# MC9S08LG32 Series Features

## 8-Bit HCS08 Central Processor Unit (CPU)

---

- Up to 40 MHz CPU at 5.5 V to 2.7 V across temperature range of  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$  and  $-40^{\circ}\text{C}$  to  $105^{\circ}\text{C}$
- HCS08 instruction set with added BGND instruction
- Support for up to 32 interrupt/reset sources

## On-Chip Memory

---

- 32 KB or 18 KB dual array flash; read/program/erase over full operating voltage and temperature
- 1984 byte random access memory (RAM)
- Security circuitry to prevent unauthorized access to RAM and flash contents

## Power-Saving Modes

---

- Two low-power stop modes (stop2 and stop3)
- Reduced-power wait mode
- Peripheral clock gating register can disable clocks to unused modules, thereby reducing currents
- Low power on-chip crystal oscillator (XOSC) that can be used in low-power modes to provide accurate clock source to real time counter and LCD controller
- 100  $\mu\text{s}$  typical wakeup time from stop3 mode

## Clock Source Options

---

- Oscillator (XOSC) — Loop-control Pierce oscillator; crystal or ceramic resonator range of 31.25 kHz to 38.4 kHz or 1 MHz to 16 MHz
- Internal Clock Source (ICS) — Internal clock source module containing a frequency-locked-loop (FLL) controlled by internal or external reference; precision trimming of internal reference allows 0.2% resolution and 2% deviation over temperature and voltage; supports bus frequencies from 1 MHz to 20 MHz

## System Protection

---

- COP reset with option to run from dedicated 1 kHz internal clock or bus clock
- Low-voltage warning with interrupt
- Low-voltage detection with reset
- Illegal opcode detection with reset
- Illegal address detection with reset
- Flash and RAM protection

## Development Support

---

- Single-wire background debug interface
- Breakpoint capability to allow single breakpoint setting during in-circuit debugging (plus two more breakpoints in on-chip debug module)

- On-chip in-circuit emulator (ICE) debug module containing three comparators and nine trigger modes; eight deep FIFO for storing change-of-flow addresses and event-only data; debug module supports both tag and force breakpoints

## Peripherals

---

- **LCD** — Up to 4 x 41 or 8 x 37 LCD driver with internal charge pump
- **ADC** — Up to 16-channel, 12-bit resolution; 2.5  $\mu\text{s}$  conversion time; automatic compare function; temperature sensor; internal bandgap reference channel; runs in stop3 and can wake up the system; fully functional from 5.5 V to 2.7 V
- **SCI** — Full duplex non-return to zero (NRZ); LIN master extended break generation; LIN slave extended break detection; wakeup on active edge
- **SPI** — Full-duplex or single-wire bidirectional; double-buffered transmit and receive; master or slave mode; MSB-first or LSB-first shifting
- **IIC** — With up to 100 kbps with maximum bus loading; multi-master operation; programmable slave address; interrupt driven byte-by-byte data transfer; supports broadcast mode and 10-bit addressing
- **TPMx** — One 6 channel and one 2 channel; selectable input capture, output compare, or buffered edge or center-aligned PWM on each channel
- **MTIM** — 8-bit counter with match register; four clock sources with prescaler dividers; can be used for periodic wakeup
- **RTC** — 8-bit modulus counter with binary or decimal based prescaler; three clock sources including one external source; can be used for time base, calendar, or task scheduling functions
- **KBI** — One keyboard control module capable of supporting 8x8 keyboard matrix
- **IRQ** — External pin for wakeup from low-power modes

## Input/Output

---

- 39, 53, or 69 GPIOs
- 8 KBI and 1 IRQ interrupt with selectable polarity
- Hysteresis and configurable pullup device on all input pins; configurable slew rate and drive strength on all output pins

## Package Options

---

- 48-pin LQFP, 64-pin LQFP, and 80-pin LQFP

| <b>Chapter 3</b>            |                                                       |      |
| <b>Modes of Operation</b>   |                                                       |      |
| 3.1                         | Introduction .....                                    | 41   |
| 3.2                         | Features .....                                        | 41   |
| 3.3                         | Run Mode .....                                        | 41   |
| 3.4                         | Active Background Mode .....                          | 41   |
| 3.5                         | Wait Mode .....                                       | 42   |
| 3.6                         | Stop Modes .....                                      | 43   |
| 3.6.1                       | Stop2 Mode .....                                      | 43   |
| 3.6.2                       | Stop3 Mode .....                                      | 44   |
| 3.6.3                       | Active BDM Enabled in Stop Mode .....                 | 45   |
| 3.6.4                       | LVD Enabled in Stop Mode .....                        | 45   |
| 3.7                         | Mode Selection .....                                  | 45   |
| 3.7.1                       | On-Chip Peripheral Modules in Stop Modes .....        | 48   |
| <b>Chapter 4</b>            |                                                       |      |
| <b>Memory</b>               |                                                       |      |
| 4.1                         | Introduction .....                                    | 49   |

| Section Number | Title                                              | Page |
|----------------|----------------------------------------------------|------|
| 4.2            | MC9S08LG32 Series Memory Map .....                 | 49   |
| 4.3            | Reset and Interrupt Vector Assignments .....       | 50   |
| 4.4            | Register Addresses and Bit Assignments.....        | 52   |
| 4.4.1          | Reserved Flash Locations .....                     | 59   |
| 4.5            | RAM.....                                           | 60   |
| 4.6            | Flash .....                                        | 60   |
| 4.6.1          | Features .....                                     | 61   |
| 4.6.2          | Program and Erase Times .....                      | 61   |
| 4.6.3          | Program and Erase Command Execution .....          | 62   |
| 4.6.4          | Burst Program Execution .....                      | 63   |
| 4.6.5          | Access Errors .....                                | 65   |
| 4.6.6          | Flash Block Protection .....                       | 65   |
| 4.6.7          | Vector Redirection .....                           | 66   |
| 4.7            | Security.....                                      | 66   |
| 4.8            | Flash Registers and Control Bits.....              | 67   |
| 4.8.1          | Flash Clock Divider Register (FCDIV) .....         | 68   |
| 4.8.2          | Flash Options Register (FOPT and NVOPT) .....      | 69   |
| 4.8.3          | Flash Configuration Register (FCNFG) .....         | 70   |
| 4.8.4          | Flash Protection Register (FPROT and NVPROT) ..... | 70   |
| 4.8.5          | Flash Status Register (FSTAT) .....                | 71   |
| 4.8.6          | Flash Command Register (FCMD) .....                | 72   |

## Chapter 5

### Resets, Interrupts, and General System Control

|       |                                                                      |    |
|-------|----------------------------------------------------------------------|----|
| 5.1   | Introduction .....                                                   | 73 |
| 5.2   | Features .....                                                       | 73 |
| 5.3   | MCU Reset.....                                                       | 73 |
| 5.4   | Computer Operating Properly (COP) Watchdog.....                      | 74 |
| 5.5   | Interrupts .....                                                     | 75 |
| 5.5.1 | Interrupt Stack Frame .....                                          | 76 |
| 5.5.2 | External Interrupt Request (IRQ) Pin .....                           | 76 |
| 5.5.3 | Interrupt Vectors, Sources, and Local Masks .....                    | 77 |
| 5.6   | Low-Voltage Detect (LVD) System .....                                | 79 |
| 5.6.1 | Power-On Reset Operation .....                                       | 79 |
| 5.6.2 | Low-Voltage Detection (LVD) Reset Operation .....                    | 79 |
| 5.6.3 | Low-Voltage Warning (LVW) Interrupt Operation .....                  | 79 |
| 5.7   | Peripheral Clock Gating .....                                        | 79 |
| 5.8   | Reset, Interrupt, and System Control Registers and Control Bits..... | 80 |
| 5.8.1 | Interrupt Pin Request Status and Control Register (IRQSC) .....      | 80 |
| 5.8.2 | System Reset Status Register (SRS) .....                             | 82 |
| 5.8.3 | System Background Debug Force Reset Register (SBDFR) .....           | 83 |
| 5.8.4 | System Options Register 1 (SOPT1) .....                              | 84 |

| Section Number | Title                                                                | Page |
|----------------|----------------------------------------------------------------------|------|
| 5.8.5          | System Options Register 2 (SOPT2) .....                              | 85   |
| 5.8.6          | System Device Identification Register (SDIDH, SDIDL) .....           | 86   |
| 5.8.7          | System Power Management Status and Control 1 Register (SPMSC1) ..... | 87   |
| 5.8.8          | System Power Management Status and Control 2 Register (SPMSC2) ..... | 88   |
| 5.8.9          | System Clock Gating Control 1 Register (SCGC1) .....                 | 90   |
| 5.8.10         | System Clock Gating Control 2 Register (SCGC2) .....                 | 91   |
| 5.8.11         | Pin Position Control Register (PINPS1) .....                         | 92   |
| 5.8.12         | Pin Position Control Register (PINPS2) .....                         | 93   |
| 5.8.13         | Pin Position Control Register (PINPS3) .....                         | 94   |
| 5.8.14         | Pin Position Control Register (PINPS4) .....                         | 95   |

## Chapter 6 Parallel Input/Output Control

|       |                                              |     |
|-------|----------------------------------------------|-----|
| 6.1   | Introduction .....                           | 97  |
| 6.2   | Pins Shared with LCD .....                   | 97  |
| 6.3   | Port Data and Data Direction .....           | 97  |
| 6.4   | Pullup, Slew Rate, and Drive Strength .....  | 98  |
| 6.4.1 | Port Internal Pullup Enable .....            | 98  |
| 6.4.2 | Port Slew Rate Enable .....                  | 99  |
| 6.4.3 | Port Drive Strength Select .....             | 99  |
| 6.5   | Open Drain Operation .....                   | 99  |
| 6.6   | Pin Behavior in Stop Modes .....             | 99  |
| 6.7   | Parallel I/O and Pin Control Registers ..... | 100 |
| 6.7.1 | Port A Registers .....                       | 100 |
| 6.7.2 | Port B Registers .....                       | 104 |
| 6.7.3 | Port C Registers .....                       | 107 |
| 6.7.4 | Port D Registers .....                       | 110 |
| 6.7.5 | Port E Registers .....                       | 113 |
| 6.7.6 | Port F Registers .....                       | 116 |
| 6.7.7 | Port G Registers .....                       | 119 |
| 6.7.8 | Port H Registers .....                       | 122 |
| 6.7.9 | Port I Registers .....                       | 125 |

