|-------------|----------------------------|
| 4003_2000              | CRC Data register (CRC_DATA)        | 32              | R/W    | FFFF_FFFFh  | <a href="#">37.2.1/825</a> |
| 4003_2004              | CRC Polynomial register (CRC_GPOLY) | 32              | R/W    | 0000_1021h  | <a href="#">37.2.2/826</a> |
| 4003_2008              | CRC Control register (CRC_CTRL)     | 32              | R/W    | 0000_0000h  | <a href="#">37.2.3/826</a> |

### 37.2.1 CRC Data register (CRC\_DATA)

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: 4003\_2000h base + 0h offset = 4003\_2000h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |    |   |   |   |   |   |   |   |

### 37.2.2 CRC Polynomial register (CRC\_GPOLY)

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

### 37.2.3 CRC Control register (CRC\_CTRL)

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

## 37.3 Functional description

### 37.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC\_CTRL[WAS], CRC\_GPOLY, necessary parameters for transposition and CRC result inversion in the applicable registers. Asserting CRC\_CTRL[WAS] enables the programming of the seed value into the CRC\_DATA register.

After a completed CRC calculation, the module can be reinitialized for a new CRC computation by reasserting CRC\_CTRL[WAS] and programming a new, or previously used, seed value. All other parameters must be set before programming the seed value and subsequent data values.

### 37.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

#### 37.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CRC\_CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 16-bit polynomial to the CRC\_GPOLY[LOW] field. The CRC\_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
4. Set CRC\_CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to CRC\_DATA[LU:LL]. CRC\_DATA[HU:HL] are not used.
6. Clear CRC\_CTRL[WAS] to start writing data values.
7. Write data values into CRC\_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC\_DATA[LU:LL].
8. When all values have been written, read the final CRC result from CRC\_DATA[LU:LL].

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

### 37.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC\_CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in the CTRL register as required for the CRC calculation. See [Transpose feature](#) and [CRC result complement](#) for details.
3. Write a 32-bit polynomial to CRC\_GPOLY[HIGH:LOW].
4. Set CRC\_CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to CRC\_DATA[HU:HL:LU:LL].
6. Clear CRC\_CTRL[WAS] to start writing data values.
7. Write data values into CRC\_DATA[HU:HL:LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC\_DATA[HU:HL:LU:LL].
8. When all values have been written, read the final CRC result from CRC\_DATA[HU:HL:LU:LL]. The CRC is calculated byte-wise, and two clocks are required to complete one CRC calculation.

Transpose and complement operations are performed on the fly while reading or writing values. See [Transpose feature](#) and [CRC result complement](#) for details.

## 37.3.3 Transpose feature

By default, the transpose feature is not enabled. However, some CRC standards require the input data and/or the final checksum to be transposed. The user software has the option to configure each transpose operation separately, as desired by the CRC standard. The data is transposed on the fly while being read or written.

Some protocols use little endian format for the data stream to calculate a CRC. In this case, the transpose feature usefully flips the bits. This transpose option is one of the types supported by the CRC module.

### 37.3.3.1 Types of transpose

The CRC module provides several types of transpose functions to flip the bits and/or bytes, for both writing input data and reading the CRC result, separately using the CTRL[TOT] or CTRL[TOTR] fields, according to the CRC calculation being used.

The following types of transpose functions are available for writing to and reading from the CRC data register:

1. CTRL[TOT] or CTRL[TOTR] is 00.

No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 01

Bits in a byte are transposed, while bytes are not transposed.

reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}

**Figure 37-2. Transpose type 01**

3. CTRL[TOT] or CTRL[TOTR] is 10.

Both bits in bytes and bytes are transposed.

reg[31:0] becomes = {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}

**Figure 37-3. Transpose type 10**

4. CTRL[TOT] or CTRL[TOTR] is 11.

Bytes are transposed, but bits are not transposed.

reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}

Figure 37-4. Transpose type 11

**NOTE**

- For 8-bit and 16-bit write accesses to the CRC data register, the data is transposed with zeros on the unused byte or bytes (taking 32 bits as a whole), but the CRC is calculated on the valid byte(s) only.
- When reading the CRC data register for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in the CRC[**HU:HL**] fields. The user software must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

**37.3.4 CRC result complement**

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

## **Chapter 38**

# **Memory-Mapped Cryptographic Acceleration Unit (MMCAU)**

### **38.1 Introduction**

The memory-mapped Cryptographic Acceleration Unit (CAU) is a coprocessor that is connected to the processor's Private Peripheral Bus (PPB). It supports the hardware implementation of a set of specialized operations to improve the throughput of software-based security encryption/decryption operations and message digest functions.

The CAU supports acceleration of the DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms. NXP provides an optimized C-function library that provides the appropriate software building blocks to implement higher-level security functions.

### **38.2 CAU Block Diagram**

A simplified block diagram is given below that illustrates the CAU and a table to show its parts.

### Figure 38-1. CAU block diagram

### Table 38-1. CAU parts table

| Item                 | Description                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Translator submodule | Provides the bridge between the PPB interface and the CAU module. Passes memory-mapped commands and data on the PPB to/from the CAU |
| 4-entry FIFO         | Contains commands and input operands and the associated control captured from the PPB and sent to the CAU                           |
| CAU                  | 3-terminal block with a command and optional input operand and a result bus. More details in following figure.                      |

The following figure shows the CAU block in more detail.

**Figure 38-2. Top-level CAU block diagram**

### 38.3 Overview

As the name suggests, the CAU provides a mechanism for memory-mapped register reads and writes to be transformed into specific commands and operands sent to the CAU coprocessor.

The CAU translator module performs the following functions:

- All the required functions affecting the transmission of commands to the CAU module.
- If needed, stalling the PPB transactions based on the state of the 4-entry command/data FIFO.
- Some basic integrity checks on PPB operations.

The set of implemented algorithms provides excellent support for network security standards, such as SSL and IPsec. Additionally, using the CAU efficiently permits the implementation of any higher level functions or modes of operation, such as HMAC, CBC, and so on based on the supported algorithms.

The cryptographic algorithms are implemented partially in software with only functions critical to increasing performance implemented in hardware. The CAU allows for efficient, fine-grained partitioning of functions between hardware and software:

- Implement the innermost security kernel functions using the coprocessor instructions.
- Implement higher level functions in software by using the standard processor instructions.

This partitioning of functions is key to minimizing size of the CAU while maintaining a high level of throughput. Using software for some functions also simplifies the CAU design. The CAU implements a set of coprocessor commands that operate on a register file of 32-bit registers.

## 38.4 Features

The CAU includes the following distinctive features:

- Supports DES, 3DES, AES, MD5, SHA-1, and SHA-256 algorithms
- Simple, flexible programming model
- Ability to send up to three commands in one data write operation

## 38.5 Memory map/Register definition

The CAU contains multiple registers used by each of the supported algorithms. The following table shows registers that are applicable to each supported algorithm and indicates the corresponding letter designations for each algorithm.

For more information on these letter designations, see the supported algorithm specifications.

| Code | Register                         | DES | AES | MD5 | SHA-1 | SHA-256 |
|------|----------------------------------|-----|-----|-----|-------|---------|
| 0    | CAU Status Register (CASR)       | —   | —   | —   | —     | —       |
| 1    | CAU Accumulator (CAA)            | —   | —   | a   | T     | T       |
| 2    | General-Purpose Register 0 (CA0) | C   | W0  | —   | A     | A       |
| 3    | General-Purpose Register 1 (CA1) | D   | W1  | b   | B     | B       |

*Table continues on the next page...*

| Code | Register                         | DES | AES | MD5 | SHA-1 | SHA-256          |
|------|----------------------------------|-----|-----|-----|-------|------------------|
| 4    | General-Purpose Register 2 (CA2) | L   | W2  | c   | C     | C                |
| 5    | General-Purpose Register 3 (CA3) | R   | W3  | d   | D     | D                |
| 6    | General-Purpose Register 4 (CA4) | —   | —   | —   | E     | E                |
| 7    | General-Purpose Register 5 (CA5) | —   | —   | —   | W     | F                |
| 8    | General-Purpose Register 6 (CA6) | —   | —   | —   | —     | G                |
| 9    | General-Purpose Register 7 (CA7) | —   | —   | —   | —     | H                |
| 10   | General-Purpose Register 8 (CA8) | —   | —   | —   | —     | W/T <sub>1</sub> |

The CAU supports only 32-bit operations and register accesses. All registers support read, write, and ALU operations. However, only bits 1–0 of the CASR are writeable. Bits 31–2 of the CASR must be written as 0 for compatibility with future versions of the CAU.

The codes listed in this section are used in the memory-mapped commands. For more details on this, see [CAU programming model](#).

### NOTE

In the following table, the "address" or "offset" refers to the command code value for the CAU registers.

### CAU memory map

| Absolute address (hex) | Register name              | Width (in bits) | Access | Reset value | Section/page               |
|------------------------|----------------------------|-----------------|--------|-------------|----------------------------|
| E008_1000              | Status Register (CAU_CASR) | 32              | R/W    | 2000_0000h  | <a href="#">38.5.1/838</a> |
| E008_1001              | Accumulator (CAU_CAA)      | 32              | R/W    | 0000_0000h  | <a href="#">38.5.2/839</a> |

## 38.6 Functional description

This section discusses the programming model and operation of the CAU.

### 38.6.1 CAU programming model

The 4-entry FIFO is indirectly mapped into a 4-KB address space associated with the CAU located on this device. This address space is effectively split into two equal regions:

- one used to directly write commands for CAU load operations
- the other used to send commands and input operands for CAU loads

Data writes on the PPB are loaded into this FIFO and automatically converted into CAU load operands by the CAU translator. Data reads on the PPB are converted into CAU store register operations where the result is returned to the processor as the read data value.

The CAU requires a 15-bit command, and optionally, a 32-bit input operand, for each CAU load, PPB write. The 15-bit command includes the 9-bit opcode and other bits statically formed by the CAU translator logic controlling the CAU.

The following figure shows the 4-KB address space and the mapping of the CAU commands in this space.

#### NOTE

- Although the indirect store/load portion of the address space in the figure below shows only the indirect load/store commands, direct load commands can also be used in this space. However, it is more efficient to use the direct load portion of the address space.
- Accesses to the reserved space in the direct load space are terminated with an error, while accesses to the reserved space in the indirect load/store space are detected as an illegal CAU command. See [CAU integrity checks](#) for details.

Figure 38-3. CAU memory map

### 38.6.1.1 Direct loads

The CAU supports writing multiple commands in each 32-bit direct write operation. Each 9-bit opcode also includes a valid bit. Therefore, one, two, or three commands can be transmitted in a single 32-bit PPB write. The following figure illustrates the accepted formats for the 32-bit CAU write data value:

Figure 38-4. Direct loads

### 38.6.1.2 Indirect loads

For CAU load operations requiring a 32-bit input operand, the address contains the 9-bit opcode to be passed to the CAU while the data is the 32-bit operand. Specifically, the CAU address and data for these indirect writes is shown in the figure below.

Figure 38-5. Indirect loads

### 38.6.1.3 Indirect stores

For CAU store operations, a PPB read is performed with the appropriate CAU store register opcode embedded in the address. This appears as another indirect command. The detail of Indirect stores is shown in the figure below.

Figure 38-6. Indirect store

## 38.6.2 CAU integrity checks

If an illegal operation or access is attempted, the PPB bus cycle is terminated with an error response and the operation is aborted and not sent to the CAU.

The CAU performs a series of address and data integrity checks as described in the following sections. The results of these checks are logically summed together and, if appropriate, a PPB error termination is generated.

### 38.6.2.1 Address integrity checks

The CAU address checking includes the following. See [Figure 38-3](#) for the CAU memory map details.

- Any CAU reference using a non-0-modulo-4 byte address ( $\text{addr}[1:0] \neq 00$ ) generates an error termination.
- For CAU writes:
  - Only the first 64 bytes of the 2-KB direct write address space can be referenced. Attempting to access regions beyond the first 64 bytes terminates with an error.
  - The second 2-KB space defines the indirect address-as-command region and any reference in this space is allowed by the CAU.

### NOTE

The CAU contains error logic to detect any illegal command sent to it. Accordingly, there are address values in this upper 2-KB region of the address space that are passed to the CAU, and then detected as illegal commands. If the CAU detects an illegal command, it sets the CASR[IC] flag and performs no operation.

- For CAU reads:
  - Any attempted read from the first 2-KB region of the address space (an attempted direct read) is illegal and produces an error termination.
  - Within the second 2-KB region of the address space, i.e.,  $\text{addr}[11] = 1$ , only a 64-byte space is treated as a legal CAU store operation. The allowable addresses are defined as:

$\text{addr}[11:0] = 1000\_10xx\_xx\_00$

where the 4-bit xxxx value specifies the CAU register number. The CAU supports a subset of the allowable register numbers, 0x0 - 0xA. Attempting a store of a reserved register produces an undefined result.

### 38.6.2.2 Data integrity checks

Direct writes can send 1, 2, or 3 commands to the CAU in a single 32-bit transfer. As shown in [Figure 38-4](#), the commands include a valid bit located at bits 31, 20, and 9 of the write data where:

- Bit 31 is the valid bit for the first command
- Bit 20 is the valid bit for the second command
- Bit 9 is the valid bit for the third command

The direct write data check validates the combination of these three valid bits. The following table presents the three legal states associated with these bits:

## Functional description

| Value of bits 31, 20, and 9 | Number of commands included |
|-----------------------------|-----------------------------|
| 100                         | 1                           |
| 110                         | 2                           |
| 111                         | 3                           |

All other combinations of bits 31, 20, and 9 are illegal and generate an error termination.

### 38.6.3 CAU commands

The CAU supports the commands shown in the following table. All other encodings are reserved. The CASR[IC] bit is set if an undefined command is issued. A specific illegal command (ILL) is defined to allow software self-checking. Reserved commands must not be issued so as to ensure compatibility with future implementations.

The CMD field specifies the 9-bit CAU opcode for the operation command.

See [Assembler equate values](#) for a set of assembly constants used in the command descriptions here. If supported by the assembler, macros can also be created for each instruction. The value CAx should be interpreted as any CAU register (CASR, CAA, and CAn).

**Table 38-2. CAU commands**

| Type           | Command name | Description       | CMD   |   |   |   |     |   |   |   |   | Operation                                                |
|----------------|--------------|-------------------|-------|---|---|---|-----|---|---|---|---|----------------------------------------------------------|
|                |              |                   | 8     | 7 | 6 | 5 | 4   | 3 | 2 | 1 | 0 |                                                          |
| Direct load    | CNOP         | No Operation      | 0x000 |   |   |   |     |   |   |   |   | —                                                        |
| Indirect load  | LDR          | Load Reg          | 0x01  |   |   |   | CAx |   |   |   |   | Op1 → CAx                                                |

### 38.6.3.1 Coprocessor No Operation (CNOP)

The CNOP command is the coprocessor no-op. It is issued by the CAU and consumes a location in the CAU FIFO, but has no effect on any CAU register.

### 38.6.3.2 Load Register (LDR)

The LDR command loads CAx with the source data specified by the write data.

### 38.6.3.3 Store Register (STR)

The STR command returns the value of CAx specified in the read address to the destination specified as read data.

### 38.6.3.4 Add to Register (ADR)

The ADR command adds the source operand specified by the write data to CAx and stores the result in CAx.

### 38.6.3.5 Reverse and Add to Register (RADR)

The RADR command performs a byte reverse on the source operand specified by the write data, adds that value to CAx, and stores the result in CAx. The table below shows an example.

**Table 38-3. RADR command example**

| Operand     | CAx before  | CAx after   |
|-------------|-------------|-------------|
| 0x0102_0304 | 0xA0B0_C0D0 | 0xA4B3_C2D1 |

### 38.6.3.6 Add Register to Accumulator (ADRA)

The ADRA command adds CAx to CAA and stores the result in CAA.

### 38.6.3.7 Exclusive Or (XOR)

The XOR command performs an exclusive-or of the source operand specified by the write data with CAx and stores the result in CAx.

### 38.6.3.8 Rotate Left (ROTL)

ROTL rotates the CAx bits to the left with the result stored back to CAx. The number of bits to rotate is the value specified by the write data modulo 32.

### 38.6.3.9 Move Register to Accumulator (MVRA)

The MVRA command moves the value from the source register CAX to the destination register CAA.

### 38.6.3.10 Move Accumulator to Register (MVAR)

The MVAR command moves the value from source register CAA to the destination register CAX.

### 38.6.3.11 AES Substitution (AESS)

The AESS command performs the AES byte substitution operation on CAX and stores the result back to CAX.

### 38.6.3.12 AES Inverse Substitution (AESIS)

The AESIS command performs the AES inverse byte substitution operation on CAX and stores the result back to CAX.

### 38.6.3.13 AES Column Operation (AESC)

The AESC command performs the AES column operation on the contents of CAX. It then performs an exclusive-or of that result with the source operand specified by the write data and stores the result in CAX.

### 38.6.3.14 AES Inverse Column Operation (AESIC)

The AESIC command performs an exclusive-or operation of the source operand specified by the write data on the contents of CAX followed by the AES inverse mix column operation on that result and stores the result back in CAX.

### 38.6.3.15 AES Shift Rows (AESR)

The AESR command performs the AES shift rows operation on registers CA0, CA1, CA2, and CA3. The table below shows an example.

**Table 38-4. AESR command example**

| Register | Before      | After       |
|----------|-------------|-------------|
| CA0      | 0x0102_0304 | 0x0106_0B00 |
| CA1      | 0x0506_0708 | 0x050A_0F04 |
| CA2      | 0x090A_0B0C | 0x090E_0308 |
| CA3      | 0x0D0E_0F00 | 0x0D02_070C |

Where:

- row 1 = CA0[31:24], CA1[31:24], CA2[31:24], CA3[31:24]
- row 2 = CA0[23:16], CA1[23:16], CA2[23:16], CA3[23:16]
- row 3 = CA0[15:8], CA1[15:8], CA2[15:8], CA3[15:8]
- row 4 = CA0[7:0], CA1[7:0], CA2[7:0], CA3[7:0]

### 38.6.3.16 AES Inverse Shift Rows (AESIR)

The AESIR command performs the AES inverse shift rows operation on registers CA0, CA1, CA2, and CA3. The table below shows an example.

**Table 38-5. AESIR command example**

| Register | Before      | After       |
|----------|-------------|-------------|
| CA0      | 0x0106_0B00 | 0x0102_0304 |
| CA1      | 0x050A_0F04 | 0x0506_0708 |
| CA2      | 0x090E_0308 | 0x090A_0B0C |
| CA3      | 0x0D02_070C | 0x0D0E_0F00 |

Where:

- row 1 = CA0[31:24], CA1[31:24], CA2[31:24], CA3[31:24]
- row 2 = CA0[23:16], CA1[23:16], CA2[23:16], CA3[23:16]
- row 3 = CA0[15:8], CA1[15:8], CA2[15:8], CA3[15:8]
- row 4 = CA0[7:0], CA1[7:0], CA2[7:0], CA3[7:0]

### 38.6.3.17 DES Round (DESR)

The DESR command performs a round of the DES algorithm and a key schedule update with the following source and destination designations: CA0=C, CA1=D, CA2=L, CA3=R. If the IP bit is set, DES initial permutation performs on CA2 and CA3 before the round operation. If the FP bit is set, DES final permutation, that is, inverse initial permutation, performs on CA2 and CA3 after the round operation. The round operation

uses the source values from registers CA0 and CA1 for the key addition operation. The KSx field specifies the shift for the key schedule operation to update the values in CA0 and CA1. The following table defines the specific shift function performed based on the KSx field.

**Table 38-6. Key shift function codes**

| KSx code | KSx define | Shift function |
|----------|------------|----------------|
| 0        | KSL1       | Left 1         |
| 1        | KSL2       | Left 2         |
| 2        | KSR1       | Right 1        |
| 3        | KSR2       | Right 2        |

### 38.6.3.18 DES Key setup (DESK)

The DESK command performs the initial key transformation, permuted choice 1, defined by the DES algorithm on CA0 and CA1 with CA0 containing bits 1–32 of the key and CA1 containing bits 33–64 of the key<sup>1</sup>. If the DC bit is set, no shift operation performs and the values C<sub>0</sub> and D<sub>0</sub> store back to CA0 and CA1, respectively. The DC bit must be set for decrypt operations. If the DC bit is not set, a left shift by one also occurs and the values C<sub>1</sub> and D<sub>1</sub> store back to CA0 and CA1, respectively. The DC bit should be cleared for encrypt operations. If the CP bit is set and a key parity error is detected, CASR[DPE] bit is set; otherwise, it is cleared.

### 38.6.3.19 Hash Function (HASH)

The HASH command performs a hashing operation on a set of registers and adds that result to the value in CAA and stores the result in CAA. The specific hash function performed is based on the HFx field as defined in the table below.

This table uses the following terms:

- $\text{ROTR}^n(\text{CAx})$ : rotate CAx register right  $n$  times
- $\text{SHR}^n(\text{CAx})$ : shift CAx register right  $n$  times

**Table 38-7. Hash Function codes**

| HFx code | HFx define | Hash Function | Hash logic                                                              |
|----------|------------|---------------|-------------------------------------------------------------------------|
| 0        | HFF        | MD5 F()       | $(\text{CA1} \& \text{CA2}) \mid (\overline{\text{CA1}} \& \text{CA3})$ |
| 1        | HFG        | MD5 G()       | $(\text{CA1} \& \text{CA3}) \mid (\text{CA2} \& \overline{\text{CA3}})$ |

*Table continues on the next page...*

1. The DES algorithm numbers the most significant bit of a block as bit 1 and the least significant as bit 64.

**Table 38-7. Hash Function codes (continued)**

| HFx code | HFx define | Hash Function         | Hash logic                                                  |
|----------|------------|-----------------------|-------------------------------------------------------------|
| 2        | HFH        | MD5 H(), SHA Parity() | $CA1 \wedge CA2 \wedge CA3$                                 |
| 3        | HFI        | MD5 I()               | $CA2 \wedge (CA1 \mid \overline{CA3})$                      |
| 4        | HFC        | SHA Ch()              | $(CA1 \& CA2) \wedge (\overline{CA1} \& CA3)$               |
| 5        | HFM        | SHA Maj()             | $(CA1 \& CA2) \wedge (CA1 \& CA3) \wedge (CA2 \& CA3)$      |
| 6        | HF2C       | SHA-256 Ch()          | $(CA4 \& CA5) \wedge (\overline{CA1} \& CA6)$               |
| 7        | HF2M       | SHA-256 Maj()         | $(CA0 \& CA1) \wedge (CA0 \& CA2) \wedge (CA1 \& CA2)$      |
| 8        | HF2S       | SHA-256 Sigma 0       | $ROTR^2(CA0) \wedge ROTR^{13}(CA0) \wedge ROTR^{22}(CA0)$   |
| 9        | HF2T       | SHA-256 Sigma 1       | $ROTR^6(CA4) \wedge ROTR^{11}(CA4) \wedge ROTR^{25}(CA4)$   |
| A        | HF2U       | SHA-256 Sigma 0       | $ROTR^7(CA8) \wedge ROTR^{18}(CA8) \wedge SHR^3(CA8)$       |
| B        | HF2V       | SHA-256 Sigma 1       | $ROTR^{17}(CA8) \wedge ROTR^{19}(CA8) \wedge SHR^{10}(CA8)$ |

### 38.6.3.20 Secure Hash Shift (SHS)

The SHS command does a set of parallel register-to-register move and shift operations for implementing SHA-1. The following source and destination assignments are made:

| Register | Value prior to command | Value after command executes |
|----------|------------------------|------------------------------|
| CA4      | CA4                    | CA3                          |
| CA3      | CA3                    | CA2                          |
| CA2      | CA2                    | $CA1 \ll 30$                 |
| CA1      | CA1                    | CA0                          |
| CA0      | CA0                    | CAA                          |
| CAA      | CAA                    | $CAA \ll 5$                  |

### 38.6.3.21 Message Digest Shift (MDS)

The MDS command does a set of parallel register-to-register move operations for implementing MD5. The following source and destination assignments are made:

| Register | Value prior to command | Value after command executes |
|----------|------------------------|------------------------------|
| CA3      | CA3                    | CA2                          |
| CA2      | CA2                    | CA1                          |
| CA1      | CA1                    | CAA                          |
| CAA      | CAA                    | CA3                          |

### 38.6.3.22 Secure Hash Shift 2 (SHS2)

The SHS2 command does an addition and a set of register to register moves in parallel for implementing SHA-256. The following source and destination assignments are made:

| Register | Value prior to command | Value after command executes |
|----------|------------------------|------------------------------|
| CA7      | CA7                    | CA6                          |
| CA6      | CA6                    | CA5                          |
| CA5      | CA5                    | CA4                          |
| CA4      | CA4                    | CA3+CA8                      |
| CA3      | CA3                    | CA2                          |
| CA2      | CA2                    | CA1                          |
| CA1      | CA1                    | CA0                          |
| CA0      | CA0                    | CAA                          |

### 38.6.3.23 Illegal command (ILL)

The ILL command is a specific illegal command that sets CASR[IC]. All other illegal commands are reserved for use in future implementations.

## 38.7 Application/initialization information

This section discusses how to initialize and use the CAU.

### 38.7.1 Code example

A code fragment is shown below as an example of how the CAU is used. This example shows the round function of the AES algorithm. Core registers are defined as follows:

- R1 points to the key schedule
- R3 contains 3 direct CAU commands
- R8 contains 2 direct CAU commands
- R9 contains an indirect CAU command
- FP points to the CAU indirect command address space
- IP points to the CAU direct command space

```

## Chapter 39

# True Random Number Generator

### 39.1 Standalone True Random Number Generator (SA-TRNG).

The Standalone True Random Number Generator (SA-TRNG) is a hardware accelerator module that generates a 512-bit entropy as needed by an entropy-consuming module or by other post-processing functions. A typical entropy consumer is a pseudo random-number generator (PRNG) that can be implemented to achieve both true randomness and cryptographic-strength random numbers using the TRNG output as its entropy seed. The PRNG is not part of this module.

The entropy generated by a TRNG is intended for direct use by functions that generate secret keys, per-message secrets, random challenges, and other similar quantities used in cryptographic algorithms. In each of these cases, it is important that a random number be difficult to guess or predict. It is important that a random number is at least as difficult to predict as it is difficult to break the cryptographic algorithm with which it is being used. This stringent requirement is particularly difficult to fulfill if the entropy source from a TRNG contains bias and/or correlation. To increase the trustworthiness/quality of the generated random data, PRNGs are often used to post process the output of a TRNG.

This document describes only the TRNG design functionality and usage.

Note that before entropy can be obtained from the TRNG, it must be initialized and instantiated in a particular mode by setting the appropriate TRNG registers.

The TRNG contains the following sub modules: IP Slave bus (SkyBlue bus) interface, the TRNG Core and the free running oscillator (OSC).

#### 39.1.1 Standalone True Random Number Generator Block Diagram

The following figure is a top-level diagram of the True Random Number Generator.

Figure 39-1. SA TRNG Block Diagram

### 39.1.2 TRNG Functional Description.

The TRNG consists of several functional sub-modules. Its overall functionality can be easily described from the top level in terms of generating entropy for seed generation. The functionality of each sub-module is briefly described in the following subsections.

TRNG is based on collecting bits from a random noise source. This random noise source is a ring oscillator that is sensitive to random noise (temperature variations, voltage variations, cross-talk and other random noise) within the device in which the TRNG is used. This noise causes various small changes in the period of the oscillator. Therefore, if the count of the ring oscillator clock cycles is sampled after a known period of time, this count will vary each time the sample is taken. By using the variance in this count over a large number of samples, random bits can be derived.

The TRNG comprises two entropy sources, each of which provides a single bit of output. Concatenated together, these 2 output bits are expected to provide 1 bit of entropy every 100 clock cycles. In addition to generating entropy, the TRNG also performs several statistical tests on its output.

### 39.1.3 SA-TRNG hardware functional description.

SA-TRNG functionality consists of several major subcomponents. This table describes these subcomponents.

**Table 39-1. SA-TRNG subcomponents.**

| Description                                                                                                                                    | Cross-reference(s)                                                 |

| True Random Number Generator (TRNG)                                                                                                            | <a href="#">Standalone True Random Number Generator (SA-TRNG).</a> |

#### 39.1.3.1 Software Use Cases for the Stand Alone TRNG.

There are four things that a user (programmer/integrator) will want to do with a TRNG.

- Initialization.

Set up the parameters to proper values, and start generation of the first block of entropy. This is done once.

- Read entropy from the TRNG, and start generation of the next block of entropy.

This is done many times and is the normal flow of operation.

- Run a self-test on the TRNG, to assure proper continued operation.

This involves taking TRNG off-line, setting some self-test parameters, running TRNG, and then reading the statistical test registers, to see that they are within proper operation values. This may not be needed, as TRNG has built-in self-test.

- Off-line determination and checking of TRNG parameter values.

This is done in development in order to determine the proper initialization and self-test parameters. The TRNG is taken off-line. Test parameter values are written and entropy generation is started. If the statistical tests indicate poor operation (i.e., failing statistical tests), the entropy\_delay value should be increased and entropy generation should be re-started. Every case is a variation of setting TRNG parameter values, starting or re-starting entropy generation and reading out the entropy. This process requires pausing or stopping and re-starting the TRNG.

The TRNG is designed to operate as a slave module on the standard IP Slave Bus. By understanding the TRNG register descriptions in "TRNG Register Descriptions" section below, the TRNG module can be controlled via the IP slave bus. In order to write to most TRNG registers, the MCTL register must be initialized in programming mode as described in the "TRNG Register Descriptions" section. At Power On Reset (POR), the TRNG resets to programming mode. And the it will not generate entropy until it is out of programming mode (in run mode) and access to Entropy Registers have been enabled.

Here is an example program flow of using the TRNG.

- After POR the TRNG will be reset into programming mode with the OK to stop bit set (MCTL[TSTOP\_OK]=1). The TRNG must be put into Run Mode for Entropy Generation to begin (MCTL[PRGM]=0). Additionally, in order to have access to the Entropy registers and other critical TRNG registers, the TRNG access bit must be set (MCTL[TRNG\_ACC]=1). Using the default self test limits that exist after bootup, the entropy valid bit can be polled until asserted (MCTL[ENT\_VAL]=1). Alternatively, if using the interrupt, and the interrupts are enabled via the INT\_MASK register and the ipi\_rng\_int\_b is asserted when MCTL[ENT\_VAL]=1.
- After the polling completes, the 512-bit entropy generated by the TRNG can be read. The values can be read in any order from entropy register 0 to register 15 (ENT0 to ENT 15). After reading ENT 15, the old entropy value is reset and a new entropy value is generated.

### NOTE

Reading ENT 15 always resets the entropy, so should always be read last.

- You can poll again for the new entropy value or you can use the Interrupt Status Register to handle reading the entropy values when the entropy valid interrupt is triggered.
- The interrupt can be masked or cleared as needed. See the Interrupt Status Register description.
- To change the self-test limits, the seed counters, how fast the entropy is generated, and how entropy is sampled, see the register description section. In particular, see the the TRNG Frequency Count Minimum Limit Register (FRQMIN), the seed control register (SCML), the statistical run length registers, and other parameter registers.
- Once in Run Mode, the entropy is re-generated automatically after ENT 15 is read. To stop the TRNG or access to TRNG registers at any point while in running mode, you can always set MCTL[TRNG\_ACC]=0. Setting the TRNG back to programming mode (MCTL[PRGM]=1) also achieves the purpose of stopping entropy generation.

### 39.1.3.2 Register interface (IP Slave bus)

The TRNG's register interface (32-bit IP bus) is used to read and write registers within TRNG for the following purposes:

**Table 39-2. Summary of register interface uses**

| Purpose                                                                                                                                        | For more information, see                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| During chip initialization time                                                                                                                |                                                                                                                                                      |
| To configure TRNG including initialization of the <ul style="list-style-type: none"> <li>Registers</li> <li>TRNG Register Interface</li> </ul> |                                                                                                                                                      |
| During hardware and software debugging                                                                                                         |                                                                                                                                                      |
| Read status registers                                                                                                                          | <ul style="list-style-type: none"> <li>RNG TRNG Status Register</li> <li>For all registers, see the TRNG Register Descriptions" appendix.</li> </ul> |

#### NOTE

Accesses to registers must use full-word (32-bit) reads or writes.

### 39.1.3.3 TRNG0 Register Descriptions

All accesses of undefined addresses always return zero and assert IPS transfer error. Writes to undefined and read-only addresses are ignored. Undefined addresses are those undocumented, protected or reserved addresses within and outside the range of the addresses defined in the memory map below. Although many of the TRNG0 registers hold more than 32 bits, the register addresses shown in the Memory Map below represent how these registers are accessed over the register bus as 32-bit words.

The format and fields in each TRNG0 register are defined below. Some of the register format figures apply to several different registers. In such cases a different register name will be associated with each of the register offset addresses that appear at the top of the register format figure. Although these registers share the same format, they are independent registers. In addition, many registers can be accessed at multiple addresses. In these cases there will be a single register name and the list of addresses at which that register is accessible will be indicated as aliases. Unless noted in the individual register descriptions, registers are reset only at Power-On Reset (POR).

**39.1.3.3.1 TRNG0 Memory Map**

| Offset    | Register                                                      | Width<br>(In bits) | Access | Reset value            |

- Reset occurs at POR, and when TRNG0\_MCTL[RST\_DEF] is written to 1.

### 39.1.3.3.2 TRNG0 Miscellaneous Control (TRNG0\_MCTL)

#### 39.1.3.3.2.1 Address

| Register   | Offset |
|------------|--------|
| TRNG0_MCTL | 0h     |

#### 39.1.3.3.2.2 Function

This register is intended to be used for programming, configuring and testing the RNG. It is the main register to read/write, in order to enable Entropy generation, to stop entropy generation and to block access to entropy registers. This is done via the special TRNG\_ACC and PRGM bits below.

The TRNG0 Miscellaneous Control Register is a read/write register used to control the RNG's True Random Number Generator (TRNG) access, operation and test.

#### NOTE

Note that in many cases two RNG registers share the same address, and a particular register at the shared address is selected based upon the value in the PRGM field of the TRNG0\_MCTL register.

### 39.1.3.3.2.3 Diagram

### 39.1.3.3.2.4 Fields

| Field          | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-17<br>—     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 16<br>PRGM     | Programming Mode Select. When this bit is 1, the TRNG is in Program Mode, otherwise it is in Run Mode. No Entropy value will be generated while the TRNG is in Program Mode. Note that different RNG registers are accessible at the same address depending on whether PRGM is set to 1 or 0. This is noted in the RNG register descriptions.                                                                                                                                                                                                                                |
| 15-14<br>—     | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 13<br>TSTOP_OK | TRNG_OK_TO_STOP. Software should check that this bit is a 1 before transitioning TRNG0 to low power mode (TRNG0 clock stopped). TRNG0 turns on the TRNG free-running ring oscillator whenever new entropy is being generated and turns off the ring oscillator when entropy generation is complete. If the TRNG0 clock is stopped while the TRNG ring oscillator is running, the oscillator will continue running even though the TRNG0 clock is stopped. TSTOP_OK is asserted when the TRNG ring oscillator is not running. and therefore it is ok to stop the TRNG0 clock. |
| 12<br>ERR      | Read: Error status. 1 = error detected. 0 = no error.<br>Write: Write 1 to clear errors. Writing 0 has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 11<br>TST_OUT  | Read only: Test point inside ring oscillator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 10<br>ENT_VAL  | Read only: Entropy Valid. Will assert only if TRNG ACC bit is set, and then after an entropy value is generated. Will be cleared at most one (1) bus clock cycle after reading the TRNG0_ENT15 register. (TRNG0_ENT0 through TRNG0_ENT14 should be read before reading TRNG0_ENT15).                                                                                                                                                                                                                                                                                         |
| 9<br>FCT_VAL   | Read only: Frequency Count Valid. Indicates that a valid frequency count may be read from TRNG0_FRQCNT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 8<br>FCT_FAIL  | Read only: Frequency Count Fail. The frequency counter has detected a failure. This may be due to improper programming of the TRNG0_FRQMAX and/or TRNG0_FRQMIN registers, or a hardware failure in the ring oscillator. This error may be cleared by writing a 1 to the ERR bit.                                                                                                                                                                                                                                                                                             |

Table continues on the next page...

| Field            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>FOR_SCLK    | Force System Clock. If set, the system clock is used to operate the TRNG, instead of the ring oscillator. This is for test use only, and indeterminate results may occur. This bit is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this bit. This bit is cleared by writing the RST_DEF bit to 1.                                                                                                                                                                                                                                                     |
| 6<br>RST_DEF     | Reset Defaults. Writing a 1 to this bit clears various TRNG registers, and bits within registers, to their default state. This bit is writable only if PRGM bit is 1, or PRGM bit is being written to 1 simultaneously to writing this bit. Reading this bit always produces a 0.                                                                                                                                                                                                                                                                                                                    |
| 5<br>TRNG_ACC    | TRNG Access Mode. If this bit is set to 1, the TRNG will generate an Entropy value that can be read via the TRNG0_ENT0-TRNG0_ENT15 registers. The Entropy value may be read once the ENT VAL bit is asserted. Also see TRNG0_ENTa register descriptions (For a = 0 to 15).                                                                                                                                                                                                                                                                                                                           |
| 4<br>UNUSED      | This bit is unused but write-able. Must be left as zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 39.1.3.3.3 TRNG0 Statistical Check Miscellaneous (TRNG0\_SCMISC)

#### 39.1.3.3.3.1 Address

| Register     | Offset |
|--------------|--------|
| TRNG0_SCMISC | 4h     |

#### 39.1.3.3.3.2 Function

The TRNG0 Statistical Check Miscellaneous Register contains the Long Run Maximum Limit value and the Retry Count value. This register is accessible only when the TRNG0\_MCTL[PRGM] bit is 1, otherwise this register will read zeroes, and cannot be written.

### 39.1.3.3.3 Diagram

- Reset occurs at POR, and when TRNG0\_MCTL[RST\_DEF] is written to 1.

### 39.1.3.3.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20<br>—      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                |
| 19-16<br>RTY_CT | RETRY COUNT. If a statistical check fails during the TRNG Entropy Generation, the RTY_CT value indicates the number of times a retry should occur before generating an error. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |
| 15-8<br>—       | Reserved.                                                                                                                                                                                                                                                                                                                                                                                |
| 7-0<br>LRUN_MAX | LONG RUN MAX LIMIT. This value is the largest allowable number of consecutive samples of all 1, or all 0, that is allowed during the Entropy generation. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the POR reset value by writing the TRNG0_MCTL[RST_DEF] bit to 1.                        |

### 39.1.3.3.4 TRNG0 Poker Range (TRNG0\_PKRRNG)

#### 39.1.3.3.4.1 Address

| Register     | Offset |
|--------------|--------|
| TRNG0_PKRRNG | 8h     |

### 39.1.3.3.4.2 Function

The TRNG0 Poker Range Register defines the difference between the TRNG Poker Maximum Limit and the minimum limit. These limits are used during the TRNG Statistical Check Poker Test.

### 39.1.3.3.4.3 Diagram

### 39.1.3.3.4.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>—      | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 15-0<br>PKR_RNG | Poker Range. During the TRNG Statistical Checks, a "Poker Test" is run which requires a maximum and minimum limit. The maximum is programmed in the PKRMAX[PKR_MAX] register, and the minimum is derived by subtracting the PKR_RNG value from the programmed maximum value. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. Note that the minimum allowable Poker result is PKR_MAX - PKR_RNG + 1. |

### 39.1.3.3.5 TRNG0 Poker Maximum Limit (TRNG0\_PKRMAX)

#### 39.1.3.3.5.1 Address

| Register     | Offset | Description                                           |
|--------------|--------|-------------------------------------------------------|
| TRNG0_PKRMAX | Ch     | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

### 39.1.3.3.5.2 Function

The TRNG0 Poker Maximum Limit Register defines Maximum Limit allowable during the TRNG Statistical Check Poker Test. Note that this offset (0x0C) is used as TRNG0\_PKRMAX only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as the TRNG0\_PKRSQ readback register.

### 39.1.3.3.5.3 Diagram

### 39.1.3.3.5.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-24<br>—      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 23-0<br>PKR_MAX | <p>Poker Maximum Limit.</p> <p>During the TRNG Statistical Checks, a "Poker Test" is run which requires a maximum and minimum limit. The maximum allowable result is programmed in the TRNG0_PKRMAX[PKR_MAX] register. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. Note that the TRNG0_PKRMAX and TRNG0_PKRRNG registers combined are used to define the minimum allowable Poker result, which is <math>PKR\_MAX - PKR\_RNG + 1</math>. Note that if TRNG0_MCTL[PRGM] bit is 0, this register address is used to read the Poker Test Square Calculation result in register TRNG0_PKRSQ, as defined in the following section.</p> |

### 39.1.3.3.6 TRNG0 Poker Square Calculation Result (TRNG0\_PKRSQ)

#### 39.1.3.3.6.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_PKRSQ | Ch     | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

### 39.1.3.3.6.2 Function

The TRNG0 Poker Square Calculation Result Register is a read-only register used to read the result of the TRNG Statistical Check Poker Test's Square Calculation. This test starts with the TRNG0\_PKRMAX value and decreases towards a final result, which is read here. For the Poker Test to pass, this final result must be less than the programmed TRNG0\_PKRRNG value. Note that this offset (0x0C) is used as TRNG0\_PKRMAX if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_PKRSQ readback register, as described here.

### 39.1.3.3.6.3 Diagram

| 31-24<br>—     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 23-0<br>PKR_SQ | <p>Poker Square Calculation Result.</p> <p>During the TRNG Statistical Checks, a "Poker Test" is run which starts with the value TRNG0_PKRMAX[PKR_MAX]. This value decreases according to a "sum of squares" algorithm, and must remain greater than zero, but less than the TRNG0_PKRRNG[PKR_RNG] limit. The resulting value may be read through this register, if TRNG0_MCTL[PRGM] bit is 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Poker Test Maximum Limit in register TRNG0_PKRMAX, as defined in the previous section.</p> |

### 39.1.3.3.7 TRNG0 Seed Control (TRNG0\_SDCTL)

### 39.1.3.3.7.1 Address

| Register    | Offset |
|-------------|--------|
| TRNG0_SDCTL | 10h    |

### 39.1.3.3.7.2 Function

The TRNG0 Seed Control Register contains two fields. One field defines the length (in system clocks) of each Entropy sample (ENT\_DLY), and the other field indicates the number of samples that will taken during each TRNG Entropy generation (SAMP\_SIZE).

### 39.1.3.3.7.3 Diagram

### 39.1.3.3.7.4 Fields

| Field             | Function                                                                                                                                                                                                                                                                                                          |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>ENT_DLY  | Entropy Delay. Defines the length (in system clocks) of each Entropy sample taken. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to its reset value at POR.                                                                |
| 15-0<br>SAMP_SIZE | Sample Size. Defines the total number of Entropy samples that will be taken during Entropy generation. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

### 39.1.3.3.8 TRNG0 Sparse Bit Limit (TRNG0\_SBLIM)

### 39.1.3.3.8.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SBLIM | 14h    | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

### 39.1.3.3.8.2 Function

The TRNG0 Sparse Bit Limit Register is used when Von Neumann sampling is selected during Entropy Generation. It defines the maximum number of consecutive Von Neumann samples which may be discarded before an error is generated. Note that this address (0x14) is used as TRNG0\_SBLIM only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this address is used as TRNG0\_TOTSAM readback register.

### 39.1.3.3.8.3 Diagram

### 39.1.3.3.8.4 Fields

| Field         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-10<br>—    | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 9-0<br>SB_LIM | Sparse Bit Limit. During Von Neumann sampling (if enabled by TRNG0_MCTL[SAMP_MODE], samples are discarded if two consecutive raw samples are both 0 or both 1. If this discarding occurs for a long period of time, it indicates that there is insufficient Entropy. The Sparse Bit Limit defines the maximum number of consecutive samples that may be discarded before an error is generated. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. Note that if TRNG0_MCTL[PRGM] bit is 0, this register address is used to read the Total Samples count in register TRNG0_TOTSAM, as defined in the following section. |

### 39.1.3.3.9 TRNG0 Total Samples (TRNG0\_TOTSAM)

#### 39.1.3.3.9.1 Address

| Register     | Offset | Description                                           |
|--------------|--------|-------------------------------------------------------|
| TRNG0_TOTSAM | 14h    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

#### 39.1.3.3.9.2 Function

The TRNG0 Total Samples Register is a read-only register used to read the total number of samples taken during Entropy generation. It is used to give an indication of how often a sample is actually used during Von Neumann sampling. Note that this offset (0x14) is used as TRNG0\_SBLIM if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_TOTSAM readback register, as described here.

#### 39.1.3.3.9.3 Diagram

#### 39.1.3.3.9.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20<br>—      | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 19-0<br>TOT_SAM | Total Samples. During Entropy generation, the total number of raw samples is counted. This count is useful in determining how often a sample is used during Von Neumann sampling. The count may be read through this register, if TRNG0_MCTL[PRGM] bit is 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Sparse Bit Limit in register TRNG0_SBLIM, as defined in the previous section. |

### 39.1.3.3.10 TRNG0 Frequency Count Minimum Limit (TRNG0\_FRQMIN)

#### 39.1.3.3.10.1 Address

| Register     | Offset |
|--------------|--------|
| TRNG0_FRQMIN | 18h    |

#### 39.1.3.3.10.2 Function

The TRNG0 Frequency Count Minimum Limit Register defines the minimum allowable count taken by the Entropy sample counter during each Entropy sample. During any sample period, if the count is less than this programmed minimum, a Frequency Count Fail is flagged in TRNG0\_MCTL[FCT\_FAIL] and an error is generated.

#### 39.1.3.3.10.3 Diagram

#### 39.1.3.3.10.4 Fields

| Field           | Function                                                                                                                                                                                                                                                             |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22<br>—      | Reserved. Always 0.                                                                                                                                                                                                                                                  |
| 21-0<br>FRQ_MIN | Frequency Count Minimum Limit. Defines the minimum allowable count taken during each entropy sample. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field will read zeroes if TRNG0_MCTL[PRGM] = 0. This field is cleared to its reset value at POR. |

### 39.1.3.3.11 TRNG0 Frequency Count (TRNG0\_FRQCNT)

**39.1.3.3.11.1 Address**

| Register     | Offset | Description                                           |
|--------------|--------|-------------------------------------------------------|
| TRNG0_FRQCNT | 1Ch    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

**39.1.3.3.11.2 Function**

The TRNG0 Frequency Count Register is a read-only register used to read the frequency counter within the TRNG entropy generator. It will read all zeroes unless TRNG0\_MCTL[TRNG\_ACC] = 1. Note that this offset (0x1C) is used as TRNG0\_FRQMAX if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_FRQCNT readback register, as described here.

**39.1.3.3.11.3 Diagram****39.1.3.3.11.4 Fields**

| Field          | Function                                                                                                                                                                                                                                                                                                                |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22<br>—     | Reserved. Always 0.                                                                                                                                                                                                                                                                                                     |
| 21-0<br>FRQ_CT | Frequency Count. If TRNG0_MCTL[TRNG_ACC] = 1, reads a sample frequency count taken during entropy generation. Requires TRNG0_MCTL[PRGM] = 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Poker Test Maximum Limit in register TRNG0_PKRMAX, as defined in the previous section. |

**39.1.3.3.12 TRNG0 Frequency Count Maximum Limit (TRNG0\_FRQMAX)**

### 39.1.3.3.12.1 Address

| Register     | Offset | Description                                           |
|--------------|--------|-------------------------------------------------------|
| TRNG0_FRQMAX | 1Ch    | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

### 39.1.3.3.12.2 Function

The TRNG0 Frequency Count Maximum Limit Register defines the maximum allowable count taken by the Entropy sample counter during each Entropy sample. During any sample period, if the count is greater than this programmed maximum, a Frequency Count Fail is flagged in TRNG0\_MCTL[FCT\_FAIL] and an error is generated. Note that this address (001C) is used as TRNG0\_FRQMAX only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this address is used as TRNG0\_FRQCNT readback register.

### 39.1.3.3.12.3 Diagram

### 39.1.3.3.12.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-22<br>—      | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                                                       |
| 21-0<br>FRQ_MAX | Frequency Counter Maximum Limit. Defines the maximum allowable count taken during each entropy sample. This field is writable only if TRNG0_MCTL[PRGM] bit is 1. This field is cleared to its reset value at POR. Note that if TRNG0_MCTL[PRGM] bit is 0, this register address is used to read the Frequency Count result in register TRNG0_FRQCNT, as defined in the following section. |

### 39.1.3.3.13 TRNG0 Statistical Check Monobit Count (TRNG0\_SCMC)

#### 39.1.3.3.13.1 Address

| Register   | Offset | Description                                           |
|------------|--------|-------------------------------------------------------|
| TRNG0_SCMC | 20h    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

#### 39.1.3.3.13.2 Function

The TRNG0 Statistical Check Monobit Count Register is a read-only register used to read the final monobit count after entropy generation. This counter starts with the value in TRNG0\_SCML[MONO\_MAX], and is decremented each time a one is sampled. Note that this offset (0x20) is used as TRNG0\_SCML if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCMC readback register, as described here.

#### 39.1.3.3.13.3 Diagram

#### 39.1.3.3.13.4 Fields

| Field           | Function                                                                                                                                                                                                                                                                              |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>—      | Reserved. Always 0.                                                                                                                                                                                                                                                                   |
| 15-0<br>MONO_CT | Monobit Count. Reads the final Monobit count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0. Note that if TRNG0_MCTL[PRGM] bit is 1, this register address is used to access the Statistical Check Monobit Limit in register TRNG0_SCML, as defined in the previous section. |

### 39.1.3.3.14 TRNG0 Statistical Check Monobit Limit (TRNG0\_SCML)

#### 39.1.3.3.14.1 Address

| Register   | Offset | Description                                           |
|------------|--------|-------------------------------------------------------|
| TRNG0_SCML | 20h    | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

#### 39.1.3.3.14.2 Function

The TRNG0 Statistical Check Monobit Limit Register defines the allowable maximum and minimum number of ones/zero detected during entropy generation. To pass the test, the number of ones/zeros generated must be less than the programmed maximum value, and the number of ones/zeros generated must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0\_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this offset (0x20) is used as TRNG0\_SCML only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCMC readback register.

#### 39.1.3.3.14.3 Diagram

#### 39.1.3.3.14.4 Fields

| Field             | Function                                                                                                                                                                                                                                              |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-16<br>MONO_RNG | Monobit Range. The number of ones/zeros detected during entropy generation must be greater than MONO_MAX - MONO_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

*Table continues on the next page...*

## Standalone True Random Number Generator (SA-TRNG).

| Field            | Function                                                                                                                                                                                                                                                                                                             |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-0<br>MONO_MAX | Monobit Maximum Limit. Defines the maximum allowable count taken during entropy generation. The number of ones/zeros detected during entropy generation must be less than MONO_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

### 39.1.3.3.15 TRNG0 Statistical Check Run Length 1 Count (TRNG0\_SCR1C)

#### 39.1.3.3.15.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR1C | 24h    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

#### 39.1.3.3.15.2 Function

The TRNG0 Statistical Check Run Length 1 Counters Register is a read-only register used to read the final Run Length 1 counts after entropy generation. These counters start with the value in TRNG0\_SCRxC1L[RUN1\_MAX]. The R1\_1\_CT decrements each time a single one is sampled (preceded by a zero and followed by a zero). The R1\_0\_CT decrements each time a single zero is sampled (preceded by a one and followed by a one). Note that this offset (0x24) is used as TRNG0\_SCRxC1L if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCRxC1C readback register, as described here.

## 39.1.3.3.18 TRNG0 Statistical Check Run Length 2 Limit (TRNG0\_SCR2L)

### 39.1.3.3.18.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR2L | 28h    | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

### 39.1.3.3.18.2 Function

The TRNG0 Statistical Check Run Length 2 Limit Register defines the allowable maximum and minimum number of runs of length 2 detected during entropy generation. To pass the test, the number of runs of length 2 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 2 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0\_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x28) is used as TRNG0\_SCRxC2L only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this address is used as TRNG0\_SCRxC2C readback register.

| Field             | Function                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-30<br>—        | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                              |
| 29-16<br>RUN2_RNG | Run Length 2 Range. The number of runs of length 2 (for both 0 and 1) detected during entropy generation must be greater than RUN2_MAX - RUN2_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.                                                                              |
| 15-14<br>—        | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                              |
| 13-0<br>RUN2_MAX  | Run Length 2 Maximum Limit. Defines the maximum allowable runs of length 2 (for both 0 and 1) detected during entropy generation. The number of runs of length 2 detected during entropy generation must be less than RUN2_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

### 39.1.3.3.19 TRNG0 Statistical Check Run Length 3 Count (TRNG0\_SCR3C)

#### 39.1.3.3.19.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR3C | 2Ch    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

#### 39.1.3.3.19.2 Function

The TRNG0 Statistical Check Run Length 3 Counters Register is a read-only register used to read the final Run Length 3 counts after entropy generation. These counters start with the value in TRNG0\_SCRxC3L[RUN3\_MAX]. The R3\_1\_CT decrements each time three consecutive ones are sampled (preceded by a zero and followed by a zero). The R3\_0\_CT decrements each time three consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x2C) is used as TRNG0\_SCRxC3L if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCRxC3C readback register, as described here.

| Field            | Function                                                                                                                            |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 31-29<br>—       | Reserved. Always 0.                                                                                                                 |
| 28-16<br>R3_1_CT | Runs of Ones, Length 3 Count. Reads the final Runs of Ones, length 3 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0. |
| 15-13            | Reserved. Always 0.                                                                                                                 |

Table continues on the next page...

| Field           | Function                                                                                                                                |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| —               |                                                                                                                                         |
| 12-0<br>R3_0_CT | Runs of Zeroes, Length 3 Count. Reads the final Runs of Zeroes, length 3 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0. |

### 39.1.3.3.20 TRNG0 Statistical Check Run Length 3 Limit (TRNG0\_SCR3L)

#### 39.1.3.3.20.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR3L | 2Ch    | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

#### 39.1.3.3.20.2 Function

The TRNG0 Statistical Check Run Length 3 Limit Register defines the allowable maximum and minimum number of runs of length 3 detected during entropy generation. To pass the test, the number of runs of length 3 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 3 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0\_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x2C) is used as TRNG0\_SCRxC3L only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this address is used as TRNG0\_SCRxC3C readback register.

| 28-16<br>RUN3_RNG | Run Length 3 Range. The number of runs of length 3 (for both 0 and 1) detected during entropy generation must be greater than RUN3_MAX - RUN3_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.                                                                              |
| 15-13<br>—        | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                              |
| 12-0<br>RUN3_MAX  | Run Length 3 Maximum Limit. Defines the maximum allowable runs of length 3 (for both 0 and 1) detected during entropy generation. The number of runs of length 3 detected during entropy generation must be less than RUN3_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

### 39.1.3.3.21 TRNG0 Statistical Check Run Length 4 Count (TRNG0\_SCR4C)

#### 39.1.3.3.21.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR4C | 30h    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

#### 39.1.3.3.21.2 Function

The TRNG0 Statistical Check Run Length 4 Counters Register is a read-only register used to read the final Run Length 4 counts after entropy generation. These counters start with the value in TRNG0\_SCRxC4L[RUN4\_MAX]. The R4\_1\_CT decrements each time four consecutive ones are sampled (preceded by a zero and followed by a zero). The R4\_0\_CT decrements each time four consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x30) is used as TRNG0\_SCRxC4L if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCRxC4C readback register, as described here.

| 27-16<br>RUN4_RNG | Run Length 4 Range. The number of runs of length 4 (for both 0 and 1) detected during entropy generation must be greater than RUN4_MAX - RUN4_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.                                                                              |
| 15-12<br>—        | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                              |
| 11-0<br>RUN4_MAX  | Run Length 4 Maximum Limit. Defines the maximum allowable runs of length 4 (for both 0 and 1) detected during entropy generation. The number of runs of length 4 detected during entropy generation must be less than RUN4_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

## 39.1.3.3.23 TRNG0 Statistical Check Run Length 5 Count (TRNG0\_SCR5C)

### 39.1.3.3.23.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR5C | 34h    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

### 39.1.3.3.23.2 Function

The TRNG0 Statistical Check Run Length 5 Counters Register is a read-only register used to read the final Run Length 5 counts after entropy generation. These counters start with the value in TRNG0\_SCRxC5L[RUN5\_MAX]. The R5\_1\_CT decrements each time five consecutive ones are sampled (preceded by a zero and followed by a zero). The R5\_0\_CT decrements each time five consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x34) is used as TRNG0\_SCRxC5L if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCRxC5C readback register, as described here.

| 26-16<br>R5_1_CT | Runs of One, Length 5 Count. Reads the final Runs of Ones, length 5 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0.  |
| 15-11<br>—       | Reserved. Always 0.                                                                                                                 |
| 10-0<br>R5_0_CT  | Runs of Zero, Length 5 Count. Reads the final Runs of Ones, length 5 count after entropy generation. Requires TRNG0_MCTL[PRGM] = 0. |

### 39.1.3.3.24 TRNG0 Statistical Check Run Length 5 Limit (TRNG0\_SCR5L)

### 39.1.3.3.24.1 Address

| Register    | Offset | Description                                           |
|-------------|--------|-------------------------------------------------------|
| TRNG0_SCR5L | 34h    | Accessible at this address when TRNG0_MCTL[PRGM] = 1] |

### 39.1.3.3.24.2 Function

The TRNG0 Statistical Check Run Length 5 Limit Register defines the allowable maximum and minimum number of runs of length 5 detected during entropy generation. To pass the test, the number of runs of length 5 (for samples of both 0 and 1) must be less than the programmed maximum value, and the number of runs of length 5 must be greater than (maximum - range). If this test fails, the Retry Counter in TRNG0\_SCMISC will be decremented, and a retry will occur if the Retry Count has not reached zero. If the Retry Count has reached zero, an error will be generated. Note that this address (0x34) is used as TRNG0\_SCRxC5L only if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this address is used as TRNG0\_SCRxC5C readback register.

|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| —                |                                                                                                                                                                                                                                                                                                                                                                  |
| 10-0<br>RUN5_MAX | Run Length 5 Maximum Limit. Defines the maximum allowable runs of length 5 (for both 0 and 1) detected during entropy generation. The number of runs of length 5 detected during entropy generation must be less than RUN5_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

### 39.1.3.3.25 TRNG0 Statistical Check Run Length 6+ Count (TRNG0\_SCR6PC)

#### 39.1.3.3.25.1 Address

| Register     | Offset | Description                                           |
|--------------|--------|-------------------------------------------------------|
| TRNG0_SCR6PC | 38h    | Accessible at this address when TRNG0_MCTL[PRGM] = 0] |

#### 39.1.3.3.25.2 Function

The TRNG0 Statistical Check Run Length 6+ Counters Register is a read-only register used to read the final Run Length 6+ counts after entropy generation. These counters start with the value in TRNG0\_SCRxC6PL[RUN6P\_MAX]. The R6P\_1\_CT decrements each time six or more consecutive ones are sampled (preceded by a zero and followed by a zero). The R6P\_0\_CT decrements each time six or more consecutive zeroes are sampled (preceded by a one and followed by a one). Note that this offset (0x38) is used as TRNG0\_SCRxC6PL if TRNG0\_MCTL[PRGM] is 1. If TRNG0\_MCTL[PRGM] is 0, this offset is used as TRNG0\_SCRxC6PC readback register, as described here.

#### 39.1.3.3.25.3 Diagram

| Field              | Function                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-27<br>—         | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                                                |
| 26-16<br>RUN6P_RNG | Run Length 6+ Range. The number of runs of length 6 or more (for both 0 and 1) detected during entropy generation must be greater than RUN6P_MAX - RUN6P_RNG, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1.                                                                                     |
| 15-11<br>—         | Reserved. Always 0.                                                                                                                                                                                                                                                                                                                                                                |
| 10-0<br>RUN6P_MAX  | Run Length 6+ Maximum Limit. Defines the maximum allowable runs of length 6 or more (for both 0 and 1) detected during entropy generation. The number of runs of length 6 or more detected during entropy generation must be less than RUN6P_MAX, else a retry or error will occur. This register is cleared to the default POR value by writing the TRNG0_MCTL[RST_DEF] bit to 1. |

### 39.1.3.3.27 TRNG0 Status (TRNG0\_STATUS)

#### 39.1.3.3.27.1 Address

| Register     | Offset |
|--------------|--------|
| TRNG0_STATUS | 3Ch    |

### 39.1.3.3.27.2 Function

Various statistical tests are run as a normal part of the TRNG's entropy generation process. The least-significant 16 bits of the TRNG0\_STATUS register reflect the result of each of these tests. The status of these bits will be valid when the TRNG has finished its entropy generation process. Software can determine when this occurs by polling the ENT\_VAL bit in the TRNG0 Miscellaneous Control Register.

Note that there is a very small probability that a statistical test will fail even though the TRNG is operating properly. If this happens the TRNG will automatically retry the entire entropy generation process, including running all the statistical tests. The value in RETRY\_CT is decremented each time an entropy generation retry occurs. If a statistical check fails when the retry count is nonzero, a retry is initiated. But if a statistical check fails when the retry count is zero, an error is generated by the RNG. By default RETRY\_CT is initialized to 1, but software can increase the retry count by writing to the RTY\_CT field in the TRNG0\_SCMISC register.

All 0s will be returned if this register address is read while the RNG is in Program Mode (see PRGM field in TRNG0\_MCTL register. If this register is read while the RNG is in Run Mode the value returned will be formatted as follows.

### 39.1.3.3.27.3 Diagram

### 39.1.3.3.27.4 Fields

| Field             | Function                                                                                                                                                                |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-20<br>—        | Reserved. Always 0.                                                                                                                                                     |
| 19-16<br>RETRY_CT | RETRY COUNT. This represents the current number of entropy generation retries left before a statistical test failure will cause the RNG to generate an error condition. |
| 15                | Test Fail, Mono Bit. If TFMB=1, the Mono Bit Test has failed.                                                                                                           |

### 39.1.3.3.28 TRNG0 Entropy Read (TRNG0\_ENTa)

#### 39.1.3.3.28.1 Address

For a = 0 to 15:

| Register   | Offset         | Description |
|------------|----------------|-------------|
| TRNG0_ENTa | 40h + (a × 4h) | Word a      |

### 39.1.3.3.28.2 Function

The RNG TRNG can be programmed to generate an entropy value that is readable via the SkyBlue bus. To do this, set the TRNG0\_MCTL[TRNG\_ACC] bit to 1. Once the entropy value has been generated, the TRNG0\_MCTL[ENT\_VAL] bit will be set to 1. At this point, TRNG0\_ENT0 through TRNG0\_ENT15 may be read to retrieve the 512-bit entropy value. Note that once TRNG0\_ENT15 is read, the entropy value will be cleared and a new value will begin generation, so it is important that TRNG0\_ENT15 be read last. These registers are readable only when TRNG0\_MCTL[PRGM] = 0 (Run Mode), TRNG0\_MCTL[TRNG\_ACC] = 1 (TRNG access mode) and TRNG0\_MCTL[ENT\_VAL] = 1. After at most one (1) bus clock cycle of reading a valid TRNG0\_ENT15 register value, reading any TRNG0\_ENT0 through TRNG0\_ENT15 register would return zeroes.

### 39.1.3.3.28.3 Diagram

### 39.1.3.3.28.4 Fields

| Field       | Function                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31-0<br>ENT | Entropy Value. Will be non-zero only if TRNG0_MCTL[PRGM] = 0 (Run Mode) and TRNG0_MCTL[ENT_VAL] = 1 (Entropy Valid). The most significant bits of the entropy are read from the lowest offset, and the least significant bits are read from the highest offset. Note that reading the highest offset also clears the entire entropy value, and starts a new entropy generation. |

### 39.1.3.3.29 TRNG0 Statistical Check Poker Count 1 and 0 (TRNG0\_PKRCNT10)

#### 39.1.3.3.29.1 Address

| Register       | Offset |
|----------------|--------|
| TRNG0_PKRCNT10 | 80h    |

#### 39.1.3.3.29.2 Function

The TRNG0 Statistical Check Poker Count 1 and 0 Register is a read-only register used to read the final Poker test counts of 1h and 0h patterns. The Poker 0h Count increments each time a nibble of sample data is found to be 0h. The Poker 1h Count increments each time a nibble of sample data is found to be 1h. Note that this register is readable only if TRNG0\_MCTL[PRGM] is 0, otherwise zeroes will be read.

#### 39.1.3.3.29.3 Diagram

#### 39.1.3.3.29.4 Fields

| Field             | Function                                                                                                         |
|-------------------|------------------------------------------------------------------------------------------------------------------|
| 31-16<br>PKR_1_CT | Poker 1h Count. Total number of nibbles of sample data which were found to be 1h. Requires TRNG0_MCTL[PRGM] = 0. |
| 15-0<br>PKR_0_CT  | Poker 0h Count. Total number of nibbles of sample data which were found to be 0h. Requires TRNG0_MCTL[PRGM] = 0. |

### 39.1.3.3.30 TRNG0 Statistical Check Poker Count 3 and 2 (TRNG0\_PKRCNT32)

#### 39.1.3.3.30.1 Address

| Register       | Offset |
|----------------|--------|
| TRNG0_PKRCNT32 | 84h    |

#### 39.1.3.3.30.2 Function

The TRNG0 Statistical Check Poker Count 3 and 2 Register is a read-only register used to read the final Poker test counts of 3h and 2h patterns. The Poker 2h Count increments each time a nibble of sample data is found to be 2h. The Poker 3h Count increments each time a nibble of sample data is found to be 3h. Note that this register is readable only if TRNG0\_MCTL[PRGM] is 0, otherwise zeroes will be read.

### 39.1.3.3.37 TRNG0 Security Configuration (TRNG0\_SEC\_CFG)

**39.1.3.3.37.1 Address**

| Register      | Offset |
|---------------|--------|
| TRNG0_SEC_CFG | B0h    |

**39.1.3.3.37.2 Function**

The TRNG0 Security Configuration Register is a read/write register used to control the test mode, programmability and state modes of the TRNG0. Many bits are place holders for this version. More configurability will be added here. Clears on asynchronous reset. For TRNG0 releases before 2014/July/01, offsets 0xA0 to 0xAC used to be 0xB0 to 0xBC respectively. So, update newer tests that use these registers, if hard coded.

**39.1.3.3.37.3 Diagram****39.1.3.3.37.4 Fields**

| Field        | Function                                                                                                                                                                                                                                                                                                                                                               |

### 39.1.3.3.38 TRNG0 Interrupt Control (TRNG0\_INT\_CTRL)

#### 39.1.3.3.38.1 Address

| Register       | Offset |
|----------------|--------|
| TRNG0_INT_CTRL | B4h    |

#### 39.1.3.3.38.2 Function

The TRNG0 Interrupt Control Register is a read/write register used to control the status for the (currently) three important interrupts that are generated by the TRNG. See TRNG0\_INT\_STATUS register description above. Each interrupt can be cleared by de-asserting the corresponding bit in the TRNG0\_INT\_CTRL register. Only a new interrupt will reassert the corresponding bit in the status register. Even if the interrupt is cleared or masked, interrupt status information can be read from the TRNG0\_MCTL register.