## Chapter 7 Keyboard Interrupt (S08KBIV2)

|       |                                   |     |
|-------|-----------------------------------|-----|
| 7.1   | Introduction .....                | 128 |
| 7.1.1 | Module Configuration .....        | 128 |
| 7.1.2 | KBI Clock Gating .....            | 128 |
| 7.1.3 | Features .....                    | 130 |
| 7.1.4 | Modes of Operation .....          | 130 |
| 7.1.5 | Block Diagram .....               | 130 |
| 7.2   | External Signal Description ..... | 131 |

| Section Number | Title                                         | Page |
|----------------|-----------------------------------------------|------|
| 7.3            | Register Definition .....                     | 131  |
| 7.3.1          | KBI Status and Control Register (KBISC) ..... | 131  |
| 7.3.2          | KBI Pin Enable Register (KBIPE) .....         | 132  |
| 7.3.3          | KBI Edge Select Register (KBIES) .....        | 132  |
| 7.4            | Functional Description .....                  | 133  |
| 7.4.1          | Edge Only Sensitivity .....                   | 133  |
| 7.4.2          | Edge and Level Sensitivity .....              | 133  |
| 7.4.3          | KBI Pullup/Pulldown Resistors .....           | 134  |
| 7.4.4          | KBI Initialization .....                      | 134  |

## Chapter 8 Central Processor Unit (S08CPUV5)

|       |                                            |     |
|-------|--------------------------------------------|-----|
| 8.1   | Introduction .....                         | 135 |
| 8.1.1 | Features .....                             | 135 |
| 8.2   | Programmer's Model and CPU Registers ..... | 136 |
| 8.2.1 | Accumulator (A) .....                      | 136 |
| 8.2.2 | Index Register (H:X) .....                 | 136 |
| 8.2.3 | Stack Pointer (SP) .....                   | 137 |
| 8.2.4 | Program Counter (PC) .....                 | 137 |
| 8.2.5 | Condition Code Register (CCR) .....        | 137 |
| 8.3   | Addressing Modes .....                     | 139 |
| 8.3.1 | Inherent Addressing Mode (INH) .....       | 139 |
| 8.3.2 | Relative Addressing Mode (REL) .....       | 139 |
| 8.3.3 | Immediate Addressing Mode (IMM) .....      | 139 |
| 8.3.4 | Direct Addressing Mode (DIR) .....         | 139 |
| 8.3.5 | Extended Addressing Mode (EXT) .....       | 140 |
| 8.3.6 | Indexed Addressing Mode .....              | 140 |
| 8.4   | Special Operations .....                   | 141 |
| 8.4.1 | Reset Sequence .....                       | 141 |
| 8.4.2 | Interrupt Sequence .....                   | 141 |
| 8.4.3 | Wait Mode Operation .....                  | 142 |
| 8.4.4 | Stop Mode Operation .....                  | 142 |
| 8.4.5 | BGND Instruction .....                     | 143 |
| 8.5   | HCS08 Instruction Set Summary .....        | 144 |

## Chapter 9 LCD Module (S08LCDLPV1)

|       |                                     |     |
|-------|-------------------------------------|-----|
| 9.1   | Introduction .....                  | 158 |
| 9.1.1 | LCD Clock Sources .....             | 158 |
| 9.1.2 | LCD Modes of Operation .....        | 158 |
| 9.1.3 | LCD Status after Stop2 Wakeup ..... | 158 |
| 9.1.4 | LCD Clock Gating .....              | 158 |

| Section Number | Title                                                              | Page |
|----------------|--------------------------------------------------------------------|------|
| 9.1.5          | Features .....                                                     | 160  |
| 9.1.6          | Modes of Operation .....                                           | 161  |
| 9.1.7          | Block Diagram .....                                                | 161  |
| 9.2            | External Signal Description .....                                  | 162  |
| 9.2.1          | LCD[44:0] .....                                                    | 163  |
| 9.2.2          | $V_{LL1}$ , $V_{LL2}$ , $V_{LL3}$ .....                            | 163  |
| 9.2.3          | $V_{cap1}$ , $V_{cap2}$ .....                                      | 163  |
| 9.3            | Register Definition .....                                          | 163  |
| 9.3.1          | LCD Control Register 0 (LCDC0) .....                               | 163  |
| 9.3.2          | LCD Control Register 1 (LCDC1) .....                               | 164  |
| 9.3.3          | LCD Voltage Supply Register (LCDSUPPLY) .....                      | 165  |
| 9.3.4          | LCD Regulated Voltage Control Register (LCDRVC) .....              | 166  |
| 9.3.5          | LCD Blink Control Register (LCDBCTL) .....                         | 167  |
| 9.3.6          | LCD Status Register (LCDS) .....                                   | 168  |
| 9.3.7          | LCD Pin Enable Registers 0–5 (LCDPEN0–LCDPEN5) .....               | 168  |
| 9.3.8          | Backplane Enable Registers 0–5 (BPEN0–BPEN5) .....                 | 169  |
| 9.3.9          | LCD Waveform Registers (LCDWF[44:0]) .....                         | 170  |
| 9.4            | Functional Description .....                                       | 174  |
| 9.4.1          | LCD Driver Description .....                                       | 175  |
| 9.4.2          | LCDWF Registers .....                                              | 183  |
| 9.4.3          | LCD Display Modes .....                                            | 183  |
| 9.4.4          | LCD Charge Pump, Voltage Divider, and Power Supply Operation ..... | 185  |
| 9.4.5          | Resets .....                                                       | 188  |
| 9.4.6          | Interrupts .....                                                   | 189  |
| 9.5            | Initialization Section .....                                       | 189  |
| 9.5.1          | Initialization Sequence .....                                      | 189  |
| 9.5.2          | Initialization Examples .....                                      | 190  |
| 9.6            | Application Information .....                                      | 194  |
| 9.6.1          | LCD Seven Segment Example Description .....                        | 195  |
| 9.6.2          | LCD Contrast Control .....                                         | 198  |
| 9.6.3          | Stop Mode Recovery .....                                           | 199  |

## Chapter 10

### Analog-to-Digital Converter (S08ADC12V1)

|        |                                        |     |
|--------|----------------------------------------|-----|
| 10.1   | Introduction .....                     | 200 |
| 10.1.1 | ADC shared with LCD .....              | 200 |
| 10.1.2 | ADC Reference and Supply Voltage ..... | 200 |
| 10.1.3 | ADC Clock Gating .....                 | 200 |
| 10.1.4 | Module Configurations .....            | 201 |
| 10.1.5 | Features .....                         | 204 |
| 10.1.6 | ADC Module Block Diagram .....         | 204 |
| 10.2   | External Signal Description .....      | 205 |

| Section Number | Title                                        | Page |
|----------------|----------------------------------------------|------|
| 10.2.1         | Analog Power ( $V_{DDA}$ ) .....             | 206  |
| 10.2.2         | Analog Ground ( $V_{SSA}$ ) .....            | 206  |
| 10.2.3         | Voltage Reference High ( $V_{REFH}$ ) .....  | 206  |
| 10.2.4         | Voltage Reference Low ( $V_{REFL}$ ) .....   | 206  |
| 10.2.5         | Analog Channel Inputs (ADx) .....            | 206  |
| 10.3           | Register Definition .....                    | 206  |
| 10.3.1         | Status and Control Register 1 (ADCSC1) ..... | 206  |
| 10.3.2         | Status and Control Register 2 (ADCSC2) ..... | 208  |
| 10.3.3         | Data Result High Register (ADCRH) .....      | 208  |
| 10.3.4         | Data Result Low Register (ADCRL) .....       | 209  |
| 10.3.5         | Compare Value High Register (ADCCVH) .....   | 209  |
| 10.3.6         | Compare Value Low Register (ADCCVL) .....    | 210  |
| 10.3.7         | Configuration Register (ADCCFG) .....        | 210  |
| 10.3.8         | Pin Control 1 Register (APCTL1) .....        | 211  |
| 10.3.9         | Pin Control 2 Register (APCTL2) .....        | 212  |
| 10.3.10        | Pin Control 3 Register (APCTL3) .....        | 213  |
| 10.4           | Functional Description .....                 | 214  |
| 10.4.1         | Clock Select and Divide Control .....        | 215  |
| 10.4.2         | Input Select and Pin Control .....           | 215  |
| 10.4.3         | Hardware Trigger .....                       | 215  |
| 10.4.4         | Conversion Control .....                     | 215  |
| 10.4.5         | Automatic Compare Function .....             | 218  |
| 10.4.6         | MCU Wait Mode Operation .....                | 218  |
| 10.4.7         | MCU Stop3 Mode Operation .....               | 219  |
| 10.4.8         | MCU Stop2 Mode Operation .....               | 219  |
| 10.5           | Initialization Information .....             | 220  |
| 10.5.1         | ADC Module Initialization Example .....      | 220  |
| 10.6           | Application Information .....                | 222  |
| 10.6.1         | External Pins and Routing .....              | 222  |
| 10.6.2         | Sources of Error .....                       | 223  |

## Chapter 11 Internal Clock Source (S08ICSV3)

|        |                                      |     |
|--------|--------------------------------------|-----|
| 11.1   | Introduction .....                   | 226 |
| 11.1.1 | Features .....                       | 228 |
| 11.1.2 | Block Diagram .....                  | 228 |
| 11.1.3 | Modes of Operation .....             | 229 |
| 11.2   | External Signal Description .....    | 230 |
| 11.3   | Register Definition .....            | 230 |
| 11.3.1 | ICS Control Register 1 (ICSC1) ..... | 231 |
| 11.3.2 | ICS Control Register 2 (ICSC2) ..... | 233 |
| 11.3.3 | ICS Trim Register (ICSTRM) .....     | 233 |

| Section Number | Title                                                  | Page |
|----------------|--------------------------------------------------------|------|
| 11.3.4         | ICS Status and Control (ICSSC) .....                   | 234  |
| 11.4           | Functional Description .....                           | 236  |
| 11.4.1         | Operational Modes .....                                | 236  |
| 11.4.2         | Mode Switching .....                                   | 238  |
| 11.4.3         | Bus Frequency Divider .....                            | 239  |
| 11.4.4         | Low Power Bit Usage .....                              | 239  |
| 11.4.5         | DCO Maximum Frequency with 32.768 kHz Oscillator ..... | 239  |
| 11.4.6         | Internal Reference Clock .....                         | 239  |
| 11.4.7         | External Reference Clock .....                         | 240  |
| 11.4.8         | Fixed Frequency Clock .....                            | 240  |
| 11.4.9         | Local Clock .....                                      | 240  |

## Chapter 12

### Inter-Integrated Circuit (S08IICV2)

|        |                                              |     |
|--------|----------------------------------------------|-----|
| 12.1   | Introduction .....                           | 241 |
| 12.1.1 | Module Configuration .....                   | 241 |
| 12.1.2 | IIC Clock Gating .....                       | 241 |
| 12.1.3 | Features .....                               | 243 |
| 12.1.4 | Modes of Operation .....                     | 243 |
| 12.1.5 | Block Diagram .....                          | 243 |
| 12.2   | External Signal Description .....            | 244 |
| 12.2.1 | SCL — Serial Clock Line .....                | 244 |
| 12.2.2 | SDA — Serial Data Line .....                 | 244 |
| 12.3   | Register Definition .....                    | 244 |
| 12.3.1 | IIC Address Register (IICxA) .....           | 245 |
| 12.3.2 | IIC Frequency Divider Register (IICxF) ..... | 245 |
| 12.3.3 | IIC Control Register (IICxC1) .....          | 248 |
| 12.3.4 | IIC Status Register (IICxS) .....            | 248 |
| 12.3.5 | IIC Data I/O Register (IICxD) .....          | 249 |
| 12.3.6 | IIC Control Register 2 (IICxC2) .....        | 250 |
| 12.4   | Functional Description .....                 | 251 |
| 12.4.1 | IIC Protocol .....                           | 251 |
| 12.4.2 | 10-bit Address .....                         | 254 |
| 12.4.3 | General Call Address .....                   | 255 |
| 12.5   | Resets .....                                 | 255 |
| 12.6   | Interrupts .....                             | 255 |
| 12.6.1 | Byte Transfer Interrupt .....                | 255 |
| 12.6.2 | Address Detect Interrupt .....               | 256 |
| 12.6.3 | Arbitration Lost Interrupt .....             | 256 |
| 12.7   | Initialization/Application Information ..... | 257 |

| Section Number | Title | Page |
|----------------|-------|------|
|----------------|-------|------|

## Chapter 13

### Serial Communications Interface (S08SCIV4)

|        |                                                  |     |
|--------|--------------------------------------------------|-----|
| 13.1   | Introduction .....                               | 259 |
| 13.1.1 | Module Instances .....                           | 259 |
| 13.1.2 | Module Configuration .....                       | 259 |
| 13.1.3 | SCI Clock Gating .....                           | 259 |
| 13.1.4 | Features .....                                   | 261 |
| 13.1.5 | Modes of Operation .....                         | 261 |
| 13.1.6 | Block Diagram .....                              | 262 |
| 13.2   | Register Definition .....                        | 264 |
| 13.2.1 | SCI Baud Rate Registers (SCIxBDH, SCIxBDL) ..... | 264 |
| 13.2.2 | SCI Control Register 1 (SCIxC1) .....            | 265 |
| 13.2.3 | SCI Control Register 2 (SCIxC2) .....            | 266 |
| 13.2.4 | SCI Status Register 1 (SCIxS1) .....             | 267 |
| 13.2.5 | SCI Status Register 2 (SCIxS2) .....             | 269 |
| 13.2.6 | SCI Control Register 3 (SCIxC3) .....            | 270 |
| 13.2.7 | SCI Data Register (SCIxD) .....                  | 271 |
| 13.3   | Functional Description .....                     | 271 |
| 13.3.1 | Baud Rate Generation .....                       | 271 |
| 13.3.2 | Transmitter Functional Description .....         | 272 |
| 13.3.3 | Receiver Functional Description .....            | 273 |
| 13.3.4 | Interrupts and Status Flags .....                | 275 |
| 13.3.5 | Additional SCI Functions .....                   | 276 |

## Chapter 14

### Serial Peripheral Interface (S08SPIV4)

|        |                                             |     |
|--------|---------------------------------------------|-----|
| 14.1   | Introduction .....                          | 278 |
| 14.1.1 | Module Configuration .....                  | 278 |
| 14.1.2 | SPI Clock Gating .....                      | 278 |
| 14.1.3 | Features .....                              | 280 |
| 14.1.4 | Block Diagrams .....                        | 280 |
| 14.1.5 | SPI Baud Rate Generation .....              | 282 |
| 14.2   | External Signal Description .....           | 283 |
| 14.2.1 | SPSCK — SPI Serial Clock .....              | 283 |
| 14.2.2 | MOSI — Master Data Out, Slave Data In ..... | 283 |
| 14.2.3 | MISO — Master Data In, Slave Data Out ..... | 283 |
| 14.2.4 | $\overline{SS}$ — Slave Select .....        | 283 |
| 14.3   | Modes of Operation .....                    | 284 |
| 14.3.1 | SPI in Stop Modes .....                     | 284 |
| 14.4   | Register Definition .....                   | 284 |
| 14.4.1 | SPI Control Register 1 (SPIxC1) .....       | 284 |
| 14.4.2 | SPI Control Register 2 (SPIxC2) .....       | 285 |

| Section Number | Title                                 | Page |
|----------------|---------------------------------------|------|
| 14.4.3         | SPI Baud Rate Register (SPIxBR) ..... | 286  |
| 14.4.4         | SPI Status Register (SPIxS) .....     | 287  |
| 14.4.5         | SPI Data Register (SPIxD) .....       | 288  |
| 14.5           | Functional Description .....          | 289  |
| 14.5.1         | Master Mode .....                     | 289  |
| 14.5.2         | Slave Mode .....                      | 290  |
| 14.5.3         | SPI Clock Formats .....               | 291  |
| 14.5.4         | Special Features .....                | 293  |
| 14.5.5         | SPI Interrupts .....                  | 295  |
| 14.5.6         | Mode Fault Detection .....            | 295  |

## Chapter 15

### Real-Time Counter (S08RTCV1)

|        |                                               |     |
|--------|-----------------------------------------------|-----|
| 15.1   | Introduction .....                            | 297 |
| 15.1.1 | RTC Clock Gating .....                        | 297 |
| 15.1.2 | Features .....                                | 299 |
| 15.1.3 | Modes of Operation .....                      | 299 |
| 15.1.4 | Block Diagram .....                           | 300 |
| 15.2   | External Signal Description .....             | 300 |
| 15.3   | Register Definition .....                     | 300 |
| 15.3.1 | RTC Status and Control Register (RTCSC) ..... | 301 |
| 15.3.2 | RTC Counter Register (RTCCNT) .....           | 302 |
| 15.3.3 | RTC Modulo Register (RTCMOD) .....            | 302 |
| 15.4   | Functional Description .....                  | 302 |
| 15.4.1 | RTC Operation Example .....                   | 303 |
| 15.5   | Initialization/Application Information .....  | 304 |

## Chapter 16

### Timer/Pulse-Width Modulator (S08TPMV3)

|        |                                                 |     |
|--------|-------------------------------------------------|-----|
| 16.1   | Introduction .....                              | 306 |
| 16.1.1 | TPM External Clock .....                        | 306 |
| 16.1.2 | Module Instances .....                          | 306 |
| 16.1.3 | Module Configuration .....                      | 306 |
| 16.1.4 | TPM Clock Gating .....                          | 307 |
| 16.1.5 | Features .....                                  | 308 |
| 16.1.6 | Modes of Operation .....                        | 308 |
| 16.1.7 | Block Diagram .....                             | 309 |
| 16.2   | Signal Description .....                        | 311 |
| 16.2.1 | Detailed Signal Descriptions .....              | 311 |

# Chapter 1

## Device Overview

The MC9S08LG32 and MC9S08LG16 are the members of the low-cost, low-power, and high-performance HCS08 family of 8-bit microcontroller units (MCUs). All MCUs in the family use the enhanced HCS08 core and are available with a variety of memory sizes and package types.

The MC9S08LG32 series MCUs are targeted to serve automotive, consumer and industrial markets. Please check the ordering part numbers for different qualification tier products in *Ordering Information section of MC9S08LG32 Data Sheet*.

### 1.1 Devices in the MC9S08LG32 Series

Table 1-1 summarizes the feature set available in the MC9S08LG32 series of MCUs.

**Table 1-1. MC9S08LG32 series Features by MCU and Package**

| Feature            | MC9S08LG32       |                  |                  | MC9S08LG16       |                  |
|--------------------|------------------|------------------|------------------|------------------|------------------|
| Flash size (bytes) | 32,768           |                  |                  | 18,432           |                  |
| RAM size (bytes)   | 1984             |                  |                  |                  |                  |

| IIC                | yes              |                  |                  |                  |                  |
| IRQ                | yes              |                  |                  |                  |                  |
| KBI                | 8 pin            |                  |                  |                  |                  |
| GPIOs              | 69               | 53               | 39               | 53               | 39               |
| RTC                | yes              |                  |                  |                  |                  |
| MTIM               | yes              |                  |                  |                  |                  |
| SCI1               | yes              |                  |                  |                  |                  |
| SCI2               | yes              |                  |                  |                  |                  |
| SPI                | yes              |                  |                  |                  |                  |
| TPM1 channels      | 2                |                  |                  |                  |                  |
| TPM2 channels      | 6                |                  |                  |                  |                  |
| XOSC               | yes              |                  |                  |                  |                  |

## 1.2 MCU Block Diagram

The block diagram in Figure 1-1 shows the structure of the MC9S08LG32 series MCU.

Figure 1-1. MC9S08LG32 Series Block Diagram

Table 1-2 provides the functional version of the on-chip modules.

**Table 1-2. Module Versions**

| Module                            |         | Version |
|-----------------------------------|---------|---------|
| Analog-to-Digital Converter       | (ADC12) | 1       |
| Central Processor Unit            | (CPU)   | 5       |
| Inter-Integrated Circuit          | (IIC)   | 2       |
| Internal Clock Source             | (ICS)   | 3       |
| Keyboard Interrupt                | (KBI)   | 2       |
| Liquid Crystal Display Module     | (LCD)   | 1       |
| Low Power Oscillator              | (XOSC)  | 1       |
| Modulo Timer                      | (MTIM)  | 1       |
| On-Chip In-Circuit Debug/Emulator | (DBG)   | 3       |
| Real Time Counter                 | (RTC)   | 1       |
| Serial Communications Interface   | (SCI)   | 4       |
| Serial Peripheral Interface       | (SPI)   | 4       |
| Timer Pulse Width Modulator       | (TPM)   | 3       |

## 1.3 System Clock Distribution

Figure 1-2 shows a simplified clock connection diagram of the ICS. Some modules in the MCU have selectable clock inputs as shown. The clock inputs to the modules indicate the clock(s) that are used to drive the module function. All memory-mapped registers associated with the modules are clocked with BUSCLK. The ICS supplies the following clock sources:

- ICSOUT — This clock source is used as the CPU clock and is divided by 2 to generate the peripheral bus clock, BUSCLK. Control bits in the ICS control registers determine which of the three clock sources is connected:
  - Internal reference clock
  - External reference clock
  - Frequency-locked loop (FLL) output
 For more information on configuring the ICSOUT clock, see [Chapter 11, “Internal Clock Source \(S08ICSV3\).”](#)
- ICSLCLK — This clock source is derived from the digitally controlled oscillator (DCO) of the ICS when the ICS is configured to run off the internal or external reference clock. The development tools can select this internal self-clocked source (~ 8 MHz) to speed up the BDC communications in systems where the bus clock is slow.
- ICSECLK — This is an external reference clock and can be selected as the alternate clock for ADC. The “Optional External Reference Clock” section in [Chapter 11, “Internal Clock Source \(S08ICSV3\).”](#) explains the ICSECLK in more detail. For more information regarding the use of ICSECLK with this module, see [Chapter 10, “Analog-to-Digital Converter \(S08ADC12V1\).”](#)
- ICSIRCLK — This is an internal reference clock and can be selected as the RTC clock source, or as ALTCLK source for the LCD. [Chapter 11, “Internal Clock Source \(S08ICSV3\).”](#) explains the ICSIRCLK in more detail. For more information regarding use of ICSIRCLK with these modules, see [Chapter 15, “Real-Time Counter \(S08RTCV1\).”](#) and [Chapter 9, “LCD Module \(S08LCDLPV1\).”](#)
- ICSFFCLK — This fixed frequency clock (FFCLK) is generated after it is synchronized with the bus clock. The frequency of the ICSFFCLK is determined by the settings of the ICS. For more information, see the “Fixed Frequency Clock” section in [Chapter 11, “Internal Clock Source \(S08ICSV3\).”](#) It can be selected as a clock source for the MTIM and TPM modules. For information regarding use of ICSFFCLK with these modules, see [Chapter 16, “Timer/Pulse-Width Modulator \(S08TPMV3\).”](#) and [Chapter 17, “Modulo Timer \(S08MTIMV1\).”](#)
- LPOCLK — This clock is generated from an internal low power oscillator (LPO) that is completely independent of the ICS module. The LPOCLK can be selected as the clock source to the COP and RTC module. See [Section 5.4, “Computer Operating Properly \(COP\) Watchdog,”](#) and [Chapter 15, “Real-Time Counter \(S08RTCV1\).”](#) for details on using the LPOCLK with these modules.
- OSCOUT — This is the output of the XOSC module and can be selected as the LCD and RTC clock source. This clock source can be used for LCD and RTC in stop2 mode. For more information regarding use of OSCOUT with these modules, see [Chapter 15, “Real-Time Counter \(S08RTCV1\).”](#) and [Chapter 9, “LCD Module \(S08LCDLPV1\).”](#)

- **TPMCLK** — The TPMCLK is an optional external clock source for the TPM modules. The TPMCLK must be limited to 1/4th of the frequency of the bus clock for synchronization. For more information, see the “External TPM Clock Sources” section in [Chapter 16, “Timer/Pulse-Width Modulator \(S08TPMV3\).”](#)
- **TMRCLK** — The TMRCLK is an optional external clock source for the MTIM module. For more information, see [Chapter 17, “Modulo Timer \(S08MTIMV1\).”](#)

### NOTE

ICSERCLK is a gated version of OSCOUT. ICSECLK is not available in STOP modes while OSCOUT is available if ERCLKEN and EREFSTEN are set.

**Figure 1-2. System Clock Distribution Diagram**

## Chapter 2

# Pins and Connections

### 2.1 Introduction

This section describes signals that connect to the package pins. It includes pinout diagrams, recommended system connections, and detailed discussions of signals.

### 2.2 Device Pin Assignment

This section shows the pin assignments for MC9S08LG32 series. The priority of functions on a pin is in ascending order from left to right and bottom to top. Another view of pinouts and function priority is given in [Table 2-1](#).

Figure 2-1. 80-Pin LQFP

**NOTE**

$V_{REFH}/V_{REFL}$  are internally connected to  $V_{DDA}/V_{SSA}$ .

Figure 2-2. 64-Pin LQFP

### NOTE

$V_{REFH}/V_{REFL}$  are internally connected to  $V_{DDA}/V_{SSA}$ .

Figure 2-3. 48-Pin LQFP

**NOTE**

$V_{REFH}/V_{REFL}$  are internally connected to  $V_{DDA}/V_{SSA}$ .

## 2.3 Recommended System Connections

Figure 2-4 shows pin connections that are common to MC9S08LG32 series application systems.

## NOTES:

- RESET pin can only be used to reset into user mode, you can not enter BDM using RESET pin. To enter BDM, hold MS low during POR or write a 1 to BDFR in SBDFFR with MS low after issuing BDM command.
- RC filter on RESET pin recommended for noisy environments.
- When PTC6 is configured as RESET, pin becomes bi-directional with output being open-drain drive containing an internal pullup device.
- When PTC5 is configured as BKGD, pin becomes bi-directional.
- LCD mode shown is for Charge pump enabled, other configurations are necessary for different LCD modes.

**Figure 2-4. Basic System Connections**

### 2.3.1 Power

$V_{DD}$  and  $V_{SS}$  are primary power supply pins for the MCU. This voltage source supplies power to all I/O buffer circuitry and to an internal voltage regulator. The internal voltage regulator provides a regulated lower-voltage source for the CPU and other internal circuitry of the MCU.

The LCD/GPIO can be powered differently. For additional information, see [Chapter 6, “Parallel Input/Output Control.”](#)

Typically, application systems have two separate capacitors across the power pins. In this case, there must be a bulk electrolytic capacitor, such as a 10- $\mu$ F tantalum capacitor, to provide bulk charge storage for the overall system, and a 0.1- $\mu$ F ceramic bypass capacitor located as near to the MCU power pins as practical to suppress high-frequency noise.

$V_{DDA}$  and  $V_{SSA}$  are the analog power supply pins for the MCU. This voltage source supplies power to the ADC modules.

$V_{REFH}$  and  $V_{REFL}$  pins are the voltage reference high and the voltage reference low inputs, respectively, for the ADC module. For this MCU,  $V_{DDA}$  shares the  $V_{REFH}$  pin and  $V_{SSA}$  shares the  $V_{REFL}$  pin.

### 2.3.2 Oscillator

Immediately after reset, the MCU uses an internally generated clock provided by the internal clock source (ICS) module. The ICS can be configured to run off the on-chip oscillator (ICSERCLK). The output of the oscillator (OSCOUT) is used to run the RTC and LCD bypassing the ICS. The oscillator can be configured to run in stop2 or stop3 modes. For more information, see [Section 1.3, “System Clock Distribution,”](#) and [Chapter 11, “Internal Clock Source \(S08ICSV3\).”](#)

The oscillator (XOSC) in this MCU is a Pierce oscillator that can accommodate a crystal or ceramic resonator. An external clock source can optionally be connected to the EXTAL input pin.

Refer to [Figure 2-4](#) for the following discussion.  $R_S$  (when used) and  $R_F$  must be low-inductance resistors, such as carbon composition resistors. Wire-wound resistors and some metal film resistors have too much inductance.  $C_1$  and  $C_2$  normally must be high-quality ceramic capacitors that are specifically designed for high-frequency applications.

$R_F$  provides a bias path to keep the EXTAL input in its linear range during crystal startup; its value is not generally critical. Typical systems use 1 M $\Omega$  to 10 M $\Omega$ . Higher values are sensitive to humidity and lower values reduce gain and (in extreme cases) could prevent startup.

$C_1$  and  $C_2$  are typically in the 5 pF to 25 pF range and are chosen to match the requirements of a specific crystal or resonator. Be sure to consider the printed circuit board (PCB) capacitance and the MCU pin capacitance when selecting  $C_1$  and  $C_2$ . The crystal manufacturer typically specifies a load capacitance, which is the series combination of  $C_1$  and  $C_2$  (which are usually of the same size). As a first-order approximation, use 10 pF as an estimate of combined pin and PCB capacitance for each oscillator pin (EXTAL and XTAL).

### 2.3.3 $\overline{\text{RESET}}$

After a power-on reset (POR), the PTC6/ $\overline{\text{RESET}}$  pin defaults to  $\overline{\text{RESET}}$ . Clearing RSTPE in SOPT1 configures the pin to be an output-only pin with an open-drain drive and an internal pullup device. RSTPE is a write-once bit; so once written, it becomes read-only until the next reset. This bit is sticky and is reset only at POR or LVD; it retains its value across other resets. When enabled, the  $\overline{\text{RESET}}$  pin can be used to reset the MCU from an external source when the pin is driven low.

Internal POR and low-voltage reset circuitry typically make external reset circuitry unnecessary. This pin is normally connected to the standard 6-pin background debug connector, so a development system can directly reset the MCU system. A manual external reset can be added by supplying a simple switch to ground (pull reset pin low to force a reset).

Whenever any non-POR reset is initiated (whether from an external signal or from an internal system), the enabled  $\overline{\text{RESET}}$  pin is driven low for about 34 bus cycles. The reset circuitry decodes the cause of reset and records it by setting a corresponding bit in the system reset status register (SRS).

#### NOTE

This pin does not contain a clamp diode to  $V_{DD}$  and must not be driven above  $V_{DD}$ .

The voltage on the internally pulled up  $\overline{\text{RESET}}$  pin, when measured, is below  $V_{DD}$ . The internal gates connected to this pin are pulled to  $V_{DD}$ . If the  $\overline{\text{RESET}}$  pin is required to drive to a  $V_{DD}$  level, an external pullup must be used.

In EMC-sensitive applications, an external RC filter is recommended on the  $\overline{\text{RESET}}$  pin, if enabled.

### 2.3.4 Background / Mode Select (BKGD/MS)

During POR or background debug force reset (for more information, see [Section 5.8.3, “System Background Debug Force Reset Register \(SBDFFR\)”](#)), the PTC5/BKGD/MS pin functions as a mode select pin. Immediately after any reset, the pin functions as the background pin and can be used for background debug communication. When BKGD/MS function is enabled with BKGDPE = 1, an internal pullup device automatically becomes active. Clearing BKGDPE in SOPT1 configures the pin to be an output-only pin.

The background debug communication function is enabled when BKGDPE in SOPT1 is set. BKGDPE is set following any reset of the MCU and must be cleared to use the PTC5/BKGD/MS pin's alternative pin functions.

After any reset, if nothing is connected to this pin, the MCU enters normal operating mode. If a debug system is connected to the 6-pin standard background debug header, it can hold BKGD/MS low. It can do this during a POR or after issuing a background debug force reset. This forces the MCU to active background mode.

The BKGD/MS pin is used primarily with BDC communications, and features a custom protocol that uses 16 clock cycles of the target MCU's BDC clock per bit time. The target MCU's BDC clock can run as fast

as the bus clock, so no significant capacitance must be connected to the BKGD/MS pin that could interfere with background serial communications.

Although the BKGD/MS pin is a pseudo open-drain pin, the background debug communication protocol provides brief, actively driven, high speedup pulses to ensure fast rise times. Small capacitances from cables and the absolute value of the internal pullup device play a minimal role in determining rise and fall times on the BKGD/MS pin.

#### NOTE

Ensure this pin is not low when the part is coming out of POR or BDFR reset. Exit from stop2 causes POR, therefore POR includes the exit from stop2. Because the pin defaults to BKGD/MS function out of reset, a low value on this pin while coming out of POR or BDFR causes the part to boot into BDM mode. If this pin is not being used at all, it must be tied high. A pullup is recommended when using this pin as GPIO.