#### 39.1.3.3.38.3 Diagram

### 39.1.3.3.39 TRNG0 Mask (TRNG0\_INT\_MASK)

#### 39.1.3.3.39.1 Address

| Register       | Offset |
|----------------|--------|
| TRNG0_INT_MASK | B8h    |

#### 39.1.3.3.39.2 Function

The TRNG0 Interrupt Mask Register is a read/write register used to disable/mask the status reporting of the (currently) three important interrupts that are generated by the TRNG. See TRNG0\_INT\_STATUS register description above. Each interrupt can be masked/disabled by de-asserting the corresponding bit in the TRNG0\_INT\_MASK register. Only setting this bit high will re-enable the interrupt in the status register. Even if the interrupt is cleared or masked, interrupt status information can be read from the TRNG0\_MCTL register.

### 39.1.3.3.40 TRNG0 Interrupt Status (TRNG0\_INT\_STATUS)

#### 39.1.3.3.40.1 Address

| Register         | Offset |
|------------------|--------|
| TRNG0_INT_STATUS | BCh    |

#### 39.1.3.3.40.2 Function

The TRNG0 Interrupt Status Register is a read register used to control and provide status for the (currently) three important interrupts that are generated by the TRNG. The `ipi_rng_int_b` interrupt signals that TRNG0 has either generated a Frequency Count Fail, Entropy Valid or Error Interrupt. The cause of the interrupt can be decoded by checking the least significant bits of the TRNG0\_INT\_STATUS register. Each interrupt can be temporarily cleared by de-asserting the corresponding bit in the TRNG0\_INT\_CTRL register. To mask the interrupts, clear the corresponding bits in the TRNG0\_INT\_MASK register. The description of each of the 3 interrupts is defined in the Block Guide under the TRNG0\_MCTL register description. Even if the interrupt is cleared or masked, interrupt status information can be read from the TRNG0\_MCTL register.

## 39.1.4 Another TRNG usage example.

The TRNG can be used by a post processing pseudo-random number generator function. For example, TRNG can be used to seed a hardware or software based implementation of a DRBG defined by SP800-90.

## **Chapter 40**

# **16-bit SAR Analog-to-Digital Converter (ADC)**

## **40.1 Chip-specific ADC information**

### **40.1.1 ADC instantiation information**

This device contains one ADC.

#### **40.1.1.1 Number of ADC channels**

The number of ADC channels present on the device is determined by the pinout of the specific device package. For details regarding the number of ADC channel available on a particular package, refer to the signal multiplexing chapter of this MCU.

#### **40.1.2 DMA Support on ADC**

Applications may require continuous sampling of the ADC (4K samples/sec) that may have considerable load on the CPU. Though using PDB to trigger ADC may reduce some CPU load, the ADC supports DMA request functionality for higher performance when the ADC is sampled at a very high rate or cases where PDB is bypassed. The ADC can trigger the DMA (via DMA req) on conversion completion.

### 40.1.3 ADC0 Connections/Channel Assignment

#### NOTE

As indicated by the following sections, each ADCx\_DPx input and certain ADCx\_DMx inputs may operate as single-ended ADC channels in single-ended mode.

#### 40.1.3.1 ADC0 Channel Assignment for 144-Pin Package

1. ADCx\_CFG2[MUXSEL] bit selects between ADCx\_SEn channels a and b. Refer to MUXSEL description in ADC chapter for details.
2. This is the PMC bandgap 1V reference voltage. Prior to reading from this ADC channel, ensure that you enable the bandgap buffer by setting the PMC\_REGSC[BGBE] bit. Refer to the device data sheet for the bandgap voltage ( $V_{BG}$ ) specification.

## 40.1.4 ADC Channels MUX Selection

The following figure shows the assignment of ADCx\_SEn channels a and b through a MUX selection to ADC. To select between alternate set of channels, refer to ADCx\_CFG2[MUXSEL] bit settings for more details.

Figure 40-1. ADCx\_SEn channels a and b selection

## 40.1.5 ADC Reference Options

The ADC supports the following references:

- VREFH/VREFL - connected as the primary reference option

ADCx\_SC2[REFSEL] bit selects the voltage reference sources for ADC. Refer to REFSEL description in ADC chapter for more details.

### 40.1.6 ADC triggers

The ADC supports both software and hardware triggers. The primary hardware mechanism for triggering the ADC is the PDB. The PDB itself can be triggered by other peripherals. For example: LPTMR Output signal is connected to the PDB. The PDB input trigger can receive the LPTMR Output trigger forcing ADC conversions in run mode (where PDB is enabled). On the other hand, the ADC can conduct conversions in low power modes, not triggered by PDB. This allows the ADC to do conversions in low power mode and store the output in the result register. The ADC generates interrupt when the data is ready in the result register that wakes the system from low power mode. The PDB can also be bypassed by using the ADCxTRGSEL bits in the SIM\_SOPT7 register.

For operation of triggers in different modes, refer to Power Management chapter.

### 40.1.7 Alternate clock

#### NOTE

This ALTCLK option is only usable when OSCERCLK is in the MHz range. A system with OSCERCLK in the kHz range has the optional clock source below minimum ADC clock operating frequency.

**Table 40-1. ADC Conversion Clock Options**

| ADCx_CFG[ADICLK] | ADC defined selection      | Chip clock                          | Note |
|------------------|----------------------------|-------------------------------------|------|
| 00               | Bus Clock                  | Fast Peripheral Clock               |      |
| 01               | ALTCLK2                    | N/A                                 |      |
| 10               | ALTCLK                     | OSCERCLK                            | 1    |
| 11               | Asynchronous clock (ADACK) | N/A - sourced from within ADC block | 1    |

1. For ADC operation in Compute only, PSTOP1, Stop, and VLPS, ADACK and the alternate clock sources are allowed clock sources.

### 40.1.8 ADC low-power modes

This table shows the ADC low-power modes and the corresponding chip low-power modes.

**Table 40-2. ADC low-power modes**

| Module mode    | Chip mode                  |
|----------------|----------------------------|
| Wait           | Wait, VLPW                 |
| Normal Stop    | Stop, VLPS                 |
| Low Power Stop | VLLS3, VLLS2, VLLS1, VLLS0 |

## 40.2 Introduction

The 16-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

### NOTE

For the chip specific modes of operation, see the power management information of the device.

### 40.2.1 Features

Following are the features of the ADC module.

- Linear successive approximation algorithm with up to 16-bit resolution
- Up to four pairs of differential and 24 single-ended external analog inputs
- Output modes:
  - differential 16-bit, 13-bit, 11-bit, and 9-bit modes
  - single-ended 16-bit, 12-bit, 10-bit, and 8-bit modes
- Output format in 2's complement 16-bit sign extended for differential modes
- Output in right-justified unsigned format for single-ended
- Single or continuous conversion, that is, automatic return to idle after single conversion
- Configurable sample time and conversion speed/power
- Conversion complete/hardware average complete flag and interrupt
- Input clock selectable from up to four sources
- Operation in low-power modes for lower noise
- Asynchronous clock source for lower noise operation with option to output the clock

- Selectable hardware conversion trigger with hardware channel select
- Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
- Temperature sensor
- Hardware average function
- Selectable voltage reference: external or alternate
- Self-Calibration mode

### 40.2.2 Block diagram

The following figure is the ADC module block diagram.

Figure 40-2. ADC block diagram

### 40.3 ADC signal descriptions

The ADC module supports up to 4 pairs of differential inputs and up to 24 single-ended inputs.

Each differential pair requires two inputs, DADPx and DADMx. The ADC also requires four supply/reference/ground connections.

**NOTE**

For the number of channels supported on this device as well as information regarding other chip-specific inputs into the ADC block, see the chip-specific ADC configuration information.

**Table 40-3. ADC signal descriptions**

| Signal             | Description                        | I/O |
|--------------------|------------------------------------|-----|
| DADP3–DADP0        | Differential Analog Channel Inputs | I   |
| DADM3–DADM0        | Differential Analog Channel Inputs | I   |
| AD $n$             | Single-Ended Analog Channel Inputs | I   |
| V <sub>REFSH</sub> | Voltage Reference Select High      | I   |
| V <sub>REFSL</sub> | Voltage Reference Select Low       | I   |
| V <sub>DDA</sub>   | Analog Power Supply                | I   |
| V <sub>SSA</sub>   | Analog Ground                      | I   |

**40.3.1 Analog Power (V<sub>DDA</sub>)**

The ADC analog portion uses V<sub>DDA</sub> as its power connection. In some packages, V<sub>DDA</sub> is connected internally to V<sub>DD</sub>. If externally available, connect the V<sub>DDA</sub> pin to the same voltage potential as V<sub>DD</sub>. External filtering may be necessary to ensure clean V<sub>DDA</sub> for good results.

**40.3.2 Analog Ground (V<sub>SSA</sub>)**

The ADC analog portion uses V<sub>SSA</sub> as its ground connection. In some packages, V<sub>SSA</sub> is connected internally to V<sub>SS</sub>. If externally available, connect the V<sub>SSA</sub> pin to the same voltage potential as V<sub>SS</sub>.

**40.3.3 Voltage Reference Select**

V<sub>REFSH</sub> and V<sub>REFSL</sub> are the high and low reference voltages for the ADC module.

The ADC can be configured to accept one of two voltage reference pairs for V<sub>REFSH</sub> and V<sub>REFSL</sub>. Each pair contains a positive reference that must be between the minimum Ref Voltage High and V<sub>DDA</sub>, and a ground reference that must be at the same potential as V<sub>SSA</sub>. The two pairs are external (V<sub>REFH</sub> and V<sub>REFL</sub>) and alternate (V<sub>ALTH</sub> and V<sub>ALT</sub>). These voltage references are selected using SC2[REFSEL]. The alternate V<sub>ALTH</sub> and

$V_{ALTL}$  voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the Voltage References specific to this MCU.

In some packages,  $V_{REFH}$  is connected in the package to  $V_{DDA}$  and  $V_{REFL}$  to  $V_{SSA}$ . If externally available, the positive reference(s) may be connected to the same potential as  $V_{DDA}$  or may be driven by an external source to a level between the minimum Ref Voltage High and the  $V_{DDA}$  potential.  $V_{REFH}$  must never exceed  $V_{DDA}$ . Connect the ground references to the same voltage potential as  $V_{SSA}$ .

### 40.3.4 Analog Channel Inputs (ADx)

The ADC module supports up to 24 single-ended analog inputs. A single-ended input is selected for conversion through the  $SC1[ADCH]$  channel select bits when  $SC1n[DIFF]$  is low.

### 40.3.5 Differential Analog Channel Inputs (DADx)

The ADC module supports up to four differential analog channel inputs. Each differential analog input is a pair of external pins,  $DADPx$  and  $DADMx$ , referenced to each other to provide the most accurate analog to digital readings. A differential input is selected for conversion through  $SC1[ADCH]$  when  $SC1n[DIFF]$  is high. All  $DADPx$  inputs may be used as single-ended inputs if  $SC1n[DIFF]$  is low. In certain MCU configurations, some  $DADMx$  inputs may also be used as single-ended inputs if  $SC1n[DIFF]$  is low. For ADC connections specific to this device, see the chip-specific ADC information.

## 40.4 Memory map and register definitions

This section describes the ADC registers.

**ADC memory map**

**40.4.1 ADC Status and Control Registers 1 (ADCx\_SC1n)**

SC1A is used for both software and hardware trigger modes of operation.

To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC can have more than one status and control register: one for each conversion. The SC1B–SC1n registers indicate potentially multiple SC1 registers for use only in hardware trigger mode. See the chip configuration information about the number of SC1n registers specific to this device. The SC1n registers have identical fields, and are used in a "ping-pong" approach to control ADC operation.

At any one point in time, only one of the SC1n registers is actively controlling ADC conversions. Updating SC1A while SC1n is actively controlling a conversion is allowed, and vice-versa for any of the SC1n registers specific to this MCU.

Writing SC1A while SC1A is actively controlling a conversion aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, writes to SC1A subsequently initiate a new conversion, if SC1[ADCH] contains a value other than all 1s (module disabled).

Writing any of the SC1n registers while that specific SC1n register is actively controlling a conversion aborts the current conversion. None of the SC1B–SC1n registers are used for software trigger operation and therefore writes to the SC1B–SC1n registers do not initiate a new conversion.

Address: 4003\_B000h base + 0h offset + (4d × i), where i=0d to 1d

| 7<br>COCO        | <p>Conversion Complete Flag</p> <p>This is a read-only field that is set each time a conversion is completed when the compare function is disabled, or SC2[ACFE]=0 and the hardware average function is disabled, or SC3[AVGE]=0. When the compare function is enabled, or SC2[ACFE]=1, COCO is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled, or SC3[AVGE]=1, COCO is set upon completion of the selected number of conversions (determined by AVGS). COCO in SC1A is also set at the completion of a calibration sequence. COCO is cleared when the respective SC1n register is written or when the respective Rn register is read.</p> <p>0 Conversion is not completed.<br/>1 Conversion is completed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 6<br>AIEN        | <p>Interrupt Enable</p> <p>Enables conversion complete interrupts. When COCO becomes set while the respective AIEN is high, an interrupt is asserted.</p> <p>0 Conversion complete interrupt is disabled.<br/>1 Conversion complete interrupt is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5<br>DIFF        | <p>Differential Mode Enable</p> <p>Configures the ADC to operate in differential mode. When enabled, this mode automatically selects from the differential channels, and changes the conversion algorithm and the number of cycles to complete a conversion.</p> <p>0 Single-ended conversions and input channels are selected.<br/>1 Differential conversions and input channels are selected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ADCH             | <p>Input channel select</p> <p>Selects one of the input channels. The input channel decode depends on the value of DIFF. DAD0-DAD3 are associated with the input pin pairs DADPx and DADMx.</p> <p><b>NOTE:</b> Some of the input channel options in the bitfield-setting descriptions might not be available for your device. For the actual ADC channel assignments for your device, see the Chip Configuration details.</p> <p>The successive approximation converter subsystem is turned off when the channel select bits are all set, that is, ADCH = 11111. This feature allows explicit disabling of the ADC and isolation of the input channel from all sources. Terminating continuous conversions this way prevents an additional single conversion from being performed. It is not necessary to set ADCH to all 1s to place the ADC in a low-power state when continuous conversions are not enabled because the module automatically enters a low-power state when a conversion completes.</p> <p>00000 When DIFF=0, DADP0 is selected as input; when DIFF=1, DAD0 is selected as input.<br/>00001 When DIFF=0, DADP1 is selected as input; when DIFF=1, DAD1 is selected as input.<br/>00010 When DIFF=0, DADP2 is selected as input; when DIFF=1, DAD2 is selected as input.<br/>00011 When DIFF=0, DADP3 is selected as input; when DIFF=1, DAD3 is selected as input.<br/>00100 When DIFF=0, AD4 is selected as input; when DIFF=1, it is reserved.<br/>00101 When DIFF=0, AD5 is selected as input; when DIFF=1, it is reserved.<br/>00110 When DIFF=0, AD6 is selected as input; when DIFF=1, it is reserved.<br/>00111 When DIFF=0, AD7 is selected as input; when DIFF=1, it is reserved.</p> |

**ADCx\_SC1n field descriptions (continued)**

| Field | Description                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 01000 | When DIFF=0, AD8 is selected as input; when DIFF=1, it is reserved.                                                                                                    |
| 01001 | When DIFF=0, AD9 is selected as input; when DIFF=1, it is reserved.                                                                                                    |
| 01010 | When DIFF=0, AD10 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 01011 | When DIFF=0, AD11 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 01100 | When DIFF=0, AD12 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 01101 | When DIFF=0, AD13 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 01110 | When DIFF=0, AD14 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 01111 | When DIFF=0, AD15 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10000 | When DIFF=0, AD16 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10001 | When DIFF=0, AD17 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10010 | When DIFF=0, AD18 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10011 | When DIFF=0, AD19 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10100 | When DIFF=0, AD20 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10101 | When DIFF=0, AD21 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10110 | When DIFF=0, AD22 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 10111 | When DIFF=0, AD23 is selected as input; when DIFF=1, it is reserved.                                                                                                   |
| 11000 | Reserved.                                                                                                                                                              |
| 11001 | Reserved.                                                                                                                                                              |
| 11010 | When DIFF=0, Temp Sensor (single-ended) is selected as input; when DIFF=1, Temp Sensor (differential) is selected as input.                                            |
| 11011 | When DIFF=0, Bandgap (single-ended) is selected as input; when DIFF=1, Bandgap (differential) is selected as input.                                                    |
| 11100 | Reserved.                                                                                                                                                              |
| 11101 | When DIFF=0, $V_{REFSH}$ is selected as input; when DIFF=1, $-V_{REFSH}$ (differential) is selected as input. Voltage reference selected is determined by SC2[REFSEL]. |
| 11110 | When DIFF=0, $V_{REFSL}$ is selected as input; when DIFF=1, it is reserved. Voltage reference selected is determined by SC2[REFSEL].                                   |
| 11111 | Module is disabled.                                                                                                                                                    |

## 40.4.2 ADC Configuration Register 1 (ADCx\_CFG1)

The configuration Register 1 (CFG1) selects the mode of operation, clock source, clock divide, and configuration for low power or long sample time.

Address: 4003\_B000h base + 8h offset = 4003\_B008h

| 4<br>ADLSMP      | Sample Time Configuration<br><br>Selects between different sample times based on the conversion mode selected. This field adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption if continuous conversions are enabled and high conversion rates are not required. When ADLSMP=1, the long sample time select bits, (ADLSTS[1:0]), can select the extent of the long sample time. |

| ADICLK      | Input Clock Select<br><br>Selects the input clock source to generate the internal clock, ADCK. Note that when the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start, when CFG2[ADACKEN]=0, the asynchronous clock is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated.<br><br>00 Bus clock<br>01 Alternate clock 2 (ALTCLK2)<br>10 Alternate clock (ALTCLK)<br>11 Asynchronous clock (ADACK) |

**40.4.3 ADC Configuration Register 2 (ADCx\_CFG2)**

Configuration Register 2 (CFG2) selects the special high-speed configuration for very high speed conversions and selects the long sample time duration during long sample mode.

Address: 4003\_B000h base + Ch offset = 4003\_B00Ch

| ADLSTS           | Long Sample Time Select<br><br>Selects between the extended sample times when long sample time is selected, that is, when CFG1[ADLSMP]=1. This allows higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required.<br><br>00 Default longest sample time; 20 extra ADCK cycles; 24 ADCK cycles total.<br>01 12 extra ADCK cycles; 16 ADCK cycles total sample time.<br>10 6 extra ADCK cycles; 10 ADCK cycles total sample time.<br>11 2 extra ADCK cycles; 6 ADCK cycles total sample time.                                                                                                     |

**40.4.4 ADC Data Result Register (ADCx\_Rn)**

The data result registers (Rn) contain the result of an ADC conversion of the channel selected by the corresponding status and channel control register (SC1A:SC1n). For every status and channel control register, there is a corresponding data result register.

Unused bits in  $R_n$  are cleared in unsigned right-aligned modes and carry the sign bit (MSB) in sign-extended 2's complement modes. For example, when configured for 10-bit single-ended mode, D[15:10] are cleared. When configured for 11-bit differential mode, D[15:10] carry the sign bit, that is, bit 10 extended through bit 15.

The following table describes the behavior of the data result registers in the different modes of operation.

**Table 40-4. Data result register description**

| Conversion mode     | D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | Format                       |
|---------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|------------------------------|
| 16-bit differential | S   | D   | D   | D   | D   | D   | D  | D  | D  | D  | D  | D  | D  | D  | D  | D  | Signed 2's complement        |
| 16-bit single-ended | D   | D   | D   | D   | D   | D   | D  | D  | D  | D  | D  | D  | D  | D  | D  | D  | Unsigned right justified     |

### 40.4.5 Compare Value Registers (ADCx\_CVn)

The Compare Value Registers (CV1 and CV2) contain a compare value used to compare the conversion result when the compare function is enabled, that is, SC2[ACFE]=1. This register is formatted in the same way as the Rn registers in different modes of operation for both bit position definition and value format using unsigned or sign-extended 2's complement. Therefore, the compare function uses only the CVn fields that are related to the ADC mode of operation.

The compare value 2 register (CV2) is used only when the compare range function is enabled, that is, SC2[ACREN]=1.

Address: 4003\_B000h base + 18h offset + (4d × i), where i=0d to 1d

**40.4.8 ADC Offset Correction Register (ADCx\_OFS)**

The ADC Offset Correction Register (OFS) contains the user-selected or calibration-generated offset error correction value. This register is a 2's complement, left-justified, 16-bit value. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

**40.4.9 ADC Plus-Side Gain Register (ADCx\_PG)**

The Plus-Side Gain Register (PG) contains the gain error correction for the plus-side input in differential mode or the overall conversion in single-ended mode. PG, a 16-bit real number in binary format, is the gain adjustment factor, with the radix point fixed between PG[15] and PG[14]. This register must be written by the user with the value described in the calibration procedure. Otherwise, the gain error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

**40.4.10 ADC Minus-Side Gain Register (ADCx\_MG)**

The Minus-Side Gain Register (MG) contains the gain error correction for the minus-side input in differential mode. This register is ignored in single-ended mode. MG, a 16-bit real number in binary format, is the gain adjustment factor, with the radix point fixed between MG[15] and MG[14]. This register must be written by the user with the value described in the calibration procedure. Otherwise, the gain error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

### 40.4.11 ADC Plus-Side General Calibration Value Register (ADCx\_CLPD)

The Plus-Side General Calibration Value Registers (CLPx) contain calibration information that is generated by the calibration function. These registers contain seven calibration values of varying widths: CLP0[5:0], CLP1[6:0], CLP2[7:0], CLP3[8:0], CLP4[9:0], CLPS[5:0], and CLPD[5:0]. CLPx are automatically set when the self-calibration sequence is done, that is, CAL is cleared. If these registers are written by the user after calibration, the linearity error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

Address: 4003\_B000h base + 34h offset = 4003\_B034h

### 40.4.18 ADC Minus-Side General Calibration Value Register (ADCx\_CLMD)

The Minus-Side General Calibration Value (CLMx) registers contain calibration information that is generated by the calibration function. These registers contain seven calibration values of varying widths: CLM0[5:0], CLM1[6:0], CLM2[7:0], CLM3[8:0], CLM4[9:0], CLMS[5:0], and CLMD[5:0]. CLMx are automatically set when the self-calibration sequence is done, that is, CAL is cleared. If these registers are written by the user after calibration, the linearity error specifications may not be met.

For more information regarding the calibration procedure, please refer to the [Calibration function](#) section.

## 40.5 Functional description

The ADC module is disabled during reset, in Low-Power Stop mode, or when SC1n[ADCH] are all high; see the power management information for details. The module is idle when a conversion has completed and another conversion has not been initiated. When it is idle and the asynchronous clock output enable is disabled, or CFG2[ADACKEN]= 0, the module is in its lowest power state. The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications, the ADC module must be calibrated using the on-chip calibration function.

See [Calibration function](#) for details on how to perform calibration.

When the conversion is completed, the result is placed in the Rn data registers. The respective SC1n[COCO] is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, or, when SC1n[AIEN]=1.

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the CV1 and CV2 registers. The compare function is enabled by setting SC2[ACFE] and operates in any of the conversion modes and configurations.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting SC3[AVGE] and operates in any of the conversion modes and configurations.

### NOTE

For the chip specific modes of operation, see the power management information of this MCU.

## 40.5.1 Clock select and divide control

One of four clock sources can be selected as the clock source for the ADC module.

This clock source is then divided by a configurable value to generate the input clock ADCK, to the module. The clock is selected from one of the following sources by means of CFG1[ADICLK].

- Bus clock. This is the default selection following reset.
- ALTCLK2: As defined for this MCU. See the chip configuration information. Conversions are possible using ALTCLK2 as the input clock source while the MCU is in Normal Stop mode.
- ALTCLK: As defined for this MCU. See the chip configuration information. Conversions are possible using ALTCLK as the input clock source while the MCU is in Normal Stop mode.
- Asynchronous clock (ADACK): This clock is generated from a clock source within the ADC module. When the ADACK clock source is selected, it is not required to be active prior to conversion start. When it is selected and it is not active prior to a conversion start CFG2[ADACKEN]=0, ADACK is activated at the start of a conversion and deactivated when conversions are terminated. In this case, there is an associated clock startup delay each time the clock source is re-activated. To avoid the conversion time variability and latency associated with the ADACK clock startup, set CFG2[ADACKEN]=1 and wait the worst-case startup time of 5  $\mu$ s prior to initiating any conversions using the ADACK clock source. Conversions are possible using ADACK as the input clock source while the MCU is in Normal Stop mode. See [Power Control](#) for more information.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by CFG1[ADIV] and can be divide-by 1, 2, 4, or 8.

### 40.5.2 Voltage reference selection

The ADC can be configured to accept one of the two voltage reference pairs as the reference voltage ( $V_{REFSH}$  and  $V_{REFSL}$ ) used for conversions.

Each pair contains a positive reference that must be between the minimum Ref Voltage High and  $V_{DDA}$ , and a ground reference that must be at the same potential as  $V_{SSA}$ . The two pairs are external ( $V_{REFH}$  and  $V_{REFL}$ ) and alternate ( $V_{ALTH}$  and  $V_{ALTL}$ ). These voltage references are selected using  $SC2[REFSEL]$ . The alternate ( $V_{ALTH}$  and  $V_{ALTL}$ ) voltage reference pair may select additional external pins or internal sources depending on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

### 40.5.3 Hardware trigger and channel selects

The ADC module has a selectable asynchronous hardware conversion trigger, ADHWT, that is enabled when  $SC2[ADTRG]$  is set and a hardware trigger select event, ADHWTSn, has occurred.

This source is not available on all MCUs. See the chip-specific ADC information for information on the ADHWT source and the ADHWTSn configurations specific to this MCU.

When an ADHWT source is available and hardware trigger is enabled, that is  $SC2[ADTRG]=1$ , a conversion is initiated on the rising-edge of ADHWT after a hardware trigger select event, that is, ADHWTSn, has occurred. If a conversion is in progress when a rising-edge of a trigger occurs, the rising-edge is ignored. In continuous convert configuration, only the initial rising-edge to launch continuous conversions is observed, and until conversion is aborted, the ADC continues to do conversions on the same SCn register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The hardware trigger select event, ADHWTSn, must be set prior to the receipt of the ADHWT signal. If these conditions are not met, the converter may ignore the trigger or use the incorrect configuration. If a hardware trigger select event is asserted during a conversion, it must stay asserted until the end of current conversion and remain set until the receipt of the ADHWT signal to trigger a new conversion. The channel and status fields selected for the conversion depend on the active trigger select signal:

- ADHWTS<sub>A</sub> active selects SC1<sub>A</sub>.
- ADHWTS<sub>n</sub> active selects SC1<sub>n</sub>.

### Note

Asserting more than one hardware trigger select signal (ADHWTSn) at the same time results in unknown results. To avoid this, select only one hardware trigger select signal (ADHWTSn) prior to the next intended conversion.

When the conversion is completed, the result is placed in the Rn registers associated with the ADHWTSn received. For example:

- ADHWTSa active selects RA register
- ADHWTSn active selects Rn register

The conversion complete flag associated with the ADHWTSn received, that is, SC1n[COCO], is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled, that is, SC1[AIEN]=1.

## 40.5.4 Conversion control

Conversions can be performed as determined by CFG1[MODE] and SC1n[DIFF] as shown in the description of CFG1[MODE].

Conversions can be initiated by a software or hardware trigger.

In addition, the ADC module can be configured for:

- Low-power operation
- Long sample time
- Continuous conversion
- Hardware average
- Automatic compare of the conversion result to a software determined compare value

### 40.5.4.1 Initiating conversions

A conversion is initiated:

- Following a write to SC1A, with SC1n[ADCH] not all 1's, if software triggered operation is selected, that is, when SC2[ADTRG]=0.
- Following a hardware trigger, or ADHWT event, if hardware triggered operation is selected, that is, SC2[ADTRG]=1, and a hardware trigger select event, ADHWTSn, has occurred. The channel and status fields selected depend on the active trigger select signal:
  - ADHWTSa active selects SC1A.

- ADHWTSn active selects SC1n.
- if neither is active, the off condition is selected

### Note

Selecting more than one ADHWTSn prior to a conversion completion will result in unknown results. To avoid this, select only one ADHWTSn prior to a conversion completion.

- Following the transfer of the result to the data registers when continuous conversion is enabled, that is, when SC3[ADCO] = 1.

If continuous conversions are enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation, that is, when SC2[ADTRG] = 0, continuous conversions begin after SC1A is written and continue until aborted. In hardware triggered operation, that is, when SC2[ADTRG] = 1 and one ADHWTSn event has occurred, continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions are completed. In software triggered operation, conversions begin after SC1A is written. In hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions are also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

## 40.5.4.2 Completing conversions

A conversion is completed when the result of the conversion is transferred into the data result registers, Rn. If the compare functions are disabled, this is indicated by setting of SC1n[COCO]. If hardware averaging is enabled, the respective SC1n[COCO] sets only if the last of the selected number of conversions is completed. If the compare function is enabled, the respective SC1n[COCO] sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then the respective SC1n[COCO] sets only if the last of the selected number of conversions is completed and the compare condition is true. An interrupt is generated if the respective SC1n[AIEN] is high at the time that the respective SC1n[COCO] is set.

### 40.5.4.3 Aborting conversions

Any conversion in progress is aborted when:

- Writing to SC1A while it is actively controlling a conversion, aborts the current conversion. In Software Trigger mode, when SC2[ADTRG]=0, a write to SC1A initiates a new conversion if SC1A[ADCH] is equal to a value other than all 1s. Writing to any of the SC1B–SC1n registers while that specific SC1B–SC1n register is actively controlling a conversion aborts the current conversion. The SC1(B-n) registers are not used for software trigger operation and therefore writes to the SC1(B-n) registers do not initiate a new conversion.
- A write to any ADC register besides the SC1A-SC1n registers occurs. This indicates that a change in mode of operation has occurred and the current conversion is therefore invalid.
- The MCU is reset or enters Low-Power Stop modes.
- The MCU enters Normal Stop mode with ADACK or Alternate Clock Sources not enabled.

When a conversion is aborted, the contents of the data registers, Rn, are not altered. The data registers continue to be the values transferred after the completion of the last successful conversion. If the conversion was aborted by a reset or Low-Power Stop modes, RA and Rn return to their reset states.

### 40.5.4.4 Power control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source, but the asynchronous clock output is disabled, that is CFG2[ADACKEN]=0, the ADACK clock generator also remains in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled, that is, CFG2[ADACKEN]=1, it remains active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting CFG1[ADLPC]. This results in a lower maximum value for  $f_{\text{ADCK}}$ .

### 40.5.4.5 Sample time and total conversion time

For short sample, that is, when CFG1[ADLSMP]=0, there is a 2-cycle adder for first conversion over the base sample time of four ADCK cycles. For high-speed conversions, that is, when CFG2[ADHSC]=1, there is an additional 2-cycle adder on any conversion. The table below summarizes sample times for the possible ADC configurations.

| ADC configuration |              |             | Sample time (ADCK cycles) |            |
|-------------------|--------------|-------------|---------------------------|------------|
| CFG1[ADLSMP]      | CFG2[ADLSTS] | CFG2[ADHSC] | First or Single           | Subsequent |
| 0                 | X            | 0           | 6                         | 4          |
| 1                 | 00           | 0           | 24                        |            |
| 1                 | 01           | 0           | 16                        |            |
| 1                 | 10           | 0           | 10                        |            |
| 1                 | 11           | 0           | 6                         |            |
| 0                 | X            | 1           | 8                         | 6          |
| 1                 | 00           | 1           | 26                        |            |
| 1                 | 01           | 1           | 18                        |            |
| 1                 | 10           | 1           | 12                        |            |
| 1                 | 11           | 1           | 8                         |            |

The total conversion time depends upon:

- The sample time as determined by CFG1[ADLSMP] and CFG2[ADLSTS]
- The MCU bus frequency
- The conversion mode, as determined by CFG1[MODE] and SC1n[DIFF]
- The high-speed configuration, that is, CFG2[ADHSC]
- The frequency of the conversion clock, that is,  $f_{ADCK}$ .

CFG2[ADHSC] is used to configure a higher clock input frequency. This will allow faster overall conversion times. To meet internal ADC timing requirements, CFG2[ADHSC] adds additional ADCK cycles. Conversions with CFG2[ADHSC]=1 take two more ADCK cycles. CFG2[ADHSC] must be used when the ADCLK exceeds the limit for CFG2[ADHSC]=0.

After the module becomes active, sampling of the input begins.

1. CFG1[ADLSMP] and CFG2[ADLSTS] select between sample times based on the conversion mode that is selected.
2. When sampling is completed, the converter is isolated from the input channel and a successive approximation algorithm is applied to determine the digital value of the analog signal.
3. The result of the conversion is transferred to Rn upon completion of the conversion algorithm.

If the bus frequency is less than  $f_{ADCK}$ , precise sample time for continuous conversions cannot be guaranteed when short sample is enabled, that is, when  $CFG1[ADLSMP]=0$ .

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by  $CFG1[ADICLK]$ , and the divide ratio is specified by  $CFG1[ADIV]$ .

The maximum total conversion time for all configurations is summarized in the equation below. See the following tables for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder} + \text{HSCAdder})$$

**Equation 1. Conversion time equation**

**Table 40-5. Single or first continuous time adder (SFCAdder)**

| CFG1[ADLSMP] | CFG2[ADACKEN] | CFG1[ADICLK] | Single or first continuous time adder (SFCAdder) |
|--------------|---------------|--------------|--------------------------------------------------|
| 1            | x             | 0x, 10       | 3 ADCK cycles + 5 bus clock cycles               |
| 1            | 1             | 11           | 3 ADCK cycles + 5 bus clock cycles <sup>1</sup>  |
| 1            | 0             | 11           | 5 $\mu$ s + 3 ADCK cycles + 5 bus clock cycles   |
| 0            | x             | 0x, 10       | 5 ADCK cycles + 5 bus clock cycles               |
| 0            | 1             | 11           | 5 ADCK cycles + 5 bus clock cycles <sup>1</sup>  |
| 0            | 0             | 11           | 5 $\mu$ s + 5 ADCK cycles + 5 bus clock cycles   |

1. To achieve this time,  $CFG2[ADACKEN]$  must be 1 for at least 5  $\mu$ s prior to the conversion is initiated.

**Table 40-6. Average number factor (AverageNum)**

| SC3[AVGE] | SC3[AVGS] | Average number factor (AverageNum) |
|-----------|-----------|------------------------------------|
| 0         | xx        | 1                                  |
| 1         | 00        | 4                                  |
| 1         | 01        | 8                                  |
| 1         | 10        | 16                                 |
| 1         | 11        | 32                                 |

**Table 40-7. Base conversion time (BCT)**

| Mode             | Base conversion time (BCT) |
|------------------|----------------------------|
| 8b single-ended  | 17 ADCK cycles             |
| 9b differential  | 27 ADCK cycles             |
| 10b single-ended | 20 ADCK cycles             |
| 11b differential | 30 ADCK cycles             |
| 12b single-ended | 20 ADCK cycles             |
| 13b differential | 30 ADCK cycles             |

*Table continues on the next page...*

**Table 40-7. Base conversion time (BCT) (continued)**

| Mode             | Base conversion time (BCT) |
|------------------|----------------------------|
| 16b single-ended | 25 ADCK cycles             |
| 16b differential | 34 ADCK cycles             |

**Table 40-8. Long sample time adder (LSTAdder)**

| CFG1[ADLSMP] | CFG2[ADLSTS] | Long sample time adder (LSTAdder) |
|--------------|--------------|-----------------------------------|
| 0            | xx           | 0 ADCK cycles                     |
| 1            | 00           | 20 ADCK cycles                    |
| 1            | 01           | 12 ADCK cycles                    |
| 1            | 10           | 6 ADCK cycles                     |
| 1            | 11           | 2 ADCK cycles                     |

**Table 40-9. High-speed conversion time adder (HSCAdder)**

| CFG2[ADHSC] | High-speed conversion time adder (HSCAdder) |
|-------------|---------------------------------------------|
| 0           | 0 ADCK cycles                               |
| 1           | 2 ADCK cycles                               |

### Note

The ADCK frequency must be between  $f_{ADCK}$  minimum and  $f_{ADCK}$  maximum to meet ADC specifications.

## 40.5.4.6 Conversion time examples

The following examples use the [Equation 1 on page 947](#), and the information provided in [Table 40-5](#) through [Table 40-9](#).

### 40.5.4.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is:

- 10-bit mode, with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 8 MHz
- Long sample time disabled
- High-speed conversion disabled

The conversion time for a single conversion is calculated by using the [Equation 1 on page 947](#), and the information provided in [Table 40-5](#) through [Table 40-9](#). The table below lists the variables of [Equation 1 on page 947](#).

**Table 40-10. Typical conversion time**

| Variable   | Time                               |
|------------|------------------------------------|
| SFCAdder   | 5 ADCK cycles + 5 bus clock cycles |
| AverageNum | 1                                  |
| BCT        | 20 ADCK cycles                     |
| LSTAdder   | 0                                  |
| HSCAdder   | 0                                  |

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for a bus clock and an ADCK frequency equal to 8 MHz, the resulting conversion time is 3.75  $\mu$ s.

#### 40.5.4.6.2 Long conversion time configuration

A configuration for long ADC conversion is:

- 16-bit differential mode with the bus clock selected as the input clock source
- The input clock divide-by-8 ratio selected
- Bus frequency of 8 MHz
- Long sample time enabled
- Configured for longest adder
- High-speed conversion disabled
- Average enabled for 32 conversions

The conversion time for this conversion is calculated by using the [Equation 1 on page 947](#), and the information provided in [Table 40-5](#) through [Table 40-9](#). The following table lists the variables of the [Equation 1 on page 947](#).

**Table 40-11. Typical conversion time**

| Variable   | Time                               |
|------------|------------------------------------|
| SFCAdder   | 3 ADCK cycles + 5 bus clock cycles |
| AverageNum | 32                                 |
| BCT        | 34 ADCK cycles                     |
| LSTAdder   | 20 ADCK cycles                     |
| HSCAdder   | 0                                  |

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for bus clock equal to 8 MHz and ADCK equal to 1 MHz, the resulting conversion time is 57.625  $\mu$ s, that is, AverageNum. This results in a total conversion time of 1.844 ms.

#### 40.5.4.6.3 Short conversion time configuration

A configuration for short ADC conversion is:

- 8-bit Single-Ended mode with the bus clock selected as the input clock source
- The input clock divide-by-1 ratio selected
- Bus frequency of 20 MHz
- Long sample time disabled
- High-speed conversion enabled

The conversion time for this conversion is calculated by using the [Equation 1 on page 947](#), and the information provided in [Table 40-5](#) through [Table 40-9](#). The table below lists the variables of [Equation 1 on page 947](#).

**Table 40-12. Typical conversion time**

| Variable   | Time                               |
|------------|------------------------------------|
| SFCAdder   | 5 ADCK cycles + 5 bus clock cycles |
| AverageNum | 1                                  |
| BCT        | 17 ADCK cycles                     |
| LSTAdder   | 0 ADCK cycles                      |
| HSCAdder   | 2                                  |

The resulting conversion time is generated using the parameters listed in the preceding table. Therefore, for bus clock and ADCK frequency equal to 20 MHz, the resulting conversion time is 1.45  $\mu$ s.

#### 40.5.4.7 Hardware average function

The hardware average function can be enabled by setting SC3[AVGE]=1 to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which can select 4, 8, 16, or 32 conversions to be averaged. While the hardware average function is in progress, SC2[ADACT] will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated once the selected number of conversions have been completed. When hardware averaging is selected, the completion of a single conversion will not set SC1n[COCO].

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, Rn, and SC1n[COCO] is set. An ADC interrupt is generated upon the setting of SC1n[COCO] if the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

### Note

The hardware average function can perform conversions on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the hardware average is completed if SC1n[AIEN] is set.

## 40.5.5 Automatic compare function

The compare function can be configured to check whether the result is less than or greater-than-or-equal-to a single compare value, or, if the result falls within or outside a range determined by two compare values.

The compare mode is determined by SC2[ACFGT], SC2[ACREN], and the values in the compare value registers, CV1 and CV2. After the input is sampled and converted, the compare values in CV1 and CV2 are used as described in the following table. There are six Compare modes as shown in the following table.

**Table 40-13. Compare modes**

| SC2[ACFGT] | SC2[ACREN] | ADCCV1 relative to ADCCV2 | Function                           | Compare mode description                                                                                       |
|------------|------------|---------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 0          | 0          | —                         | Less than threshold                | Compare true if the result is less than the CV1 registers.                                                     |
| 1          | 0          | —                         | Greater than or equal to threshold | Compare true if the result is greater than or equal to CV1 registers.                                          |
| 0          | 1          | Less than or equal        | Outside range, not inclusive       | Compare true if the result is less than CV1 <b>Or</b> the result is greater than CV2.                          |
| 0          | 1          | Greater than              | Inside range, not inclusive        | Compare true if the result is less than CV1 <b>And</b> the result is greater than CV2.                         |
| 1          | 1          | Less than or equal        | Inside range, inclusive            | Compare true if the result is greater than or equal to CV1 <b>And</b> the result is less than or equal to CV2. |
| 1          | 1          | Greater than              | Outside range, inclusive           | Compare true if the result is greater than or equal to CV1 <b>Or</b> the result is less than or equal to CV2.  |

With SC2[ACREN] =1, and if the value of CV1 is less than or equal to the value of CV2, then setting SC2[ACFGT] will select a trigger-if-inside-compare-range inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than CV2, setting SC2[ACFGT] will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing SC2[ACFGT] will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, SC1n[COCO] is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, SC1n[COCO] is not set and the conversion result data will not be transferred to the result register, Rn. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated when SC1n[COCO] is set and the respective ADC interrupt is enabled, that is, SC1n[AIEN]=1.

### **Note**

The compare function can monitor the voltage on a channel while the MCU is in Wait or Normal Stop modes. The ADC interrupt wakes the MCU when the compare condition is met.

## **40.5.6 Calibration function**

The ADC contains a self-calibration function that is required to achieve the specified accuracy.

Calibration must be run, or valid calibration values written, after any reset and before a conversion is initiated. The calibration function sets the offset calibration value, the minus-side calibration values, and the plus-side calibration values. The offset calibration value is automatically stored in the ADC offset correction register (OFS), and the plus-side and minus-side calibration values are automatically stored in the ADC plus-side and minus-side calibration registers, CLPx and CLMx. The user must configure the ADC correctly prior to calibration, and must generate the plus-side and minus-side gain calibration results and store them in the ADC plus-side gain register (PG) after the calibration function completes.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, and high speed configuration according to the application's clock source availability and needs. If the

application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. For best calibration results:

- Set hardware averaging to maximum, that is, SC3[AVGE]=1 and SC3[AVGS]=11 for an average of 32
- Set ADC clock frequency  $f_{\text{ADCK}}$  less than or equal to 4 MHz
- $V_{\text{REFH}}=V_{\text{DDA}}$
- Calibrate at nominal voltage and temperature

The input channel, conversion mode continuous function, compare function, resolution mode, and differential/single-ended mode are all ignored during the calibration function.

To initiate calibration, the user sets SC3[CAL] and the calibration will automatically begin if the SC2[ADTRG] is 0. If SC2[ADTRG] is 1, SC3[CAL] will not get set and SC3[CALF] will be set. While calibration is active, no ADC register can be written and no stop mode may be entered, or the calibration routine will be aborted causing SC3[CAL] to clear and SC3[CALF] to set. At the end of a calibration sequence, SC1n[COCO] will be set. SC1n[AIEN] can be used to allow an interrupt to occur at the end of a calibration sequence. At the end of the calibration routine, if SC3[CALF] is not set, the automatic calibration routine is completed successfully.

To complete calibration, the user must generate the gain calibration values using the following procedure:

1. Initialize or clear a 16-bit variable in RAM.
2. Add the plus-side calibration results CLP0, CLP1, CLP2, CLP3, CLP4, and CLPS to the variable.
3. Divide the variable by two.
4. Set the MSB of the variable.
5. The previous two steps can be achieved by setting the carry bit, rotating to the right through the carry bit on the high byte and again on the low byte.
6. Store the value in the plus-side gain calibration register PG.
7. Repeat the procedure for the minus-side gain calibration value.

When calibration is complete, the user may reconfigure and use the ADC as desired. A second calibration may also be performed, if desired, by clearing and again setting SC3[CAL].

Overall, the calibration routine may take as many as 14k ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen. For an 8 MHz clock source, this length amounts to about 1.7 ms. To reduce this latency, the calibration values, which are offset, plus-side and minus-side gain, and plus-side and minus-side calibration values, may be stored in flash memory after an initial calibration and recovered prior to the first ADC conversion. This method can reduce the calibration latency to 20 register store operations on all subsequent power, reset, or Low-Power Stop mode recoveries.

Further information on the calibration procedure can be found in the Calibration section of [AN3949: ADC16 Calibration Procedure and Programmable Delay Block Synchronization](#).

## 40.5.7 User-defined offset function

OFS contains the user-selected or calibration-generated offset error correction value.

This register is a 2's complement, left-justified. The value in OFS is subtracted from the conversion and the result is transferred into the result registers, Rn. If the result is greater than the maximum or less than the minimum result value, it is forced to the appropriate limit for the current mode of operation.

The formatting of the OFS is different from the data result register, Rn, to preserve the resolution of the calibration value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8-bit single-ended mode, OFS[14:7] are subtracted from D[7:0]; OFS[15] indicates the sign (negative numbers are effectively added to the result) and OFS[6:0] are ignored. The same bits are used in 9-bit differential mode because OFS[15] indicates the sign bit, which maps to D[8]. For 16-bit differential mode, OFS[15:0] are directly subtracted from the conversion result data D[15:0]. In 16-bit single-ended mode, there is no field in the OFS corresponding to the least significant result D[0], so odd values, such as -1 or +1, cannot be subtracted from the result.

OFS is automatically set according to calibration requirements once the self-calibration sequence is done, that is, SC3[CAL] is cleared. The user may write to OFS to override the calibration result if desired. If the OFS is written by the user to a value that is different from the calibration value, the ADC error specifications may not be met. Storing the value generated by the calibration function in memory before overwriting with a user-specified value is recommended.

### Note

There is an effective limit to the values of offset that can be set by the user. If the magnitude of the offset is too high, the results of the conversions will cap off at the limits.

The offset calibration function may be employed by the user to remove application offsets or DC bias values. OFS may be written with a number in 2's complement format and this offset will be subtracted from the result, or hardware averaged value. To add an offset, store the negative offset in 2's complement format and the effect will be an addition. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value. The minimum value for single-ended conversions is 0x0000; for a differential conversion it is 0x8000.

To preserve accuracy, the calibrated offset value initially stored in OFS must be added to the user-defined offset. For applications that may change the offset repeatedly during operation, store the initial offset calibration value in flash so it can be recovered and added to any user offset adjustment value and the sum stored in OFS.

## 40.5.8 Temperature sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs.

The following equation provides an approximate transfer function of the temperature sensor.

$$\text{Temp} = 25 - \left( (V_{\text{TEMP}} - V_{\text{TEMP25}}) \div m \right)$$

**Equation 2. Approximate transfer function of the temperature sensor**

where:

- $V_{\text{TEMP}}$  is the voltage of the temperature sensor channel at the ambient temperature.
- $V_{\text{TEMP25}}$  is the voltage of the temperature sensor channel at 25 °C.
- $m$  is referred as temperature sensor slope in the device data sheet. It is the hot or cold voltage versus temperature slope in V/°C.

For temperature calculations, use the  $V_{\text{TEMP25}}$  and temperature sensor slope values from the ADC Electricals table.

In application code, the user reads the temperature sensor channel, calculates  $V_{TEMP}$ , and compares to  $V_{TEMP25}$ . If  $V_{TEMP}$  is greater than  $V_{TEMP25}$  the cold slope value is applied in the preceding equation. If  $V_{TEMP}$  is less than  $V_{TEMP25}$ , the hot slope value is applied in the preceding equation. ADC Electricals table may only specify one temperature sensor slope value. In that case, the user could use the same slope for the calculation across the operational temperature range.

For more information on using the temperature sensor, see the application note titled *Temperature Sensor for the HCS08 Microcontroller Family* (document AN3031).

### 40.5.9 MCU wait mode operation

Wait mode is a lower-power consumption Standby mode from which recovery is fast because the clock sources remain active.

If a conversion is in progress when the MCU enters Wait mode, it continues until completion. Conversions can be initiated while the MCU is in Wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, ADACK, and Alternate Clock sources are available as conversion clock sources while in Wait mode. The use of ALTCLK as the conversion clock source in Wait is dependent on the definition of ALTCLK for this MCU. See the Chip Configuration information on ALTCLK specific to this MCU.

If the compare and hardware averaging functions are disabled, a conversion complete event sets  $SC1n[COCO]$  and generates an ADC interrupt to wake the MCU from Wait mode if the respective ADC interrupt is enabled, that is, when  $SC1n[AIEN]=1$ . If the hardware averaging function is enabled,  $SC1n[COCO]$  will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled,  $SC1n[COCO]$  will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from Wait mode unless a new conversion is initiated by the hardware trigger.

### 40.5.10 MCU Normal Stop mode operation

Stop mode is a low-power consumption Standby mode during which most or all clock sources on the MCU are disabled.

### 40.5.10.1 Normal Stop mode with Bus Clock selected

If the Bus Clock is selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its Idle state. The contents of the ADC registers, including Rn, are unaffected by Normal Stop mode. After exiting from Normal Stop mode, a software or hardware trigger is required to resume conversions.

### 40.5.10.2 Normal Stop mode with ADACK or Alternate clock sources enabled

If ADACK or an Alternate clock source is selected as the conversion clock, the ADC continues operation during Normal Stop mode. See the chip-specific ADC information for configuration information for this device.

If a conversion is in progress when the MCU enters Normal Stop mode, it continues until completion. Conversions can be initiated while the MCU is in Normal Stop mode by means of the hardware trigger or if continuous conversions are enabled.

If the compare and hardware averaging functions are disabled, a conversion complete event sets SC1n[COCO] and generates an ADC interrupt to wake the MCU from Normal Stop mode if the respective ADC interrupt is enabled, that is, when SC1n[AIEN]=1. The result register, Rn, will contain the data from the first completed conversion that occurred during Normal Stop mode. If the hardware averaging function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, when the selected number of conversions are completed. If the compare function is enabled, SC1n[COCO] will set, and generate an interrupt if enabled, only if the compare conditions are met. If a single conversion is selected and the compare is not true, the ADC will return to its idle state and cannot wake the MCU from Normal Stop mode unless a new conversion is initiated by another hardware trigger.

## 40.6 Initialization information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module.

The user can configure the module for 16-bit, 12-bit, 10-bit, or 8-bit single-ended resolution or 16-bit, 13-bit, 11-bit, or 9-bit differential resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. For information used in this example, refer to [Table 40-8](#), [Table 40-9](#), and [Table 40-10](#).

## Note

Hexadecimal values are designated by a preceding 0x, binary values designated by a preceding %, and decimal values have no preceding character.

## 40.6.1 ADC module initialization example

### 40.6.1.1 Initialization sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is:

1. Calibrate the ADC by following the calibration instructions in [Calibration function](#).
2. Update CFG to select the input clock source and the divide ratio used to generate ADCK. This register is also used for selecting sample time and low-power configuration.
3. Update SC2 to select the conversion trigger, hardware or software, and compare function options, if enabled.
4. Update SC3 to select whether conversions will be continuous or completed only once (ADCO) and whether to perform hardware averaging.
5. Update SC1:SC1n registers to select whether conversions will be single-ended or differential and to enable or disable conversion complete interrupts. Also, select the input channel which can be used to perform conversions.

### 40.6.1.2 Pseudo-code example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low-power with a long sample time on input channel 1, where ADCK is derived from the bus clock divided by 1.

**CFG1 = 0x98 (%10011000)**

|         |        |    |                                                                             |
|---------|--------|----|-----------------------------------------------------------------------------|
| Bit 7   | ADLPC  | 1  | Configures for low power, lowers maximum clock speed.                       |
| Bit 6:5 | ADIV   | 00 | Sets the ADCK to the input clock ÷ 1.                                       |
| Bit 4   | ADLSMP | 1  | Configures for long sample time.                                            |
| Bit 3:2 | MODE   | 10 | Selects the single-ended 10-bit conversion, differential 11-bit conversion. |
| Bit 1:0 | ADICLK | 00 | Selects the bus clock.                                                      |

**SC2 = 0x00 (%00000000)**

|         |        |    |                                                                                        |
|---------|--------|----|----------------------------------------------------------------------------------------|
| Bit 7   | ADACT  | 0  | Flag indicates if a conversion is in progress.                                         |
| Bit 6   | ADTRG  | 0  | Software trigger selected.                                                             |
| Bit 5   | ACFE   | 0  | Compare function disabled.                                                             |
| Bit 4   | ACFGT  | 0  | Not used in this example.                                                              |
| Bit 3   | ACREN  | 0  | Compare range disabled.                                                                |
| Bit 2   | DMAEN  | 0  | DMA request disabled.                                                                  |
| Bit 1:0 | REFSEL | 00 | Selects default voltage reference pin pair (External pins $V_{REFH}$ and $V_{REFL}$ ). |

**SC1A = 0x41 (%01000001)**

|         |      |       |                                                          |
|---------|------|-------|----------------------------------------------------------|
| Bit 7   | COCO | 0     | Read-only flag which is set when a conversion completes. |
| Bit 6   | AIEN | 1     | Conversion complete interrupt enabled.                   |
| Bit 5   | DIFF | 0     | Single-ended conversion selected.                        |
| Bit 4:0 | ADCH | 00001 | Input channel 1 selected as ADC input channel.           |

**RA = 0xxx**

Holds results of conversion.

**CV = 0xxx**

Holds compare value when compare function enabled.

**Figure 40-3. Initialization flowchart example**

## 40.7 Application information

The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an ADC.

For guidance on selecting optimum external component values and converter parameters see [AN4373: Cookbook for SAR ADC Measurements](#).

### 40.7.1 External pins and routing

#### 40.7.1.1 Analog supply pins

Depending on the device, the analog power and ground supplies,  $V_{DDA}$  and  $V_{SSA}$ , of the ADC module are available as:

- $V_{DDA}$  and  $V_{SSA}$  available as separate pins—When available on a separate pin, both  $V_{DDA}$  and  $V_{SSA}$  must be connected to the same voltage potential as their corresponding MCU digital supply,  $V_{DD}$  and  $V_{SS}$ , and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.
- $V_{SSA}$  is shared on the same pin as the MCU digital  $V_{SS}$ .
- $V_{SSA}$  and  $V_{DDA}$  are shared with the MCU digital supply pins—In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the  $V_{SSA}$  pin. This must be the only ground connection between these supplies, if possible.  $V_{SSA}$  makes a good single point ground location.

#### 40.7.1.2 Analog voltage reference pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs used by the converter:

- $V_{REFSH}$  is the high reference voltage for the converter.
- $V_{REFSL}$  is the low reference voltage for the converter.

The ADC can be configured to accept one of two voltage reference pairs for  $V_{REFSH}$  and  $V_{REFSL}$ . Each pair contains a positive reference and a ground reference. The two pairs are external,  $V_{REFH}$  and  $V_{REFL}$  and alternate,  $V_{ALTH}$  and  $V_{ALTTL}$ . These voltage references are

selected using SC2[REFSEL]. The alternate voltage reference pair,  $V_{ALTH}$  and  $V_{ALTL}$ , may select additional external pins or internal sources based on MCU configuration. See the chip configuration information on the voltage references specific to this MCU.

In some packages, the external or alternate pairs are connected in the package to  $V_{DDA}$  and  $V_{SSA}$ , respectively. One of these positive references may be shared on the same pin as  $V_{DDA}$  on some devices. One of these ground references may be shared on the same pin as  $V_{SSA}$  on some devices.

If externally available, the positive reference may be connected to the same potential as  $V_{DDA}$  or may be driven by an external source to a level between the minimum Ref Voltage High and the  $V_{DDA}$  potential. The positive reference must never exceed  $V_{DDA}$ . If externally available, the ground reference must be connected to the same voltage potential as  $V_{SSA}$ . The voltage reference pairs must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the  $V_{REFH}$  and  $V_{REFL}$  loop. The best external component to meet this current demand is a 0.1  $\mu\text{F}$  capacitor with good high-frequency characteristics. This capacitor is connected between  $V_{REFH}$  and  $V_{REFL}$  and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum, that is, parasitic only.

### 40.7.1.3 Analog input pins

The external analog inputs are typically shared with digital I/O pins on MCU devices.

Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01  $\mu\text{F}$  capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used, they must be placed as near as possible to the package pins and be referenced to  $V_{SSA}$ .

For proper conversion, the input voltage must fall between  $V_{REFH}$  and  $V_{REFL}$ . If the input is equal to or exceeds  $V_{REFH}$ , the converter circuit converts the signal to 0xFFF, which is full scale 12-bit representation, 0x3FF, which is full scale 10-bit representation, or 0xFF, which is full scale 8-bit representation. If the input is equal to or less than  $V_{REFL}$ , the converter circuit converts it to 0x000. Input voltages between  $V_{REFH}$  and  $V_{REFL}$  are straight-line linear conversions. There is a brief current associated with  $V_{REFL}$  when the sampling capacitor is charging.

For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins must not be transitioning during conversions.

## 40.7.2 Sources of error

### 40.7.2.1 Sampling error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy.

$$RAS + RADIN = SC / (FMAX * NUMTAU * CADIN)$$

**Figure 40-4. Sampling equation**

Where:

RAS = External analog source resistance

SC = Number of ADCK cycles used during sample window

CADIN = Internal ADC input capacitance

NUMTAU =  $-\ln(\text{LSBERR} / 2^N)$

LSBERR = value of acceptable sampling error in LSBs

N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode or 16 in 16-bit mode

Higher source resistances or higher-accuracy sampling is possible by setting CFG1[ADLSMP] and changing CFG2[ADLSTS] to increase the sample window, or decreasing ADCK frequency to increase sample time.

### 40.7.2.2 Pin leakage error

Leakage on the I/O pins can cause conversion error if the external analog source resistance,  $R_{AS}$ , is high. If this error cannot be tolerated by the application, keep  $R_{AS}$  lower than  $V_{REFH} / (4 \times I_{LEAK} \times 2^N)$  for less than 1/4 LSB leakage error, where N = 8 in 8-bit mode, 10 in 10-bit mode, 12 in 12-bit mode, or 16 in 16-bit mode.

### 40.7.2.3 Noise-induced errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1  $\mu\text{F}$  low-ESR capacitor from  $V_{\text{REFH}}$  to  $V_{\text{REFL}}$ .
- There is a 0.1  $\mu\text{F}$  low-ESR capacitor from  $V_{\text{DDA}}$  to  $V_{\text{SSA}}$ .
- If inductive isolation is used from the primary supply, an additional 1  $\mu\text{F}$  capacitor is placed from  $V_{\text{DDA}}$  to  $V_{\text{SSA}}$ .
- $V_{\text{SSA}}$ , and  $V_{\text{REFL}}$ , if connected, is connected to  $V_{\text{SS}}$  at a quiet point in the ground plane.
- Operate the MCU in Wait or Normal Stop mode before initiating (hardware-triggered conversions) or immediately after initiating (hardware- or software-triggered conversions) the ADC conversion.
  - For software triggered conversions, immediately follow the write to SC1 with a Wait instruction or Stop instruction.
  - For Normal Stop mode operation, select ADACK or an Alternate clock as the clock source. Operation in Normal Stop reduces  $V_{\text{DD}}$  noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive  $V_{\text{DD}}$  noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in Wait or Normal Stop mode, or I/O activity cannot be halted, the following actions may reduce the effect of noise on the accuracy:

- Place a 0.01  $\mu\text{F}$  capacitor ( $C_{\text{AS}}$ ) on the selected input channel to  $V_{\text{REFL}}$  or  $V_{\text{SSA}}$ . This improves noise issues, but affects the sample rate based on the external analog source resistance.
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1 LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock, that is, ADACK, and averaging. Noise that is synchronous to ADCK cannot be averaged out.

#### 40.7.2.4 Code width and quantization error

The ADC quantizes the ideal straight-line transfer function into 65536 steps in the 16-bit mode.. Each step ideally has the same height, that is, 1 code, and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N-bit converter, where N can be 16, 12, 10, or 8, defined as 1 LSB, is:

$$1\text{LSB} = (V_{\text{REFH}}) / 2^N$$

**Equation 3. Ideal code width for an N-bit converter**

There is an inherent quantization error due to the digitization of the result. For 8-bit, 10-bit, or 12-bit conversions, the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be  $\pm 1/2$  LSB in 8-bit, 10-bit, or 12-bit modes. As a consequence, however, the code width of the first (0x000) conversion is only  $1/2$  LSB and the code width of the last (0xFF or 0x3FF) is 1.5 LSB.

For 16-bit conversions, the code transitions only after the full code width is present, so the quantization error is -1 LSB to 0 LSB and the code width of each step is 1 LSB.

#### 40.7.2.5 Linearity errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors, but the system designers must be aware of these errors because they affect overall accuracy:

- Zero-scale error ( $E_{\text{ZS}}$ ), sometimes called offset: This error is defined as the difference between the actual code width of the first conversion and the ideal code width. This is  $1/2$  LSB in 8-bit, 10-bit, or 12-bit modes and 1 LSB in 16-bit mode. If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 LSB) is used.
- Full-scale error ( $E_{\text{FS}}$ ): This error is defined as the difference between the actual code width of the last conversion and the ideal code width. This is 1.5 LSB in 8-bit, 10-bit, or 12-bit modes and 1 LSB in 16-bit mode. If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1 LSB) is used.
- Differential non-linearity (DNL): This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.

- **Integral non-linearity (INL):** This error is defined as the highest-value or absolute value that the running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- **Total unadjusted error (TUE):** This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

#### 40.7.2.6 Code jitter, non-monotonicity, and missing codes

Analog-to-digital converters are susceptible to three special forms of error:

- **Code jitter:** Code jitter occurs when a given input voltage converts to one of the two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code, and vice-versa. However, even small amounts of system noise can cause the converter to be indeterminate, between two codes, for a range of input voltages around the transition voltage.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally, the techniques discussed in [Noise-induced errors](#) reduces this error.

- **Non-monotonicity:** Non-monotonicity occurs when, except for code jitter, the converter converts to a lower code for a higher input voltage.
- **Missing codes:** Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

# Chapter 41

## 12-bit 5MSPS Analog-to-Digital Converter (HSADC)

### 41.1 Chip-specific 12-bit SAR HSADC information

#### 41.1.1 HSADC instantiation

This device has two instances of the HSADC: HSADC0 and HSADC1. Each of the HSADC modules has two ADC hard blocks that are independent of each other, that is, HSADC0 controls HSADC0A and HSADC0B, HSADC1 controls HSADC1A and HSADC1B.

For internal connection between HSADCs and other peripherals (for triggering HSADC acquisitions and/or triggering other peripherals after an HSADC scan is complete) via XBARA/XBARB/AOI, see the XBARA/XBARB/AOI signal assignment sections.

The SIM module contains configurable registers to control the HSADC blocks. The trigger source for SYNC0 and SYNC1 for both HSADCs is selected in the SIM\_SOPT7 register. The HSADCs conversion clocks are controlled with SIM\_ADCCOPT register.

The external channel pin labeling for the HSADC is: HSADC0A\_CHx, HSADC0B\_CHx, HSADC1A\_CHx, HSADC1B\_CHx, where x is an integer between 0 and 18. See the Pinouts section for details of HSADC0 and HSADC1 channel muxing.

#### 41.1.2 HSADC interconnect assignments

**Table 41-1. HSADCx Interconnect Assignments**

| Signal  | Description | I/O | Connected to<br>(external pad/<br>pin, internal<br>peripheral) | Pin Number |          |            |
|---------|-------------|-----|----------------------------------------------------------------|------------|----------|------------|
|         |             |     |                                                                | 100 LQFP   | 144 LQFP | 144 MAPBGA |

### 41.1.3 HSADC clock sources

In this device, IP clock is sourced from the System (CPU) clock and adc\_8\_clk is sourced from MCGIRCLK.

### 41.1.4 Input triggering via PDB

With the PDB configured in any mode, and the HSADC configured for SYNC input pulse initiated scans, the PDB is unable to trigger multiple scans when the pause feature is also used. This is because of a feedback mechanism that is required by the PDB that the HSADC digital wrapper does not provide. In this case, the HSADC configuration is as follows:

1. SDIS < 0xFFFFE, to sample multiple channels
2. SCTRL configured to wait for PDB input sync pulse after each or any one of the samples (other than the first sample in the list)
3. SYNC\_A = 1 or SYNC\_B = 1 to enable the SYNC input
4. HSADC SYNC trigger configured to the PDB via either SIM\_SOPT7 or the XBARA register setting (XBARA\_SEL6[SEL12] or XBARA\_SEL21[SEL42] for HSADCxA triggers or XBARA\_SEL6[SEL13] or XBARA\_SEL21[SEL43] for HSADCxB triggers).

In this configuration, the PDB initiates the scan, but the scan stops at the first sample disabled by SCTRL and no more samples are initiated. The PDB may continue running (depending on the PDB settings) but it does not issue any triggers. If the application requires that the pause feature be used in conjunction with the PDB trigger source, then the PDB must be disabled and then re-enabled to continue triggering after the pause. It is recommended to use the interrupt service routine or interrupt flag (SC[PDBIF]) to determine when to restart the PDB. If the pre-trigger functionality is being used, the channel flag can be used to determine when to restart the PDB. Either the MCU core or the DMA can disable and re-enable the PDB.

## 41.2 Introduction

### 41.2.1 Overview

The 12-bit SAR High Speed Analog-to-Digital Converter control block (HSADC) is a digital block that handles two 12-bit SAR ADCs (HSADCxA and HSADCxB). It generates the controls to have the two ADCs operating in sequence or simultaneously. It also captures the ADCs results and stores them to be read by the CPU.

### 41.2.2 Features

The HSADC system consists of two separated analog-to-digital converters, each with nineteen analog input multiplexers and its own sample and hold circuit. A common digital control module configures and controls the functioning of the two converters.

The HSADC with a 12-bit resolution provides a sample rate of 2x5MSPS. Each ADC has 15 analog inputs, for external signal connections and four analog inputs for internal voltage reference connections. The converter requires a minimum input clock of 140 kHz and maximum 80 MHz. The targeted conversion time is 200ns at 75 MHz. Each HSADC block can scan up to 16 channels sequentially, and each selected channel can be from any of the two ADCs. It can scan and store up to eight measurements for each of the two ADC converters operating either synchronously or asynchronously in parallel or 16 measurements in serial operation. Other features include single ended or differential input, synchronization inputs, synchronized or continuous scan of inputs, interrupts for end of scan, out of range or zero crossing, signed and unsigned results, and ability to add sample correction factors.

HSADC features include:

- 12/10/8/6 bits selectable resolution (RES).

- Designed for maximum ADC clock frequency of 80 MHz and minimum of about 140 kHz.
- Sampling rate up to 5.71/6.66/8/10 million samples per second, for 12/10/8/6 bits resolution, respectively, with 80 MHz input clock.
- Single-ended or differential inputs.
- Analog input multiplexer supporting up to 15 external and 4 internal single-ended analog inputs per ADC.
- Each ADC conversion requires at least 1.5 ADC clock cycle for sampling time plus 12.5 ADC clock cycles to finish the conversion (for RES=12 bits).
- Built-in algorithm to obtain each ADC's calibration factors (single-ended and differential modes).
- Can scan up to 16 channels sequentially, from a selection of 2x19 possible inputs making use of the internal 19 channel analog mux (15 channels for external pins, 4 channels for internal Vrefs) of each ADC. Up to 16 conversions are supported.
- Can be synchronized with other peripherals that are connected to an internal Inter-Peripheral Crossbar module, such as the PWM, through the SYNCx/B input signals and the EOSx/B output signals.
- Each ADC converter has eight result registers. Each result register can be configured to store any channel from either a single ended input conversion or differential input conversion. All eight results can come from just one converter.
- Sequential scan mode: two ADCs closely coupled, can sequentially acquire 16 ADC measurements on one triggered event.
- Parallel synchronous scan mode: two ADC converters scanning in parallel and simultaneously provide 16 measurements in 8 conversion times.
- Parallel independent scan mode: each ADC can independently acquire 8 ADC measurements triggered by s/w or hardware event.
- Pause control for each conversion request on the scan list. A new trigger SYNCx input event is necessary to continue the scan.
- Optional interrupts to indicate the end of scan, an out-of-range limit detection, a zero-crossing event, or the end of the calibration cycle.
- Optional DMA function to transfer conversion results at the end of a scan or when a sample is ready to be read.
- Optional sample correction by subtracting a pre-programmed offset value.
- Signed or unsigned result.

## 41.2.3 Modes of Operation

## 41.2.4 Block Diagram

The following figure illustrates the dual SAR HSADC system. It is composed by:

- Analog blocks: 19x1 multiplexers, voltage reference circuits, and SAR ADCs
- Digital wrapper: ADC controllers, output result storage registers, and bus interface.

The 19x1 multiplexer selects one analog input to be sampled and converted by the SAR ADC converter. Selection of the input channel is accomplished with the CLISTn registers. Input mode selection is programmed using the CTRL1[CHNCFG\_L] and CTRL2[CHNCFG\_H].

The SAR ADCs that perform the analog to digital conversion of the selected analog input convert one 12-bit result in 12.5 ADC input clock cycles. The total conversion time consists of 1.5 ADC clocks to sample the channel, and 12.5 ADC clocks for a 12-bit result.

The digital wrapper allows the user to configure a list of necessary conversions synchronized to trigger signals SYNCA and SYNCB.

**41.3.1 HSADC Control Register 1 (HSADCx\_CTRL1)**

The HSADCx\_CTRL1 register provides the mode of scanning for the A and B converters, the input mode, and various interrupt enables. The STOPA, STARTA, SYNCA, and EOSIEA fields in CTRL1 control all types of scans except parallel scans in the B converter when CTRL2[SIMULT]=0. Non-simultaneous parallel scan modes allow independent parallel scanning in the A and B converter. CTRL2[STOPB], CTRL2[STARTB], CTRL2[SYNCB], and CTRL2[EOSIEB] are used to control B converter scans in non-simultaneous parallel scan modes.

| 7–4<br>CHNCFG_L | <p>CHCNF (Channel Configure Low) bits</p> <p>The bits configure the analog inputs for either single ended or differential conversions. Differential measurements return the max value <math>((2^{12})-1)</math> when the + input is <math>V_{REFH}</math> and the - input is <math>V_{REFLO}</math>, return 0 when the + input is at <math>V_{REFLO}</math> and the - input is at <math>V_{REFH}</math>, and scale linearly between based on the voltage difference between the two signals. Single ended measurements return the max value when the input is at <math>V_{REFH}</math>, return 0 when the input is at <math>V_{REFLO}</math>, and scale linearly between based on the amount by which the input exceeds <math>V_{REFLO}</math>.</p> <p>xxx1 <b>Inputs = ANA0-ANA1</b> — Configured as differential pair (ANA0 is + and ANA1 is --)<br/> xxx0 <b>Inputs = ANA0-ANA1</b> — Both configured as single ended inputs<br/> xx1x <b>Inputs = ANA2-ANA3</b> — Configured as differential pair (ANA2 is + and ANA3 is --)<br/> xx0x <b>Inputs = ANA2-ANA3</b> — Both configured as single ended inputs<br/> x1xx <b>Inputs = ANB0-ANB1</b> — Configured as differential pair (ANB0 is + and ANB1 is --)<br/> x0xx <b>Inputs = ANB0-ANB1</b> — Both configured as single ended inputs<br/> 1xxx <b>Inputs = ANB2-ANB3</b> — Configured as differential pair (ANB2 is + and ANB3 is --)<br/> 0xxx <b>Inputs = ANB2-ANB3</b> — Both configured as single ended inputs</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3<br>Reserved   | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SMODE           | <p>HSADC Scan Mode Control</p> <p>This field controls the HSADC module's scan mode. All scan modes use 16 sample slots defined by the CLIST1-4 registers. A scan is the process of stepping through a subset of these sample slots, converting the input indicated by a slot, and storing the result. Unused slots may be disabled using the SDIS register. Input pairs ANA0-1, ANA2-3, ANA4-5, ANA6-7, ANB0-1, ANB2-3, ANB4-5, and ANB6-7 may be configured as differential pairs using the CHNCFG fields. When a slot refers to either member of a differential pair, a differential measurement on that pair is made; otherwise, a single ended measurement is taken on that input. The CTRL*[CHNCFG] fields' descriptions detail differential and single ended measurement. The SMODE field determines whether the slots are used to perform one long sequential scan or two shorter parallel scans, each performed by one of the two converters. SMODE controls how these scans are initiated and terminated. It also controls whether the scans are performed once or repetitively. For details, refer to <a href="#">Sequential versus parallel sampling</a> and <a href="#">Scan Sequencing</a>.</p> <p>Parallel scans may be simultaneous (CTRL2[SIMULT] is 1) or non-simultaneous. Simultaneous parallel scans perform the A and B converter scan in lock step using one set of shared controls. Non-simultaneous parallel scans operate the A and B converters independently, with each converter using its own set of controls. Refer to the CTRL2[SIMULT] bit's description for details. Setting any sequential mode overrides the setting of CTRL2[SIMULT].</p> <p>000 <b>Once (single) sequential</b> — Upon start or an enabled sync signal, samples are taken one at a time starting with CLIST1[SAMPLE0], until the first disabled sample is encountered. If no disabled sample is encountered, conversion concludes after CLIST4[SAMPLE15]. If the scan is initiated by a SYNC signal, only one scan is completed because the CTRL*[SYNC*] bit is cleared automatically by the initial SYNC detection. CTRL*[SYNC*] can be set again at any time during the scan.</p> |

## HSADCx\_CTRL1 field descriptions (continued)

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 001   | <b>Once parallel</b> — Upon start or an armed and enabled sync signal: In parallel, converter A converts SAMPLEs 0-7, and converter B converts SAMPLEs 8-15. When CTRL2[SIMULT] is 1 (default), scanning stops when either converter encounters a disabled sample or both converters complete all 8 samples. When CTRL2[SIMULT] is 0, a converter stops scanning when it encounters a disabled sample or completes all 8 samples. If the scan is initiated by a SYNC signal, only one scan is completed because the CTRL*[SYNC*] bit is cleared automatically by the initial SYNC detection. CTRL*[SYNC*] can be set again at any time during the scan. If CTRL2[SIMULT] is 0, the B converter must be rearmed by writing CTRL2[SYNCB].                                        |
| 010   | <b>Loop sequential</b> — Upon an initial start or enabled sync pulse, up to 16 samples in the order SAMPLEs 0-15 are taken one at a time until a disabled sample is encountered. The process repeats perpetually until CTRL1[STOPA] is set. While a loop mode is running, any additional start commands or sync pulses are ignored unless the scan is paused using the SCTRL[SC*] bits. If PWR[ASB] or PWR[APD] is the selected power mode control, (PWR[PUDELAY] x 32) is applied only on the first conversion.                                                                                                                                                                                                                                                               |
| 011   | <b>Loop parallel</b> — Upon an initial start or enabled sync pulse, converter A converts SAMPLEs 0-7, and converter B converts SAMPLEs 8-15. Each time a converter completes its current scan, it immediately restarts its scan sequence. This process continues until the CTRL*[STOP*] bit is asserted. While a loop is running, any additional start commands or sync pulses are ignored unless the scan is paused using the SCTRL[SC*] bits. When CTRL2[SIMULT] is 1 (default), scanning restarts when either converter encounters a disabled sample. When CTRL2[SIMULT] is 0, a converter restarts scanning when it encounters a disabled sample. If PWR[ASB] or PWR[APD] is the selected power mode control, (PWR[PUDELAY] x 32) is applied only on the first conversion. |
| 100   | <b>Triggered sequential</b> — Upon start or an enabled sync signal, samples are taken one at a time starting with CLIST1[SAMPLE0], until the first disabled sample is encountered. If no disabled sample is encountered, conversion concludes after CLIST4[SAMPLE15]. If external sync is enabled, new scans start for each SYNC pulse that does not overlap with a current scan in progress.                                                                                                                                                                                                                                                                                                                                                                                  |
| 101   | <b>Triggered parallel (default)</b> — Upon start or an enabled sync signal: In parallel, converter A converts SAMPLEs 0-7, and converter B converts SAMPLEs 8-15. When CTRL2[SIMULT] is 1 (default), scanning stops when either converter encounters a disabled sample. When CTRL2[SIMULT] is 0, a converter stops scanning when it encounters a disabled sample. If external sync is enabled, new scans start for each SYNC pulse that does not overlap with a current scan in progress.                                                                                                                                                                                                                                                                                      |
| 11x   | <b>Reserved</b> —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**HSADCx\_CTRL2 field descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>DMAENB | <p>DMA enable</p> <p>During parallel scan modes when SIMULT=0, this bit enables DMA for converter B.</p> <p>When this bit is asserted, the DMA source selected by CTRL3[DMASRC] causes the conversion results to be transferred by the DMA controller.</p> <p>0 DMA is not enabled.<br/>1 DMA is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 14<br>STOPB  | <p>Stop</p> <p>During parallel scan modes when SIMULT = 0, this bit enables stop control of a B converter parallel scan.</p> <p>When this bit is asserted, the current scan is stopped and no further scans can start. Any further SYNCB input pulses (see CTRL2[SYNCB]) or writes to CTRL2[STARTB] are ignored until this bit has been cleared. After the ADC is in stop mode, the result registers can be modified by the processor. Any changes to the result registers in stop mode are treated as if the analog core supplied the data. Therefore, limit checking, zero crossing, and associated interrupts can occur when authorized. This is not the same as the chip's STOP mode.</p> <p>0 Normal operation<br/>1 Stop mode</p>                                                                                                                                                                                                                                                                                                                                          |
| 13<br>STARTB | <p>STARTB Conversion</p> <p>During parallel scan modes when SIMULT = 0, this bit enables start control of a B converter parallel scan.</p> <p>A scan is started by writing 1 to this bit. This is a write only bit. Writing 1 to it again while the scan remains in process, is ignored.</p> <p>The ADC must be in a stable power configuration prior to writing the start bit. Refer to the functional description of power modes for further details.</p> <p>0 No action<br/>1 Start command is issued</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12<br>SYNCB  | <p>SYNCB Enable</p> <p>During parallel scan modes when CTRL2[SIMULT]=0, setting this bit to 1 permits a B converter parallel scan to be initiated by asserting the SYNCB input for at least one ADC clock cycle. CTRL2[SYNCB] is cleared in ONCE mode, CTRL1[SMODE=000 or 001], when the first SYNC input is detected. This prevents unintentionally starting a new scan after the first scan has completed.</p> <p>The ADC must be in a stable power mode prior to SYNCB input assertion. Refer to the functional description of power modes for further details.</p> <p>In "once" scan modes, only a first SYNCB input pulse is honored. CTRL2[SYNCB] is cleared in this mode when the first SYNCB input is detected. This prevents unintentionally starting a new scan after the first scan has completed. CTRL2[SYNCB] can be set again at any time including while the scan remains in process.</p> <p>0 B converter parallel scan is initiated by a write to CTRL2[STARTB] only<br/>1 Use a SYNCB input pulse or CTRL2[STARTB] to initiate a B converter parallel scan</p> |
| 11<br>EOSIEB | <p>End Of Scan Interrupt Enable</p> <p>During parallel scan modes when SIMULT = 0, this bit enables interrupt control for a B converter parallel scan.</p> <p>This bit enables an EOSIB interrupt to be generated upon completion of the scan. For looping scan modes, the interrupt will trigger after the completion of each iteration of the loop.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 10–7<br>CHNCFG_H | <p>CHNCFG_H (Channel Configure High) bits</p> <p>The bits configure the analog inputs for either single ended or differential conversions. Differential measurements return the max value <math>((2^{**12})-1)</math> when the + input is <math>V_{REFH}</math> and the - input is <math>V_{REFLO}</math>, return 0 when the + input is at <math>V_{REFLO}</math> and the - input is at <math>V_{REFH}</math>, and scale linearly between based on the voltage difference between the two signals. Single ended measurements return the max value when the input is at <math>V_{REFH}</math>, return 0 when the input is at <math>V_{REFLO}</math>, and scale linearly between based on the amount by which the input exceeds <math>V_{REFLO}</math>.</p> <p><b>Note:</b> See section <a href="#">Input Multiplex Function</a> for details when using ANA6/7 or ANB6/7.</p> <p>xxx1 <b>Inputs = ANA4-ANA5</b> — Configured as differential pair (ANA4 is + and ANA5 is --)</p> <p>xxx0 <b>Inputs = ANA4-ANA5</b> — Both configured as single ended inputs</p> <p>xx1x <b>Inputs = ANA6-ANA7</b> — Configured as differential pair (ANA6 is + and ANA7 is --)</p> <p>xx0x <b>Inputs = ANA6-ANA7</b> — Both configured as single ended inputs</p> <p>x1xx <b>Inputs = ANB4-ANB5</b> — Configured as differential pair (ANB4 is + and ANB5 is --)</p> <p>x0xx <b>Inputs = ANB4-ANB5</b> — Both configured as single ended inputs</p> <p>1xxx <b>Inputs = ANB6-ANB7</b> — Configured as differential pair (ANB6 is + and ANB7 is --)</p> <p>0xxx <b>Inputs = ANB6-ANB7</b> — Both configured as single ended inputs</p> |
| 6<br>SIMULT      | <p>Simultaneous mode</p> <p>This bit only affects parallel scan modes. By default (CTRL2[SIMULT]=1) parallel scans operate in simultaneous mode. The scans in the A and B converter operate simultaneously and always result in pairs of simultaneous conversions in the A and B converter. CTRL1[STOPA], CTRL1[SYNCA], and CTRL1[STARTA] control bits and the SYNCA input are used to start and stop scans in both converters simultaneously. A scan ends in both converters when either converter encounters a disabled sample slot. When the parallel scan completes, the STAT[EOSIA] triggers if CTRL1[EOSIEA] is set. The STAT[CIPA] status bit indicates that a parallel scan is in process.</p> <p>When CTRL2[SIMULT]=0, parallel scans in the A and B converters operate independently. The B converter has its own independent set of the above controls (with a B suffix) which control its operation and report its status. Each converter's scan continues until its sample list is exhausted (8 samples) or a disabled sample IN ITS LIST is encountered. For looping parallel scan mode, each converter starts its next iteration as soon as the previous iteration in that converter is complete and continues until the CTRL*[STOP*] bit for that converter is asserted.</p> <p>0 Parallel scans done independently</p> <p>1 Parallel scans done simultaneously (default)</p>                                                                                                                                                                                                                       |

**41.3.3 HSADC Zero Crossing Control 1 Register (HSADCx\_ZXCTRL1)**

The HSADC Zero crossing 1 register controls the zero cross feature for each of the eight ADC conversions made on HSADC channels acquired by SAMPLE0 to SAMPLE7 in the CLIST1 and CLIST2 registers. Each of the ZCE<sub>n</sub> fields corresponds to the SAMPLE<sub>n</sub> channel selected. For example, ZCE7 field will enable/disable zero cross detect on the HSADC channel selected by SAMPLE7 field in CLIST2 register.

### 41.3.4 HSADC Zero Crossing Control 2 Register (HSADCx\_ZXCTRL2)

The HSADC Zero Crossing Control 2 register controls the zero cross feature for each of the eight ADC conversions made on HSADC channels acquired by SAMPLE8 to SAMPLE15 in the CLIST3 and CLIST4 registers. Each of the ZCEn fields corresponds to the SAMPLEn channel selected. For example, ZCE15 field will enable/disable zero cross detect on the HSADC channel selected by SAMPLE15 field in CLIST4 register.

### HSADCx\_CLIST1 field descriptions (continued)

| Field | Description                                                                |
|-------|----------------------------------------------------------------------------|
|       | This sample and all subsequent samples can be disabled by setting SDIS[0]. |
| 0000  | Single Ended: ANA0, Differential: ANA0+, ANA1- —                           |
| 0001  | Single Ended: ANA1, Differential: ANA0+, ANA1- —                           |
| 0010  | Single Ended: ANA2, Differential: ANA2+, ANA3- —                           |
| 0011  | Single Ended: ANA3, Differential: ANA2+, ANA3- —                           |
| 0100  | Single Ended: ANA4, Differential: ANA4+, ANA5- —                           |
| 0101  | Single Ended: ANA5, Differential: ANA4+, ANA5- —                           |
| 0110  | Single Ended: ANA6, Differential: ANA6+, ANA7- —                           |
| 0111  | Single Ended: ANA7, Differential: ANA6+, ANA7- —                           |
| 1000  | Single Ended: ANB0, Differential: ANB0+, ANB1- —                           |
| 1001  | Single Ended: ANB1, Differential: ANB0+, ANB1- —                           |
| 1010  | Single Ended: ANB2, Differential: ANB2+, ANB3- —                           |
| 1011  | Single Ended: ANB3, Differential: ANB2+, ANB3- —                           |
| 1100  | Single Ended: ANB4, Differential: ANB4+, ANB5- —                           |
| 1101  | Single Ended: ANB5, Differential: ANB4+, ANB5- —                           |
| 1110  | Single Ended: ANB6, Differential: ANB6+, ANB7- —                           |
| 1111  | Single Ended: ANB7, Differential: ANB6+, ANB7- —                           |

### 41.3.6 HSADC Channel List Register 2 (HSADCx\_CLIST2)

This register configures the analog inputs to be sampled. For ANx6 and ANx7, see [Input Multiplex Function](#) for more details.

Address: Base address + Ah offset

| Bit   | 15      | 14 | 13 | 12 | 11      | 10 | 9 | 8 | 7       | 6 | 5 | 4 | 3       | 2 | 1 | 0 |
|-------|---------|----|----|----|---------|----|---|---|---------|---|---|---|---------|---|---|---|

## 41.3.7 HSADC Channel List Register 3 (HSADCx\_CLIST3)

This register configures the analog inputs to be sampled. For ANx6 and ANx7, see [Input Multiplex Function](#) for more details.

Address: Base address + Ch offset

| Bit   | 15       | 14 | 13 | 12 | 11       | 10 | 9 | 8 | 7       | 6 | 5 | 4 | 3       | 2 | 1 | 0 |

## 41.3.8 HSADC Channel List Register 4 (HSADCx\_CLIST4)

This register configures the analog inputs to be sampled. For ANx6 and ANx7, see [Input Multiplex Function](#) for more details.

Address: Base address + Eh offset

**41.3.9 HSADC Sample Disable Register (HSADCx\_SDIS)**

Each field of SDIS corresponds to a SAMPLEx field in one or multiple CLISTn registers. For example, bit 0 of SDIS will enable/disable CLIST1[SAMPLE0], and bit 15 of SDIS will enable/disable CLIST4[SAMPLE15].

If an SDIS bit is clear, then the corresponding SAMPLEx field will be enabled in an HSADC scan. If the SDIS bit is set, then the corresponding SAMPLEx field will be disabled and the HSADC scan will be halted and subsequent ADC conversions will also not occur. The HSADC will sequentially scan in order SAMPLE0, SAMPLE1, SAMPLE2,... and so on. If SDIS=0xFFFE, then an HSADC scan will acquire SAMPLE0 while SAMPLE1, SAMPLE2, and all other acquisitions will not occur. The 4-bit wide SAMPLEx fields are found in the CLISTn registers which select a particular HSADC channel and whether it will be a differential or single ended conversion.

**41.3.10 HSADC Status Register (HSADCx\_STAT)**

This register provides the current status of the HSADC module. STAT[HLMTI] and STAT[LLMTI] are cleared by writing 1s to all asserted bits in the limit status register, LIMSTAT. Likewise, the STAT[ZCI] bit, is cleared by writing 1s to all asserted bits in the zero crossing status register, ZXSTAT. The STAT[EOSIx] bits are cleared by writing a one to them.

Except for CIPA, CIPB, DUMMYA, DUMMYB, CALONA, and CALONB, this register's fields are sticky. Once set to a one state, they require some specific action to clear them. They are not cleared automatically on the next scan sequence.

41.3.11 HSADC Ready Register (HSADCx\_RDY)

This register provides the current status of the HSADC conversions. RDY[RDYx] bits are cleared by reading their corresponding result registers (RSLTx).

HSADCx\_RDY field descriptions

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RDY   | <div>Ready Sample</div> <div>These bits indicate samples fifteen through zero are ready to be read. These bits are cleared after a read from the respective results register. The RDY[RDYn] bits are set as the individual channel conversions are completed. Polling the RDY[RDYn] bits can determine if a particular sample is ready to be read.</div> <div>0 Sample not ready or has been read</div> <div>1 Sample ready to be read</div> |

41.3.12 HSADC Low Limit Status Register (HSADCx\_LOLIMSTAT)

The low limit status register latches in the result of the comparison between the result of the sample and the respective low limit register, LOLIM0-15. For example, if the result for the channel programmed in CLIST1[SAMPLE0] is lower than the value programmed into the LOLIM0 register, then LOLIMSTAT[LLS0] is set to one. An interrupt is generated if the CTRL1[LLMTIE] bit is set. These bits are sticky. They are not cleared automatically by subsequent conversions. Each bit is cleared only by writing a value of one to that specific bit.

**HSADCx\_LOLIMSTAT field descriptions**

| Field | Description           |
|-------|-----------------------|
| LLS   | Low Limit Status Bits |

**41.3.13 HSADC High Limit Status Register (HSADCx\_HILIMSTAT)**

The high limit status register latches in the result of the comparison between the result of the sample and the respective high limit register, HILIM0-15. For example, if the result for the channel programmed in CLIST1[SAMPLE0] is greater than the value programmed into the HILIM0 register, then the HILIMSTAT[HLS0] bit is set to one. An interrupt is generated if the CTRL1[HLMTIE] bit is set. These bits are sticky. They are not cleared automatically by subsequent conversions. Each bit is cleared only by writing a value of one to that specific bit.

**HSADCx\_ZXSTAT field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | The zero crossing condition is determined by examining the ADC value after it has been adjusted by the offset for the result register. Each bit of the register is cleared by writing a one to that register bit.                                                                        |
| 0     | Either: <ul style="list-style-type: none"> <li>• A sign change did not occur in a comparison between the current channelx result and the previous channelx result, or</li> <li>• Zero crossing control is disabled for channelx in the zero crossing control register, ZXCTRL</li> </ul> |
| 1     | In a comparison between the current channelx result and the previous channelx result, a sign change condition occurred as defined in the zero crossing control register (ZXCTRL)                                                                                                         |

**41.3.15 HSADC Result Registers with sign extension (HSADCx\_RSLTn)**

The result registers contain the converted results from a scan. The CLIST1[SAMPLE0] result is loaded into RSLT0, CLIST1[SAMPLE1] result in RSLT1, and so on. In a parallel scan mode, the first channel pair designated by CLIST1[SAMPLE0] and CLIST3[SAMPLE8] are stored in RSLT0 and RSLT8, respectively. The measured ADC raw conversion made by SAMPLEn is not stored directly into its corresponding RSLTn register. The values stored in the corresponding OFFSTn register is subtracted from the SAMPLn raw conversion then stored into the RSLTn register.

$RSLTn = SAMPLEn \text{ conversion} - OFFSTn \text{ value. (if } BYPA/BYPB = 1)$

If  $BYPA/BYPB = 0$  then  $RSLTn \text{ register} = SAMPLEn \text{ conversion} + \text{cal factor} - OFFSTn$ . See ADC Calibration section for further details.

**Note**

When writing to this register, only the RSLT portion of the value written is used. This value is modified and the result of the subtraction is stored. The SEXT bit is only set as a result of this subtraction and is not directly determined by the value written.

**Note**

When using conversions of 10, 8, or 6 bits resolution, only the MSB bits (10, or 8, or 6 bits) of the RSLT portion should be considered. The remaining bits have no meaning.

Address: Base address + 1Ch offset + (2d × i), where i=0d to 15d

## HSADCx\_RSLTn field descriptions

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>SEXT   | Sign Extend<br><br>This is the sign-extend bit of the result. RSLT*[SEXT] set to one implies a negative result; RSLT*[SEXT] set to zero implies a positive result. If <b>unsigned</b> results are required, then the respective offset register must be set to a value of zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 14–3<br>RSLT | Digital Result of the Conversion<br><br>RSLT can be interpreted as either a signed integer or a signed fractional number. As a signed fractional number, the RSLT can be used directly. As a signed integer, it is an option to right shift with sign extend (ASR) three places and interpret the number, or accept the number as presented, knowing there are missing codes. The lower three bits are always going to be zero.<br><br>Negative results, RSLT*[SEXT] = 1, are always presented in two's complement format. If it is a requirement of your application that the result registers always be positive, the offset registers must always be set to zero.<br><br>The interpretation of the numbers programmed into the limit and offset registers, LOLIM, HILIM, and OFFST should match your interpretation of the result register. |

## 41.3.16 HSADC Low Limit Registers (HSADCx\_LOLIMn)

Each HSADC sample is compared against the values in the limit registers. The comparison is based upon the raw conversion value with no offset correction applied. The limit register used corresponds to the result register the value will be written to. The low limit register is used for the comparison of Result < Low Limit. The low limit checking can be disabled by programming the respective low limit register with 0000h. At reset, limit checking is disabled.

Address: Base address + 3Ch offset + (2d × i), where i=0d to 15d

|       |    |      |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 41.3.17 HSADC High Limit Registers (HSADCx\_HILIMn)

Each HSADC sample is compared against the values in the limit registers. The comparison is based upon the raw conversion value with no offset correction applied. The limit register used corresponds to the result register the value will be written to. The high limit register is used for the comparison of Result > High Limit. The limit checking can be disabled by programming the respective high limit register with 7FF8h. At reset, limit checking is disabled.

Address: Base address + 5Ch offset + (2d × i), where i=0d to 15d

### 41.3.18 HSADC Offset Register (HSADCx\_OFFSTn)

The value of the OFFSTn register is used to correct the ADC result before it is stored in the RSLTn register.

The offset value is subtracted from the raw ADC result. To obtain unsigned results, program the respective offset register with a value of \$0000, thus giving a result range of \$0000 to \$7FF8.