### 2.3.5 IRQ

The PTF2/IRQ pin can be used as a wakeup source for the MCU. For stop2 wakeup, this pin has an analog path which is enabled based on the input buffer enable for this pin, irrespective of whether or not this pin is configured as IRQ.

#### NOTE

Care needs to be taken that if this pin is configured as input, it is not low during stop2 mode, otherwise the part exits stop2 mode irrespective of whether this pin is configured as IRQ or not. This pin can be disabled as a wakeup source if it is configured as an output.

### 2.3.6 LCD Pins

#### 2.3.6.1 LCD Power Pins

The  $V_{LL1}$ ,  $V_{LL2}$ ,  $V_{LL3}$ ,  $V_{cap1}$ , and  $V_{cap2}$  pins are dedicated to providing power to the LCD module. On 64-pin and 80-pin packages the  $V_{LL3\_2}$  pin must be tied to  $V_{LL3}$  on board. For more information about LCD pins, see [Chapter 9, “LCD Module \(S08LCDLPV1\).”](#)

#### 2.3.6.2 LCD Driver Pins

The MC9S08LG32 series of MCUs provide 45 LCD driver pins for the 80-pin packages, 37 pins for the 64-pin packages, and 29 pins for the 48-pin packages. Each LCD pin has pin enable control, so you can choose to use any LCD pin as either LCD driver or GPIO. If the LCD module is disabled, the LCD driver pins become high-impedance and the LCD/GPIO pins are configured as GPIO. The LCD pins are open-drain after resets except for stop2 wakeup. For more information about LCD driver pins, see [Chapter 9, “LCD Module \(S08LCDLPV1\).”](#)

Pins that have shared function with the LCD have special behavior based on the state of the VSUPPLY bits in the LCDSUPPLY register. These pins can operate as full complementary drive or open drain drive

depending on the VSUPPLY bits. When  $V_{LL3}$  is connected to  $V_{DD}$  externally, VSUPPLY = 11, FCDEN = 1, and RVEN = 0, the pins operate as full complementary drive. For all other VSUPPLY modes, the LCD/GPIO operates as open drain.

### NOTE

For GPIO muxed with LCD pins, full complimentary or open drain drive is controlled by the LCD controller. When LCD pins are configured as open drain GPIOs, then the internal pullup is not disabled in output mode and is controlled by the GPIO pull control register. This can cause some leakage from the pads if a pullup is enabled and a zero is being driven.

## 2.3.7 General-Purpose I/O (GPIO) and Peripheral Ports

The MC9S08LG32 series of MCUs support up to 69 GPIO pins including 2 output-only pins that are shared with on-chip peripheral functions (timers, serial I/O, LCD, ADC, etc.). The GPIO output-only pins (PTC5/BKGD/MS and PTC6/RESET) are bi-directional when configured as BKGD and RESET, respectively.

GPIO that is muxed with LCD pins can be configured to reference  $V_{DD}$  or  $V_{LL3}$ . See [Section 2.3.6.2, “LCD Driver Pins,”](#) for more details.

When a port pin is configured as a general-purpose output or a peripheral uses the port pin as an output, the software can select one of the two drive strengths and can enable or disable the slew rate control. When a port pin is configured as a general-purpose input or a peripheral uses the port pin as an input, the software can enable a pullup device.

When an on-chip peripheral system is controlling a pin, the data direction control bits still determine what is read from port data registers even though the peripheral module controls the pin direction by controlling an enable for the pin’s output buffer. For information about controlling these pins as general-purpose I/O pins, see [Chapter 6, “Parallel Input/Output Control.”](#)

### NOTE

- To avoid extra current drain from floating input pins, the reset initialization routine in the application program must either enable on-chip pullup devices or change the direction of unused or non-bonded pins to outputs so they do not float.
- When using  $\overline{\text{RESET}}$  pin as bi-directional reset and LCD pins as open-drain GPIO, the internal pullups are not disabled when these pins are used in output mode. This can cause some current leakage through the pads if zero is driven. This is also true for stop2 mode.

**Table 2-1. Pin Availability by Package Pin-Count**

| Packages |    |    | <-- Lowest Priority --> Highest |       |       |       |       |

## Chapter 3

# Modes of Operation

### 3.1 Introduction

This chapter describes the operating modes of the MC9S08LG32 series. It also describes entry, exit, and the functionality of each mode.

### 3.2 Features

- Active background mode for code development.
- Run mode — CPU clocks can be run at full speed and the internal supply is fully regulated.
- Wait mode — CPU shuts down to conserve power; system clocks are running and full regulation is maintained.
- Stop modes — System clocks are stopped and voltage regulator is in standby.
  - Stop3 — All internal circuits are powered for fast recovery.
  - Stop2 — Partial power down of internal circuits, RAM content is retained, and the I/O states are held.

### 3.3 Run Mode

This is the normal operating mode for the MC9S08LG32 series. In this mode, the CPU executes code from internal memory with execution beginning at the address fetched from memory at 0xFFFFE–0xFFFF after reset.

### 3.4 Active Background Mode

The active background mode functions are managed through the BDC in the HCS08 core. The BDC and the on-chip debug module (DBG), provide the means for analyzing MCU operation during software development.

Active background mode is entered by any of six methods:

- When the BKGD/MS pin is low during POR
- When the BKGD/MS pin is low immediately after issuing a background debug force reset (for more information, see [Section 5.8.3, “System Background Debug Force Reset Register \(SBD FR\)”](#))
- When a BACKGROUND command is received through the BKGD/MS pin
- When a BGND instruction is executed
- When encountering a BDC breakpoint

- When encountering a DBG breakpoint

### NOTE

The MCU needs to be unsecure for the last four methods.

After entering active background mode, the CPU is held in a suspended state while it waits for serial background commands instead of executing instructions from the user application program.

The background commands are of two types:

- Non-intrusive commands — These commands are defined as commands that can be issued while the user program is running. Non-intrusive commands can be issued through the BKGD pin while the MCU is in run mode. Non-intrusive commands can also be executed when the MCU is in active background mode. Non-intrusive commands include:
  - Memory access commands
  - Memory-access-with-status commands
  - BDC register access commands
  - The BACKGROUND command
- Active background commands— These commands can only be executed while the MCU is in active background mode. Active background commands include commands to:
  - Read or write CPU registers
  - Trace one user program instruction at a time
  - Leave active background mode to return to the user application program (GO)

Active background mode is used to program a bootloader or user application program into the flash program memory before the MCU is operated in run mode for the first time. When the MC9S08LG32 series is shipped from the Freescale Semiconductor factory, the flash program memory is erased by default, unless specifically noted. As a result, no program can be executed in run mode until the flash memory is initially programmed. Active background mode can also be used to erase and reprogram the flash memory after it has been previously programmed.

For additional information about the active background mode, refer to the [Chapter 18, “Development Support.”](#)

## 3.5 Wait Mode

Wait mode is entered by executing a WAIT instruction. Upon execution of the WAIT instruction, the CPU enters a low-power state in which it is not clocked. The I bit in CCR is cleared when the CPU enters wait mode, enabling interrupts. When an interrupt request occurs, the CPU exits the wait mode and resumes processing beginning with the stacking operations that lead to the interrupt service routine.

While the MCU is in wait mode, there are some restrictions on which background debug commands can be used. Only the BACKGROUND command and memory-access-with-status commands are available when the MCU is in wait mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the MCU is either in stop or wait mode. The BACKGROUND command can be used to wake the MCU from the wait mode and enter active background mode.

The clocks to the peripherals are controlled by SCGC registers in this mode. For lowest possible current in WAIT mode, all peripherals which are not required must be clock gated before entering in this mode.

## 3.6 Stop Modes

One of the two stop modes (stop2 or stop3) is entered upon execution of a STOP instruction when the STOPE bit in the system option 1 register (SOPT1) is set. In both the stop modes, the bus and the CPU clocks are halted.

- In stop3, the voltage regulator is in standby and ICS module can be configured to leave the reference clocks running.
- In stop2, the voltage regulator is in partial powerdown.

See [Chapter 11, “Internal Clock Source \(S08ICSV3\),”](#) for more information.

If the STOPE bit is not set when the CPU executes a STOP instruction, the MCU does not enter either of the stop modes and an illegal opcode reset is forced. Stop modes are selected by setting the appropriate bits in the System Power Management Status and Control Registers, SPMSC1 and SPMSC2.

[Table 3-1](#) shows all control bits that affect the stop mode selection and the modes selected under various conditions. The selected mode is entered following the execution of a STOP instruction.

**Table 3-1. Stop Mode Selection**

| Register | SOPT1 | BDCSCR             | SPMSC1              |       | SPMSC2 | Stop Mode                                                              |
|----------|-------|--------------------|---------------------|-------|--------|------------------------------------------------------------------------|
| Bit name | STOPE | ENBDM <sup>1</sup> | LVDE                | LVDSE | PPDC   |                                                                        |
|          | 0     | x                  | x                   |       | x      | Stop modes disabled; illegal opcode reset if STOP instruction executed |
|          | 1     | 1                  | x                   |       | x      | Stop3 with BDM enabled <sup>2</sup>                                    |
|          | 1     | 0                  | Both bits must be 1 |       | x      | Stop3 with voltage regulator active                                    |
|          | 1     | 0                  | Either bit a 0      |       | 0      | Stop3 (with Voltage regulator in Standby)                              |
|          | 1     | 0                  | Either bit a 0      |       | 1      | Stop2                                                                  |

<sup>1</sup> ENBDM is located in the BDCSCR that is only accessible through BDC commands, see [Chapter 18, “Development Support.”](#)

<sup>2</sup> When in stop3 mode with BDM enabled, the S<sub>ID</sub>D is near the R<sub>ID</sub>D levels because internal clocks are enabled.

### 3.6.1 Stop2 Mode

To enter stop2, execute a STOP instruction under the conditions as shown in [Table 3-1](#). Most of an internal circuitry of the MCU is powered off in stop2 mode with an exception of the RAM, the low power oscillator, RTC and the LCD module. Upon entering stop2 mode, all I/O pin control signals are latched so that the pins retain their states during stop2. The LCD driver pins continue to drive the signals necessary to display the LCD data.

To exit from stop2 mode, assert the wakeup pins (PTC6/ $\overline{\text{RESET}}$  or PTF2/IRQ) or through RTC interrupt or POR.

## NOTE

When PTC6/ $\overline{\text{RESET}}$  or PTF2/IRQ is used as an active low wakeup source it must be configured as an input prior to executing a STOP instruction. PTC6/ $\overline{\text{RESET}}$  and PTF2/IRQ can be disabled as a wakeup if it is configured as output port. For lowest power consumption in stop2, these pins must not be left open if configured as input (enable the internal pullup or tie an external pullup device).