Address: Base address + 7Ch offset + (2d × i), where i=0d to 15d

**41.3.19 HSADC Power Control Register (HSADCx\_PWR)**

This register controls the power management features of the HSADC module. There are individual manual power down controls for the two ADC converters and their internal voltage reference generators. There are also five distinct power modes. The following terms are used to describe power modes and their related controls.

|                                       |                                                                                                                                                                                                                                                                                        |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power down state                      | Each converter and voltage reference generator can individually be put into a power down state. When powered down, the unit consumes no power. Results of scans referencing a powered down converter are undefined. At least one converter must be powered up to use the HSADC module. |
| Manual power down controls            | Each converter and voltage reference generator have a manual power control bit capable of putting that component into the power down state. Converters have other mechanisms that can automatically put them into the power down state.                                                |
| Idle state                            | The HSADC module is idle when neither of the two converters has a scan in process.                                                                                                                                                                                                     |
| Active state                          | The HSADC module is active when at least one of the two converters has a scan in process.                                                                                                                                                                                              |
| Startup delay                         | Auto-powerdown and auto-standby power modes cause a startup delay when the HSADC module goes between the power down and active states to allow time to power up the internal ADC LDO.                                                                                                  |
| Dummy conversion or calibration delay | Auto-powerdown and auto-standby power modes cause a dummy conversion execution delay or a calibration execution delay after the HSADC module is powered up.                                                                                                                            |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>ASB         | <p>Auto Standby</p> <p>This bit selects auto-standby mode. PWR[ASB] is ignored if PWR[APD] is 1. When the HSADC is idle, auto-standby mode selects the auto-standby clock as the HSADC clock source and puts the converters into standby mode. At the start of any scan, the conversion clock is selected as the ADC clock and then a delay of (PWR[PUDELAY] x32) ADC clock cycles and one ADC dummy conversion or the calibration cycle are imposed for ADC levels to stabilize. After this delay, the HSADC initiates the scan. When the HSADC returns to the idle state, the standby clock is again selected and the converters revert to the standby state.</p> <p><b>NOTE:</b> PWR[ASB] can be set at the same time or prior to clearing PWR[PDB/A]. Otherwise the high speed conversion clock is used in the power-up delay counting before going to standby idle state.</p> <p>0 Auto standby mode disabled<br/>1 Auto standby mode enabled</p> |

| 9–4<br>PUDELAY    | <p>Power Up Delay</p> <p>This 6-bit field multiplied by 32 determines the number of ADC clocks provided to power up an ADC converter (after setting PWR[PDA] and PWR[PDB] to 0) before allowing a scan to start. It also determines the number of ADC clocks of delay provided in auto-powerdown (APD) and auto-standby (ASB) modes between when the ADC goes from the idle to active state and when the scan is allowed to start. The default value is 18 that means a power-up time of about 18x32 ADC clocks. Accuracy of the initial conversions in a scan will be degraded if PWR[PUDELAY] is set to a too small value.</p>                                                                                                                                                                                                                                                                                                                       |

|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p><b>NOTE:</b> PWR[PUDELAY] defaults to a value that is typically sufficient for any power mode. The latency of a scan can be reduced by reducing PWR[PUDELAY] to the lowest value for which accuracy is not degraded. Refer to the data sheet for further details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 3<br>APD      | <p>Auto Powerdown</p> <p>Auto-powerdown mode powers down converters when not in use for a scan. PWR[APD] takes precedence over PWR[ASB]. When a scan is started in PWR[APD] mode, a delay of (PWR[PUDELAY] x 32) ADC clock cycles is imposed during which the needed converter(s) are powered up. The HSADC then initiates a scan equivalent to that done when PWR[APD] is not active. When the scan is completed, the converter(s) are powered down again.</p> <p><b>NOTE:</b> If PWR[ASB] or PWR[APD] are asserted while a scan is in progress, that scan is unaffected and the HSADC waits to enter its low power state until after all conversions are complete and both ADCs are idle (for sequential or parallel simultaneous scan modes).</p> <p>PWR[ASB] and PWR[APD] are not useful in looping modes. The continuous nature of scanning means that the low power state can never be entered.</p> <p>0 Auto Powerdown Mode is not active<br/>1 Auto Powerdown Mode is active</p>                                                                                                                                                                                |
| 2<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 1<br>PDB      | <p>Manual Power Down for Converter B</p> <p>This bit forces ADC converter B to power down.</p> <p>Asserting this bit powers down converter B immediately, except when it is in power-up phase. The results of a scan using converter B will be invalid while PWR[PDB] is asserted. When PWR[PDB] is cleared, converter B is either continuously powered up (PWR[APD] = 0) or automatically powered up when needed (PWR[APD]=1).</p> <p>When clearing this bit in any power mode except auto-powerdown (PWR[APD]=1) or auto-standby (PWR[ASB]=1), wait (PWR[PUDELAY] x 32) ADC clock cycles before initiating a scan to stabilize power levels within the converter. PWR[PSTSB] can be polled to determine when the (PWR[PUDELAY] x 32) time has elapsed. Failure to follow this procedure can result in loss of accuracy of the calibration procedure and of the initial samples.</p> <p><b>NOTE:</b> During power-up delay phase if the stop request (STOPB) is set, the power-down request is only recognized at the end of this phase, after the ADC reset is applied (two ADC clock cycles).</p> <p>0 Power Up ADC converter B<br/>1 Power Down ADC converter B</p> |
| 0<br>PDA      | <p>Manual Power Down for Converter A</p> <p>This bit forces ADC converter A to power down.</p> <p>Asserting this bit powers down converter A immediately, except when it is in power-up phase. **41.3.20 HSADC Scan Control Register (HSADCx\_SCTRL)**

This register is an extension to the CLIST1-4 registers, providing the ability to pause and await a new sync while processing samples programmed in the CLIST\*[SAMPLE0â€“SAMPLE15] fields.

These 16 control bits are used to determine whether a sample in a scan occurs immediately or if the sample waits for an enabled sync input to occur. The sync input must occur after the conversion of the current sample completes. During sequential mode scans, the SCTRL[SC] bits are used in order from SC0 to SC15. During simultaneous parallel scan modes, the bits are used in order from SC0 to SC3 and SC8-SC11. In non-simultaneous parallel scans, ADCA uses the bits in order from SC0 to SC3 followed by SC8 to SC11. ADCB will use bits SC4 to SC7 followed by SC12 to SC15 in non-simultaneous parallel scans.

When setting SCTRL[SC0], there is no need to set CTRL1[STARTA] or CTRL2[STARTB]. Just clear CTRL1[STOPA] or CTRL2[STOPB] and the first enabled sync input will start the scan.

Setting SC0 delays sample 0 until a sync pulse occurs. Setting SC1 delays sample 1 until a sync pulse occurs after completing sample 0.

### 41.3.21 HSADC Power Control Register 2 (HSADCx\_PWR2)

The PWR2 register is only used in parallel non-simultaneous mode. It provides an independent clock speed for ADCB, therefore ADCB and ADCA can have different conversion rates.

### 41.3.22 HSADC Control Register 3 (HSADCx\_CTRL3)

The CTRL3 register selects the HSADC bit resolution for both ADCA and ADCB. Both ADCA and ADCB bit resolutions will be the same, and cannot be different.

Address: Base address + A8h offset

**41.3.23 HSADC Scan Interrupt Enable Register (HSADCx\_SCINTEN)**

This register is used with the ready register (RDY) to select the samples that will generate a scan interrupt. If SCINTEN is set, an interrupt occurs when the corresponding RDY bit is set, after the conversion is completed for the SAMPLEn.

Address: Base address + AAh offset

|       |         |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15–8<br>SAMPT_B | Sampling Time for ADCB.<br><br>This field is used to configure the sampling time for ADCB. The sampling time is related to the ADCB clock period (TclkB). The resultant sampling time is $(1.5 + \text{SAMPT\_B}) \times \text{TclkB}$ . In sequential or parallel simultaneous mode the effective value is SAMPT_A. |
| SAMPT_A         | Sampling Time for ADCA.<br><br>This field is used to configure the sampling time for ADCA. The sampling time is related to the ADCA clock period (TclkA). The resultant sampling time is $(1.5 + \text{SAMPT\_A}) \times \text{TclkA}$ .                                                                             |

### 41.3.25 HSADCs Calibration Configuration (HSADCx\_CALIB)

This register controls the request of calibration for ADCA and ADCB. The values obtained from this ADC internal calibration process are used in the ADCs calibration sub-block.

Address: Base address + AEh offset

| Bit   | 15 | 14 | 13 | 12 | 11 | 10 | 9        | 8        |

## 41.4 Functional Description

This HSADC system is composed of two SAR ADC blocks, ADCA and ADCB, that are controlled by this digital controller called HSADC wrapper. Each SAR ADC has an input signal multiplex that can handle up to 19 analog inputs each (ANA0~ANA18, ANB0~ANB7). The channel selection is done in a way that is equivalent to be done in two steps as follows:

- An 8x1 MUX controlled by the register SAMPLEn[2:0], with SAMPLEn[3] being used to select between the two ADCs. The inputs can be called ANA0~ANA7 and ANB0~ANB7 for simplicity, considered that SAMPLEn[2:0] can vary from 0 to 7.
- The input signal for input ANA6 of the above MUX comes with another additional MUX controlled by register CH6\_SELA[2:0]. The same is valid for ANA7 controlled by CH7\_SELA[2:0], for ANB6 controlled by CH6\_SELB[2:0], and for ANB7 controlled by CH7\_SELB[2:0].

### NOTE

If ANA6/ANB6 and ANA7/ANB7 MUXes are configured first and remains fixed for an interval of time, we can consider that the HSADC wrapper controller is just selecting eight input channels for each ADC when running the programmed list of conversions because it is processing only the SAMPLEn values.

### NOTE

For simplicity, when the analog input channels are referred just as ANA0~ANA7 or ANB0~ANB7, it is considered the selection for ANA6~7 and ANB6~7 are already done in register MUX67\_SEL.

The two ADCs operate independently and can run sequentially or in parallel by request of the HSADC control. The two converters store their results in an accessible buffer, awaiting further processing from the CPU.

Starting a single conversion actually begins a sequence of conversions, or a scan. The scan process is initiated either by a SYNC signal or by writing a 1 to a START bit. The HSADC operates in either sequential scan mode or parallel scan mode. In sequential scan mode, scan sequence is determined by defining sixteen sample slots that are processed in order, SAMPLE[0:15]. In parallel scan mode, converter A processes SAMPLE[0:7] in order, and converter B processes SAMPLE[8:15] in order. SAMPLE slots can be disabled using the HSADC\_SDIS control register to terminate a scan early.

In sequential scan mode, a scan takes up to sixteen single-ended or differential samples, one at a time. Please see the following figure.

### NOTE

Please consider in this diagram that ANA6, ANA7, ANB6, and ANB7 are outputs already considering the additional multiplexers controlled by configuration register MUX67\_SEL fields. Refer to Input Multiplex section for details.

**Figure 41-2. HSADC Input Channel Mux (Sequential Mode)**

In parallel scan mode, eight of the sixteen samples are allocated to converter A and eight are allocated to converter B. The two converters operate in parallel, and each can take at most eight samples. Converter A can sample only analog inputs ANA[0:18], and converter B can sample only analog inputs ANB[0:18].

**Figure 41-3. HSADC Parallel Scan Mode**

Parallel scan mode can be simultaneous or non-simultaneous. In simultaneous scan mode, the parallel scans in the two converters occur simultaneously and result in simultaneous pairs of conversions, one by converter A and one by converter B. The two converters share the same start, stop, sync, end-of-scan interrupt enable controls, and interrupts. Scanning in both converters terminates when either converter encounters a disabled sample.

In non-simultaneous scan mode, the parallel scans in the two converters occur independently. Each converter has its own start, stop, sync, end-of-scan interrupt enable controls, and interrupts. Scanning in either converter terminates only when that converter encounters a disabled sample.

The HSADC system can be configured to perform a single scan and halt (once mode), perform a scan whenever triggered (triggered mode), or perform the scan sequence repeatedly until manually stopped (loop mode). The once mode differs from the triggered

mode only in that SYNC input signals must be re-armed after each use and subsequent SYNC inputs are ignored until the SYNC input is re-armed. This arming can occur any time after the SYNC pulse, including while the scan is still in process.

Optional interrupts can be generated at the end of a scan sequence. Interrupts are available simply to indicate that a scan has ended, that a sample is out of range, or several different zero crossing conditions. Range is determined by the high and low limit registers, LOLIMn and HILIMn.

### 41.4.1 HSADC Sample Conversion Operating Modes

This HSADC system has two ADCs. Each ADC consists of a sequential, algorithmic architecture using a SAR ADC as shown in the following figure. The SAR sections resolve the required number of bits, one on each ADC conversion clock cycle. The maximum clock speed is 80 MHz, so a complete 12-bit conversion can be accommodated in 150 ns, not including sample or post-processing time.

Each HSADC has analog input selection, interface/controls, SAR ADC block, and the calibration and offset function. The calibration block is a special feature of the HSADC. It is a digital block that under user request runs the necessary ADC conversions automatically to obtain the offset error of the ADC. This error value is used for error correction in the A/D conversions. For details of each feature see this block specification.

**Figure 41-4. Top-Level Diagram of Dual HSADC System**

### 41.4.1.1 Input Multiplex Function

The channel selection is controlled by settings in the registers below:

- CLIST1, CLIST2, CLIST3, CLIST4 (fields SAMPLE0~15)
- CTRL1[CHNCFG\_L]
- CTRL2[CHNCFG\_H]
- MUX67\_SEL (fields CH6\_SELA, CH7\_SELA, CH6\_SELB, and CH7\_SELB)

There are two sets of analog inputs basically identified as ANAx (19 inputs for ADC A) and ANBx (19 inputs for ADC B). Each group of inputs is divided as follows:

- HSADCA:
  - ANA0~5
  - ANA6/8/10/12/14/16/18 (one of them is selected by CH6\_SELA[2:0] and can be called ANA6 for simplicity)
  - ANA7/9/11/13/15/17 (one of them is selected by CH7\_SELA[2:0] and can be called ANA7 for simplicity)
- HSADCB:
  - ANB0~5
  - ANB6/8/10/12/14/16/18 (one of them is selected by CH6\_SELB[2:0] and can be called ANB6 for simplicity)
  - ANB7/9/11/13/15/17 (one of them is selected by CH7\_SELB[2:0] and can be called ANB7 for simplicity)

Considering single-ended or differential conversion, the selection can be described as follows:

- Single-ended mode: one of the primary inputs listed above is selected to be sampled
- Differential mode: one of the following pairs is selected (x = A or B)
  - ANx0 - ANx1, or ANx2 - ANx3, or ANx4 - ANx5, or ANx6 and ANx7, ANx8 and ANx9, ANx10 and ANx11, ANx12 and ANx13, ANx14 and ANx15, ANx16 and ANx17, ANx18 and VREFL.

The following tables show how an analog input signal is selected to be sampled and converted on ADC A and ADC B. See the chip-specific information on pinouts and signal multiplexing to know which analog inputs are implemented.

**Table 41-2. Analog Input Multiplex Control for HSADCA**

#### 41.4.1.2 HSADC Input Mode of Operation

The HSADC has two input operating modes: single-ended mode and differential mode. For a given sample, the mode of operation is determined by the CTRL1[CHNCFG\_L] or CTRL2[CHNCFG\_H] fields (see Analog input multiplex tables ADC A and ADC B):

- Single-ended mode (CHNCFG\_L/H bit=0). The input multiplex of the ADC selects one of the 19 analog inputs and directs it to the plus terminal of the A/D core. The minus terminal of the A/D core is connected to the  $V_{REFL}$  reference. The ADC measures the voltage of the selected analog input and compares it against the  $(V_{REFH} - V_{REFL})$  reference voltage range.
- Differential mode (CHNCFG\_L/H bit=1). The ADC measures the voltage difference between two analog inputs and compares that value against the  $(V_{REFH} - V_{REFL})$  voltage range. The input is selected as an input pair: ANA0/1, ANA2/3, ANA4/5, and so on. The plus terminal of the A/D core is connected to the even analog input, and the minus terminal is connected to the odd analog input.

In Differential mode, each of the following pairs of analog inputs represents a differential pair:

- ANA[0:1], ANA[2:3], ANA[4:5], ANA[6:7]
- ANB[0:1], ANB[2:3], ANB[4:5], ANB[6:7]

**NOTE**

Differential pair ANA[6:7] is selected from the following combinations only: (ANA6 - ANA7), or (ANA8 - ANA9), ..., or (ANA16 - ANA17), or (ANA18 - VREFL). Similar pairs are valid for ANB[6:7].

A mix and match combination of single-ended and differential configurations may exist. For example:

- ANA[0:1] differential; ANA[2:3] single-ended
- ANA[4:5] differential; ANA[6/8/10/12/14/16:7/9/11/13/15/17] single-ended
- ANB[0:1] differential; ANB[2:3] single-ended
- ANB[4:5] differential; ANB[6/8/10/12/14/16:7/9/11/13/15/17] single-ended

**41.4.1.2.1 Single-Ended Samples**

The ADC module performs a ratio metric conversion. For single-ended measurements, the digital result is proportional to the ratio of the analog input to the reference voltage:

$$\text{SingleEndedValue} = \text{round}(((V_{\text{IN}} - V_{\text{REFL}}) / (V_{\text{REFH}} - V_{\text{REFL}})) \times 4096) \times 8$$

$V_{\text{IN}}$  is the applied voltage at the input pin.

$V_{\text{REFH}}$  and  $V_{\text{REFL}}$  are the voltages at the external reference pins on the device (typically  $V_{\text{REFH}}=V_{\text{DDA}}$  and  $V_{\text{REFL}}=V_{\text{SSA}}$ ).

**Note:** The 12-bit result is rounded to the nearest LSB.

**Note:** The ADC is a 12-bit function with 4096 possible states. However, the 12 bits have been left shifted by 3 bits on the 16-bit data bus. As a result, the magnitude of this function, as read from the data bus, is now 32760.

**41.4.1.2.2 Differential Samples**

For differential measurements, the digital result is proportional to the ratio of the difference in the inputs to the difference in the reference voltages ( $V_{\text{REFH}}$  and  $V_{\text{REFL}}$ ).

When differential measurements are converted, the following formula is useful:

$$\text{DifferentialValue} = \text{round}\left(\left(\frac{V_{\text{IN1}} - V_{\text{IN2}}}{V_{\text{REFH}} - V_{\text{REFL}}} \times 2048\right) + 2048\right) \times 8$$

$V_{\text{IN1}} - V_{\text{IN2}}$  = Applied voltage at the input pins

$V_{\text{REFH}}$  and  $V_{\text{REFL}}$  = Voltage at the external reference pins on the device (typically  $V_{\text{REFH}}=V_{\text{DDA}}$  and  $V_{\text{REFL}}=V_{\text{SSA}}$ )

**Note:** The 12-bit result is rounded to the nearest LSB.

**Note:** The ADC is a 12-bit function with 4096 possible states. However, the 12 bits have been left shifted three bits on the 16-bit data bus, so the magnitude of this function, as read from the data bus, is now 32760.

## 41.4.2 HSADC Calibration

Each ADC in the HSADC is equipped with a self-calibration digital sub-block that starts the calculation of the offset error only under external request. The ADC internal logic executes all necessary conversion cycles to obtain the offset error. It executes a dummy conversion plus eight AD conversions of an internal reference to obtain a medium value of the offset error.

The HSADC wrapper control requests to the ADCs to execute the calibration just after the power-up delay. It is necessary to configure the bit fields in the CALIB register to indicate the desired types of calibrations (single-ended and/or differential). The resultant offset value from the calibration is stored in a mapped register (CALVAL\_A and CALVAL\_B) to be used later by the ADCs. So the procedure to obtain the calibration from power-up can be described as follows:

- Before powering-up the HSADC, configure the REQSINGA/B and REQDIFFA/B fields to request the desired calibrations to be executed.
- The ADC is powered-up and then the single-ended/differential modes of calibration cycles are executed automatically by the ADC. It takes about 81 ADC clock cycles to calculate the calibration factor for each input mode.
- The resultant factor (offset) values from each calibration is stored in the register CALVAL\_A for ADC A, and CALVAL\_B for ADC B.
- When the calibration is completed, the status bits STAT[EOCALIA] and STAT[EOCALIB] are set to indicate the end of calibration process. An interrupt request is generated if CALIB[EOCALIEA] or CALIB[EOCALIEB] are set.
- When a conversion is requested to some ADC, the respective calibration factor (single-ended or differential) is read from the CALVAL\_A/CALVAL\_B register and pre-loaded into the internal register of that ADC to be used during the conversion.
- Once the calibration is completed, clear the STAT[EOCALIx] (where x is either A or B) by writing a '1' to it. If this is not done, no subsequent calibrations can be performed.

It is also possible to request the calibration after the power-up by setting the bit fields CALIB[CAL\_REQA/B]. In this case the request is served just after the end of a scan. The request bit is automatically cleared when the calibration is started. Also in this request the desired calibrations are configured using the bit fields REQSINGA/B and REQDIFFA/B.

### 41.4.3 HSADC Data Processing

The ADC block provides a 12-bit representation for some analog signal levels, and this data includes the error compensation factor. The raw result of an ADC conversion for a given SAMPLEn slot (n=0 to 15) must include the calibration factor (BYPx=0) when conversion precision is required. This result is checked for limit violations (HILIMn and LOLIMn). This value is also sent to an adder for offset correction, as the following figure shows. The adder subtracts the OFFSTn register value from each sample, and the resultant value is stored in the result register (RSLTn). This RSLTn value is checked for zero-crossing, as shown. Appropriate interrupts are asserted, if enabled.

The result value sign is determined from the ADC unsigned result minus the respective offset register value (OFFSTn). If the offset register is programmed with a value of zero, the result register value is unsigned and equals the A/D converter unsigned result. The range of the result (RSLTn) is 0000H–7FF8H, assuming that the offset register (OFFSTn) is cleared to all zero. This is equal to the raw value of the ADC.

The processor can write the result registers used for the results of a scan when the STOP bit for that scan is asserted. This write operation is treated as if it comes from the ADC block, so the limit checking, zero crossing, and the offset registers function as if in normal mode. For example, if the STOP bit is set to one and the processor writes to RSLT5, the data written to the RSLT5 is multiplexed to the ADC digital logic inputs, processed, and stored into RSLT5 as if the ADC had provided the data. This test data must be justified, as illustrated by the RSLT register definition and does not include the sign bit.

**Figure 41-5. Result Register Data Manipulation**

#### 41.4.4 Sequential versus parallel sampling

Scans are either sequential or parallel. All scan modes use the sixteen sample slots in the CLIST1–4 registers (SAMPLE [0:15]). The slots are used to define which input or differential pair to measure at each step in a scan sequence. The SDIS register defines which sample slots are enabled. Input pairs ANA0/1, ANA2/3, ANA4/5, ANA6/7, ANB0/1, ANB2/3, ANB4/5, and ANB6/7 can be set to be measured differentially using the CHNCFG\_L/H fields.

##### NOTE

ANA6/7 and ANB6/7 are referred as the output selection of inputs: ANA6/8/10/12/14/16/18 and ANA7/9/11/13/15/17 for ANA6/7; ANB6/8/10/12/14/16/18 and ANB7/9/11/13/15/17 for ANB6/7, as described in the Input Multiplex section.

##### 41.4.4.1 Sequential scan mode

Sequential scans have the following characteristics:

- Up to sixteen sample slots are sampled one at a time in order, SAMPLE [0:15]
- Each sample refers to any of the sixteen analog inputs ANA0–ANB7<sup>1</sup>, so the same input can be referenced by more than one sample slot
- All samples have the full functionality of offset subtraction and high/low limit compare
- Scanning is initiated when CTRL1 [STARTA] bit is written with a 1 or when CTRL1[SYNCA] is set and the SYNCA input goes high
- A scan ends when the first disabled sample slot is encountered per the SDIS register
- Completion of the scan triggers the STAT[EOSIA] interrupt if the CTRL1[EOSIEA] interrupt enable is set. If CTRL1[DMAENA] is set and CTRL3[DMASRC]=0 a DMA request is made and a transfer of the result data can be initiated by the DMA.
- CTRL1[STARTA] and SYNCA input are ignored while a scan is in process. Scanning stops and cannot be initiated when CTRL1 [STOPA] is set.

##### 41.4.4.2 Parallel scan mode

The parallel scans differ in that converter A performs up to eight samples (SAMPLE[0:7]) in parallel with converter B (SAMPLE[8:15]). This mode has the following characteristics:

- SAMPLEs[0:7] can reference only the ANA[0:7] inputs

1. ANA6, ANA7, ANB6, ANB7 expand the input channel mux by additional selection of 13 channels for each of the ADCs. See Input Multiplex data for details.

- SAMPLEs[8:15] can reference only the ANB[0:7] inputs
- Within the constraints above, any sample can reference any pin, and more than one sample slot can reference the same sample and the same input
- All samples have the full functionality of offset subtraction and high/low limit compare

### Simultaneous mode

- By default (when CTRL2[SIMULT]=1), the scans in both converters are initiated when CTRL1[STARTA] is written with a 1 or when CTRL1[SYNCA] has a value of 1 and the SYNCA input goes high
- The scan in both converters terminates when either converter encounters a disabled sample slot
- Completion of a scan triggers the STAT[EOSIA] interrupt if the CTRL1[EOSIEA] interrupt enable is set. If CTRL1[DMAENA] is set and CTRL3[DMASRC]=0 then a DMA initiates a transfer of the result data.
- Samples are always taken simultaneously in both the A and B converters. Setting CTRL1 [STOPA] stops and prevents the initiation of scanning in both converters.

### Non-simultaneous mode

- Setting CTRL2[SIMULT]=0 (non-simultaneous mode) causes parallel scanning to operate independently in the A and B converter
- Each converter has its own set of START, STOP, SYNC, DMAEN, and EOSIE control bits, SYNC input, EOSI interrupt, and CIP status indicators (suffix A for converter A and suffix B for converter B)
- Though still operating in parallel, the scans in the A and B converter start and stop independently according to their own controls and can be simultaneous, phase shifted, or asynchronous depending on when scans are initiated on the respective converters
- The number of conversions for A and B can be different (still up to a maximum of 8) and each converter's scan completes when a disabled sample is encountered in that converter's sample list only
- CTRL1[STOPA] stops the A converter only and CTRL2[STOPB] stops the B converter only
- Looping scan modes iterate independently
- Each converter independently restarts its scan after completing its list or encountering a disabled sample slot.

## 41.4.5 Scan Sequencing

The sequential and parallel scan modes fall into three types based on how they repeat:

- Once scan. A once scan executes a sequential or parallel scan only once each time it is started. It differs from a triggered scan in that sync inputs must be re-armed after each use (CTRL\*[SYNC\*]).
- Triggered scan. Identical to the corresponding once scan modes except that re-arming of CTRL\*[SYNC\*] bits is not necessary.
- Looping scan. Automatically restarts a scan, either parallel or sequential, as soon as the previous scan completes. In parallel looping scan modes, the A converter scan restarts as soon as the A converter scan completes and the B converter scan restarts as soon as the B converter scan completes. All subsequent start and sync pulses are ignored after the scan begins unless the scan is paused by the SCTRL[SC] bits. Scanning can only be terminated by setting the STOP bit.

All scan modes ignore sync pulses while a scan is in process unless the scan is paused by the SCTRL[SC] bits. The once scan modes continue to ignore sync pulses even after the scan completes until the CTRL\*[SYNC\*] bit is set again. However, a re-arm can occur any time including during the scan. The SYNCA input is re-armed by setting CTRL1[SYNCA], and the SYNCB input is re-armed by setting CTRL2[SYNCB]. A re-arm can be performed any time after a scan starts.

## 41.4.6 Power Management

The five supported power modes are discussed in order from highest to lowest power usage at the expense of increased conversion latency and/or startup delay. Changes to the device configuration that affect the power modes should be made while PWR[PDA] and PWR[PDB] are both asserted. See the Clocks section for details on the various clocks referenced here.

### 41.4.6.1 Low Power Modes

In the following table, the low-power modes are discussed in order from highest to lowest power usage.

| Mode         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal power | At least one ADC converter is powered up (PWR[PDA] or PWR[PDB] is 0), and PWR[APD] and PWR[ASB] are both 0. The HSADC uses the conversion clock as the ADC clock source in either active or idle. The conversion clock should be configured to or near 80 MHz to minimize conversion latency. No startup delay (PWR[PUDELAY] x 32) nor dummy conversion is imposed.                                                                                                |
| Auto-standby | At least one ADC converter is powered up (PWR[PDA] or PWR[PDB] is 0), PWR[APD] is 0, and PWR[ASB] is 1. A second clock signal is applied to the HSADC module and is divided by 20 to generate a ~140 kHz auto-standby clock. The HSADC uses the conversion clock when active and the 140 kHz auto-standby clock when idle. The auto-standby state automatically engages when the HSADC is idle. The conversion ADC clock should be configured to or near 80 MHz to |

*Table continues on the next page...*

| Mode           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | minimize conversion latency when active. At the start of all scans, there is a startup delay of (PWR[PUDELAY] x32) ADC clocks to engage the conversion clock and revert from standby to normal mode. Auto-standby is a compromise between normal and auto-powerdown modes. This mode offers moderate power savings at the cost of a moderate latency when leaving the idle state to start a new scan.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Auto-Powerdown | At least one ADC converter is powered up (PWR[PDA] or PWR[PDB] is 0) and PWR[APD] is 1. The conversion clock should be configured to or near 80 MHz to minimize conversion latency when active. The HSADC uses the conversion clock when active. For maximum power savings, it gates off the conversion clock and powers down the converters when idle. At the start of all scans, there is a startup delay of (PWR[PUDELAY] x32) ADC clocks to stabilize normal mode from a completely powered off condition. This mode saves more power than auto-standby but requires more startup latency when leaving the idle state to start a scan (higher PWR[PUDELAY] value).                                                                                                                                                                                                                                    |
| Standby        | At least one ADC converter is powered up (PWR[PDA] or PWR[PDB] is 0), the PWR[ASB] bit is 0, and the HSADC clock for conversions has a very low frequency (~ 4MHz) because the chip is in standby mode. The ADC clock operates continuously at about 140 kHz without loss of conversion accuracy. Though no startup delay (PWR[PUDELAY] x32) is imposed, the latency of a scan is affected by the low frequency of the ADC clock.<br><br>To use auto-powerdown mode and standby mode together, set PWR[APD]. This hybrid mode converts at an ADC clock rate of 140 kHz when active, and it gates off the HSADC clock and powers down the converters when idle. At the start of all scans, there is a startup delay of (PWR[PUDELAY] x32) ADC clock cycles to engage the conversion clock and revert power-up the converters. This is the slowest and lowest power operational configuration of the HSADC. |
| Powerdown      | Both HSADC converter voltage references are powered down (PWR[PDA] and PWR[PDB]).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

#### 41.4.6.2 Startup in Different Power Modes

The HSADC voltage reference and converters are powered down (PWR[PDn]=1) on reset. Individual converters and voltage references can be manually powered down when not in use (PWR[PDA]=1 or PWR[PDB]=1). When the HSADC reference is powered down, the output reference voltages are set to low (VSSA) and the HSADC data output is driven low.

A delay of (PWR[PUDELAY] x32) ADC clock cycles is imposed when PWR[PDA] or PWR[PDB] are cleared to power up a regulator and also to transition from an idle state in which neither converter has a scan in process to an active state in which at least one converter has a scan in process. It is recommended to use two PWR[PUDELAY] values: a large value for full power up and a moderate value for transitioning from auto-standby to full power up.

To start up in normal mode or standby power mode, perform the following steps:

1. Set PWR[PUDELAY] to the large power up value.
2. Clear PWR[ASB] and PWR[APD].
3. Clear the PWR[PDA] and/or PWR[PDB] to power up the required converters.
4. Poll the status bits until all required converters are powered up.
5. Start scan operations. This will provide a full power-up delay before scans begin.

Normal mode does not use (PWR[PUDELAY] x32) at start of scan, so no further delay is imposed.

To start up in auto-standby, use the normal mode startup procedure first. Before starting scan operations, set PWR[PUDELAY] to the moderate standby recovery value, and set PWR[ASB]. Auto-standby mode automatically reduces current levels until active and then imposes the (PWR[PUDELAY] x32) to allow current levels to rise from standby to full power levels.

To start up in auto powerdown mode, perform the following steps:

1. Set PWR[PUDELAY] to the large power-up value.
2. Clear PWR[ASB] and set PWR[APD].
3. Clear the PWR[PDA] and/or PWR[PDB] for the required converters.

Converters remain powered off until scanning goes active. Before a scan starts, there is a large (PWR [PUDELAY] x32) to go from the powered down to the fully powered state.

To avoid ambiguity and ensure that the proper delays are applied when powering up or starting scans, both regulators should be powered off (PWR[PDA]=PWR[PDB]=1) when the clock or power controls are configured.

Attempts to start a scan during the (PWR[PUDELAY] x32) are ignored until the appropriate PWR[PSTS<sub>n</sub>] bits are cleared.

Any attempt to use a converter when it is powered down or with the voltage references disabled will result in invalid results. It is possible to read HSADC result registers after converter power down for results calculated before power-down. A new scan sequence must be started with a SYNC pulse or a write to the START bit before new valid results are available.

In auto-powerdown mode, when the HSADC goes from idle to active, a converter is powered up only if it is required for the scan as determined by the CLIST1-4 and SDIS registers.

### **41.4.6.3 Stop Mode of Operation**

Any conversion sequence can be stopped by setting the relevant STOP bit. Any further sync pulses or writes to the start bit are ignored until the STOP bit is cleared. In stop mode, the results registers can be modified by writes from the processor. Any write to the result register when the HSADC is in Stop mode is treated as if the analog core has supplied the data, so limit checking and zero crossing interrupts can occur if enabled. When clearing the STOP bit and asserting START bit again, the conversion sequence restarts from the first command (SAMPLE0). See [HSADC Data Processing](#) for details.

## 41.5 Clocks

The HSADC has two external clock inputs to drive two clock domains within the HSADC wrapper module.

**Table 41-4. Clock Summary**

| Clock input | Characteristics                           |
|-------------|-------------------------------------------|
| IP Clock    | Maximum rate is 240 MHz.                  |
| adc_8_clk   | 4 MHz for auto-standby power saving mode. |

The IP clock is enabled and its rate is determined on the SoC configuration. The ADC conversion clock is derived from this clock therefore some care should be taken before enabling the ADCs.

The conversion clock (IP clock) is the primary source for the ADC clock and is always selected as the ADC clock when conversions are in process. After configuring the rate of the IP clock source, it is necessary to configure CTRL2[DIVA] and PWR2[DIVB] so that conversion clock frequency falls between 140 kHz and 80 MHz. Operating the ADC at out-of-spec conversion clock frequencies or reconfiguring the parameters that affect clock rates or power modes while the regulators are powered up (PWR[PDA]=0 or PWR[PDB]=0) can negatively affect conversion accuracy.

The ADC clock is active 100 percent of the time in looping modes or in normal power mode. It is also active during all ADC powerup sequences for a period of time determined by the PWR[PUDELAY] field multiplied by 32. If a conversion is initiated in power savings mode, then the ADC clock continues until the conversion sequence completes. And finally, the ADC clock must be also active in low power standby mode at least with the minimum specified frequency (140 kHz).

The following diagram shows the structure of the clocking system.

**Figure 41-6. ADC Clock Generation**

ADC\_8\_CLK clocks a divider to generate the auto-standby clock, which is selected as the ADC clock only during auto-standby power mode (for any scan mode) and only when both converters are idle (for sequential or parallel simultaneous scan modes). Auto-standby power mode requires the ADC\_8\_CLK to be 4 MHz clock. This mode provides substantial power savings yet requires less latency when switching back to the conversion clock at the start of a scan than auto-powerdown mode. The latter mode uses only the conversion clock as the ADC clock source but fully powers down the converters when idle.

The standby mode is also possible if a low frequency IP\_CLK is used. It is required to ensure a minimum of 140 kHz ADC conversion clock rate while a conversion is in process. This configuration, referred to as HSADC module standby power mode, provides accurate ADC conversions at a very low power level.

The ADC clock is the output clock for the converter. During the conversion list scan operation, the converter receives the conversion clock that is the divided version of the conversion clock source (IP\_CLK). During auto-standby mode, the converter also requires to receive a clock signal with frequency higher than 140kHz. The ADC\_CLK is also provided to an external output for debug and failure analysis.

## 41.6 Interrupts

The following table summarizes the HSADC interrupts.

**Table 41-5. Interrupt Summary**

| Interrupt       | Source                                                                         | Description                                                                                                                           |
|-----------------|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| HSADC_ERR_INT_B | STAT[[ZCI],<br>STAT[LLMTI],<br>STAT[HLMTI],<br>STAT[EOCALIA],<br>STAT[EOCALIB] | Zero Crossing, low Limit, high limit and end of calibration on ADCs interrupt                                                         |
| HSADC_CC0_INT_B | STAT[EOSI0]<br>RDY[RDY[15:0]]                                                  | Conversion Complete and Scan Interrupt for any scan type (except converter B scan in non-simultaneous parallel scan mode (see EOSI0)) |
| HSADC_CC1_INT_B | STAT[EOSI1]<br>RDY[RDY[7:4]]<br>RDY[RDY[15:12]]                                | Conversion Complete and Scan Interrupt for converter B scan in non-simultaneous parallel scan mode (see EOSI1)                        |

HSADC interrupts fall into three categories:

1. Threshold or calibration end interrupts

- These are caused by four different events. All of these interrupts are optional and enabled through control register CTRL1 or through calibration register CALIB.
- Zero crossing — occurs if the current result value has a sign change from the previous result as configured by the ZXCTRL register.
- Low limit exceeded error — occurs when the current result value is less than the low limit register value. The raw result value is compared to LOLIM[LLMT] before the offset register value is subtracted.
- High limit exceeded error — is asserted if the current result value is greater than the high limit register value. The raw result value is compared to HILIM[HLMT] before the offset register value is subtracted.
- End of calibration — asserts when a requested calibration on ADC A or ADC B is completed.

2. Conversion complete interrupts

- They are generated upon completion of any scan and convert sequence when CTRL1[EOSIEA]=1
- Additional bits may need to be set in the Interrupt Control Module to enable the CPU to receive the interrupt signal.

3. Scan interrupts

- They are generated when a sample is converted. This allows processing of intermediate conversion data during a scan.
- The interrupt occurs when any sample has its SCTRL[SC] and SCHLTEN[SchLTEN] bits enabled (set), and the RDY[RDY] bit for that sample is asserted. Use these registers to determine which sample triggered the interrupt.

## 41.7 Timing Specifications

The following figure shows a timing diagram for the HSADC module. The HSADC is assumed to be in Once or Triggered mode, so the converter is considered in idle state prior to the SYNC pulse (or START bit write). The ADC clock is switching at the conversion rate as programmed in the configuration registers. The sequence of events in the HSADC system is as follows:

1. When the SYNC pulse occurs, the ADC clock is synchronized to this pulse as shown in the figure by forcing a low state on to the ADC clock. Then the CIP (conversion in progress) status bit is asserted in the following ADC clock. The MUX controls to select the analog input are also changed during this first ADC clock cycle.
2. The sampling time starts in the following ADC clock cycle and ends 1.5 ADC clock cycle later if the sampling time configured at the register HSADC\_SAMPTIM is 0. If the value of this register is 1, then the sampling time is 2.5 ADC clock cycles long. Then the conversion phase starts.
3. The conversion phase lasts 12.5 ADC clock cycles for 12 bits resolution. This time includes the calibration correction operation. The conversion result is then available to be sampled after some hardware delay. So it can be processed on the HSADC and stored in the registers HSADC\_RSLTn.
4. When a conversion phase ends a new sampling phase can be started if a new input signal is selected as shown in the diagram.
5. If the EOSIx bit is set and enabled by EOSIEx then the IRQ is asserted to indicate the end of a scan. The CPU can then read the conversion results in the mapped registers HSADC\_RSLTn.

# Chapter 42

## Comparator (CMP)

### 42.1 Chip-specific CMP information

#### 42.1.1 CMP instantiation information

This chip has four high speed CMP modules each with a 6-bit DAC to provide a reference voltage.

#### NOTE

The CMP0\_out and CMP1\_out are inter-connected to the RX pin of UART0 and UART1 on chip. See SIM\_SCI0RXSRC[1:0] and SIM\_SCI1RXSRC[1:0] for the details.

#### 42.1.2 CMP Signal Assignments

#### NOTE

For more details see SIM\_MISCTRL and SIM\_SOPT7 registers

**Table 42-1. CMP Signal assignments**

| Instance | Signal | Description   | I/O   | Connected to | Ext Pin Mux / SIM | Pin Number |          |            |
|----------|--------|---------------|-------|--------------|-------------------|------------|----------|------------|
|          |        |               |       |              |                   | 100 LQFP   | 144 LQFP | 144 MAPBGA |
| CMP0     | IN0    | input channel | input | CMP0_IN0     | PTC6              | 78         | 111      | C8         |
|          | IN1    | input channel | input | CMP0_IN1     | PTC7              | 79         | 112      | B8         |

### 42.1.3 CMP voltage references

The 6-bit DAC sub-block supports selection of two references. For this device, Vin1 input is connected to VREFH and the Vin2 input is connected to VDDA.

### 42.1.4 CMP external references

Each CMP has its own 6-bit DAC sub-block which feeds the IN7 of the comparator. Additionally the output of bandgap is provided to IN6 of each comparator.

### 42.1.5 External window/sample input

Individual PDB pulse-out signals control each CMP Sample/Window timing.

## 42.2 Introduction

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference  $V_{in}$  into 64 voltage levels. A 6-bit digital signal input selects the output voltage level, which varies from  $V_{in}$  to  $V_{in}/64$ .  $V_{in}$  can be selected from two voltage sources,  $V_{in1}$  and  $V_{in2}$ . The 6-bit DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

### 42.2.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions

- Two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with longer propagation delay
- DMA transfer support
  - A comparison event can be selected to trigger a DMA transfer
- Functional in all modes of operation except VLLS0
- The window and filter functions are not available in the following modes:
  - Stop
  - VLPS
  - VLLS<sub>x</sub>

### 42.2.2 6-bit DAC key features

The 6-bit DAC has the following features:

- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

### 42.2.3 ANMUX key features

The ANMUX has the following features:

- Two 8-to-1 channel mux
- Operational over the entire supply range

### 42.2.4 CMP, DAC and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.

Figure 42-1. CMP, DAC and ANMUX block diagram

### 42.2.5 CMP block diagram

The following figure shows the block diagram for the CMP module.

**Figure 42-2. Comparator module block diagram**

In the CMP block diagram:

- The Window Control block is bypassed when  $CR1[WE] = 0$
- If  $CR1[WE] = 1$ , the comparator output will be sampled on every bus clock when  $WINDOW=1$  to generate COUTA. Sampling does NOT occur when  $WINDOW = 0$ .
- The Filter block is bypassed when not in use.
- The Filter block acts as a simple sampler if the filter is bypassed and  $CR0[FILTER\_CNT]$  is set to 0x01.
- The Filter block filters based on multiple samples when the filter is bypassed and  $CR0[FILTER\_CNT]$  is set greater than 0x01.
  - If  $CR1[SE] = 1$ , the external SAMPLE input is used as sampling clock
  - If  $CR1[SE] = 0$ , the divided bus clock is used as sampling clock

- If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which is crossing clock domain boundaries, must be resynchronized to the bus clock.
- CR1[WE] and CR1[SE] are mutually exclusive.

## 42.3 Memory map/register definitions

**CMP memory map**

| Absolute address (hex) | Register name                              | Width (in bits) | Access | Reset value | Section/ page               |

## 42.4 Functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM.

CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CR1[INV] = 1.

SCR[IER] and SCR[IEF] are used to select the condition which will cause the CMP module to assert an interrupt to the processor. SCR[CFF] is set on a falling-edge and SCR[CFR] is set on rising-edge of the comparator output. The optionally filtered CMPO can be read directly through SCR[COUT].

### 42.4.1 CMP functional modes

There are the following main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CR0[FILTER\_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CR1[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CR1[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

**Table 42-2. Comparator sample/filter controls**

| Mode # | CR1[EN] | CR1[WE] | CR1[SE] | CR0[FILTER_CNT] | FPR[FILT_PER] | Operation                                                                                                                                                                                                                                                                 |

| All other combinations of CR1[EN], CR1[WE], CR1[SE], CR0[FILTER_CNT], and FPR[FILT_PER] are illegal. |         |         |         |                 |               |                                                                                                                                                                                                                  |

For cases where a comparator is used to drive a fault input, for example, for a motor-control module such as FTM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

### Note

Filtering and sampling settings must be changed only after setting CR1[SE]=0 and CR0[FILTER\_CNT]=0x00. This resets the filter to a known state.

#### 42.4.1.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

#### 42.4.1.2 Continuous mode (#s 2A & 2B)

**Figure 42-3. Comparator operation in Continuous mode**

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. SCR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unlocked mode. COUT and COUTA are identical.

For control configurations which result in disabling the filter block, see the [Filter Block Bypass Logic](#) diagram.

#### 42.4.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)

**Figure 42-4. Sampled, Non-Filtered (# 3A): sampling point externally driven**

In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising-edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).

**Figure 42-5. Sampled, Non-Filtered (# 3B): sampling interval internally derived**

#### 42.4.1.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unlocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, CR0[FILTER\_CNT]>1, which activates filter operation.

**Figure 42-7. Sampled, Filtered (# 4B): sampling point internally derived**

The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now,  $CR0[FILTER\_CNT] > 1$ , which activates filter operation.

#### 42.4.1.5 Windowed mode (#s 5A & 5B)

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

#### NOTE

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.

Figure 42-8. Windowed mode operation

Figure 42-9. Windowed mode

For control configurations which result in disabling the filter block, see [Filter Block Bypass Logic](#) diagram.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

#### 42.4.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in [Figure 42-8](#), and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

**Figure 42-10. Windowed/resampled mode operation**

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by FPR[FILT\_PER] and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of CR0[FILTER\_CNT] must be 1.

### 42.4.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function +  $((CR0[FILTER\_CNT] * FPR[FILT\_PER]) + 1) * \text{bus clock}$  for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

Figure 42-11. Windowed/Filtered mode

## 42.4.2 Power modes

### 42.4.2.1 Wait mode operation

During Wait and VLPW modes, the CMP, if enabled, continues to operate normally and a CMP interrupt can wake the MCU.

### 42.4.2.2 Stop mode operation

Depending on clock restrictions related to the MCU core or core peripherals, the MCU is brought out of stop when a compare event occurs and the corresponding interrupt is enabled. Similarly, if CR1[OPE] is enabled, the comparator output operates as in the normal operating mode and comparator output is placed onto the external pin. In Stop modes, the comparator can be operational in both:

- High-Speed (HS) Comparison mode when CR1[PMODE] = 1
- Low-Speed (LS) Comparison mode when CR1[PMODE] = 0

It is recommended to use the LS mode to minimize power consumption.

If stop is exited with a reset, all comparator registers are put into their reset state.

### 42.4.2.3 Background Debug Mode Operation

When the microcontroller is in active background debug mode, the CMP continues to operate normally.

### 42.4.3 Startup and operation

A typical startup sequence is listed here.

- The time required to stabilize COUT will be the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function and filter. See the Data Sheets for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the [Low-pass filter](#).
- During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and SCR[CFR]/SCR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.
- When programmed for filtering modes, COUT will initially be equal to 0, until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

## 42.4.4 Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT.

Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.

Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT\_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

### 42.4.4.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CR0[FILTER\_CNT] > 0x01 and
- Setting FPR[FILT\_PER] to a nonzero value or setting CR1[SE]=1

If using the divided bus clock to drive the filter, it will take samples of COUTA every FPR[FILT\_PER] bus clock cycles.

The filter output will be at logic 0 when first initialized, and will subsequently change when all the consecutive CR0[FILTER\_CNT] samples agree that the output value has changed. In other words, SCR[COUT] will be 0 for some initial period, even when COUTA is at logic 1.

Setting both CR1[SE] and FPR[FILT\_PER] to 0 disables the filter and eliminates switching current associated with the filtering process.

#### Note

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CR0[FILTER\_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CR1[SE]=1, the filter takes samples of COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CR0[FILTER\_CNT] samples agree that the output value has changed.

#### 42.4.4.2 Latency issues

The value of FPR[FILT\_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CR0[FILTER\_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CR0[FILTER\_CNT].

The values of FPR[FILT\_PER] or SAMPLE period and CR0[FILTER\_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CR0[FILTER\_CNT].

The following table summarizes maximum latency values for the various modes of operation *in the absence of noise*. Filtering latency is restarted each time an actual output transition is masked by noise.

**Table 42-3. Comparator sample/filter maximum latencies**

| Mode # | CR1[EN] | CR1[WE] | CR1[SE] | CR0[FILTER_CNT] | FPR[FILT_PER] | Operation                  | Maximum latency <sup>1</sup>                                        |
|--------|---------|---------|---------|-----------------|---------------|----------------------------|---------------------------------------------------------------------|
| 1      | 0       | X       | X       | X               | X             | Disabled                   | N/A                                                                 |
| 2A     | 1       | 0       | 0       | 0x00            | X             | Continuous Mode            | $T_{PD}$                                                            |
| 2B     | 1       | 0       | 0       | X               | 0x00          |                            |                                                                     |
| 3A     | 1       | 0       | 1       | 0x01            | X             | Sampled, Non-Filtered mode | $T_{PD} + T_{SAMPLE} + T_{per}$                                     |
| 3B     | 1       | 0       | 0       | 0x01            | > 0x00        |                            | $T_{PD} + (FPR[FILT\_PER] * T_{per}) + T_{per}$                     |
| 4A     | 1       | 0       | 1       | > 0x01          | X             | Sampled, Filtered mode     | $T_{PD} + (CR0[FILTER\_CNT] * T_{SAMPLE}) + T_{per}$                |
| 4B     | 1       | 0       | 0       | > 0x01          | > 0x00        |                            | $T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + T_{per}$  |
| 5A     | 1       | 1       | 0       | 0x00            | X             | Windowed mode              | $T_{PD} + T_{per}$                                                  |
| 5B     | 1       | 1       | 0       | X               | 0x00          |                            | $T_{PD} + T_{per}$                                                  |
| 6      | 1       | 1       | 0       | 0x01            | 0x01 - 0xFF   | Windowed / Resampled mode  | $T_{PD} + (FPR[FILT\_PER] * T_{per}) + 2T_{per}$                    |
| 7      | 1       | 1       | 0       | > 0x01          | 0x01 - 0xFF   | Windowed / Filtered mode   | $T_{PD} + (CR0[FILTER\_CNT] * FPR[FILT\_PER] * T_{per}) + 2T_{per}$ |

1.  $T_{PD}$  represents the intrinsic delay of the analog component plus the polarity select logic.  $T_{SAMPLE}$  is the clock period of the external sample clock.  $T_{per}$  is the period of the bus clock.

## 42.5 CMP interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both.

The following table gives the conditions in which the interrupt request is asserted and deasserted.

| When                                                           | Then                                |
|----------------------------------------------------------------|-------------------------------------|
| SCR[IER] and SCR[CFR] are set                                  | The interrupt request is asserted   |
| SCR[IEF] and SCR[CFF] are set                                  | The interrupt request is asserted   |
| SCR[IER] and SCR[CFR] are cleared for a rising-edge interrupt  | The interrupt request is deasserted |
| SCR[IEF] and SCR[CFF] are cleared for a falling-edge interrupt | The interrupt request is deasserted |

## 42.6 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

## 42.7 CMP Asynchronous DMA support

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.

## 42.8 Digital-to-analog converter

The figure found here shows the block diagram of the DAC module.

It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC Control Register (DACCR). Its supply reference source can be selected from two sources  $V_{in1}$  and  $V_{in2}$ . The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

Figure 42-12. 6-bit DAC block diagram

## 42.9 DAC functional description

This section provides DAC functional description information.

### 42.9.1 Voltage reference source select

- $V_{in1}$  connects to the primary voltage source as supply reference of 64 tap resistor ladder
- $V_{in2}$  connects to an alternate voltage source

### 42.10 DAC resets

This module has a single reset input, corresponding to the chip-wide peripheral reset.

### 42.11 DAC clocks

This module has a single clock input, the bus clock.

### 42.12 DAC interrupts

This module has no interrupts.

### 42.13 CMP Trigger Mode

CMP and DAC are configured to CMP Trigger mode when `CMP_CR1[TRIGM]` is set to 1.

In addition, the CMP must be enabled. If the DAC is to be used as a reference to the CMP, it must also be enabled.

CMP Trigger mode depends on an external timer resource to periodically enable the CMP and 6-bit DAC in order to generate a triggered compare.

Upon setting `TRIGM`, the CMP and DAC are placed in a standby state until an external timer resource trigger is received.

## Chapter 43

# 12-bit Digital-to-Analog Converter (DAC)

### 43.1 Chip-specific DAC information

#### 43.1.1 12-bit DAC Instantiation Information

This device contains one 12-bit digital-to-analog converter (DAC) with programmable reference generator output. The DAC includes a 16 deep 12bit FIFO for DMA support.

DAC0\_OUT signal is connected to CMP3\_IN3 and CMP1\_IN3/PTE30.

DAC0\_buffer\_limit output signal feeds DMAUX source 45.

DAC\_12B\_SYNC input signals is connected to XBARA\_OUT15, PDB0\_DAC\_trig, and PDB1\_DAC\_trig outputs.

#### 43.1.2 12-bit DAC Output

The output of the DAC can be placed on an external pin or selected as an input to the analog comparator or ADC.

#### 43.1.3 12-bit DAC Reference

For this device VREFH and VDDA are selectable as the DAC reference. VREFH is connected to the DACREF\_1 input and VDDA is connected to the DACREF\_2 input. Use DACx\_C0[DACRFS] control bit to select between these two options.

**NOTE**

It must be noted that if the DAC and ADC use the same reference simultaneously, some degradation of ADC accuracy is to be expected due to DAC switching.

## 43.2 Introduction

The 12-bit digital-to-analog converter (DAC) is a low-power, general-purpose DAC. The output of the DAC can be placed on an external pin or set as one of the inputs to the analog comparator, op-amps, or ADC.

## 43.3 Features

The features of the DAC module include:

- On-chip programmable reference generator output. The voltage output range is from  $1/4096 V_{in}$  to  $V_{in}$ , and the step is  $1/4096 V_{in}$ , where  $V_{in}$  is the input voltage.
- $V_{in}$  can be selected from two reference sources
- Static operation in Normal Stop mode
- 16-word data buffer supported with configurable watermark and multiple operation modes
- DMA support

## 43.4 Block diagram

The block diagram of the DAC module is as follows:

Figure 43-1. DAC block diagram

## 43.5 Memory map/register definition

The DAC has registers to control analog comparator and programmable voltage divider to perform the digital-to-analog functions.

## DAC memory map

| Absolute address (hex) | Register name                        | Width (in bits) | Access | Reset value | Section/ page               |

### 43.5.3 DAC Status Register (DACx\_SR)

If DMA is enabled, the flags can be cleared automatically by DMA when the DMA request is done. Writing 0 to a field clears it whereas writing 1 has no effect. After reset, DACBFRPTF is set and can be cleared by software, if needed. The flags are set only when the data buffer status is changed.

Address: 4003\_F000h base + 20h offset = 4003\_F020h

|       |   |   |   |   |   |         |          |          |

#### DACx\_C2 field descriptions

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–4<br>DACBFRP | DAC Buffer Read Pointer<br><br>In normal mode it keeps the current value of the buffer read pointer. FIFO mode, it is the FIFO read pointer. It is writable in FIFO mode. User can configure it to same address to reset FIFO as empty.                                                                                                                                                                                                                                                                                              |
| DACBFUP        | DAC Buffer Upper Limit<br><br>In normal mode it selects the upper limit of the DAC buffer. The buffer read pointer cannot exceed it. In FIFO mode it is the FIFO write pointer. User cannot set Buffer Up limit in FIFO mode. In Normal mode its reset value is MAX. When IP is configured to FIFO mode, this register becomes Write_Pointer, and its value is initially set to equal READ_POINTER automatically, and the FIFO status is empty. It is writable and user can configure it to the same address to reset FIFO as empty. |

## 43.6 Functional description

The 12-bit DAC module can select one of the two reference inputs—DACREF\_1 and DACREF\_2 as the DAC reference voltage,  $V_{in}$  by C0 [DACRFS]. See the chip-specific DAC information to determine the source options for DACREF\_1 and DACREF\_2.

When the DAC is enabled, it converts the data in DACDAT0[11:0] or the data from the DAC data buffer to a stepped analog output voltage. The output voltage range is from  $V_{in}$  to  $V_{in}/4096$ , and the step is  $V_{in}/4096$ .

### 43.6.1 DAC data buffer operation

When the DAC is enabled and the buffer is not enabled, the DAC module always converts the data in DAT0 to the analog output voltage.

When both the DAC and the buffer are enabled, the DAC converts the data in the data buffer to analog output voltage. The data buffer read pointer advances to the next word whenever a hardware or software trigger event occurs.

The data buffer can be configured to operate in Normal mode, Swing mode, One-Time Scan mode or FIFO mode. When the buffer operation is switched from one mode to another, the read pointer does not change. The read pointer can be set to any value between 0 and C2[DACBFUP] by writing C2[DACBFRP].

### 43.6.1.1 DAC data buffer interrupts

There are several interrupts and associated flags that can be configured for the DAC buffer. SR[DACBFRPBF] is set when the DAC buffer read pointer reaches the DAC buffer upper limit, that is, C2[DACBFRP] = C2[DACBFUP]. SR[DACBFRPTF] is set when the DAC read pointer is equal to the start position, 0. Finally, SR[DACBFWMF] is set when the DAC buffer read pointer has reached the position defined by C1[DACBFWM]. C1[DACBFWM] can be used to generate an interrupt when the DAC buffer read pointer is between 1 to 4 words from C2[DACBFUP].

### 43.6.1.2 Modes of DAC data buffer operation

The following table describes the different modes of data buffer operation for the DAC module.

**Table 43-1. Modes of DAC data buffer operation**

| Modes                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Buffer Normal mode        | This is the default mode. The buffer works as a circular buffer. The read pointer increases by one, every time the trigger occurs. When the read pointer reaches the upper limit, it goes to 0 directly in the next trigger event.                                                                                                                                                                                                         |
| Buffer Swing mode         | This mode is similar to the normal mode. However, when the read pointer reaches the upper limit, it does not go to 0. It will descend by 1 in the next trigger events until 0 is reached.                                                                                                                                                                                                                                                  |
| Buffer One-time Scan mode | The read pointer increases by 1 every time the trigger occurs. When it reaches the upper limit, it stops there. If read pointer is reset to the address other than the upper limit, it will increase to the upper address and stop there again.<br><br><b>NOTE:</b> If the software set the read pointer to the upper limit, the read pointer will not advance in this mode.                                                               |
| FIFO Mode                 | In FIFO mode, the buffer is organized as a FIFO. For a valid write to any DACDATx, the data is put into the FIFO, and the write pointer is automatically incremented. The module is connected internally to a 32bit interface. For any 16bit or 8bit FIFO access, address bit[1] needs to be 0; otherwise, the write is ignored. For any 32bit FIFO access, the Write_Pointer needs to be an EVEN number; otherwise, the write is ignored. |

**Table 43-1. Modes of DAC data buffer operation**

| Modes | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p><b>NOTE:</b> A successful 32bit FIFO write will increase the write pointer by 2. Any write will cause the FIFO over-flow will be ignored, the cases includes: 1.FIFO is full, the write will be ignored. 2.FIFO is nearly full (FIFO_SIZE-1), 32bit write will be ignored.</p> <p><b>NOTE:</b> For 8bit write, address bit[0] determine which byte lane will be written to the FIFO according to little endian alignment. Only both byte lanes are written will the write pointer increase. User need to make sure 8bit access happened in pair and both upper &amp; lower bytes are written. There is no requirement on which byte write first. In FIFO mode, there is no change to read access of DACDATx (from normal mode), read to DACDATx will return the DATA addressed by the access address to the data buffer, and both write pointer and read pointer in FIFO mode will NOT be changed by read access. FIFO write can be happened when DAC is not enabled for 1st data conversion enable. But FIFO mode need to work at buffer Enabled at DACC1[DACBFEN].</p> <p>In FIFO mode, the DATA BUF will be organized as FIFO.</p> |

### 43.6.2 DMA operation

When DMA is enabled, DMA requests are generated instead of interrupt requests. The DMA Done signal clears the DMA request.

The status register flags are still set and are cleared automatically when the DMA completes.

### 43.6.3 Resets

During reset, the DAC is configured in the default mode and is disabled.

### 43.6.4 Low-Power mode operation

The following table shows the wait mode and the stop mode operation of the DAC module.

**Table 43-2. Modes of operation**

| Modes of operation | Description                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wait mode          | The DAC will operate normally, if enabled.                                                                                                                                              |
| Stop mode          | If enabled, the DAC module continues to operate in Normal Stop mode and the output voltage will hold the value before stop.<br><br>In low-power stop modes, the DAC is fully shut down. |

**NOTE**

The assignment of module modes to core modes is chip-specific. For module-to-core mode assignments, see the chapter that describes how modules are configured.

# Chapter 44

## FlexTimer Module (FTM)

### 44.1 Chip-specific FTM information

#### 44.1.1 Instantiation Information

This device contains four FlexTimer modules.

The following table shows how these modules are configured. This adheres to Kinetis K series FTM instantiations.

**Table 44-1. FTM Instantiations**

| FTM instance | Number of channels | Features/usage                        |
|--------------|--------------------|---------------------------------------|
| FTM0         | 8                  | 3-phase motor control                 |
| FTM1         | 2 <sup>1</sup>     | Quadrature decoder or general purpose |
| FTM2         | 2 <sup>1</sup>     | Quadrature decoder or general purpose |
| FTM3         | 8                  | 3-phase motor control                 |

1. These registers are not available in FTM1 and FTM2: C2SC, C3SC, C4SC, C5SC, C6SC, C7SC, C2V, C3V, C4V, C5V, C6V, and C7V

#### 44.1.2 External Clock Options

By default each FTM is clocked by the internal fast peripheral clock (the FTM refers to it as system clock). Each module contains a register setting that allows the module to be clocked from an external clock instead. There are three external FTM\_CLKINx pins that can be selected by any FTM module via the SIM\_SOPT4 register as an external clock source. The pinmux options may provide optional external inputs.

- FTM\_CLKIN0 can provide an external input clock to all or either of FTM0, FTM1, FTM2, and FTM3

- FTM\_CLKIN1 can provide an external input clock to all or either of FTM0, FTM1, FTM2, and FTM3
- FTM\_CLKIN2 can provide an external input clock to all or either of FTM0, FTM1, FTM2, and FTM3

### 44.1.3 Fixed frequency clock

The fixed frequency clock for each FTM is MCGFFCLK.

### 44.1.4 FTM Interrupts

The FlexTimer has multiple sources of interrupt. However, these sources are OR'd together to generate a single interrupt request per FTM module to the interrupt controller. When an FTM interrupt occurs, read the FTM status registers (FMS, SC, and STATUS) to determine the exact interrupt source.

### 44.1.5 FTM Fault Detection Inputs KV5x

The following fault detection input options for the FTM modules are selected via the SIM\_SOPT4 register. The external pin option is selected by default.

- FTM0 FAULT0 = FTM0\_FLT0 pin or CMP0 output via SIM Option register control
- FTM0 FAULT1 = FTM0\_FLT1 pin or CMP1 output via SIM Option register control
- FTM0 FAULT2 = FTM0\_FLT2 pin or CMP2 output via SIM Option register control
- FTM0\_FAULT3 = XBARA\_OUT49 or FTM0\_FLT3 pin selected by bit in SIM\_SOPT4 register
- FTM1 FAULT0 = FTM1\_FLT0 pin or CMP0 output via SIM option register control
- FTM1 FAULT1 = XBAR\_OUT50
- FTM2 FAULT0 = FTM2\_FLT0 pin or CMP0 output via SIM option register control
- FTM2 FAULT1 = XBAR\_OUT51
- FTM3 FAULT0 = FTM3\_FLT0 pin or CMP0 output via SIM Option register control
- FTM3 FAULT1 = reserved
- FTM3 FAULT2 = reserved
- FTM3 FAULT3 = XBARA\_OUT52

### 44.1.6 FTM Hardware Triggers KV5x

The FTM input synchronization hardware triggers are connected in the chip as follows:

- FTM0 hardware trigger 0 = FTM0\_SYNCBIT of SIM\_OPTx register, CMP0 Output or FTM1 Match output.
- FTM0 hardware trigger 1 = PDB0 channel 0 trigger Output or FTM1 Match output
- FTM0 hardware trigger 2 = XBARA\_OUT34
- FTM1 hardware trigger 0 = FTM1\_SYNCBIT of SIM\_OPTx register, CMP0 Output or FTM0 Match output
- FTM1 hardware trigger 1 = CMP1 Output
- FTM1 hardware trigger 2 = XBARA\_OUT35
- 
- FTM2 hardware trigger 0 = FTM2\_SYNCBIT of SIM\_OPTx register, CMP0 Output or FTM0 Match output
- FTM2 hardware trigger 1 = CMP2 Output
- FTM2 hardware trigger 2 = XBARA\_OUT36
- FTM3 hardware trigger 0 = FTM3\_SYNCBIT of SIM\_OPTx register, CMP0 Output or FTM1 Match output
- FTM3 hardware trigger 1 = PDB1 channel 0 Trigger Output or FTM1 Match output
- FTM3 hardware trigger 2 = XBARA\_OUT37

### 44.1.7 Input capture options for FTM module instances

The following input capture source options are selected via SIM\_SOPTx. The external pin option is selected by default.

- FTM1 channel 0 input capture = FTM1\_CH0 pin or CMP0 output or CMP1 output via FTM1ICH0SRC bit in SIM\_SOPT9 register
- FTM1 channel 1 input capture = FTM1\_CH1 pin or exclusive OR of FTM1\_CH0, FTM1\_CH1, and XBARA\_OUT42 via FTM1ICH1SRC bit in SIM\_SOPT9 register
- FTM2 channel 0 input capture = FTM2\_CH0 pin or CMP0 output or CMP1 output via FTM2ICH0SRC bit in SIM\_SOPT9 register
- FTM2 channel 1 input capture = FTM2\_CH1 pin or exclusive OR of FTM2\_CH0, FTM2\_CH1, and FTM1\_CH1 via FTM2ICH1SRC bit in SIM\_SOPT9 register

### 44.1.8 FTM Hall sensor support

For 3 phase motor control sensor-ed applications the use of Hall sensors, generally 3 sensors placed 120 degrees apart around the rotor, are deployed to detect position and speed. Each of the 3 sensors provides a pulse that applied to an input capture pin, can then be analyzed and both speed and position can be deduced. This device has two 2-channel FTMs. (FTM1 and FTM2) and thus provides 4 input capture pins. To simplify the calculations required by the CPU on each hall sensor's input, if all 3 inputs are "exclusively OR'd " into one timer channel and the free running counter is refreshed on every edge then this can simplify the speed calculation.

Via the SIM module and SIM\_SOPT4 register the FTM2CH1SRC bit provides the choice of normal FTM2\_CH1 input or the XOR of FTM2\_CH0, FTM2\_CH1 and FTM1\_CH1 pins that will be applied to FTM2\_CH1.

Note: If the user utilizes FTM1\_CH1 to be an input to FTM2\_CH1, FTM1\_CH0 can still be utilized for other functions.

**Figure 44-1. FTM Hall Sensor Configuration**

### 44.1.9 FTM modulation implementation

FTM0 and FTM3 support a modulation function where the output channels when configured as PWM or Output Compare mode modulate another timer output when the channel signal is asserted. Any of the 8 channels of FTM0 and any of the 8 channels of FTM3 can be configured to support this modulation function.

The SIM\_SOPT8 register has eight control bits (FTM0CHySRC) that allow the user to select normal PWM/Output Compare mode on the corresponding FTM timer channel or modulate with FTM1\_CH1. The diagram below shows the implementation for FTM0. FTM3 has similar implementation controlled by SIM\_SOPT8[FTM3CHySRC] on each of its 8 channels with modulation possible via FTM2\_CH1. See SIM Block Guide for further information.

When FTM1\_CH1 is used to modulate an FTM0 channel, then the user must configure FTM1\_CH1 to provide a signal that has a higher frequency than the modulated FTM0 channel output. Also it limits the use of the FTM1\_CH0 function, as the FTM1\_CH1 will be programmed to provide a 50% duty PWM signal and limit the start and modulus values for the free running counter. FTM2 has a similar restriction when FTM2\_CH1 is used for modulating an FTM3 channel.

### NOTE

FTM1 channel 1 output and LPTMR0 prescaler output provide the carrier signal for FTM3 Timer Modulation mode.

#### 44.1.10 FTM output triggers for other modules

The FTM output triggers can be selected as input triggers for the PDB and ADC modules. PDB, XBARA, and XBARB need be configured before FTM output triggers can be used as ADC input triggers. See the [PDB](#), [XBARA](#), and [XBARB](#) chapters for more information.

FTM0 has 8 channels of trigger capability which are ORed together to force an output trigger. This EXTTRG0 signal is connected to PDB0 channel 1000 input, PDB1 channel 1000 input, XBARA\_IN16 and XBARB\_IN4.

FTM0 INIT ( restart of counter/timer overflow function) provides an output to XBARA\_IN17, XBARB\_IN5

Individual FTM0 channels trigger signal outputs are also assigned to the DMAMUX

FTM0\_CH0 event output to DMAMUX source 24

FTM0\_CH1 event output to DMAMUX source 25

FTM0\_CH2 event output to DMAMUX source 26

FTM0\_CH3 event output to DMAMUX source 27

FTM0\_CH4 event output to DMAMUX source 28

FTM0\_CH5 event output to DMAMUX source 29

FTM0\_CH6 event output to DMAMUX source 30

FTM0\_CH7 event output to DMAMUX source 31

FTM1 has 2 channels of trigger capability which are ORed together to force an output trigger. This EXTRRG1 signal is connected to PDB0 channel 1001 input, PDB1 channel 1001 input, XBARA\_IN36 and XBARB\_IN16.

FTM1 INIT ( restart of counter/timer overflow function) provides an output to XBARA\_IN37, XBARB\_IN17

FTM1\_CH0 event output to DMAMUX source 32, UART0TXSRC and UART1TXSRC of SIM\_OPTx register.

FTM1\_CH1 event output to DMAMUX source 33

FTM2 has 2 channels of trigger capability which are ORed together to force an output trigger. This EXTRRG1 signal is connected to PDB0 channel 1010 input, PDB1 channel 1010 input, XBARA\_IN56 and XBARB\_IN32.

FTM2 INIT ( restart of counter/timer overflow function) provides an output to XBARA\_IN57, XBARB\_IN33

FTM2\_CH0 event output to DMAMUX1 source 32

FTM2\_CH1 event output to DMAMUX1 source 33

FTM3 has 8 channels of trigger capability which are ORed together to force an output trigger. This EXTTRG3 signal is connected to PDB0 channel 1011 input, PDB1 channel 1011 input, XBARA\_IN18 and XBARB\_IN6.

FTM0 INIT ( restart of counter/timer overflow function) provides an output to XBARA\_IN19, XBARB\_IN7

FTM3\_CH0 event output to DMAMUX source 36

FTM3\_CH1 event output to DMAMUX source 37

FTM3\_CH2 event output to DMAMUX source 38  
 FTM3\_CH3 event output to DMAMUX source 39  
 FTM3\_CH4 event output to DMAMUX source 54  
 FTM3\_CH5 event output to DMAMUX source 55  
 FTM3\_CH6 event output to DMAMUX source 56  
 FTM3\_CH7 event output to DMAMUX source 57

### 44.1.11 FTM Global Time Base

This chip provides the optional FTM global time base feature (see ).

FTM0 provides the only source for the FTM global time base. The other FTM modules can share the time base as shown in the following figure:

Figure 44-2. FTM Global Time Base Configuration

### 44.1.12 FTM BDM and debug halt mode

In the FTM chapter, references to the chip being in "BDM" are the same as the chip being in "debug halt mode".

## 44.2 Introduction

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

### 44.2.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the Timer PWM Module – TPM, used for many years on our HCS08 family of 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Fault control inputs
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, fault control, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

More than one FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

## 44.2.2 Features

The FTM features include:

- FTM source clock is selectable.
  - The source clock can be the system clock, the fixed frequency clock, or an external clock
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than the system clock
  - Selecting external clock connects FTM clock to a chip level input pin therefore allowing to synchronize the FTM counter with an off chip clock source
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter
  - It can be a free-running counter or a counter with initial and final value
  - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:
  - The capture can occur on rising edges, falling edges or both edges
  - An input filter can be selected for some channels
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode

- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Initialization trigger
- Software control of PWM outputs
- Up to 4 fault inputs for global fault control
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- The generation of an interrupt when the fault condition is detected
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

### 44.2.3 Modes of operation

When the chip is in an active BDM mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

### 44.2.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CHn (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

#### NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

Figure 44-3. FTM block diagram

## 44.3 FTM signal descriptions

Table 44-2 shows the user-accessible signals for the FTM.

**Table 44-2. FTM signal descriptions**

| Signal | Description                                                                             | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|-----------------------------------------------------------------------------------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EXTCLK | External clock. FTM external clock can be selected to drive the FTM counter.            | I   | The external clock input signal is used as the FTM counter clock if selected by CLKS[1:0] bits in the SC register. This clock signal must not exceed 1/4 of system clock frequency. The FTM counter prescaler selection and settings are also used when an external clock is selected.                                                                                                                                                                                                                                                                                                                                                  |
| CHn    | FTM channel (n), where n can be 7-0                                                     | I/O | Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| FAULTj | Fault input (j), where j can be 3-0                                                     | I   | The fault input signals are used to control the CHn channel output state. If a fault is detected, the FAULTj signal is asserted and the channel output is put in a safe state. The behavior of the fault logic is defined by the FAULTM[1:0] control bits in the MODE register and FAULTEN bit in the COMBINEm register. Note that each FAULTj input may affect all channels selectively since FAULTM[1:0] and FAULTEN control bits are defined for each pair of channels. Because there are several FAULTj inputs, maximum of 4 for the FTM module, each one of these inputs is activated by the FAULTJEN bit in the FLTCTRL register. |
| PHA    | Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A. | I   | The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .                                                                                                                                                                                                                                                                                                                                                                                            |
| PHB    | Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B. | I   | The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the <a href="#">Quadrature Decoder mode</a> .                                                                                                                                                                                                                                                                                                                                                                                            |

## 44.4 Memory map and register definition

### 44.4.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

**Note**

Do not write in the region from the CNTIN register through the PWMLOAD register when FTMEN = 0.

**NOTE**

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

## 44.4.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

**FTM memory map**

| Absolute address (hex) | Register name                              | Width (in bits) | Access | Reset value | Section/ page               |
|------------------------|--------------------------------------------|-----------------|--------|-------------|-----------------------------|

44.4.3 Status And Control (FTMx\_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

**44.4.4 Counter (FTMx\_CNT)**

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

## 44.4.5 Modulo (FTMx\_MOD)

The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see [Counter](#).

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

44.4.7 Channel (n) Value (FTMx\_CnV)

These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d

44.4.8 Counter Initial Value (FTMx\_CNTIN)

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to [Registers updated from write buffers](#).

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

| INIT              | Initial Value Of The FTM Counter |

**44.4.9 Capture And Compare Status (FTMx\_STATUS)**

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

**44.4.10 Features Mode Selection (FTMx\_MODE)**

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Fault control mode and interrupt
- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

*Table continues on the next page...*

**FTMx\_MODE field descriptions (continued)**

| Field | Description                                                                      |
|-------|----------------------------------------------------------------------------------|
| 0     | TPM compatibility. Free running counter and synchronization compatible with TPM. |
| 1     | Free running counter and synchronization are different from TPM behavior.        |

**44.4.11 Synchronization (FTMx\_SYNC)**

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

**NOTE**

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See [PWM synchronization](#).

**44.4.13 Output Mask (FTMx\_OUTMASK)**

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to [PWM synchronization](#).

**44.4.14 Function For Linked Channels (FTMx\_COMBINE)**

This register contains the control bits used to configure the fault control, synchronization, deadtime insertion, Dual Edge Capture mode, Complementary, and Combine mode for each pair of channels (n) and (n+1), where n equals 0, 2, 4, and 6.

Address: Base address + 64h offset

**44.4.15 Deadtime Insertion Control (FTMx\_DEADTIME)**

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 68h offset

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | 10 Divide the system clock by 4.<br>11 Divide the system clock by 16.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DTVAL | <p>Deadtime Value</p> <p>Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS.</p> <p>Deadtime insert value = (DTPS × DTVAL).</p> <p>DTVAL selects the number of deadtime counts inserted as follows:</p> <p>When DTVAL is 0, no counts are inserted.</p> <p>When DTVAL is 1, 1 count is inserted.</p> <p>When DTVAL is 2, 2 counts are inserted.</p> <p>This pattern continues up to a possible 63 counts.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> |

**44.4.16 FTM External Trigger (FTMx\_EXTTRIG)**

This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period. See [Channel trigger output](#) and [Initialization trigger](#).

Channels 6 and 7 are not used to generate channel triggers.

Address: Base address + 6Ch offset

FTMx\_EXTTRIG field descriptions

**44.4.17 Channels Polarity (FTMx\_POL)**

This register defines the output polarity of the FTM channels.

**NOTE**

The safe value that is driven in a channel output when the fault control is enabled and a fault condition is detected is the inactive state of the channel. That is, the safe value of a channel is the value of its POL bit.

**44.4.19 Input Capture Filter Control (FTMx\_FILTER)**

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

**NOTE**

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register).<br/>1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).</p> |
| 0<br>QUADEN    | <p>Quadrature Decoder Mode Enable</p> <p>Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See <a href="#">Table 44-3</a>.</p> <p>This field is write protected. It can be written only when MODE[WPDIS] = 1.</p> <p>0 Quadrature Decoder mode is disabled.<br/>1 Quadrature Decoder mode is enabled.</p>                                                                             |

## 44.4.22 Configuration (FTMx\_CONF)

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset

**44.4.24 Synchronization Configuration (FTMx\_SYNCONF)**

This register selects the PWM synchronization configuration, SWOCTRL, INVCTRL and CNTIN registers synchronization, if FTM clears the TRIGj bit, where j = 0, 1, 2, when the hardware trigger j is detected.

Address: Base address + 8Ch offset

**44.4.25 FTM Inverting Control (FTMx\_INVCTRL)**

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

#### 44.4.26 FTM Software Output Control (FTMx\_SWOCTRL)

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

## 44.4.27 FTM PWM Load (FTMx\_PWMLOAD)

Enables the loading of the MOD, CNTIN, C(n)V, and C(n+1)V registers with the values of their write buffers when the FTM counter changes from the MOD register value to its next value or when a channel (j) match occurs. A match occurs for the channel (j) when FTM counter = C(j)V.

## 44.5 Functional description

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

## Functional description

FTM counting is up.  
Channel (n) is in high-true EPWM mode.  
PS[2:0] = 001  
CNTIN = 0x0000  
MOD = 0x0004  
CnV = 0x0002

Figure 44-4. Notation used

### 44.5.1 Clock source

The FTM has only one clock domain: the system clock.

#### 44.5.1.1 Counter clock source

The CLKS[1:0] bits in the SC register selects clock sources for the FTM counter or disables the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

The fixed frequency clock is an alternative clock source for the FTM counter that allows the selection of a clock other than the system clock or an external clock. This clock input is defined by chip integration; see the chip-specific FTM information for further details. Due to FTM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed 1/2 of the system clock frequency.

The external clock passes through a synchronizer clocked by the system clock to assure that counter transitions are properly aligned to system clock transitions. Therefore, to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the system clock frequency.

## 44.5.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

Figure 44-5. Example of the prescaler counter

## 44.5.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- [Up counting](#)
- [Up-down counting](#)
- [Quadrature Decoder mode](#)

### 44.5.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

Functional description

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is  $(MOD - CNTIN + 0x0001) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

Figure 44-6. Example of FTM up and signed counting

Table 44-5. FTM counting based on CNTIN value

| When                                  | Then                                                                                                                 |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| CNTIN = 0x0000                        | The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.      |
| CNTIN[15] = 1                         | The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed. |
| CNTIN[15] = 0 and CNTIN $\neq$ 0x0000 | The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.                   |

FTM counting is up

CNTIN = 0x0000

MOD = 0x0004

**Figure 44-7. Example of FTM up counting with CNTIN = 0x0000**

### Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.
- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

## Functional description

FTM counting is up  
MOD = 0x0005  
CNTIN = 0x0015

**Figure 44-8. Example of up counting when the value of CNTIN is greater than the value of MOD**

### 44.5.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is  $2 \times (\text{MOD} - \text{CNTIN}) \times \text{period of the FTM counter clock}$ .

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

FTM counting is up-down  
 CNTIN = 0x0000  
 MOD = 0x0004

**Figure 44-9. Example of up-down counting when CNTIN = 0x0000**

### Note

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if  $\text{CnV} > \text{CNTIN}$ , or
- if  $\text{CnV} = 0$  or if  $\text{CnV}[15] = 1$ . In this case, 0% CPWM is generated.

### 44.5.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

**Figure 44-10. Example when the FTM counter is free running**

The FTM counter is also a free running counter when:

Functional description

- FTMEN = 1
- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

44.5.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- [FTM counter synchronization](#).
- A channel in Input Capture mode with ICRST = 1 ([FTM Counter Reset in Input Capture Mode](#)).

44.5.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

Figure 44-11. Periodic TOF when NUMTOF = 0x02

**Figure 44-12. Periodic TOF when NUMTOF = 0x00**

#### 44.5.4 Input Capture mode

The Input Capture mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0
- MSnB:MSnA = 0:0, and
- ELSnB:ELSnA  $\neq$  0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

**Figure 44-13. Input Capture mode**

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

#### 44.5.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

**Figure 44-14. Channel input filter**

When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by  $\text{CHnFVAL}[3:0]$  ( $\times 4$  system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when  $\text{CHnFVAL}[3:0]$  bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If ( $\text{CHnFVAL}[3:0] \neq 0000$ ), then the input signal is delayed by the minimum pulse width ( $\text{CHnFVAL}[3:0] \times 4$  system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer, one rising edge to the filter output, plus one more to the edge detector. In other words,  $\text{CHnF}$  is set  $(4 + 4 \times \text{CHnFVAL}[3:0])$  system clock periods after a valid edge occurs on the channel input.

The clock for the counter in the channel input filter is the system clock divided by 4.

**Figure 44-15. Channel input filter example**

The figure below shows an example of input capture with filter enabled and the delay added by each part of the input capture logic. Note that the input signal is delayed only by the synchronizer and edge detector logic if the filter is disabled.

Figure 44-16. Input capture example

#### 44.5.4.2 FTM Counter Reset in Input Capture Mode

If the channel (n) is in input capture mode and  $\text{FTMx\_CnSC} [\text{ICRST} = 1]$ , then when the selected input capture event occurs in the channel (n) input signal, the current value of the FTM counter is captured into the CnV register, the CHnF bit is set, the channel (n) interrupt is generated (if CHnIE = 1) and the FTM counter is reset to the CNTIN register value.

This allows the FTM to measure a period/pulse being applied to FTM\_CHn (counts of the FTM clock input) without having to implement a subtraction calculation in software subsequent to the event occurring.

The figure below shows the FTM counter reset when the selected input capture event is detected in a channel in input capture mode with  $\text{ICRST} = 1$ .

**Figure 44-17. Example of the Input Capture mode with ICRST = 1**

### NOTE

- It is expected that the ICRST bit be set only when the channel is in input capture mode.
- In this case, if the FTM counter is reset, then the prescaler counter ([Prescaler](#)) and the TOF counter ([When the TOF bit is set](#)) also are reset.

## 44.5.5 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB:MSnA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

## Functional description

MOD = 0x0005  
CnV = 0x0003

**Figure 44-18. Example of the Output Compare mode when the match toggles the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 44-19. Example of the Output Compare mode when the match clears the channel output**

MOD = 0x0005  
CnV = 0x0003

**Figure 44-20. Example of the Output Compare mode when the match sets the channel output**

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

## 44.5.6 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0

- $DECAPEN = 0$
- $COMBINE = 0$
- $CPWMS = 0$ , and
- $MSnB = 1$

The EPWM period is determined by  $(MOD - CNTIN + 0x0001)$  and the pulse width (duty cycle) is determined by  $(CnV - CNTIN)$ .

The  $CHnF$  bit is set and the channel (n) interrupt is generated if  $CHnIE = 1$  at the channel (n) match (FTM counter =  $CnV$ ), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

**Figure 44-21. EPWM period and pulse width with  $ELSnB:ELSnA = 1:0$**

If ( $ELSnB:ELSnA = 0:0$ ) when the counter reaches the value in the  $CnV$  register, the  $CHnF$  bit is set and the channel (n) interrupt is generated if  $CHnIE = 1$ , however the channel (n) output is not controlled by FTM.

If ( $ELSnB:ELSnA = 1:0$ ), then the channel (n) output is forced high at the counter overflow when the  $CNTIN$  register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter =  $CnV$ ). See the following figure.

**Figure 44-22. EPWM signal with  $ELSnB:ELSnA = 1:0$**

If ( $ELSnB:ELSnA = X:1$ ), then the channel (n) output is forced low at the counter overflow when the  $CNTIN$  register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter =  $CnV$ ). See the following figure.

**Figure 44-23. EPWM signal with ELSnB:ELSnA = X:1**

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set. Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

### Note

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if CNTIN < CnV ≤ MOD,
- 100% EPWM signal when CNTIN > CnV or CnV > MOD.

## 44.5.7 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by  $2 \times (CnV - CNTIN)$  and the period is determined by  $2 \times (MOD - CNTIN)$ . See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

**Figure 44-24. CPWM period and pulse width with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

**Figure 44-25. CPWM signal with ELSnB:ELSnA = 1:0**

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

## Functional description

MOD = 0x0008  
CnV = 0x0005

**Figure 44-26. CPWM signal with ELSnB:ELSnA = X:1**

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

## 44.5.8 Combine mode

The Combine mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1, and
- CPWMS = 0

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD – CNTIN + 0x0001) and the PWM pulse width (duty cycle) is determined by (IC(n+1)V – C(n)V).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)V). The CH(n+1)F bit is set and the channel (n+1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced high at the channel (n) match (FTM counter = C(n)V). See the following figure.

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n+1)V). It is forced low at the channel (n) match (FTM counter = C(n)V). See the following figure.

In Combine mode, the ELS(n+1)B and ELS(n+1)A bits are not used in the generation of the channels (n) and (n+1) output. However, if (ELSnB:ELSnA = 0:0) then the channel (n) output is not controlled by FTM, and if (ELSnB:ELSnA = 0:0) then the channel (n+1) output is not controlled by FTM.

**Figure 44-27. Combine mode**

The following figures illustrate the PWM signals generation using Combine mode.

**Figure 44-28. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V < C(n+1)V)**

**Figure 44-29. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n+1)V = MOD)$**

**Figure 44-30. Channel (n) output if  $(C(n)V = CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$**

**Figure 44-31. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(C(n)V$  is Almost Equal to  $CNTIN)$  and  $(C(n+1)V = MOD)$**

**Figure 44-32. Channel (n) output if  $C(n)V = \text{CNTIN}$  and  $\text{CNTIN} < C(n+1)V < \text{MOD}$  and  $C(n+1)V$  is Almost Equal to MOD)**

**Figure 44-33. Channel (n) output if  $C(n)V$  and  $C(n+1)V$  are not between CNTIN and MOD**

**Figure 44-34. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $C(n)V = C(n+1)V$**

**Figure 44-35. Channel (n) output if  $C(n)V = C(n+1)V = CNTIN$**

**Figure 44-36. Channel (n) output if  $C(n)V = C(n+1)V = MOD$**

**Figure 44-37. Channel (n) output if  $(CNTIN < C(n)V < MOD)$  and  $(CNTIN < C(n+1)V < MOD)$  and  $(C(n)V > C(n+1)V)$**

**Figure 44-38. Channel (n) output if  $(C(n)V < CNTIN)$  and  $(CNTIN < C(n+1)V < MOD)$**

Figure 44-39. Channel (n) output if  $(C(n+1)V < CNTIN)$  and  $(CNTIN < C(n)V < MOD)$

Figure 44-40. Channel (n) output if  $(C(n)V > MOD)$  and  $(CNTIN < C(n+1)V < MOD)$

**Figure 44-41. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V < MOD)$**

**Figure 44-42. Channel (n) output if  $(C(n+1)V > MOD)$  and  $(CNTIN < C(n)V = MOD)$**

### 44.5.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter =  $C(n)V$ , is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter =  $C(n+1)V$ . So, Combine mode allows the generation of asymmetrical PWM signals.

### 44.5.9 Complementary mode

The Complementary mode is selected when:

## Functional description

- QUADEN = 0
- DECAPEN = 0
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0

**Figure 44-43. Channel (n+1) output in Complementary mode with  $(ELSnB:ELSnA = 1:0)$**

**Figure 44-44. Channel (n+1) output in Complementary mode with  $(ELSnB:ELSnA = X:1)$**

## NOTE

The complementary mode is not available in Output Compare mode.

## 44.5.10 Registers updated from write buffers

### 44.5.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

**Table 44-6. CNTIN register update**

| When                                                                                                        | Then CNTIN register is updated                            |
|-------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| CLKS[1:0] = 0:0                                                                                             | When CNTIN register is written, independent of FTMEN bit. |
| <ul style="list-style-type: none"> <li>FTMEN = 0, or</li> <li>CNTINC = 0</li> </ul>                         | At the next system clock after CNTIN was written.         |
| <ul style="list-style-type: none"> <li>FTMEN = 1,</li> <li>SYNCMODE = 1, and</li> <li>CNTINC = 1</li> </ul> | By the <a href="#">CNTIN register synchronization</a> .   |

### 44.5.10.2 MOD register update

The following table describes when MOD register is updated:

**Table 44-7. MOD register update**

| When                                                                                      | Then MOD register is updated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLKS[1:0] = 0:0                                                                           | When MOD register is written, independent of FTMEN bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <ul style="list-style-type: none"> <li>CLKS[1:0] ≠ 0:0, and</li> <li>FTMEN = 0</li> </ul> | According to the CPWMS bit, that is: <ul style="list-style-type: none"> <li>If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000.</li> <li>If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).</li> </ul> |
| <ul style="list-style-type: none"> <li>CLKS[1:0] ≠ 0:0, and</li> <li>FTMEN = 1</li> </ul> | By the <a href="#">MOD register synchronization</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 44.5.10.3 CnV register update

The following table describes when CnV register is updated:

**Table 44-8. CnV register update**

| When                                                                                      | Then CnV register is updated                            |
|-------------------------------------------------------------------------------------------|---------------------------------------------------------|
| CLKS[1:0] = 0:0                                                                           | When CnV register is written, independent of FTMEN bit. |
| <ul style="list-style-type: none"> <li>CLKS[1:0] ≠ 0:0, and</li> <li>FTMEN = 0</li> </ul> | According to the selected mode, that is:                |

*Table continues on the next page...*

**Table 44-8. CnV register update (continued)**

| When                                                                                      | Then CnV register is updated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 44.5.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

#### Note

The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

#### 44.5.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when TRIGn = 1, where n = 0, 1 or 2 corresponding to each one of the input signals, respectively. The hardware trigger input n is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the TRIGn bit is cleared when 0 is written to it or when the trigger n event is detected.

In this case, if two or more hardware triggers are enabled (for example, TRIG0 and TRIG1 = 1) and only trigger 1 event occurs, then only TRIG1 bit is cleared. If a trigger n event occurs together with a write setting TRIGn bit, then the synchronization is initiated, but TRIGn bit remains set due to the write operation.

**Note**  
All hardware trigger inputs have the same behavior.

**Figure 44-45. Hardware trigger event with HWTRIGMODE = 0**

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

### NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

#### 44.5.11.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see [Boundary cycle and loading points](#) and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

**Figure 44-46. Software trigger event**

#### 44.5.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In **Up counting** mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in **Up-down counting** mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

**Figure 44-47. Boundary cycles and loading points**

#### 44.5.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

**Figure 44-48. MOD register synchronization flowchart**

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 0), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected

loading point. If the trigger event was a hardware trigger, then the trigger enable bit (TRIGn) is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 44-49. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 0), and software trigger was used**

**Figure 44-50. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 1), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 44-51. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used**

**Figure 44-52. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used**

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