Upon wakeup from stop2 mode, the MCU starts up as from a POR with the following sequence:

- All module control and status registers are reset, except for SPMSC1-SPMSC2, RTCSC, RTCCNT, RTCMOD, LCDPEN<sub>x</sub>, LCDBPEN<sub>x</sub>, and LCDWFR<sub>x</sub>.
- The LVD reset function is enabled and the MCU remains in the reset state if V<sub>DD</sub> is below the LVD trip point.
- The CPU takes the reset vector

In addition to the above, upon waking up from stop2 mode, the PPDF bit in SPMSC2 is set. This flag is used to direct user code to go to a stop2 recovery routine. PPDF remains set and the I/O pin states remain latched until a 1 is written to PPDACK in SPMSC2.

If using the low-power oscillator during stop2 mode, you reconfigure the ICSC2 register that contains oscillator control bits before PPDACK is written.

To maintain I/O states for pins that were configured as GPIO before entering stop2, you restore the contents of the I/O port registers to the port registers before writing to the PPDACK bit. If the port registers are not restored from RAM before writing to PPDACK, then the pins are switched to their reset states when PPDACK is written.

For pins that were configured as peripheral I/O, you reconfigure the peripheral module that interfaces to the pin before writing to the PPDACK bit. If the peripheral module is not enabled before writing to PPDACK, the pins are controlled by their associated port control registers when the I/O latches are opened.

If enabled, LCD functionality continues in stop2 mode and upon stop2 recovery the LCD control registers (LCDC0, LCDC1, LCDSUPPLY, LCDRVC, LCDBCTL, and LCDS) must be re-initialized before writing the PPDACK.

### 3.6.2 Stop3 Mode

To enter stop3 mode, execute a STOP instruction under the conditions shown in [Table 3-1](#). The states of all the internal registers and logic, RAM contents, and I/O pin states are maintained.

Stop3 mode can be exited by asserting  $\overline{\text{RESET}}$ , or by an interrupt from one of the following sources: LVW, RTC, ADC, IRQ, SCI1, SCI2, LCD, or KBI.

If stop3 is exited by means of the  $\overline{\text{RESET}}$  pin, the MCU is reset and operation resumes after taking the reset vector. Using an internal interrupt sources to exit, results in the MCU taking an appropriate interrupt vector.

### 3.6.3 Active BDM Enabled in Stop Mode

Entry into active background mode from run mode is enabled if the ENBDM bit in BDCSCR is set. This register is described in [Chapter 18, “Development Support.”](#) If ENBDM is set when the CPU executes a STOP instruction, the system clocks to the background debug logic remain active when the MCU enters the stop mode. Because of this, background debug communication remains possible. In addition, the voltage regulator does not enter its low-power standby state, but maintains full internal regulation. If you attempt to enter the stop2 mode with ENBDM set, the MCU enters the stop3 mode instead.

Most background commands are not available in the stop mode. The memory-access-with-status commands do not allow memory access, but they report an error indicating that the MCU is in either stop or wait mode. The BACKGROUND command can be used to wake the MCU from the stop mode and enter the active background mode if the ENBDM bit is set. After entering the background debug mode, all background commands are available.

### 3.6.4 LVD Enabled in Stop Mode

The LVD system can generate a reset or an interrupt when the supply voltage drops below the LVD or LVW threshold respectively. If the LVD is enabled in stop (LVDE and LVDSE bits in SPMSC1 both set), the voltage regulator remains active during stop mode. If you attempt to enter the stop2 mode with LVD enabled for stop, the MCU enters the stop3 mode instead.

## 3.7 Mode Selection

Several control signals are used to determine the current operating mode of the device. [Table 3-2](#) shows the conditions for each of the device’s operating modes.

**Table 3-2. Power Mode Selections**

| Mode of Operation                                                                                                                                      | BDCSCR<br>BDM      | SPMSC1<br>PMC |       | SPMSC2<br>PMC | CPU & Periph CLKs                                                               | Affects on<br>Sub-System |                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|---------------|-------|---------------|---------------------------------------------------------------------------------|--------------------------|------------------------------------------|
|                                                                                                                                                        | ENBDM <sup>1</sup> | LVDE          | LVDSE | PPDC          |                                                                                 | BDM<br>Clock             | Voltage<br>Regulator                     |
| RUN mode                                                                                                                                               | 0                  | x             | x     | x             | On. ICS in any mode.                                                            | off                      | on                                       |
|                                                                                                                                                        | 1                  |               |       |               |                                                                                 | on                       |                                          |
| WAIT mode—(Assumes<br>WAIT instruction executed.)                                                                                                      | 0                  | x             | x     | x             | CPU clock is off;<br>peripheral clocks on. ICS<br>state is same as RUN<br>mode. | off                      | on                                       |
|                                                                                                                                                        | 1                  |               |       |               |                                                                                 | on                       |                                          |
| Stop3—(Assumes STOPE<br>bit is set and STOP<br>instruction executed.) Note<br>that stop3 is used in place of<br>stop2 if the BDM or LVD is<br>enabled. | 0                  | 0             | x     | 0             | ICS in STOP. |                                                                                                                                           | ENBDM <sup>1</sup> | LVDE          | LVDSE | PPDC          |                                       | BDM<br>Clock             | Voltage<br>Regulator |
| Stop2—(Assumes STOPE<br>bit is set and STOP<br>instruction executed.) If BDM<br>or LVD is enabled, stop3 is<br>invoked rather than stop2. | 0                  | 0             | x     | 1             | OSCOOUT optionally on. <sup>2,3</sup> | off                      | partial<br>powerdown |
|                                                                                                                                           |                    | 1             | 0     |               |                                       |                          |                      |

<sup>1</sup> ENBDM is located in the BDC status and control register (BDCSCR) which is write-accessible only through BDC commands.

<sup>2</sup> Configured within the ICS module based on the settings of IREFSTEN, EREFSTEN, IRCLKEN and ERCLKEN.

<sup>3</sup> In stop2, the CPU, flash, ICS and all peripheral modules are powered down except for the RTC and LCD.

| Mode  | Regulator State   |
|-------|-------------------|
| Run   | Full on           |
| Wait  | Full on           |
| Stop3 | Standby           |
| Stop2 | Partial powerdown |

**Figure 3-1. Allowable Power Mode Transitions for the MC9S08LG32 Series**

Figure 3-1 illustrates mode state transitions allowed between the legal states shown in Table 3-1.

Table 3-3 defines triggers for the various state transitions shown in Figure 3-1.

**Table 3-3. Triggers for Transitions Shown in Figure 3-1.**

| Transition # | From  | To    | Trigger                                                           |
|--------------|-------|-------|-------------------------------------------------------------------|
| 1            | Run   | Wait  | WAIT instruction                                                  |
|              | Wait  | Run   | Interrupt or reset                                                |
| 2            | Run   | Stop3 | Pre-configure settings shown in Table 3-1, issue STOP instruction |
|              | Stop3 | Run   | Interrupt or reset                                                |

**Table 3-3. Triggers for Transitions Shown in [Figure 3-1](#). (continued)**

| Transition # | From  | To    | Trigger                                                                                  |
|--------------|-------|-------|------------------------------------------------------------------------------------------|
| 3            | Run   | Stop2 | Pre-configure settings shown in <a href="#">Table 3-1</a> , issue STOP instruction       |
|              | Stop2 | Run   | assert zero on wakeup pins (PTC6/RESET or PTF2/IRQ) <sup>1</sup> or RTC interrupt or POR |

<sup>1</sup> An analog connection from these pins to the on-chip regulator wakes up the regulator, which initiates a power-on-reset sequence.

### 3.7.1 On-Chip Peripheral Modules in Stop Modes

When the MCU enters any stop mode, system clocks to the internal peripheral modules are stopped. Even in the exception case (ENBDM = 1), where clocks to the background debug logic continue to operate, clocks to the peripheral systems are halted to reduce power consumption. Refer to [Section 3.6.1, “Stop2 Mode,”](#) and [Section 3.6.2, “Stop3 Mode,”](#) for specific information on system behavior in stop modes.

**Table 3-4. Stop and Low Power Mode Behavior**

| Peripheral         | Mode                       |                            |
|--------------------|----------------------------|----------------------------|
|                    | Stop2                      | Stop3                      |
| CPU                | Off                        | Standby                    |
| RAM                | Standby                    | Standby                    |
| FLASH              | Off                        | Standby                    |
| Port I/O Registers | Off                        | Standby                    |
| ADC                | Off                        | Optionally On <sup>1</sup> |
| BDM                | Off <sup>2</sup>           | Optionally On              |
| COP                | Off                        | Off                        |
| ICS                | Off                        | Optionally On <sup>3</sup> |
| IIC                | Off                        | Standby                    |
| IRQ                | Wake Up                    | Optionally On              |
| KBI                | Off                        | Optionally On              |
| LVD/LVW            | Off <sup>4</sup>           | Optionally On              |
| LCD                | Optionally On              | Optionally On              |
| MTIM               | Off                        | Optionally On              |
| SC1x               | Off                        | Standby                    |
| SPI                | Off                        | Standby                    |
| RTC                | Optionally On              | Optionally On              |
| TPMx               | Off                        | Standby                    |
| Voltage Regulator  | Partial Powerdown          | Optionally On <sup>5</sup> |
| XOSC               | Optionally On <sup>6</sup> | Optionally On <sup>6</sup> |
| I/O Pins           | States Held                | Peripheral Control         |

<sup>1</sup> Requires the asynchronous ADC clock. For stop3, LVD must be enabled to run in stop if converting the bandgap channel.

<sup>2</sup> If ENBDM is set when entering stop2, the MCU will actually enter stop3.

<sup>3</sup> IRCLKEN and IREFSTEN set in ICSC1, else in standby.

<sup>4</sup> If LVDSE is set when entering stop2, the MCU will actually enter stop3.

<sup>5</sup> Requires the LVD to be enabled, else in standby. See [Section 3.6.4, “LVD Enabled in Stop Mode.”](#)

<sup>6</sup> ERCLKEN and EREFSTEN set in ICSC2, else in standby.

## Chapter 4 Memory

### 4.1 Introduction

This chapter describes the on-chip memory in the MC9S08LG32 series of MCUs. It details the memory map, vector and bit assignments, registers and control bits, and other RAM and flash features.

### 4.2 MC9S08LG32 Series Memory Map

As shown in [Figure 4-1](#), on-chip memory in the MC9S08LG32 series of MCUs consists of RAM, flash memory for nonvolatile data storage, and I/O and control/status registers. The registers are divided into four groups:

- Direct-page registers (0x0000 through 0x005F)
- LCD data registers (0x0820 through 0x085C)
- High-page registers (0x1800 through 0x187A)
- Nonvolatile registers (0xFFB0 through 0xFFBF)

Note:  
0x085C-0x085F is reserved. Unlike un-implemented spaces, access to these locations would not cause illegal address reset.