**Figure 44-53. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)**

#### 44.5.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see [MOD register synchronization](#).

#### 44.5.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the [MOD register synchronization](#). However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

#### 44.5.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

**Figure 44-54. OUTMASK register synchronization flowchart**

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 44-55. OUTMASK synchronization with (SYNCMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used**

**Figure 44-56. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#). An example with a hardware trigger follows.

**Figure 44-57. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used**

#### 44.5.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

Figure 44-58. INVCTRL register synchronization flowchart

#### 44.5.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

Figure 44-59. SWOCTRL register synchronization flowchart

#### 44.5.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n+1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

**Figure 44-60. FTM counter synchronization**

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

**Figure 44-61. FTM counter synchronization flowchart**

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGN bit is cleared according to [Hardware trigger](#). Examples with software and hardware triggers follow.

**Figure 44-62. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used**

**Figure 44-63. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used**

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to [Hardware trigger](#).

**Figure 44-64. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used**

## 44.5.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INV<sub>m</sub> = 1 (where m represents a channel pair)

The INV<sub>m</sub> bit in INVCTRL register is updated with its buffer value according to [INVCTRL register synchronization](#)

In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 44-65. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode**

Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.

NOTE

INV(m) bit selects the inverting to the pair channels (n) and (n+1).

**Figure 44-66. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode**

### Note

The inverting feature is not available in Output Compare mode.

## 44.5.13 Software output control

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CHnOC = 1

## Functional description

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to [SWOCTRL register synchronization](#).

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.

NOTE  
CH(n)OCV = 1 and CH(n+1)OCV = 0.

**Figure 44-67. Example of software output control in Combine and Complementary mode**

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

**Table 44-9. Software output control behavior when (COMP = 0)**

| CH(n)OC | CH(n+1)OC | CH(n)OCV | CH(n+1)OCV | Channel (n) Output      | Channel (n+1) Output    |
|---------|-----------|----------|------------|-------------------------|-------------------------|
| 0       | 0         | X        | X          | is not modified by SWOC | is not modified by SWOC |
| 1       | 1         | 0        | 0          | is forced to zero       | is forced to zero       |
| 1       | 1         | 0        | 1          | is forced to zero       | is forced to one        |
| 1       | 1         | 1        | 0          | is forced to one        | is forced to zero       |
| 1       | 1         | 1        | 1          | is forced to one        | is forced to one        |

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

**Table 44-10. Software output control behavior when (COMP = 1)**

| CH(n)OC | CH(n+1)OC | CH(n)OCV | CH(n+1)OCV | Channel (n) Output      | Channel (n+1) Output    |
|---------|-----------|----------|------------|-------------------------|-------------------------|
| 0       | 0         | X        | X          | is not modified by SWOC | is not modified by SWOC |
| 1       | 1         | 0        | 0          | is forced to zero       | is forced to zero       |
| 1       | 1         | 0        | 1          | is forced to zero       | is forced to one        |
| 1       | 1         | 1        | 0          | is forced to one        | is forced to zero       |
| 1       | 1         | 1        | 1          | is forced to one        | is forced to zero       |

### Note

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n+1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

## 44.5.14 Deadtime insertion

The deadtime insertion is enabled when (DTEN = 1) and (DTVAL[5:0] is non-zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTPS[1:0] bits define the prescaler for the system clock and the DTVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If  $POL(n) = 0$ ,  $POL(n+1) = 0$ , and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If  $POL(n) = 1$ ,  $POL(n+1) = 1$ , and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

## Functional description

when the channel (n+1) match (FTM counter =  $C(n+1)V$ ) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n+1) output is cleared.

**Figure 44-68. Deadtime insertion with  $ELSnB:ELSnA = 1:0$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

**Figure 44-69. Deadtime insertion with  $ELSnB:ELSnA = X:1$ ,  $POL(n) = 0$ , and  $POL(n+1) = 0$**

### NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

## 44.5.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ( $((C(n)+1)V - C(n)V) \times \text{system clock}$ ), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ( $((\text{MOD} - \text{CNTIN} + 1 - (C(n+1)V - C(n)V)) \times \text{system clock})$ ), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

**Figure 44-70. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle**

**Figure 44-71. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle**

### 44.5.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see [OUTMASK register synchronization](#).

If CHnOM = 1, then the channel (n) output is forced to its inactive state (POLn bit value). If CHnOM = 0, then the channel (n) output is unaffected by the output mask. See the following figure.

Figure 44-72. Output mask with POLn = 0

The following table shows the output mask result before the polarity control.

Table 44-11. Output mask result for channel (n) before the polarity control

| CHnOM | Output Mask Input | Output Mask Result |
|-------|-------------------|--------------------|
| 0     | inactive state    | inactive state     |
|       | active state      | active state       |
| 1     | inactive state    | inactive state     |
|       | active state      | inactive state     |

## 44.5.16 Fault control

The fault control is enabled if (FAULTM[1:0]  $\neq$  0:0).

FTM can have up to four fault inputs. FAULTnEN bit (where n = 0, 1, 2, 3) enables the fault input n and FFLTRnEN bit enables the fault input n filter. FFVAL[3:0] bits select the value of the enabled filter in each enabled fault input.

First, each fault input signal is synchronized by the system clock; see the synchronizer block in the following figure. Following synchronization, the fault input n signal enters the filter block. When there is a state change in the fault input n signal, the 5-bit counter is reset and starts counting up. As long as the new state is stable on the fault input n, the counter continues to increment. If the 5-bit counter overflows, that is, the counter exceeds the value of the FFVAL[3:0] bits, the new fault input n value is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the fault input n signal before validation (counter overflow), the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by FFVAL[3:0] bits ( $\times$  system clock) is regarded as a glitch and is not passed on to the edge detector.

The fault input n filter is disabled when the FFVAL[3:0] bits are zero or when FAULTnEN = 0. In this case, the fault input n signal is delayed 2 rising edges of the system clock and the FAULTFn bit is set on 3th rising edge of the system clock after a rising edge occurs on the fault input n.

If FFVAL[3:0]  $\neq$  0000 and FAULTnEN = 1, then the fault input n signal is delayed (3 + FFVAL[3:0]) rising edges of the system clock, that is, the FAULTFn bit is set (4 + FFVAL[3:0]) rising edges of the system clock after a rising edge occurs on the fault input n.

\* where n = 3, 2, 1, 0

**Figure 44-73. Fault input n control block diagram**

If the fault control and fault input n are enabled and a rising edge at the fault input n signal is detected, a fault condition has occurred and the FAULTFn bit is set. The FAULTF bit is the logic OR of FAULTFn[3:0] bits. See the following figure.

**Figure 44-74. FAULTF and FAULTIN bits and fault interrupt**

If the fault control is enabled ( $\text{FAULTM}[1:0] \neq 0:0$ ), a fault condition has occurred and ( $\text{FAULTEN} = 1$ ), then outputs are forced to their safe values:

- Channel (n) output takes the value of  $\text{POL}(n)$
- Channel (n+1) takes the value of  $\text{POL}(n+1)$

The fault interrupt is generated when ( $\text{FAULTF} = 1$ ) and ( $\text{FAULTIE} = 1$ ). This interrupt request remains set until:

- Software clears the FAULTF bit by reading FAULTF bit as 1 and writing 0 to it
- Software clears the FAULTIE bit
- A reset occurs

## 44.5.16.1 Automatic fault clearing

If the automatic fault clearing is selected ( $\text{FAULTM}[1:0] = 1:1$ ), then the channels output disabled by fault control is again enabled when the fault input signal (FAULTIN) returns to zero and a new PWM cycle begins. See the following figure.

## NOTE

The channel (n) output is after the fault control with automatic fault clearing and POLn = 0.

**Figure 44-75. Fault control with automatic fault clearing**

### 44.5.16.2 Manual fault clearing

If the manual fault clearing is selected (FAULTM[1:0] = 0:1 or 1:0), then the channels output disabled by fault control is again enabled when the FAULTF bit is cleared and a new PWM cycle begins. See the following figure.

## NOTE

The channel (n) output is after the fault control with manual fault clearing and POLn = 0.

**Figure 44-76. Fault control with manual fault clearing**

### 44.5.16.3 Fault inputs polarity control

The FLTjPOL bit selects the fault input j polarity, where  $j = 0, 1, 2, 3$ :

- If FLTjPOL = 0, the fault j input polarity is high, so the logical one at the fault input j indicates a fault.
- If FLTjPOL = 1, the fault j input polarity is low, so the logical zero at the fault input j indicates a fault.

### 44.5.17 Polarity control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

### 44.5.18 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

**Table 44-12. Initialization behavior when (COMP = 0 and DTEN = 0)**

| CH(n)OI | CH(n+1)OI | Channel (n) Output | Channel (n+1) Output |
|---------|-----------|--------------------|----------------------|
| 0       | 0         | is forced to zero  | is forced to zero    |
| 0       | 1         | is forced to zero  | is forced to one     |
| 1       | 0         | is forced to one   | is forced to zero    |
| 1       | 1         | is forced to one   | is forced to one     |

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

**Table 44-13. Initialization behavior when (COMP = 1 or DTEN = 1)**

| CH(n)OI | CH(n+1)OI | Channel (n) Output | Channel (n+1) Output |
|---------|-----------|--------------------|----------------------|
| 0       | X         | is forced to zero  | is forced to one     |
| 1       | X         | is forced to one   | is forced to zero    |

#### Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

### 44.5.19 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.

pair channels (m) - channels (n) and (n+1)

**NOTE**

The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

**Figure 44-77. Priority of the features used at the generation of channels (n) and (n+1) outputs signals**

**Note**

The **Initialization** feature must not be used with **Inverting** and **Software output control** features.

## 44.5.20 Channel trigger output

If CH(j)TRIG bit of the FTM External Trigger (FTM\_EXTTRIG) register is set, where  $j = 0, 1, 2, 3, 4$ , or  $5$ , then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal which has one FTM clock period width and is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.

**Figure 44-78. Channel match trigger**

### 44.5.21 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

## Functional description

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.
- When there is a write to CNT register.
- When there is the [FTM counter synchronization](#).
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.
- If the channel (n) is in Input Capture mode, (ICRST = 1) and the selected input capture event occurs in the channel (n) input.

The following figures show these cases.

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 44-79. Initialization trigger is generated when the FTM counting achieves the CNTIN register value**

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 44-80. Initialization trigger is generated when there is a write to CNT register**

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 44-81. Initialization trigger is generated when there is the FTM counter synchronization**

CNTIN = 0x0000  
MOD = 0x000F  
CPWMS = 0

**Figure 44-82. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits**

**NOTE**

Channel (n) input after its synchronizer and filter  
MOD = 0xFFFF  
CNTIN = 0x0000  
PS[2:0] = 3'b000  
ICRST = 1'b1

**Figure 44-83. Initialization trigger is generated if the channel (n) is in Input Capture mode, ICRST = 1 and the selected input capture event occurs in the channel (n) input**

The initialization trigger output provides a trigger signal that is used for on-chip modules.

### 44.5.22 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for [Input Capture mode](#) and FTM counter must be configured to the [Up counting](#).

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.

NOTE

- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

Figure 44-84. Capture Test mode

## 44.5.23 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

**Table 44-14. Channel DMA transfer request**

| DMA | CHnIE | Channel DMA Transfer Request                                 | Channel Interrupt                                 |
|-----|-------|--------------------------------------------------------------|---------------------------------------------------|
| 0   | 0     | The channel DMA transfer request is not generated.           | The channel interrupt is not generated.           |
| 0   | 1     | The channel DMA transfer request is not generated.           | The channel interrupt is generated if (CHnF = 1). |
| 1   | 0     | The channel DMA transfer request is not generated.           | The channel interrupt is not generated.           |
| 1   | 1     | The channel DMA transfer request is generated if (CHnF = 1). | The channel interrupt is not generated.           |

If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

**Table 44-15. Clear CHnF bit when DMA = 1**

| CHnIE | How CHnF Bit Can Be Cleared                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 0     | CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit. |
| 1     | CHnF bit is cleared when the channel DMA transfer is done.                                                                              |

## 44.5.24 Dual Edge Capture mode

The Dual Edge Capture mode is selected if DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.

**Figure 44-85. Dual Edge Capture mode block diagram**

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n+1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the C(n)V and C(n+1)V registers are read. The only requirement is that C(n)V must be read before C(n+1)V.

### Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.

- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in [Free running counter](#).

#### 44.5.24.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

#### 44.5.24.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the CH(n)F and CH(n+1)F bits to start new measurements.

### 44.5.24.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1) and the channel (n+1) to capture falling edges (ELS(n+1)B:ELS(n+1)A = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0) and the channel (n+1) to capture rising edges (ELS(n+1)B:ELS(n+1)A = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

## Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 44-86. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

**Figure 44-87. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement**

#### 44.5.24.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges ( $ELS(n)B:ELS(n)A = 0:1$  and  $ELS(n+1)B:ELS(n+1)A = 0:1$ ), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges ( $ELS(n)B:ELS(n)A = 1:0$  and  $ELS(n+1)B:ELS(n+1)A = 1:0$ ), then the period between two consecutive falling edges is measured.

The period measurement can be made in [One-Shot Capture mode](#) or [Continuous Capture mode](#).

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

**Figure 44-88. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges**

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set

when the second rising edge is detected, that is, the edge selected by  $ELS(n+1)B:ELS(n+1)A$  bits. The  $CH(n+1)F$  bit indicates when two edges of the period were captured and the  $C(n)V$  and  $C(n+1)V$  registers are ready for reading.

Note

- The commands set DECAPEN, set DECAP, clear  $CH(n)F$ , and clear  $CH(n+1)F$  are made by the user.

**Figure 44-89. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges**

#### 44.5.24.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in  $C(n)V$  and  $C(n+1)V$  registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n+1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal. C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

**Figure 44-90. Dual Edge Capture mode read coherency mechanism**

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

### 44.5.25 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

**Figure 44-91. Quadrature Decoder block diagram**

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; [Filter for Input Capture mode](#). The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n+1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

### Note

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

### Note

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If  $QUADMODE = 1$ , then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

**Figure 44-92. Quadrature Decoder – Count and Direction Encoding mode**

If  $QUADMODE = 0$ , then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If  $PHAPOL = 0$  and  $PHBPOL = 0$ , then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

## Functional description

**Figure 44-93. Quadrature Decoder – Phase A and Phase B Encoding mode**

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

**Figure 44-94. FTM Counter overflow in up counting for Quadrature Decoder mode**

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

**Figure 44-95. FTM counter overflow in down counting for Quadrature Decoder mode**

#### 44.5.25.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

**Figure 44-96. Motor position jittering in a mid count value**

The following figure shows motor jittering produced by the phase B and A pulses respectively:

**Figure 44-97. Motor position jittering near maximum and minimum count value**

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

## 44.5.26 BDM mode

When the chip is in BDM mode, the BDMMODE[1:0] bits select the behavior of the FTM counter, the CH(n)F bit, the channels output, and the writes to the MOD, CNTIN, and C(n)V registers according to the following table.

**Table 44-16. FTM behavior when the chip is in BDM mode**

| BDMMODE | FTM Counter | CH(n)F Bit | FTM Channels Output                                                       | Writes to MOD, CNTIN, and C(n)V Registers              |
|---------|-------------|------------|---------------------------------------------------------------------------|--------------------------------------------------------|
| 00      | Stopped     | can be set | Functional mode                                                           | Writes to these registers bypass the registers buffers |
| 01      | Stopped     | is not set | The channels outputs are forced to their safe value according to POLn bit | Writes to these registers bypass the registers buffers |
| 10      | Stopped     | is not set | The channels outputs are frozen when the chip enters in BDM mode          | Writes to these registers bypass the registers buffers |

*Table continues on the next page...*

**Table 44-16. FTM behavior when the chip is in BDM mode (continued)**

| BDMMODE | FTM Counter     | CH(n)F Bit | FTM Channels Output | Writes to MOD, CNTIN, and C(n)V Registers |
|---------|-----------------|------------|---------------------|-------------------------------------------|
| 11      | Functional mode | can be set | Functional mode     | Functional mode                           |

Note that if BDMMODE[1:0] = 2'b00 then the channels outputs remain at the value when the chip enters in BDM mode, because the FTM counter is stopped. However, the following situations modify the channels outputs in this BDM mode.

- Write any value to CNT register; see [Counter reset](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for those channels set to Output Compare mode.
- FTM counter is reset by PWM Synchronization mode; see [FTM counter synchronization](#). In this case, the FTM counter is updated with the CNTIN register value and the channels outputs are updated to the initial value – except for channels in Output Compare mode.
- In the channels outputs initialization, the channel (n) output is forced to the CH(n)OI bit value when the value 1 is written to INIT bit. See [Initialization](#).

### Note

The BDMMODE[1:0] = 2'b00 must not be used with the [Fault control](#). Even if the fault control is enabled and a fault condition exists, the channels outputs values are updated as above.

### Note

If CLKS[1:0] = 2'b00 in BDM, a non-zero value is written to CLKS in BDM, and CnV = CNTIN when the BDM is disabled, then the CHnF bit is set (since if the channel is a 0% EPWM signal) when the BDM is disabled.

## 44.5.27 Intermediate load

The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

**Table 44-17. When possible loading points are enabled**

| Loading point                                            | Enabled         |
|----------------------------------------------------------|-----------------|
| When the FTM counter wraps from MOD value to CNTIN value | Always          |
| At the channel (j) match (FTM counter = C(j)V)           | When CHjSEL = 1 |

The following figure shows some examples of enabled loading points.

**NOTE**

- (a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0  
 (d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0  
 (e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0  
 (f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

**Figure 44-98. Loading points for intermediate load**

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

**Table 44-18. Conditions for loads occurring at the next enabled loading point**

| When a new value was written | Then                                                     |
|------------------------------|----------------------------------------------------------|
| To the MOD register          | The MOD register is updated with its write buffer value. |

Table continues on the next page...

**Table 44-18. Conditions for loads occurring at the next enabled loading point (continued)**

| When a new value was written                                                                | Then                                                         |
|---------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| To the CNTIN register and CNTINC = 1                                                        | The CNTIN register is updated with its write buffer value.   |
| To the C(n)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)   | The C(n)V register is updated with its write buffer value.   |
| To the C(n+1)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1) | The C(n+1)V register is updated with its write buffer value. |

**NOTE**

- If ELSjB and ELSjA bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELSjB and ELSjA bits are zero, then the generated signal is not available on channel (j) output.
- If CHjIE = 1, then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.

**44.5.28 Global time base (GTB)**

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

**Figure 44-99. Global time base (GTB) block diagram**

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb\_in*, and the output signal *gtb\_out*. The GTBEEN bit enables *gtb\_in* to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when *gtb\_in* is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the *gtb\_out* signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the *gtb\_in* and *gtb\_out* signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

### NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the *gtb\_in* signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

#### 44.5.28.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

## 44.6 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 00b);
- the timer overflow interrupt is zero, see [Timer Overflow Interrupt](#);
- the channels interrupts are zero, see [Channel \(n\) Interrupt](#);
- the fault interrupt is zero, see [Fault Interrupt](#);
- the channels are in input capture mode, see [Input Capture mode](#);
- the channels outputs are zero;
- the channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0:0) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configured (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) ([Counter reset](#)).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).

**Figure 44-100. FTM behavior after reset when the channel (n) is in Combine mode**

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control ([Software output control](#)) or the initialization ([Initialization](#)) to update the channel output to the selected value (item 4).

**Figure 44-101. FTM behavior after reset when the channel (n) is in Output Compare mode**

## 44.7 FTM Interrupts

### 44.7.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

### 44.7.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

### 44.7.3 Fault Interrupt

The fault interrupt is generated when (FAULTIE = 1) and (FAULTF = 1).

## 44.8 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer operation. This procedure can also be used to do a new configuration of the FlexTimer operation.

- Define the POL bits.
- Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels output are in the safe value.
- (Re)Configuration FTM counter and channels to generation of periodic signals - Disable the clock. If the selected mode is Quadrature Decoder, then disable this mode. Examples of the (re)configuration:
  - Write to MOD.
  - Write to CNTIN.
  - Select OC, EPWM, CPWM, Combine, Complement modes for all channels that will be used
  - Select the high-true and low-true channels modes.
  - Write to CnV for all channels that will be used .
  - (Re)Configure deadtime and fault control.
  - Do not use the SWOC without SW synchronization (see item 6).
  - Do not use the Inverting without SW synchronization (see item 6).
  - Do not use the Initialization.
  - Do not change the polarity control.
  - Do not configure the HW synchronization

- Write any value to CNT. The FTM Counter is reset and the channels output are updated according to new configuration.
- Enable the clock. Write to CLKS[1:0] bits a value different from zero. If in the Quadrature Decoder mode, enable this mode.
- Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
  - Select synchronization for Output Mask Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
  - Write to SYNCONF.
    - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0).
    - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1].
    - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1].
    - SW Synchronization for SWOM (always): SWOM = 1. No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2'b00): SWWRBUF = 0 and CNTINC = 0.
    - SW Synchronization for counter reset (always): SWRSTCNT = 1.
    - Enhanced synchronization (always): SYNCMODE = 1
  - If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.
  - If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.
  - Write to OUTMASK to enable the masked channels.
- Generate the Software Trigger Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

# Chapter 45

## Low-Power Timer (LPTMR)

### 45.1 Chip-specific LPTMR information

#### 45.1.1 Low power timer instantiations

This device contains one LPTMR module with one 16-bit channel.

LPT/HSCMP0 pulse counting:

LPTMR\_ALT0 input is the selectable source to count pulses resulting from HSCMP0 Output (LPT\_ALT0 = HSCMP0 Output).

#### 45.1.2 LPTMR prescaler/glitch filter clocking options

The prescaler and glitch filter of the LPTMR module can be clocked from one of four sources determined by the LPTMR0\_PSR[PCS] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

**NOTE**

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

| LPTMR0_PSR[PCS] | Prescaler/glitch filter clock number | Chip clock                                                                           |
|-----------------|--------------------------------------|--------------------------------------------------------------------------------------|
| 00              | 0                                    | MCGIRCLK — internal reference clock (not available in VLPS <sup>1</sup> /VLLS modes) |
| 01              | 1                                    | LPO — 1 kHz clock (not available in VLLS0 mode)                                      |
| 10              | 2                                    | ERCLK32K — secondary external reference clock                                        |

Table continues on the next page...

| LPTMR0_PSR[PCS] | Prescaler/glitch filter clock number | Chip clock                                                                        |
|-----------------|--------------------------------------|-----------------------------------------------------------------------------------|
| 11              | 3                                    | OSCERCLK_UNDIV — Undivided external reference clock (not available in VLLS0 mode) |

1. MCGIRCLK is optional in VLPS mode.

See [Clock Distribution](#) for more details on these clocks.

### 45.1.3 LPTMR pulse counter input options

The LPTMR\_CSR[TPS] bitfield configures the input source used in pulse counter mode. The following table shows the chip-specific input assignments for this bitfield.

| LPTMR_CSR[TPS] | Pulse counter input number | Chip input     |
|----------------|----------------------------|----------------|
| 00             | 0                          | CMP0 output    |
| 01             | 1                          | LPTMR_ALT1 pin |
| 10             | 2                          | LPTMR_ALT2 pin |
| 11             | 3                          | LPTMR_ALT3 pin |

## 45.2 Introduction

The low-power timer (LPTMR) can be configured to operate as a time counter with optional prescaler, or as a pulse counter with optional glitch filter, across all power modes, including the low-leakage modes. It can also continue operating through most system reset events, allowing it to be used as a time of day counter.

### 45.2.1 Features

The features of the LPTMR module include:

- 16-bit time counter or pulse counter with compare
  - Optional interrupt can generate asynchronous wakeup from any low-power mode
  - Hardware trigger output
  - Counter supports free-running mode or reset on compare
- Configurable clock source for prescaler/glitch filter
- Configurable input source for pulse counter
  - Rising-edge or falling-edge

## 45.2.2 Modes of operation

The following table describes the operation of the LPTMR module in various modes.

**Table 45-1. Modes of operation**

| Modes       | Description                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------|
| Run         | The LPTMR operates normally.                                                                                                 |
| Wait        | The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request. |
| Stop        | The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request. |
| Low-Leakage | The LPTMR continues to operate normally and may be configured to exit the low-power mode by generating an interrupt request. |
| Debug       | The LPTMR operates normally in Pulse Counter mode, but counter does not increment in Time Counter mode.                      |

## 45.3 LPTMR signal descriptions

**Table 45-2. LPTMR signal descriptions**

| Signal              | I/O | Description             |
|---------------------|-----|-------------------------|
| LPTMR0_ALT <i>n</i> | I   | Pulse Counter Input pin |

### 45.3.1 Detailed signal descriptions

**Table 45-3. LPTMR interface—detailed signal descriptions**

| Signal             | I/O | Description                                                                                         |                                                                                                                                                                                                                                                 |
|--------------------|-----|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPTMR_ALT <i>n</i> | I   | Pulse Counter Input<br>The LPTMR can select one of the input pins to be used in Pulse Counter mode. |                                                                                                                                                                                                                                                 |
|                    |     | State meaning                                                                                       | Assertion—If configured for pulse counter mode with active-high input, then assertion causes the CNR to increment.<br><br>Deassertion—If configured for pulse counter mode with active-low input, then deassertion causes the CNR to increment. |
|                    |     | Timing                                                                                              | Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.                                                                                                                                               |

## 45.4 Memory map and register definition

### LPTMR memory map

| Absolute address (hex) | Register name                                        | Width (in bits) | Access | Reset value | Section/page                |
|------------------------|------------------------------------------------------|-----------------|--------|-------------|-----------------------------|

## 45.5 Functional description

### 45.5.1 LPTMR power and reset

The LPTMR remains powered in all power modes, including low-leakage modes. If the LPTMR is not required to remain operating during a low-power mode, then it must be disabled before entering the mode.

The LPTMR is reset only on global Power On Reset (POR) or Low Voltage Detect (LVD). When configuring the LPTMR registers, the CSR must be initially written with the timer disabled, before configuring the PSR and CMR. Then, CSR[TIE] must be set as the last step in the initialization. This ensures the LPTMR is configured correctly and the LPTMR counter is reset to zero following a warm reset.

### 45.5.2 LPTMR clocking

The LPTMR prescaler/glitch filter can be clocked by one of the four clocks. The clock source must be enabled before the LPTMR is enabled.

#### NOTE

The clock source selected need to be configured to remain enabled in low-power modes, otherwise the LPTMR will not operate during low-power modes.

In Pulse Counter mode with the prescaler/glitch filter bypassed, the selected input source directly clocks the CNR and no other clock source is required. To minimize power in this case, configure the prescaler clock source for a clock that is not toggling.

#### NOTE

The clock source or pulse input source selected for the LPTMR should not exceed the frequency  $f_{LPTMR}$  defined in the device datasheet.

### 45.5.3 LPTMR prescaler/glitch filter

The LPTMR prescaler and glitch filter share the same logic which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

#### NOTE

The prescaler/glitch filter configuration must not be altered when the LPTMR is enabled.

#### 45.5.3.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks the CNR. When the LPTMR is enabled, the CNR will increment every  $2^2$  to  $2^{16}$  prescaler clock cycles. After the LPTMR is enabled, the first increment of the CNR will take an additional one or two prescaler clock cycles due to synchronization logic.

#### 45.5.3.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments the CNR on every clock cycle. When the LPTMR is enabled, the first increment will take an additional one or two prescaler clock cycles due to synchronization logic.

#### 45.5.3.3 Glitch filter

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks the CNR. When the LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

| If                                                                                                                   | Then                                         |
|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| The selected input source remains deasserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising edges | The glitch filter output will also deassert. |
| The selected input source remains asserted for at least $2^1$ to $2^{15}$ consecutive prescaler clock rising-edges   | The glitch filter output will also assert.   |

#### NOTE

The input is only sampled on the rising clock edge.

The CNR will increment each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which the CNR can increment is once every  $2^2$  to  $2^{16}$  prescaler clock edges. When first enabled, the glitch filter will wait an additional one or two prescaler clock edges due to synchronization logic.

#### **45.5.3.4 Glitch filter bypassed**

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the CNR every time it asserts. Before the LPTMR is first enabled, the selected input source is forced to be asserted. This prevents the CNR from incrementing if the selected input source is already asserted when the LPTMR is first enabled.

#### **45.5.4 LPTMR compare**

When the CNR equals the value of the CMR and increments, the following events occur:

- CSR[TCF] is set.
- LPTMR interrupt is generated if CSR[TIE] is also set.
- LPTMR hardware trigger is generated.
- CNR is reset if CSR[TFC] is clear.

When the LPTMR is enabled, the CMR can be altered only when CSR[TCF] is set. When updating the CMR, the CMR must be written and CSR[TCF] must be cleared before the LPTMR counter has incremented past the new LPTMR compare value.

#### **45.5.5 LPTMR counter**

The CNR increments by one on every:

- Prescaler clock in Time Counter mode with prescaler bypassed
- Prescaler output in Time Counter mode with prescaler enabled
- Input source assertion in Pulse Counter mode with glitch filter bypassed
- Glitch filter output in Pulse Counter mode with glitch filter enabled

The CNR is reset when the LPTMR is disabled or if the counter register overflows. If CSR[TFC] is cleared, then the CNR is also reset whenever CSR[TCF] is set.

The CNR continues incrementing when the core is halted in Debug mode when configured for Pulse Counter mode, the CNR will stop incrementing when the core is halted in Debug mode when configured for Time Counter mode.

The CNR cannot be initialized, but can be read at any time. On each read of the CNR, software must first write to the CNR with any value. This will synchronize and register the current value of the CNR into a temporary register. The contents of the temporary register are returned on each read of the CNR.

When reading the CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing, otherwise incorrect data may be returned.

### 45.5.6 LPTMR hardware trigger

The LPTMR hardware trigger asserts at the same time the CSR[TCF] is set and can be used to trigger hardware events in other peripherals without software intervention. The hardware trigger is always enabled.

| When                                                      | Then                                                                                                       |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| The CMR is set to 0 with CSR[TFC] clear                   | The LPTMR hardware trigger will assert on the first compare and does not deassert.                         |
| The CMR is set to a nonzero value, or, if CSR[TFC] is set | The LPTMR hardware trigger will assert on each compare and deassert on the following increment of the CNR. |

### 45.5.7 LPTMR interrupt

The LPTMR interrupt is generated whenever CSR[TIE] and CSR[TCF] are set. CSR[TCF] is cleared by disabling the LPTMR or by writing a logic 1 to it.

CSR[TIE] can be altered and CSR[TCF] can be cleared while the LPTMR is enabled.

The LPTMR interrupt is generated asynchronously to the system clock and can be used to generate a wakeup from any low-power mode, including the low-leakage modes, provided the LPTMR is enabled as a wakeup source.

# Chapter 46

## Programmable Delay Block (PDB)

### 46.1 Chip-specific PDB information

#### 46.1.1 PDB Instantiation

This chip has two PDBs that primarily provide delayed triggering from the FTM's to the ADCs. Each PDB has two channels, one pulse output and one DAC trigger. One channel of each PDB has two pre-trigger outputs for driving the 16bit SAR ADC. The input mux capability has been increased by having an XBARA output trigger the PDBs.

**NOTE**

- For the BB, TOS, and EN field in CHnC1 register, and the CF and ERR fields in the CHnS register, the lower two bits are valid, other bits are always 0.
- For the POEN field in the POEN register, the lower four bits are valid, other bits are always 0.

##### 46.1.1.1 PDB0 Output Triggers

**Table 46-1. PDB0 output triggers**

|                                |                                                                            |
|--------------------------------|----------------------------------------------------------------------------|
| Number of PDB channels         | 2                                                                          |
| Number of pre-triggers per PDB | 2 on CH1                                                                   |

## 46.2 Introduction

The Programmable Delay Block (PDB) provides controllable delays from either an internal or an external trigger, or a programmable interval tick, to the hardware trigger inputs of ADCs and/or generates the interval triggers to DACs, so that the precise timing between ADC conversions and/or DAC updates can be achieved. The PDB can optionally provide pulse outputs (Pulse-Out's) that are used as the sample window in the CMP block.

### 46.2.1 Features

- Up to 15 trigger input sources and one software trigger source
- Up to 8 configurable PDB channels for ADC hardware trigger

- One PDB channel is associated with one ADC
- One trigger output for ADC hardware trigger and up to 8 pre-trigger outputs for ADC trigger select per PDB channel
- Trigger outputs can be enabled or disabled independently
- One 16-bit delay register per pre-trigger output
- Optional bypass of the delay registers of the pre-trigger outputs
- Operation in One-Shot or Continuous modes
- Optional back-to-back mode operation, which enables the ADC conversions complete to trigger the next PDB channel
- One programmable delay interrupt
- One sequence error interrupt
- One channel flag and one sequence error flag per pre-trigger
- DMA support
- Up to 8 DAC interval triggers
  - One interval trigger output per DAC
  - One 16-bit delay interval register per DAC trigger output
  - Optional bypass of the delay interval trigger registers
  - Optional external triggers
- Up to 8 pulse outputs (pulse-out's)
  - Pulse-out's can be enabled or disabled independently
  - Programmable pulse width

### NOTE

The number of PDB input and output triggers are chip-specific. See the chip-specific PDB information for details.

## 46.2.2 Implementation

In this section, the following letters refer to the number of output triggers:

- N—Total available number of PDB channels.

- $n$ —PDB channel number, valid from 0 to  $N-1$ .
- $M$ —Total available pre-trigger per PDB channel.
- $m$ —Pre-trigger number, valid from 0 to  $M-1$ .
- $X$ —Total number of DAC interval triggers.
- $x$ —DAC interval trigger output number, valid from 0 to  $X-1$ .
- $Y$ —Total number of Pulse-Out's.
- $y$ —Pulse-Out number, valid value is from 0 to  $Y-1$ .

### **NOTE**

The number of module output triggers to core is chip-specific.  
For module to core output triggers implementation, see the chip configuration information.

## **46.2.3 Back-to-back acknowledgment connections**

PDB back-to-back operation acknowledgment connections are chip-specific. For implementation, see the chip configuration information.

## **46.2.4 DAC External Trigger Input Connections**

The implementation of DAC external trigger inputs is chip-specific. See the chip configuration information for details.

## **46.2.5 Block diagram**

This diagram illustrates the major components of the PDB.

**Figure 46-1. PDB block diagram**

In this diagram, only one PDB channel  $n$ , one DAC interval trigger  $x$ , and one Pulse-Out  $y$  are shown. The PDB-enabled control logic and the sequence error interrupt logic are not shown.

## 46.2.6 Modes of operation

PDB ADC trigger operates in the following modes:

- Disabled—Counter is off, all pre-trigger and trigger outputs are low if PDB is not in back-to-back operation of Bypass mode.
- Debug—Counter is paused when processor is in Debug mode, and the counter for the DAC trigger is also paused in Debug mode.
- Enabled One-Shot—Counter is enabled and restarted at count zero upon receiving a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1. In each PDB channel, an enabled pre-trigger asserts once per trigger input event. The trigger output asserts whenever any of the pre-triggers is asserted.
- Enabled Continuous—Counter is enabled and restarted at count zero. The counter is rolled over to zero again when the count reaches the value specified in the modulus register, and the counting is restarted. This enables a continuous stream of pre-triggers/trigger outputs as a result of a single trigger input event.
- Enabled Bypassed—The pre-trigger and trigger outputs assert immediately after a positive edge on the selected trigger input source or software trigger is selected and SC[SWTRIG] is written with 1, that is the delay registers are bypassed. It is possible to bypass any one or more of the delay registers; therefore, this mode can be used in conjunction with One-Shot or Continuous mode.

## 46.3 PDB signal descriptions

This table shows the detailed description of the external signal.

**Table 46-6. PDB signal descriptions**

| Signal | Description                                                                                                                                                                  | I/O |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| EXTRG  | External Trigger Input Source<br><br>If the PDB is enabled and external trigger input source is selected, a positive edge on the EXTRG signal resets and starts the counter. | I   |

## 46.4 Memory map and register definition

## PDB memory map

| Absolute address (hex) | Register name                                           | Width (in bits) | Access | Reset value | Section/page                 |
|------------------------|---------------------------------------------------------|-----------------|--------|-------------|------------------------------|

| 0<br>LDOK     | Load OK<br><br>Writing 1 to LDOK bit updates the MOD, IDLY, CHnDLYm, DACINTx, and POyDLY registers with the values previously written to their internal buffers (and stored there). The new values of MOD, IDLY, CHnDLYm, DACINTx, and POyDLY registers will take effect according to the setting of the LDMOD field (Load Mode Select). Before 1 is written to the LDOK field, the values in the internal buffers of these registers are not effective, and new values cannot be written to the internal buffers until the existing values in the internal buffers are loaded into their corresponding registers. <ul style="list-style-type: none"> <li>LDOK can be written only when PDBEN is set, or LDOK can be written at the same time when PDBEN is written to 1.</li> <li>LDOK is automatically cleared when the values in the internal buffers are loaded into the registers or when PDBEN bit (PDB Enable) is cleared.</li> <li>Writing 0 to LDOK has no effect.</li> </ul> |

## 46.4.2 Modulus register (PDBx\_MOD)

**Note:** This register is internally buffered, and any values written to the register are written to its internal buffer instead; in other words, the internal device bus does not write directly to this register. The value in this register's internal buffer is loaded into this register only after "1" is written to the SC[LDOK] bit.

**PDBx\_CHnS field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0     | Sequence error not detected on PDB channel's corresponding pre-trigger.                                                                                                                                                                                                                                                                                                                                                                        |
| 1     | Sequence error detected on PDB channel's corresponding pre-trigger. ADCn block can be triggered for a conversion by one pre-trigger from PDB channel <i>n</i> . When one conversion, which is triggered by one of the pre-triggers from PDB channel <i>n</i> , is in progress, new trigger from PDB channel's corresponding pre-trigger <i>m</i> cannot be accepted by ADCn, and ERR[m] is set. Writing 0's to clear the sequence error flags. |

**46.4.7 Channel n Delay 0 register (PDBx\_CHnDLY0)**

**Note:** This register is internally buffered, and any values written to the register are written to its internal buffer instead; in other words, the internal device bus does not write directly to this register. The value in this register's internal buffer is loaded into this register only after "1" is written to the SC[LDOK] bit.

Address: Base address + 18h offset + (40d × i), where i=0d to 1d

## 46.5 Functional description

### 46.5.1 PDB pre-trigger and trigger outputs

The PDB contains a counter whose output is compared to several different digital values. If the PDB is enabled, then a trigger input event will reset the counter and make it start to count. A trigger input event is defined as a rising edge being detected on a selected trigger input source, or if a software trigger is selected and SC[SWTRIG] is written with 1. For each channel, a delay  $m$  determines the time between assertion of the trigger input event to the time at which changes in the pre-trigger  $m$  output signal are started. The time is defined as:

- Trigger input event to pre-trigger  $m = (\text{prescaler} \times \text{multiplication factor} \times \text{delay } m) + 2$  peripheral clock cycles
- Add 1 additional peripheral clock cycle to determine the time when the channel trigger output changes.

Each channel is associated with 1 ADC block. PDB channel  $n$  pre-trigger outputs 0 to  $M$ ; each pre-trigger output is connected to ADC hardware trigger select and hardware trigger inputs. The pre-triggers are used to precondition the ADC block before the actual trigger occurs. When the ADC receives the rising edge of the trigger, the ADC will start the conversion according to the precondition determined by the pre-triggers. The ADC contains  $M$  sets of configuration and result registers, allowing it to alternate conversions between  $M$  different analog sources (like a ping-pong game). The pre-trigger outputs are used to specify which signal will be sampled next. When a pre-trigger  $m$  is asserted, the ADC conversion is triggered with set  $m$  of the configuration and result registers.

The waveforms shown in the following diagram show the pre-trigger and trigger outputs of PDB channel  $n$ . The delays can be independently set using the CHnDLY $m$  registers, and the pre-triggers can be enabled or disabled in CHnC1[EN[ $m$ ]].

**Figure 46-2. Pre-trigger and trigger outputs**

The delay in  $CHnDLYm$  register can be optionally bypassed, if  $CHnC1[TOS[m]]$  is cleared. In this case, when the trigger input event occurs, the pre-trigger  $m$  is asserted after 2 peripheral clock cycles.

The PDB can be configured for back-to-back operation. Back-to-back operation enables the ADC conversion completions to trigger the next PDB channel pre-trigger and trigger outputs, so that the ADC conversions can be triggered on the next set of configuration and results registers. When back-to-back operation is enabled by setting  $CHnC1[BB[m]]$ , then the delay  $m$  is ignored and the pre-trigger  $m$  is asserted 2 peripheral cycles after the acknowledgment  $m$  is received. The acknowledgment connections in this MCU are described in [Back-to-back acknowledgment connections](#).

When a pre-trigger from a PDB channel  $n$  is asserted, the associated lock of the pre-trigger becomes active. The associated lock is released by the rising edge of the corresponding  $ADCnSC1[COCO]$ ; the  $ADCnSC1[COCO]$  should be cleared after the conversion result is read, so that the next rising edge of  $ADCnSC1[COCO]$  can be generated to clear the lock later. The lock becomes inactive when:

- the rising edge of corresponding  $ADCnSC1[COCO]$  occurs,
- or the corresponding PDB pre-trigger is disabled,
- or the PDB is disabled

The channel  $n$  trigger output is suppressed when any of the locks of the pre-triggers in channel  $n$  is active. If a new pre-trigger  $m$  asserts when there is active lock in the PDB channel  $n$ , then a register flag bit  $CHnS[ERR[m]]$  (associated with the pre-trigger  $m$ ) is set. If  $SC[PDBEIE]$  is set, then the sequence error interrupt is generated. A sequence error typically happens because the delay  $m$  is set too short and the pre-trigger  $m$  asserts before the previously triggered ADC conversion finishes.