Figure 4-1. MC9S08LG32 Series Memory Maps

### 4.3 Reset and Interrupt Vector Assignments

Table 4-1 shows the address assignments for reset and interrupt vectors. The vector names shown in this table are labels used in the Freescale Semiconductor equate file for the MC9S08LG32 series.

Table 4-1. Reset and Interrupt Vectors (Sheet 1 of 2)

| Address<br>(High/Low)           | Vector                                              | Vector Name |
|---------------------------------|-----------------------------------------------------|-------------|
| 0xFF80:FF81<br>↕<br>0xFFC8:FFC9 | Unused Vector Space<br>(available for user program) |             |

Table 4-1. Reset and Interrupt Vectors (Sheet 2 of 2) (continued)

| Address<br>(High/Low) | Vector              | Vector Name |
|-----------------------|---------------------|-------------|
| 0xFFCA:0xFFCB         | RTC                 | Vrtc        |
| 0xFFCC:0xFFCD         | Modulo Timer        | Vmtim       |
| 0xFFCE:0xFFCF         | TPM2 Overflow       | Vtpm2ovf    |

| 0xFFE2:0xFFE3         | SCI2 Transmit       | Vsci2tx     |
| 0xFFE4:0xFFE5         | SCI2 Receive        | Vsci2rx     |
| 0xFFE6:0xFFE7         | SCI2 Error          | Vsci2err    |
| 0xFFE8:0xFFE9         | SPI                 | Vspi        |
| 0xFFEA:0xFFEB         | LCD Frame           | Vlcd        |
| 0xFFEC:0xFFED         | SCI1 Transmit       | Vsci1tx     |
| 0xFFEE:0xFFEF         | SCI1 Receive        | Vsci1rx     |
| 0xFFFF0:0xFFFF1       | SCI1 Error          | Vsci1err    |
| 0xFFFF2:0xFFFF3       | TPM1 Overflow       | Vtpm1ovf    |
| 0xFFFF4:0xFFFF5       | TPM1 Channel 1      | Vtpm1ch1    |
| 0xFFFF6:0xFFFF7       | TPM1 Channel 0      | Vtpm1ch0    |
| 0xFFFF8:0xFFFF9       | Low Voltage Warning | Vlvw        |
| 0xFFFFA:0xFFFFB       | IRQ                 | Virq        |
| 0xFFFFC:0xFFFFD       | SWI                 | Vswi        |
| 0xFFFFE:0xFFFFF       | Reset               | Vreset      |

## 4.4 Register Addresses and Bit Assignments

The register groups in the MC9S08LG32 series consist of the following locations in the memory map:

- Direct-page registers are located at the first 96 locations. Access these locations with efficient direct addressing mode instructions.
- LCD Registers, LCDPENx, LCDBPENx, LCDWFX are located at the end of the RAM module.
- High-page registers are used much less often, so they are located above 0x1800 in the memory map. This leaves more room in the direct page registers for more frequently used registers and RAM.
- The nonvolatile register area consists of a block of 16 locations in flash memory at 0xFFB0–0xFFBF. Nonvolatile register locations include:
  - NVPROT and NVOPT are loaded into working registers at reset
  - An 8-byte backdoor comparison key that optionally allows controlled access to secure memory

Because the nonvolatile register locations are flash memory, they must be erased and programmed like other flash memory locations.

Direct-page registers can be accessed with efficient direct addressing mode instructions. Bit manipulation instructions can be used to access any bit in any direct-page register. [Table 4-2](#) is a summary of all user-accessible direct-page registers and control bits.

The direct page registers in [Table 4-2](#) can use the more efficient direct addressing mode, which requires only the lower byte of the address. Because of this, the lower byte of the address in column one is shown in bold text. In [Table 4-4](#) and [Table 4-5](#), the whole address in column one is shown in bold. In [Table 4-2](#), [Table 4-4](#), and [Table 4-5](#), the register names in column two are shown in bold to set them apart from the bit names to the right. Cells that are not associated with named bits are shaded. A shaded cell with a 0 indicates this unused bit always reads as a 0. Shaded cells with dashes indicate unused or reserved bit locations that could read as 1s or 0s. When writing to these bits, write a 0 unless otherwise specified.

Table 4-2. Direct-Page Register Summary (Sheet 1 of 3)

| Address | Register Name | Bit 7  | 6       | 5      | 4      | 3      | 2      | 1      | Bit 0  |

High-page registers, shown in [Table 4-4](#), are accessed much less often than other I/O and control registers so they have been located outside the direct addressable memory space, starting at 0x1800.

Table 4-4. High-Page Register Summary (Sheet 1 of 3)

| Address            | Register Name | Bit 7   | 6       | 5       | 4       | 3       | 2       | 1       | Bit 0   |
|--------------------|---------------|---------|---------|---------|---------|---------|---------|---------|---------|
| 0x1800             | SRS           | POR     | PIN     | COP     | ILOP    | ILAD    | 0       | LVD     | 0       |

## 4.4.1 Reserved Flash Locations

Several reserved flash memory locations, shown in Table 4-5, are used for storing values used by several registers. These registers include an 8-byte backdoor key, NVBACKKEY, which can be used to gain access to secure memory resources. During reset events, the contents of NVPROT and NVOPT in the reserved flash memory are transferred into corresponding FPROT and FOPT registers in the high-page registers area to control security and block protection options.

Locations 0xFFAE and 0xFFAF are reserved for ICS FTRIM and ICS TRIM values respectively. These locations are left blank at the factory. Third party tools can program these locations with the trim values. User can copy these values to corresponding ICS registers to get ICS trimmed clock frequency

Table 4-5. Reserved Flash Memory Addresses

| Address         | Register Name | Bit 7                 | 6      | 5 | 4 | 3 | 2 | 1   | Bit 0 |
|-----------------|---------------|-----------------------|--------|---|---|---|---|-----|-------|
| 0xFFB0 – 0xFFB7 | NVBACKKEY     | 8-Byte Comparison Key |        |   |   |   |   |     |       |
| 0xFFB8 – 0xFFBC | Reserved      | —                     | —      | — | — | — | — | —   | —     |
| 0xFFBD          | NVPROT        | FPS                   |        |   |   |   |   |     | FPDIS |
| 0xFFBE          | Reserved      | —                     | —      | — | — | — | — | —   | —     |
| 0xFFBF          | NVOPT         | KEYEN                 | FNORED | 0 | 0 | 0 | 0 | SEC |       |

Provided the key enable (KEYEN) bit is 1, the 8-byte comparison key can be used to temporarily disengage memory security. This key mechanism can be accessed only through user code running in secure memory. (A security key cannot be entered directly through background debug commands.) This security key can be disabled completely by programming the KEYEN bit to 0. If the security key is disabled, the only way to disengage security is by mass erasing the flash if needed (normally through the background

debug interface) and verifying that flash is blank. To avoid returning to secure mode after the next reset, program the security bits (SEC) to the unsecured state (1:0).

## 4.5 RAM

The MC9S08LG32 series includes static RAM. The locations in RAM below 0x0100 can be accessed using the more efficient direct addressing mode, and any single bit in this area can be accessed with the bit manipulation instructions (BCLR, BSET, BRCLR, and BRSET). Locating the most frequently accessed program variables in this area of RAM is preferred.

At power-on, the contents of RAM are uninitialized. RAM data is unaffected by any reset provided that the supply voltage does not drop below the minimum value for RAM retention ( $V_{RAM}$ ).

For compatibility with M68HC05 MCUs, the HCS08 resets the stack pointer to 0x00FF. In the MC9S08LG32 series, it is usually best to reinitialize the stack pointer to the top of the RAM so the direct page RAM can be used for frequently accessed RAM variables and bit-addressable program variables. Include the following 2-instruction sequence in your reset initialization routine (where RamLast is equated to the highest address of the RAM in the Freescale Semiconductor-provided equate file).

```
LDHX      #RamLast+1      ;point one past RAM
TXS                      ;SP<= (H:X-1)
```

When security is enabled, the RAM is considered a secure memory resource and is not accessible through background debug mode (BDM) or through code executing from non-secure memory. See [Section 4.7, “Security,”](#) for a detailed description of the security feature.

## 4.6 Flash

The flash memory is intended primarily for program storage. In-circuit programming allows the operating program to be loaded into the flash memory after final assembly of the application product. It is possible to program the entire array through the single-wire background debug interface. Because no special voltages are needed for flash erase and programming operations, in-application programming is also possible through other software-controlled communication paths. For a more detailed discussion of in-circuit and in-application programming, refer to the *HCS08 Family Reference Manual, Volume I*, Freescale Semiconductor document order number HCS08RMv1/D.

Because the MC9S08LG32 series contains two flash arrays, program and erase operations can be conducted on one array while executing code from the other. The security and protection features treat the two arrays as a single memory entity. Programming and erasing of each flash array is conducted through the same command interface detailed in the following sections.

It is not possible to page erase or program both arrays at the same time. The mass erase command erases both arrays, and the blank check command checks both arrays.

### 4.6.1 Features

Features of the flash memory include:

- Flash size
  - MC9S08LG32: 32,768 bytes (16,384 bytes in Flash A, 16,384 bytes in Flash B)
  - MC9S08LG16: 18,432 bytes (2,048 bytes in Flash A, 16,384 in Flash B)
- Single power supply program and erase
- Command interface for fast program and erase operation
- Up to 100,000 program/erase cycles at typical voltage and temperature
- Flexible block protection
- Security feature for flash and RAM
- Auto power-down for low-frequency read accesses

### 4.6.2 Program and Erase Times

Before any program or erase command can be accepted, the flash clock divider register (FCDIV) must be written to set the internal clock for the flash module to a frequency ( $f_{FCLK}$ ) between 150 kHz and 200 kHz (see [Section 4.8.1, “Flash Clock Divider Register \(FCDIV\)”](#)). This register can be written only once, so normally this write is performed during reset initialization. FCDIV cannot be written if the access error flag, FACCERR in FSTAT, is set. Ensure that FACCERR is not set before writing to the FCDIV register. The command processor uses one period of the resulting clock ( $1/f_{FCLK}$ ) to time program and erase pulses. An integer number of these timing pulses is used by the command processor to complete a program or erase command.

[Table 4-6](#) shows program and erase times. The bus clock frequency and FCDIV determine the frequency of FCLK ( $f_{FCLK}$ ). The time for one cycle of FCLK is  $t_{FCLK} = 1/f_{FCLK}$ . The times are shown as a number of cycles of FCLK and as an absolute time for the case where  $t_{FCLK} = 5 \mu s$ . Program and erase times shown include overhead for the command state machine and enabling and disabling of program and erase voltages.