When the PDB counter reaches the value set in  $IDLY$  register, the  $SC[PDBIF]$  flag is set. A PDB interrupt can be generated if  $SC[PDBIE]$  is set and  $SC[DMAEN]$  is cleared. If  $SC[DMAEN]$  is set, then the PDB requests a DMA transfer when the  $SC[PDBIF]$  flag is set.

The modulus value in the MOD register is used to reset the counter back to zero at the end of the count. If SC[CONT] is set, then the counter will then resume a new count; otherwise, the counter operation will stop until the next trigger input event occurs.

### **46.5.2 PDB trigger input source selection**

The PDB has up to 15 trigger input sources, namely Trigger-In 0 to Trigger-In 14. They are connected to on-chip or off-chip event sources. The PDB can be triggered by software through SC[SWTRIG].

For the trigger input sources implemented in this MCU, see chip configuration information.

### **46.5.3 DAC interval trigger outputs**

PDB can generate the interval triggers for DACs to update their outputs periodically. DAC interval counter  $x$  is reset and started when a trigger input event occurs if DACINTCx[EXT] is cleared. When the interval counter  $x$  is equal to the value set in DACINTx register, the DAC interval trigger  $x$  output generates a pulse of one peripheral clock cycle width to update the DACx. If DACINTCx[EXT] is set, the DAC interval counter is bypassed and the interval trigger output  $x$  generates a pulse following the detection of a rising edge on the DAC external trigger input. The counter and interval trigger can be disabled by clearing the DACINTCx[TOE].

DAC interval counters are also reset when the PDB counter reaches the MOD register value; therefore, when the PDB counter rolls over to zero, the DAC interval counters starts anew.

The DAC interval trigger pulse and the ADC pre-trigger/trigger pulses together allow precise timing of DAC updates and ADC measurements. This is outlined in the typical use case described in the following diagram.

**Figure 46-3. PDB ADC triggers and DAC interval triggers use case**

### NOTE

Because the DAC interval counters share the prescaler with PDB counter, PDB must be enabled if the DAC interval trigger outputs are used in the applications.

## 46.5.4 Pulse-Out's

PDB can generate pulse outputs of configurable width.

- When the PDB counter reaches the value set in POyDLY[DLY1], then the Pulse-Out goes high.
- When the PDB counter reaches POyDLY[DLY2], then it goes low.

POyDLY[DLY2] can be set either greater or less than POyDLY[DLY1].

ADC pre-trigger/trigger outputs and Pulse-Out generation have the same time base, because they both share the PDB counter. The pulse-out connections implemented in this MCU are described in the device's chip configuration details.

### Pulse-Out generation with $DLY2 > DLY1$

### Pulse-Out generation with $DLY1 > DLY2$

Figure 46-4. How Pulse Out is generated

## 46.5.5 Updating the delay registers

The following registers control the timing of the PDB operation; and in some of the applications, they may need to become effective at the same time.

- PDB Modulus register (MOD)
- PDB Interrupt Delay register (IDLY)
- PDB Channel  $n$  Delay  $m$  register ( $CH_nDLY_m$ )

- DAC Interval  $x$  register (DACINT $x$ )
- PDB Pulse-Out  $y$  Delay register (POyDLY)

The internal registers of them are buffered and any values written to them are written first to their buffers. The circumstances that cause their internal registers to be updated with the values from the buffers are summarized as shown in the table below.

**Table 46-7. Circumstances of update to the delay registers**

| SC[LDMOD] | Update to the delay registers                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------|
| 00        | The internal registers are loaded with the values from their buffers immediately after 1 is written to SC[LDOK].             |
| 01        | The PDB counter reaches the MOD register value after 1 is written to SC[LDOK].                                               |
| 10        | A trigger input event is detected after 1 is written to SC[LDOK].                                                            |
| 11        | Either the PDB counter reaches the MOD register value, or a trigger input event is detected, after 1 is written to SC[LDOK]. |

After 1 is written to SC[LDOK], the buffers cannot be written until the values in buffers are loaded into their internal registers. SC[LDOK] is self-cleared when the internal registers are loaded, so the application code can read it to determine the updates to the internal registers.

The following diagrams show the cases of the internal registers being updated with SC[LDMOD] is 00 and x1.

**Figure 46-5. Registers update with SC[LDMOD] = 00**

Figure 46-6. Registers update with SC[LDMOD] = x1

## 46.5.6 Interrupts

PDB can generate two interrupts: PDB interrupt and PDB sequence error interrupt. The following table summarizes the interrupts.

Table 46-8. PDB interrupt summary

| Interrupt                    | Flags      | Enable bit                      |
|------------------------------|------------|---------------------------------|
| PDB Interrupt                | SC[PDBIF]  | SC[PDBIE] = 1 and SC[DMAEN] = 0 |
| PDB Sequence Error Interrupt | CHnS[ERRm] | SC[PDBEIE] = 1                  |

## 46.5.7 DMA

If SC[DMAEN] is set, PDB can generate a DMA transfer request when SC[PDBIF] is set. When DMA is enabled, the PDB interrupt is not issued.

## 46.6 Application information

### 46.6.1 Impact of using the prescaler and multiplication factor on timing resolution

Use of prescaler and multiplication factor greater than 1 limits the count/delay accuracy in terms of peripheral clock cycles (to the modulus of the prescaler X multiplication factor). If the multiplication factor is set to 1 and the prescaler is set to 2 then the only values of total peripheral clocks that can be detected are even values; if prescaler is set to 4 then the only values of total peripheral clocks that can be decoded as detected are mod(4) and so forth. If the applications need a really long delay value and use a prescaler set to 128, then the resolution would be limited to 128 peripheral clock cycles.

Therefore, use the lowest possible prescaler and multiplication factor for a given application.

# Chapter 47

## Quadrature Encoder/Decoder (ENC)

### 47.1 Chip-specific ENC information

#### 47.1.1 ENC signal assignment

This device contains one ENC module. The ENC module input signals and output signal are connected to the XBARA module which provides the capability to drive the ENC module from external pins or from a Timer. Using timer functions to drive the ENC inputs can provide a mechanism for customers to test the ENC module is functioning without connected in the intended "incremental position sensor" for motor control.

The following table shows how these modules are configured.

**Table 47-1. ENC Signal Assignment**

| ENC Signal | Assignment  | Features/usage            |
|------------|-------------|---------------------------|
| PHASEA     | XBARA_OUT44 | quadrature waveform input |
| PHASEB     | XBARA_OUT45 | quadrature waveform input |
| INDEX      | XBARA_OUT46 | refresh/reload input      |
| HOME       | XBARA_OUT47 | home position input       |
| TRIGGER    | XBARA_OUT48 | clear/snapshot input      |
| POSMATCH   | XBARA_IN45  | compare trigger output    |

#### 47.1.2 Clocks

The fast peripheral clock is the only clock required by this module in normal operation.

## 47.2 Introduction

The enhanced quadrature Encoder/ decoder module provides interfacing capability to position/speed sensors used in industrial motor control applications. It has five input signals: PHASEA, PHASEB, INDEX, TRIGGER, and HOME. This module is used to decode shaft position, revolution count and speed.

### 47.2.1 Features

- Includes logic to decode quadrature signals
- Configurable digital filter for inputs
- 32-bit position counter capable of modulo counting
- 16-bit position difference register
- Maximum count frequency equals the peripheral clock rate
- Position counter can be initialized by software or external events
- Preloadable 16-bit revolution counter
- Inputs can be connected to a general purpose timer to aid low speed velocity measurements
- Quadrature decoder filter can be bypassed
- A watchdog timer to detect a non-rotating shaft condition
- Compare function to indicate when shaft has reached a defined position
- Optional interrupt when both PHASEA and PHASEB inputs change in the same cycle

### 47.2.2 Decoder Block Diagram

The following figure shows the block diagram of the quadrature decoder module.

Figure 47-1. Quadrature Decoder Block Diagram

### 47.2.3 System Block Diagram

The following figure shows the block diagram of the quadrature decoder module integrated into an SoC.

Figure 47-2. System Block Diagram

## 47.2.4 Glitch Filter

Because the logic of the quadrature decoder must sense transitions, the inputs are first run through a glitch filter. This filter has a digital delay line sampling multiple time points on the signal and verifying a stable new state before outputting this new state to the internal logic. The sample rate of this delay line is programmable to adapt to a variety of signal bandwidths.

## 47.2.5 Edge Detect State Machine

The edge detect state machine looks for changes in the four possible states of the filtered PHASEA and PHASEB inputs, calculating the direction of motion. This information is formatted as Count\_Up and Count\_Down signals. These signals are routed into up to three up/down counters:

1. Position counter
2. Revolution counter
3. Position difference counter

## 47.2.6 Position Counter

The 32-bit position counter calculates up or down on every count pulse, generated by the difference of PHASEA and PHASEB. This counter acts as an integrator, whose count value is proportional to position. The direction of the count is determined by the count up and count down signals. Position counters may be initialized to a predetermined value by one of three different methods:

1. Software-triggered event
2. INDEX signal transition
3. HOME signal transition

The INDEX and HOME signals can be programmed to interrupt the processor. Whenever the position counter is read, either UPOS or LPOS, a snapshot of the position counter, the position difference counter, and the revolution counters are each placed into their respective hold registers. The direction of the count is determined by Count\_Up and Count\_Down signals.

### 47.2.7 Position Difference Counter

The 16-bit position difference counter contains the position difference value occurring between each read of the position register. This register counts up or down on every count pulse. The counter acts as a differentiator whose count value is proportional to the change in position since the last time the position counter was read. When the position register, the position difference counter, or the revolution counter is read, the position difference of the counter's contents is copied into the position difference hold register (POSDH) and the position difference counter is cleared.

### 47.2.8 Position Difference Counter Hold

This register stores a copy of the position difference counter at the time the position register was read. When the position register is read, the position difference of the counter's contents is copied into the position difference hold register (POSDH) and the position difference counter is cleared.

### 47.2.9 Revolution Counter

The 16-bit up/down revolution counter is intended to count or integrate revolutions by counting index pulses. The direction of the count is determined by the Count\_Up and Count\_Down signals, determined by the Phase A and B inputs. A different count direction on the rising and falling edges of the index pulse indicates the quadrature encoder changed direction on the index pulse.

### 47.2.10 Pulse Accumulator Functionality

The logic can be programmed to integrate only selected transitions of the PHASEA signal. In this way the position counter is used as a pulse accumulator. The count direction is up. The pulse accumulator can also optionally be initialized by the INDEX input.

## 47.2.11 Watchdog Timer

A watchdog timer is included. It ensures the algorithm is indicating motion in the shaft. Two successive counts indicate proper operation and will reset the timer. The time-out value is programmable. When a time-out occurs, an interrupt to the processor can be generated.

## 47.3 Signal Descriptions

Four external signals are muxed to the four pins of a quad timer module. Two internal signals can be connected to other SoC resources.

### 47.3.1 Phase A Input (PHASEA)

The PHASEA input can be connected to one of the phases from a two-phase shaft quadrature encoder output. It is used by the quadrature decoder module in conjunction with the PHASEB input to indicate a decoder increment has passed, and to calculate its direction. PHASEA is the leading phase for a shaft rotating in the positive direction. PHASEA is the trailing phase for a shaft rotating in the negative direction. It can also be used as the single input when the quadrature decoder module is used as a single phase pulse accumulator.

The PHASEA input can also be an input capture channel for one of the timer modules via the Crossbar module (XBAR).

### 47.3.2 Phase B Input (PHASEB)

The PHASEB input is used as one of the phases from a two phase shaft quadrature encoder output. It is used by the quadrature decoder module in conjunction with the PHASEA input indicating a decoder increment has passed, and to calculate its direction. PHASEB is the trailing phase for a shaft rotating in the positive direction. PHASEB is the leading phase for a shaft rotating in the negative direction.

The PHASEB input can also be an input capture channel for one of the timer modules via the Crossbar module (XBAR).

### 47.3.3 Index Input (INDEX)

Normally connected to the index pulse output of a quadrature encoder, this pulse can optionally reset the position counter and the pulse accumulator of the quadrature decoder module. It also causes a change of state on the revolution counter. The direction of this change, increment or decrement, is calculated from the PHASEA and PHASEB inputs.

The INDEX input can also be an input capture channel for one of the timer modules via the Crossbar module (XBAR).

### 47.3.4 Home Switch Input (HOME)

The HOME input can be used by the quadrature decoder and the timer module. This input can be used to trigger the initialization of the position counters (UPOS and LPOS). Often this signal is connected to a sensor signaling the motor or machine, sending notification that it has reached a defined home position.

This general purpose signal can also be connected to the timer module via the Crossbar module (XBAR).

### 47.3.5 Trigger Input (TRIGGER)

The TRIGGER input can be used to clear the position counters (UPOS and LPOS) or to take a snapshot of the POS, REV, and POSD registers. Often this signal is connected to a periodic pulse generator or timer to indicate an elapsed time period.

### 47.3.6 Position Match Output (POSMATCH)

The POSMATCH output can be used to trigger a timer channel to record the time at which the position of the shaft matches the user defined compare value (COMP). Alternatively, it can be used to indicate when the position counters (UPOS and LPOS), revolution counter (REV), or position difference counter (POSD) registers are read in order to trigger a timer channel to record the time at which the position information was read.

## 47.4 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the MCU level, while the address offset is defined at the module level. Refer to the specific chip documentation for the definition of the base address. All memory locations base and offsets are given in hex.

**ENC memory map**

| Absolute address (hex) | Register name                                   | Width (in bits) | Access | Reset value | Section/ page                |

**47.4.2 Input Filter Register (ENC\_FILT)**

This register sets the values of the input filter sample period (FILT\_PER) and the input filter sample count (FILT\_CNT).

The FILT\_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT\_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of FILT\_CNT+3.

The values of FILT\_PER and FILT\_CNT must also be traded off against the desire for minimal latency in recognizing valid input transitions. Turning on the input filter (setting FILT\_PER to a non-zero value) introduces a latency of ((FILT\_CNT+3)\*FILT\_PER+2) IPBus clock periods.

The filter latency can be measured as follows: drive the quadrature decoder inputs, PHASEA, PHASEB, INDEX, and HOME monitoring the filtered output in the input monitor register (IMR). Determine how many IPBus clock cycles it takes before the output shows up, by using the following equations, where f is FILT\_PER and s is FILT\_CNT.

1. DELAY (IPBus clock cycles) =  $f * (s+3) + 1$  (to read the filtered output)

2. DELAY (IPBus clock cycles) =  $f * (s+3) + 2$  (to monitor the output in the IMR)

One more additional IPBus clock cycle is needed to read the filtered output, and two more IPBus clock cycles are needed to monitor the filtered output in the IMR. The sample rate is set when it reaches the number  $f$ . The following examples employ the preceding equations:

- Example: when  $f = 0$ , the filter is bypassed. Therefore, DELAY = 1 or 2 clock cycles.
- Example: when  $f = 5$  and  $s = 2$ , DELAY =  $5 * (2+3) + (1 \text{ or } 2) = 26 \text{ or } 27$  clock cycles.

| 15–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 10–8<br>FILT_CNT  | Input Filter Sample Count<br>These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0x0 represents 3 samples. A value of 0x7 represents 10 samples. The value of FILT_CNT affects the input latency.                                                                                                                                                                                                                                                                                                                |
| FILT_PER          | Input Filter Sample Period<br>These bits represent the sampling period (in IPBus clock cycles) of the decoder input signals. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. Bypassing the digital filter enables the position/position difference counters to operate with count rates up to the IPBus frequency. The value of FILT_PER affects the input latency.<br><br>When changing FILT_PER from one non-zero value to another non-zero value, write a value of 0 first in order to clear the filter. |

## 47.4.3 Watchdog Timeout Register (ENC\_WTR)

This read/write register stores the timeout count for the quadrature decoder module watchdog timer. This timer is separate from the watchdog timer in the COP module.

Address: 4005\_5000h base + 4h offset = 4005\_5004h

| Field      | Description                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------|
| INIT[15:0] | This read/write register contains the value to be used to initialize the lower half of the position counter (LPOS). |

### 47.4.14 Input Monitor Register (ENC\_IMR)

This read-only register contains the values of the raw and filtered PHASEA, PHASEB, INDEX, and HOME input signals. The reset value depends on the values of the raw and filtered values of PHASEA, PHASEB, INDEX, and HOME. If these input pins are connected to a pull-up, bits 0–7 of the IMR are all ones. If these input pins are connected to a pull-down device, bits 0–7 are all zeros.

Address: 4005\_5000h base + 1Ah offset = 4005\_501Ah

| 0<br>HOME        | This is the raw HOME input.                                                             |

## 47.4.15 Test Register (ENC\_TST)

This read/write register controls and sets the frequency of a quadrature signal generator. It provides a quadrature test signal to the inputs of the quadrature decoder module. The TEST\_COUNT value is counted down to zero when the test module is enabled (TEN = 1) and the count is enabled (TCE = 1). Each count value of one represents a single quadrature cycle interpreted as a count of one by the position counter (UPOS and LPOS) if it is so enabled. Repeated writing of new values to TEST\_COUNT can cause an extra phase transition and therefore an extra count by the position counter. The period field determines in IPBus clock cycles the length of each quadrature cycle phase. This register is a factory test feature; however, it may be useful to customers' software development and testing.

Address: 4005\_5000h base + 1Ch offset = 4005\_501Ch

|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMP[15:0] | This read/write register contains the lower (least significant) half of the position compare register. When the value of POS matches the value of COMP, the CTRL[CMPIRQ] flag is set and the POSMATCH output is asserted. |

47.5 Functional Description

The following timing diagram shows the basic operation of a quadrature incremental position quadrature decoder.

Figure 47-3. Quadrature Decoder Signals

### 47.5.1 Positive versus Negative Direction

A typical quadrature encoder has three outputs:

1. PHASEA signal
2. PHASEB signal
3. INDEX pulse (not shown)

If PHASEA leads PHASEB, then motion is in the positive direction. If PHASEA trails PHASEB, then motion is in the negative direction. Transitions on these phases can be integrated to yield position or differentiated to yield velocity. The quadrature decoder is designed to perform these functions in hardware.

### 47.5.2 Prescaler for Slow or Fast Speed Measurement

For a fast moving shaft encoder, the speed can be computed by calculating the change in the position counter per unit time, or by reading the position difference counter register (POSD) and calculating speed. For applications with slow motor speeds and low line count quadrature encoders, the timer module enables high resolution velocity measurements by measuring the time period between quadrature phases. The timer module uses a 16-bit free running counter operated from a prescaled version of the IPBus clock. The prescaler divides the IPBus clock by values ranging from 1 to 128. A 60 MHz IPBus clock frequency would yield a resolution of from 17 ns to 2.1  $\mu$ s and a maximum count period of from 1.09 ms to 140 ms. For example, with a 1000 tooth decoder, speeds could be calculated down to 0.11 rpm using a prescaler.

### 47.5.3 Holding Registers and Initializing Registers

Hold registers are associated with three counters:

1. Position
2. Position difference
3. Revolution

When any of the counter registers is read, the contents of each counter register is written to the corresponding hold register. Taking a snapshot of the counters' values provides a consistent view of a system position and a velocity to be attained. The POSMATCH output can be used in conjunction with a timer channel to capture a time stamp of when these registers are read.

The position counter is 32 bits wide. To ensure it can be reliably initialized with two 16-bit accesses, two registers, an upper and a lower initialization register, are provided. The upper initialization register (UNIT) and lower initialization register (LINIT) should be modified with the desired value. Next, the position counter can be loaded by writing 1 to CTRL[SWIP]. Alternatively, either CTRL[XIP] or CTRL[HIP] can enable the position counter to be initialized in response to a HOME or INDEX signal transition.

## 47.6 Resets

There are no special requirements. This module is reset by any system reset.

## 47.7 Clocks

The IPBus clock is the only clock required by this module in normal operation.

## 47.8 Interrupts

The following table lists the module interrupts.

**Table 47-2. Interrupt Summary**

| Core Interrupt | Interrupt Flag | Interrupt Enable | Description                                                        |
|----------------|----------------|------------------|--------------------------------------------------------------------|
| ipi_int_home   | CTRL[HIRQ]     | CTRL[HIE]        | HOME signal transition interrupt                                   |
| ipi_int_index  | CTRL[XIRQ]     | CTRL[XIE]        | INDEX signal transition interrupt or roll-over/<br>under interrupt |
|                | CTRL2[ROIRQ]   | CTRL2[ROIE]      |                                                                    |
|                | CTRL2[RUIRQ]   | CTRL2[RUIE]      |                                                                    |
| ipi_int_wdog   | CTRL[DIRQ]     | CTRL[DIE]        | Watchdog timeout interrupt                                         |
| ipi_int_comp   | CTRL[CMPIRQ]   | CTRL[CMPIE]      | Compare match interrupt                                            |
| ipi_int_sab    | CTRL2[SABIRQ]  | CTRL2[SABIE]     | Simultaneous PHASEA and PHASEB change interrupt                    |

# Chapter 48

## Enhanced Flex Pulse Width Modulator (eFlexPWM)

### 48.1 Chip-specific eFlexPWM information

This device has two FlexPWM modules, FlexPWM0 and FlexPWM1.

#### 48.1.1 PWM0 with nano-edge placement

##### 48.1.1.1 PWM0 inputs

For this device, PWM0 has the following signal input connections.

Input synchronisation to the four submodules of the eFlexPWM are fed from the XBARA module, which provides flexible triggering and fault inputs from other peripherals.

| PWM0 signal    | Connected to            |
|----------------|-------------------------|
| PWM0_EXT_A0    | XBARA_OUT20             |
| PWM0_EXT_A1    | XBARA_OUT21             |
| PWM0_EXT_A2    | XBARA_OUT22             |
| PWM0_EXT_A3    | XBARA_OUT23             |
| PWM0_EXT_SYNC0 | XBARA_OUT24             |
| PWM0_EXT_SYNC1 | XBARA_OUT25             |
| PWM0_EXT_SYNC2 | XBARA_OUT26             |
| PWM0_EXT_SYNC3 | XBARA_OUT27             |
| PWM0_EXT_CLK   | XBARA_OUT28             |
| PWM0_FAULT0    | XBARA_OUT29             |
| PWM0_FAULT1    | XBARA_OUT30             |
| PWM0_FAULT2    | XBARA_OUT31             |
| PWM0_FAULT3    | XBARA_OUT32             |
| PWM0_FORCE     | XBARA_OUT33             |
| PWM0_EXTB0     | R0_PWM output of HSADC0 |

*Table continues on the next page...*

| PWM0 signal | Connected to            |
|-------------|-------------------------|
| PWM0_EXTB1  | R1_PWM output of HSADC0 |
| PWM0_EXTB2  | R2_PWM output of HSADC0 |
| PWM0_EXTB3  | R3_PWM output of HSADC0 |

### 48.1.1.2 PWM0 outputs

For this device, PWM0 has the following signal output connections.

Output trigger events from PWM0 are used to trigger other peripherals to take action via the XBARA and XBARB and AOI module. Each of the four sub modules have two trigger outputs (TRIG0) and TRIG1).

- PWM0\_OUT\_TRIG0\_0 output is connected to XBARA\_IN20 and XBARB\_IN8
- PWM0\_OUT\_TRIG0\_1 output is connected to XBARA\_IN21 and XBARB\_IN8
- PWM0\_OUT\_TRIG1\_0 output is connected to XBARA\_IN22 and XBARB\_IN9
- PWM0\_OUT\_TRIG1\_1 output is connected to XBARA\_IN23 and XBARB\_IN9
- PWM0\_OUT\_TRIG2\_0 output is connected to XBARA\_IN24 and XBARB\_IN10
- PWM0\_OUT\_TRIG2\_1 output is connected to XBARA\_IN25 and XBARB\_IN10
- PWM0\_OUT\_TRIG3\_0 output is connected to XBARA\_IN26 and XBARB\_IN11
- PWM0\_OUT\_TRIG3\_1 output is connected to XBARA\_IN27 and XBARB\_IN11

Each submodule of the PWM0 can request a DMA transfer for updating their double buffered VALx registers.

- Submodule 0 , PWM0\_WR0 output is connected to DMAMUX0 ch 6
- Submodule 1 , PWM0\_WR1 output is connected to DMAMUX0 ch 7
- Submodule 2 , PWM0\_WR2 output is connected to DMAMUX0 ch 8
- Submodule 3 , PWM0\_WR3 output is connected to DMAMUX0 ch 9

Each submodule of the PWM0 can request a DMA transfer to read CVALx registers for captured values when configured as input captures.

- Submodule 0, PWM0\_CP0 output is connected to DMAMUX0 ch 10
- Submodule 1, PWM0\_CP1 output is connected to DMAMUX0 ch 11
- Submodule 2, PWM0\_CP2 output is connected to DMAMUX0 ch 12
- Submodule 3, PWM0\_CP3 output is connected to DMAMUX0 ch 13

## 48.1.2 PWM1 without nano-edge placement

### 48.1.2.1 PWM1 Inputs

For this device, the PWM1 has the following signal input connections.

Input synchronisation to the four submodules of the PWM1 are fed from the XBARA module, which provides flexible triggering and fault inputs from other peripherals.

| PWM1 signal    | Connected to            |
|----------------|-------------------------|
| PWM1_EXT_A0    | XBARA_OUT20             |
| PWM1_EXT_A1    | XBARA_OUT21             |
| PWM1_EXT_A2    | XBARA_OUT22             |
| PWM1_EXT_A3    | XBARA_OUT23             |
| PWM1_EXT_SYNC0 | XBARA_OUT53             |
| PWM1_EXT_SYNC1 | XBARA_OUT54             |
| PWM1_EXT_SYNC2 | XBARA_OUT55             |
| PWM1_EXT_SYNC3 | XBARA_OUT56             |
| PWM1_EXT_CLK   | XBARA_OUT28             |
| PWM1_FAULT0    | XBARA_OUT29             |
| PWM1_FAULT1    | XBARA_OUT30             |
| PWM1_FAULT2    | XBARA_OUT31             |
| PWM1_FAULT3    | XBARA_OUT32             |
| PWM1_FORCE     | XBARA_OUT57             |
| PWM1_EXTB0     | R0_PWM output of HSADC1 |
| PWM1_EXTB1     | R1_PWM output of HSADC1 |
| PWM1_EXTB2     | R2_PWM output of HSADC1 |
| PWM1_EXTB3     | R3_PWM output of HSADC1 |

### 48.1.2.2 PWM1 outputs

For this device, the PWM1 has the following signal output connections.

Output trigger events from the PWM1 are used to trigger other peripherals to take action via the XBARA and XBARB and AOI module. Each of the four sub modules have two trigger outputs (TRIG0) and TRIG1).

- PWM1\_OUT\_TRIG0\_0 output is connected to XBARA\_IN52 and XBARB\_IN28
- PWM1\_OUT\_TRIG0\_1 output is connected to XBARA\_IN52 and XBARB\_IN28
- PWM1\_OUT\_TRIG1\_0 output is connected to XBARA\_IN53 and XBARB\_IN29

- PWM1\_OUT\_TRIG1\_1 output is connected to XBARA\_IN53 and XBARB\_IN29
- PWM1\_OUT\_TRIG2\_0 output is connected to XBARA\_IN54 and XBARB\_IN30
- PWM1\_OUT\_TRIG2\_1 output is connected to XBARA\_IN54 and XBARB\_IN30
- PWM1\_OUT\_TRIG3\_0 output is connected to XBARA\_IN56 and XBARB\_IN31
- PWM1\_OUT\_TRIG3\_1 output is connected to XBARA\_IN56 and XBARB\_IN31

Each submodule of the PWM1 can request a DMA transfer for updating their double buffered CVALx registers.

- Submodule 0 , PWM1\_WR0 output is connected to DMAMUX1 ch 6
- Submodule 1 , PWM1\_WR1 output is connected to DMAMUX1 ch 7
- Submodule 2 , PWM1\_WR2 output is connected to DMAMUX1 ch 8
- Submodule 3 , PWM1\_WR3 output is connected to DMAMUX1 ch 9

Each submodule of the PWM1 can request a DMA transfer to read VALx registers for captured values when configured as input captures.

- Submodule 0, PWM1\_CP0 output is connected to DMAMUX1 ch 10
- Submodule 1, PWM1\_CP1 output is connected to DMAMUX1 ch 11
- Submodule 2, PWM1\_CP2 output is connected to DMAMUX1 ch 12
- Submodule 3, PWM1\_CP3 output is connected to DMAMUX1 ch 13

## 48.2 Introduction

The pulse width modulator (PWM) module contains PWM submodules, each of which is set up to control a single half-bridge power stage. Fault channel support is provided.

This PWM module can generate various switching patterns, including highly sophisticated waveforms. It can be used to control all known Switched Mode Power Supplies (SMPS) topologies.

The primary difference between PWM0 and PWM1 is that PWM0 supports nano-edge placement whereas PWM1 supports digital dithering.

### 48.2.1 Features

- 16 bits of resolution for center, edge-aligned, and asymmetrical PWMs
- Fractional PWM clock generation for enhanced resolution of the PWM period and duty cycle
- Dithering to simulate enhanced resolution when nano-edge placement is not available
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation

- Independent control of both edges of each PWM output
- Support for synchronization to external hardware or other PWM
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a FORCE\_OUT event
- PWM\_X pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions
- Enhanced dual edge capture functionality
- The option to supply the source for each complementary PWM signal pair from any of the following:
  - Crossbar module outputs
  - External ADC input, taking into account values set in ADC high and low limit registers

## 48.2.2 Modes of Operation

Be careful when using this module in stop, wait and debug operating modes.

### CAUTION

Some applications require regular software updates for proper operation. Failure to provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, PWM outputs are placed in their inactive states in stop mode, and they can optionally be placed in inactive states in wait and debug (EOnCE) modes. PWM outputs are reactivated (assuming they were active beforehand) when these modes are exited.

**Table 48-1. Modes when PWM Operation is Restricted**

| Mode  | Description                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stop  | PWM outputs are inactive.                                                                                                                               |
| Wait  | PWM outputs are driven or inactive as a function of CTRL2[WAITEN].                                                                                      |
| Debug | CPU and peripheral clocks continue to run, but the CPU may stall for periods of time. PWM outputs are driven or inactive as a function of CTRL2[DBGEN]. |

### 48.2.3 Block Diagram

The following figure is a block diagram of the PWM.

Figure 48-1. PWM Block Diagram

### 48.2.3.1 PWM Submodule

### Figure 48-2. PWM Submodule Block Diagram

## 48.3 Signal Descriptions

The PWM has pins named PWMx\_A[n], PWMx\_B[n], PWMx\_X[n], FAULT[n], PWMx\_EXT[n]\_SYNC, EXT\_FORCE, PWMx\_EXT\_A[n], and PWMx\_EXT\_B[n]. The PWM also has an on-chip input called EXT\_CLK and output signals called PWM[n]\_OUT\_TRIGx.

### 48.3.1 PWMx\_A[n] and PWMx\_B[n] - External PWM Output Pair

These pins are the output pins of the PWM channels. These pins can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.

### 48.3.2 PWMx\_X[n] - Auxiliary PWM Output signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or used to detect the polarity of the current flowing through the complementary circuit at deadtime correction.

### 48.3.3 FAULT[n] - Fault Inputs

These are input pins for disabling selected PWM outputs.

### 48.3.4 PWMx\_EXT\_SYNC[n] - External Synchronization Signal

These input signals allow a source external to the PWM to initialize the PWM counter. In this manner, the PWM can be synchronized to external circuitry.

### 48.3.5 EXT\_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner, the PWM can be synchronized to external circuitry.

### 48.3.6 PWMx\_EXT\_A[n] and PWMx\_EXT\_B[n] - Alternate PWM Control Signals

These pins allow an alternate source to control the PWMx\_A[n] and PWMx\_B[n] outputs. Typically, either the PWMx\_EXT\_A[n] or PWMx\_EXT\_B[n] input (depending on the state of MCTRL0[IPOL]) is used for the generation of a complementary pair. Typical control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.

### 48.3.7 PWMx\_OUT\_TRIG0 and PWMx\_OUT\_TRIG1 - Output Triggers

These outputs allow the PWM submodules to control timing of ADC conversions. See the description of the Output Trigger Control Register for information about how to enable these outputs and how the compare registers match up to the output triggers.

### 48.3.8 EXT\_CLK - External Clock Signal

This signal allows a source external to the PWM (typically a timer or an off-chip source) to control the PWM clocking. In this manner, the PWM can be synchronized to the timer, or multiple chips can be synchronized to each other.

## 48.4 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level, and the address offset is defined at the module level. The PWM module has a set of registers for each PWM submodule, for the configuration logic, and for each fault channel. While the registers are 16-bit wide, they can be accessed in pairs as 32-bit registers.

Submodule registers are repeated for each PWM submodule. To designate which submodule they are in, register names are prefixed with SM0, SM1, SM2, and SM3. The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is offset \$30 from the base address for the PWM module as a whole. This \$30 offset is based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same \$30 offset. The pattern repeats for the base address of submodule 3.

The base address of the configuration registers is equal to the base address of the PWM module as a whole plus an offset of \$C0.

Fault channel registers are repeated for each fault channel. To designate which fault channel they are in, register names are prefixed with F0 and F1. The base address of fault channel 0 is equal to the base address of the PWM module as a whole plus an offset of \$C6. The base address of fault channel 1 is the base address of fault channel 0 + \$4. This \$4 offset is based on the number of registers in a fault channel. Each of the four fields in the fault channel registers corresponds to fault inputs 3-0.

**PWM memory map**

| Address offset (hex) | Absolute address (hex) | Register name                         | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|------------------------|---------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | 4003_3000              | Counter Register (PWM0_SM0CNT)        | 16              | R      | 0000h       | <a href="#">48.4.1/1318</a> |

## 48.4.1 Counter Register (PWMx\_SMnCNT)

This read-only register displays the state of the signed 16-bit submodule counter. This register is not byte accessible.

Address: Base address + 0h offset + (96d × i), where i=0d to 3d

|       |     |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| CNT   | Counter Register Bits |

## 48.4.2 Initial Count Register (PWMx\_SMnINIT)

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of CTRL2[INIT\_SEL]) or when CTRL2[FORCE] is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

## NOTE

The INIT register is buffered. The value written does not take effect until MCTRL0[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be

written when MCTRL0[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Address: Base address + 2h offset + (96d × i), where i=0d to 3d

## PWMx\_SMnCTRL field descriptions (continued)

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p><b>NOTE:</b> LDFQ takes effect when the current load cycle is complete, regardless of the state of MCTRL0[LDOK]. Reading LDFQ reads the buffered values and not necessarily the values currently in effect.</p> <p>0000 Every PWM opportunity<br/> 0001 Every 2 PWM opportunities<br/> 0010 Every 3 PWM opportunities<br/> 0011 Every 4 PWM opportunities<br/> 0100 Every 5 PWM opportunities<br/> 0101 Every 6 PWM opportunities<br/> 0110 Every 7 PWM opportunities<br/> 0111 Every 8 PWM opportunities<br/> 1000 Every 9 PWM opportunities<br/> 1001 Every 10 PWM opportunities<br/> 1010 Every 11 PWM opportunities<br/> 1011 Every 12 PWM opportunities<br/> 1100 Every 13 PWM opportunities<br/> 1101 Every 14 PWM opportunities<br/> 1110 Every 15 PWM opportunities<br/> 1111 Every 16 PWM opportunities</p> |
| 11<br>HALF    | <p>Half Cycle Reload</p> <p>This read/write bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be half way through the PWM cycle.</p> <p>0 Half-cycle reloads disabled.<br/> 1 Half-cycle reloads enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 10<br>FULL    | <p>Full Cycle Reload</p> <p>This read/write bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either CTRL[HALF] or CTRL[FULL] must be set in order to move the buffered data into the registers used by the PWM generators or CTRL[LDMOD] must be set. If both CTRL[HALF] and CTRL[FULL] are set, then reloads can occur twice per cycle.</p> <p>0 Full-cycle reloads disabled.<br/> 1 Full-cycle reloads enabled.</p>                                                                                                                                                                                                                                                                                                                                   |
| 9–8<br>DT     | <p>Deadtime</p> <p>These read only bits reflect the sampled values of the PWM_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7<br>Reserved | <p>This field is reserved.<br/> This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 6–4<br>PRSC   | <p>Prescaler</p> <p>These buffered read/write bits select the divide ratio of the PWM clock frequency selected by CTRL2[CLK_SEL].</p> <p><b>NOTE:</b> Reading CTRL[PRSC] reads the buffered values and not necessarily the values currently in effect. CTRL[PRSC] takes effect at the beginning of the next PWM cycle and only when the load okay bit, MCTRL0[LDOK], is set or CTRL[LDMOD] is set. This field cannot be written when MCTRL0[LDOK] is set.</p>                                                                                                                                                                                                                                                                                                                                                           |

|       | <p>The 16-bit signed value in this buffered, read/write register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWM_X signal is set and the local sync signal is reset. This register is not byte accessible.</p> <p><b>NOTE:</b> The VAL0 register is buffered. The value written does not take effect until MCTRL0[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL0 cannot be written when MCTRL0[LDOK] is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.</p> |

## PWMx\_SMnFRACVAL1 field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15–11<br>FRACVAL1 | <p>Fractional Value 1 Register</p> <p>These bits act as a fractional addition to the value in the VAL1 register which controls the PWM period width. The PWM period is computed in terms of IPBus clock cycles. This fractional portion is accumulated at the end of every cycle until an additional whole IPBus cycle is reached. At this time the value being used for VAL1 is temporarily incremented and the PWM cycle is extended by one clock period to compensate for the accumulated fractional values.</p> <p><b>NOTE:</b> The FRACVAL1 register is buffered. The value written does not take effect until MCTRL0[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. FRACVAL1 cannot be written when MCTRL0[LDOK] is set. Reading FRACVAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.</p> <p><b>NOTE:</b> If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. After the count reaches VAL1, the PWMX output is low for a minimum of one count every cycle. When the Master Sync signal (only originated by the Local Sync from sub-module 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.</p> |
| Reserved          | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### PWMx\_SMnVAL1 field descriptions

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VAL1  | <p>Value Register 1</p> <p>The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter reloads itself with the contents of the INIT register and asserts the local sync signal while resetting PWM_X. This register is not byte accessible.</p> <p><b>NOTE:</b> The VAL1 register is buffered. The value written does not take effect until MCTRL0[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL1 cannot be written when MCTRL0[LDOK] is set. Reading VAL1 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.</p> <p><b>NOTE:</b> When using FRACVAL1, limit the maximum value of VAL1 to 0xFFFE for unsigned applications or to 0x7FFE for signed applications, to avoid counter rollovers caused by accumulating the fractional period defined by FRACVAL1.</p> <p><b>NOTE:</b> If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. After the count reaches VAL1, the PWMX output is low for a minimum of one count every cycle. When the Master Sync signal (only originated by the Local Sync from sub-module 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.</p> |

## PWMx\_SMnVAL4 field descriptions

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VAL4  | <p>Value Register 4</p> <p>The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 high. This register is not byte accessible.</p> <p><b>NOTE:</b> The VAL4 register is buffered. The value written does not take effect until MCTRL0[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL4 cannot be written when MCTRL0[LDOK] is set. Reading VAL4 reads the value in a buffer and not necessarily the value the PWM generator is currently using.</p> |

## 48.4.14 Fractional Value Register 5 (PWMx\_SMnFRACVAL5)

Address: Base address + 1Ch offset + (96d × i), where i=0d to 3d

| 8<br>FRAC_PU     | Fractional Delay Circuit Power Up<br><br>This bit is used to power up the fractional delay analog block. The fractional delay block takes 25 us to power up after the first FRAC_PU bit in any submodule is set. The fractional delay block only powers down when the FRAC_PU bits in all submodules are 0. The fractional delay logic can only be used when the IPBus clock is running at 100 MHz. When turned off, fractional placement is disabled.<br><br>After setting this bit and waiting the 25usec, load the PWM VAL* registers with values to create a PWM output with greater than 0% duty cycle and run for at least one PWM period. This can be done without the outputs enabled and is used to clear the state of the analog block that produces the fractional delays.<br><br><b>NOTE:</b> This bit is functional only in PWMs that support nano-edge placement.<br><br>0 Turn off fractional delay logic.<br>1 Power up fractional delay logic. |

**PWMx\_SMnDMAEN field descriptions (continued)**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <p>01 Exceeding a FIFO watermark sets the DMA read request. This requires at least one of DMAEN[CA1DE], DMAEN[CA0DE], DMAEN[CB1DE], DMAEN[CB0DE], DMAEN[CX1DE], or DMAEN[CX0DE] to also be set in order to determine to which watermark(s) the DMA request is sensitive.</p> <p>10 A local sync (VAL1 matches counter) sets the read DMA request.</p> <p>11 A local reload (STS[RF] being set) sets the read DMA request.</p> |
| 5<br>CA1DE | <p>Capture A1 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture A1 FIFO data when STS[CFA1] is set. Reset clears this bit. Do not set both this bit and INTEN[CA1IE].</p>                                                                                                                                                                                                                  |
| 4<br>CA0DE | <p>Capture A0 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture A0 FIFO data when STS[CFA0] is set. Reset clears this bit. Do not set both this bit and INTEN[CA0IE].</p>                                                                                                                                                                                                                  |
| 3<br>CB1DE | <p>Capture B1 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture B1 FIFO data when STS[CFB1] is set. Reset clears this bit. Do not set both this bit and INTEN[CB1IE].</p>                                                                                                                                                                                                                  |
| 2<br>CB0DE | <p>Capture B0 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture B0 FIFO data when STS[CFB0] is set. Reset clears this bit. Do not set both this bit and INTEN[CB0IE].</p>                                                                                                                                                                                                                  |
| 1<br>CX1DE | <p>Capture X1 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture X1 FIFO data when STS[CFX1] is set. Reset clears this bit. Do not set both this bit and INTEN[CX1IE].</p>                                                                                                                                                                                                                  |
| 0<br>CX0DE | <p>Capture X0 FIFO DMA Enable</p> <p>This read/write bit enables DMA read requests for the Capture X0 FIFO data when STS[CFX0] is set. Reset clears this bit. Do not set both this bit and INTEN[CX0IE].</p>                                                                                                                                                                                                                  |

| OUT_TRIG_EN      | <p>Output Trigger Enables</p> <p>These bits enable the generation of PWM_OUT_TRIG0 and PWM_OUT_TRIG1 outputs based on the counter value matching the value in one or more of the VAL0-5 registers. VAL0, VAL2, and VAL4 are used to generate PWM_OUT_TRIG0, and VAL1, VAL3, and VAL5 are used to generate PWM_OUT_TRIG1. The PWM_OUT_TRIGx signals are only asserted as long as the counter value matches the VALx value; therefore, up to six triggers can be generated (three each on PWM_OUT_TRIG0 and PWM_OUT_TRIG1) per PWM cycle per submodule.</p> <p><b>NOTE:</b> Due to delays in creating the PWM outputs, the output trigger signals will lead the PWM output edges by 2-3 clock cycles depending on the fractional cycle value being used.</p> <p>0 PWM_OUT_TRIGx will not set when the counter value matches the VALx value.<br/>1 PWM_OUT_TRIGx will set when the counter value matches the VALx value.</p> |

## 48.4.22 Fault Disable Mapping Register 0 (PWMx\_SMnDISMAP0)

This register determines which PWM pins are disabled by the fault protection inputs. Reset sets all of the bits in the fault disable mapping register.

Address: Base address + 2Ch offset + (96d × i), where i=0d to 3d

48.4.23 Deadtime Count Register 0 (PWMx\_SMnDTCNT0)

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK\_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles. The DTCNTx registers are not byte accessible.

Address: Base address + 30h offset + (96d × i), where i=0d to 3d

|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DTCNT0 | <p>The DTCNT0 field is interpreted differently depending on whether or not the fractional delays are being used (FRCNTRL[FRAC23_EN] is set). If the fractional delays are off, then the upper 5 bits of DTCNT0 are ignored and the remaining 11 bits are used to specify the number of cycles of deadtime. In this case the maximum value is 0x07FF which indicates 2047 cycles of deadtime. If the fractional delays are being used, then the upper 11 bits of DTCNT0 represent the number of whole cycles of deadtime and the lower 5 bits of each register represent the fractional cycle added to the whole number. In this case the maximum value is 0xFFFF which represents 2047 31/32 cycles of deadtime.</p> <p>The DTCNT0 field is used to control the deadtime during 0 to 1 transitions of the PWM_A output (assuming normal polarity).</p> |

48.4.24 Deadtime Count Register 1 (PWMx\_SMnDTCNT1)

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK\_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles. The DTCNTx registers are not byte accessible.

|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAPTVAL5 | This read-only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by CAPTCTRLB[EDGB1]. Each capture increases the value of CAPTCTRLB[CB1CNT] by 1 until the maximum value is reached. Each read of this register decreases the value of CAPTCTRLB[CB1CNT] by 1 until 0 is reached. This register is not byte accessible. |

48.4.44 Mask Register (PWMx\_MASK)

MASK is double buffered and does not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Reading MASK reads the buffered values and not necessarily the values currently in effect. This double buffering can be overridden by setting the UPDATE\_MASK bits.

Address: Base address + 182h offset

### 48.4.45 Software Controlled Output Register (PWMx\_SWCOUT)

These bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

Address: Base address + 184h offset

**48.4.46 PWM Source Select Register (PWMx\_DTSRCSEL)**

The PWM source select bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Reading these bits reads the buffered value and not necessarily the value currently in effect.

Address: Base address + 186h offset

**48.4.47 Master Control Register 0 (PWMx\_MCTRL0)**

In every 4-bit field in this register, each bit acts on a separate submodule. Accordingly, the description of every bitfield refers to the effect of an individual bit.

Address: Base address + 188h offset

| Bit   | 15   | 14 | 13 | 12 | 11  | 10 | 9 | 8 | 7     | 6 | 5 | 4 | 3    | 2 | 1 | 0 |

**PWMx\_MCTRL0 field descriptions (continued)**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <p>The four read/write bits of this field enable the clocks to the PWM generator of submodules 3-0, respectively. The corresponding MCTRL0[RUN] bit must be set for each submodule that is using its input capture functions or is using the local reload as its reload source. When this bit equals zero, the submodule counter is reset. A reset clears this field.</p> <p>0 PWM generator is disabled in the corresponding submodule.<br/>1 PWM generator is enabled in the corresponding submodule.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 7–4<br>CLDOK | <p>Clear Load Okay</p> <p>The 4 bits of CLDOK field correspond to submodules 3-0, respectively. Each write-only bit is used to clear the corresponding bit of MCTRL0[LDOK]. Write a 1 to CLDOK to clear the corresponding MCTRL0[LDOK] bit. If a reload occurs within a submodule with the corresponding MCTRL0[LDOK] bit set at the same time that MCTRL0[CLDOK] is written, then the reload in that submodule will not be performed and MCTRL0[LDOK] will be cleared. CLDOK bit is self-clearing and always reads as a 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| LDOK         | <p>Load Okay</p> <p>The 4 bits of LDOK field correspond to submodules 3-0, respectively. Each read/set bit loads CTRL[PRSC] and the INIT, FRACVALx, and VALx registers of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if CTRL[LDMOD] is clear or immediately if CTRL[LDMOD] is set. Set the corresponding MCTRL0[LDOK] bit by reading it when it is logic zero and then writing a logic one to it. The VALx, FRACVALx, INIT, and CTRL[PRSC] registers of the corresponding submodule cannot be written while the the corresponding MCTRL0[LDOK] bit is set.</p> <p>In Master Reload Mode (CTRL2[RELOAD_SEL]=1), it is only necessary to set the LDOK bit corresponding to submodule0; however, it is recommended to also set the LDOK bit of the slave submodules, to prevent unwanted writes to the registers in the slave submodules.</p> <p>The MCTRL0[LDOK] bit is automatically cleared after the new values are loaded, or it can be manually cleared before a reload by writing a logic 1 to the appropriate MCTRL0[CLDOK] bit. LDOK bits cannot be written with a zero. MCTRL0[LDOK] can be set in DMA mode when the DMA indicates that it has completed the update of all CTRL[PRSC], INIT, FRACVALx, and VALx registers in the corresponding submodule. Reset clears LDOK field.</p> <p>0 Do not load new values.<br/>1 Load prescaler, modulus, and PWM values of the corresponding submodule.</p> |