**Table 4-6. Program and Erase Times**

| Parameter            | Cycles of FCLK | Time if FCLK = 200 kHz  |
|----------------------|----------------|-------------------------|
| Byte program         | 9              | 45 $\mu s$              |
| Byte program (burst) | 4              | 20 $\mu s$ <sup>1</sup> |
| Page erase           | 4000           | 20 ms                   |
| Mass erase           | 20,000         | 100 ms                  |

<sup>1</sup> Excluding start/end overhead

### 4.6.3 Program and Erase Command Execution

The FCDIV register must be initialized and any error flag is cleared before beginning command execution. The command execution steps are:

1. Write a data value to an address in the flash array. The address and data information from this write is latched into the flash interface. This write is a required first step in any command sequence. For erase and blank check commands, the value of the data is not important. For page erase commands, the address may be any address in the 512-byte page of flash to be erased. For mass erase and blank check commands, the address can be any address in the flash memory. Whole pages of 512 bytes are the smallest block of flash that may be erased.

#### NOTE

Do not program any byte in the flash more than once after a successful erase operation. Reprogramming bits to a byte that is already programmed is not allowed without first erasing the page in which the byte resides or mass erasing the entire flash memory. Programming without first erasing may disturb data stored in the flash.

2. Write the command code for the desired command to FCMD. The five valid commands are blank check (0x05), byte program (0x20), burst program (0x25), page erase (0x40), and mass erase (0x41). The command code is latched into the command buffer.
3. Write a 1 to the FCBEF bit in FSTAT to clear FCBEF and launch the command (including its address and data information).

A partial command sequence can be aborted manually by writing a 0 to FCBEF any time after the write to the memory array and before writing the 1 that clears FCBEF and launches the complete command. Aborting a command in this way sets the FACCERR access error flag, which must be cleared before starting a new command.

A strictly monitored procedure must be obeyed or the command will not be accepted. This minimizes the possibility of any unintended changes to the flash memory contents. The command complete flag (FCCF) indicates when a command is complete. The command sequence must be completed by clearing FCBEF to launch the command. [Figure 4-2](#) is a flowchart for executing all of the commands except for burst programming. The FCDIV register must be initialized before using any flash commands. This must be done only once following a reset.

4. Wait until the FCCF bit in FSTAT is set. As soon as FCCF= 1, the operation has completed successfully.

Figure 4-2. Flash Program and Erase Flowchart

#### 4.6.4 Burst Program Execution

The burst program command is used to program sequential bytes of data in less time than would be required using the standard program command. This is possible because the high voltage to the flash array does not need to be disabled between program operations. Ordinarily, when a program or erase command is issued, an internal charge pump associated with the flash memory must be enabled to supply high voltage to the array. Upon completion of the command, the charge pump is turned off. When a burst program command is issued, the charge pump is enabled and then remains enabled after completion of the burst program operation if these two conditions are met:

- The next burst program command has been queued before the current program operation has completed.
- The next sequential address selects a byte on the same physical row as the current byte being programmed. A row of flash memory consists of 64 bytes. A byte within a row is selected by addresses A5 through A0. A new row begins when addresses A5 through A0 are all zero.

The first byte of a series of sequential bytes being programmed in burst mode takes the same amount of time to program as a byte programmed in standard mode. The subsequent bytes program in the burst program time provided that the conditions above are met. In the case where the next sequential address is the beginning of a new row, the program time for that byte is the standard time instead of the burst time. This is because the high voltage to the array must be disabled and then enabled again. If a new burst command has not been queued before the current command completes, then the charge pump is disabled and the high voltage removed from the array.

Figure 4-3. Flash Burst Program Flowchart

### 4.6.5 Access Errors

An access error occurs whenever the command execution protocol is violated.

Any of the following actions causes the access error flag (FACCERR) in FSTAT to be set. Before any command can be processed, FACERR must be cleared. To clear FACCERR, write a 1 to FACCERR in FSTAT.

- Writing to a flash address before the internal flash clock frequency has been set by writing to the FCDIV register
- Writing to a flash address while FCBEF is not set (A new command cannot start until the command buffer is empty.)
- Writing a second time to a flash address before launching the previous command (There is only one write to flash for every command.)
- Writing a second time to FCMD before launching the previous command (There is only one write to FCMD for every command.)
- Writing to any flash control register other than FCMD after writing to a flash address
- Writing any command code to FCMD other than the five allowed codes (0x05, 0x20, 0x25, 0x40, or 0x41)
- Writing any flash control register other than the write to FSTAT (to clear FCBEF and launch the command) after writing the command to FCMD
- The MCU enters stop mode while a program or erase command is in progress (The command is aborted.)
- Writing the byte program, burst program, or page erase command code (0x20, 0x25, or 0x40) with a background debug command while the MCU is secured (The background debug controller can only do blank check and mass erase commands when the MCU is secure.)
- Writing 0 to FCBEF to cancel a partial command

### 4.6.6 Flash Block Protection

The block protection feature prevents the protected region of flash from program or erase changes. Block protection is controlled through the flash protection register (FPROT). When enabled, block protection begins at any 512 byte boundary below the last address of flash, 0xFFFF. (See [Section 4.8.4, “Flash Protection Register \(FPROT and NVPROT\)”](#)).

After exit from reset, FPROT is loaded with the contents of the NVPROT location, which is in the nonvolatile register block of the flash memory. FPROT cannot be changed directly from application software to prevent runaway programs from altering the block protection settings. Because NVPROT is within the last 512 bytes of flash, if any amount of memory is protected, NVPROT is itself protected and cannot be altered (intentionally or unintentionally) by the application software. FPROT can be written through background debug commands, which allows a protected flash memory to be erased and reprogrammed.

The block protection mechanism is illustrated in [Figure 4-4](#). The FPS bits are used as the upper bits of the last address of unprotected memory. This address is formed by concatenating FPS7:FPS1 with logic 1 bits as shown. For example, to protect the last 1536 bytes of memory (addresses 0xFA00 through 0xFFFF), the

FPS bits must be set to 1111 100, which results in the value 0xF9FF as the last address of unprotected memory. In addition to programming the FPS bits to the appropriate value, FPDIS (bit 0 of NVPROT) must be programmed to logic 0 to enable block protection. Therefore the value 0xF8 must be programmed into NVPROT to protect addresses 0xFA00 through 0xFFFF.

**Figure 4-4. Block Protection Mechanism**

One use of block protection is to block protect an area of flash memory for a bootloader program. This bootloader program then can be used to erase the rest of the flash memory and reprogram it. Because the bootloader is protected, it remains intact even if MCU power is lost in the middle of an erase and reprogram operation.

## 4.6.7 Vector Redirection

Whenever any block protection is enabled, the reset and interrupt vectors are protected. Vector redirection allows users to modify interrupt vector information without unprotecting bootloader and reset vector space. Vector redirection is enabled by programming the FNORED bit in the NVOPT register located at address 0xFFBF to zero. For redirection to occur, at least some portion but not all of the flash memory must be block protected by programming the NVPROT register located at address 0xFFBD. All of the interrupt vectors (memory locations 0xFFC0–0xFFFD) are redirected, though the reset vector (0xFFFE:FFFF) is not.

For example, if 512 bytes of flash are protected, the protected address region is from 0xFE00 through 0xFFFF. The interrupt vectors (0xFFC0–0xFFFD) are redirected to the locations 0xFDC0–0xFDFD. For instance, if an SPI interrupt is taken, the values in the locations 0xFDE8:FDE9 are used for the vector instead of the values in the locations 0xFFE8:FFE9. This allows you to reprogram the unprotected portion of the flash with new program code including new interrupt vector values while leaving the protected area, which includes the default vector locations, unchanged.

## 4.7 Security

The MC9S08LG32 series includes circuitry to prevent unauthorized access to the contents of flash and RAM memory. When security is engaged, flash and RAM are considered secure resources. Direct-page registers, high-page registers, and the background debug controller are considered unsecured resources. Programs executing within secure memory have normal access to any MCU memory locations and resources. Attempts to access a secure memory location with a program executing from an unsecured memory space or through the background debug interface are blocked (writes are ignored and reads return all 0s).

Security is engaged or disengaged based on the state of two nonvolatile register bits (SEC01:SEC00) in the FOPT register. During reset, the contents of the nonvolatile location NVOPT are copied from flash into the working FOPT register in high-page register space. To engage security, program the NVOPT location.

You can do this at the same time the flash memory is programmed. The 1:0 state disengages security and the other three combinations engage security. Notice the erased state (1:1) makes the MCU secure. During development, whenever the flash is erased, you must immediately program the SEC00 bit to 0 in NVOPT so SEC01:SEC00 = 1:0. This allows the MCU to remain unsecured after a subsequent reset.

The on-chip debug module cannot be enabled while the MCU is secure. The separate background debug controller can still be used for background memory access commands of unsecured resources.

You can choose to allow or disallow a security unlocking mechanism through an 8-byte backdoor security key. If the nonvolatile KEYEN bit in NVOPT/FOPT is 0, the backdoor key is disabled and there is no way to disengage security without completely erasing all flash locations. If KEYEN is 1, a secure user program can temporarily disengage security by:

1. Writing 1 to KEYACC in the FCNFG register. This makes the flash module interpret writes to the backdoor comparison key locations (NVBACKKEY through NVBACKKEY+7) as values to be compared against the key rather than as the first step in a flash program or erase command.
2. Writing the user-entered key values to the NVBACKKEY through NVBACKKEY+7 locations. These writes must be done in order starting with the value for NVBACKKEY and ending with NVBACKKEY+7. STHX must not be used for these writes because these writes cannot be done on adjacent bus cycles. User software normally would get the key codes from outside the MCU system through a communication interface such as a serial I/O.
3. Writing 0 to KEYACC in the FCNFG register. If the 8-byte key that was just written matches the key stored in the flash locations, SEC01:SEC00 are automatically changed to 1:0 and security disengages until the next reset.

The security key can be written only from secure memory (either RAM or flash), so it cannot be entered through background commands without the cooperation of a secure user program.

The backdoor comparison key (NVBACKKEY through NVBACKKEY+7) is located in flash memory locations in the nonvolatile register space so users can program these locations exactly as they would program any other flash memory location. The nonvolatile registers are in the same 512-byte block of flash as the reset and interrupt vectors, so block protecting that space also block protects the backdoor comparison key. Block protects cannot be changed from user application programs, so if the vector space is block protected, the backdoor security key mechanism cannot permanently change the block protect, security settings, or the backdoor key.

Security can always be disengaged through the background debug interface by taking these steps:

1. Disable any block protections by writing FPROT. FPROT can be written only with background debug commands, not from application software.
2. Mass erase flash if necessary.
3. Blank check flash. Provided flash is completely erased, security is disengaged until the next reset.

To avoid returning to secure mode after the next reset, program NVOPT so SEC01:SEC00 = 1:0.

## 4.8 Flash Registers and Control Bits

The flash module has six 8-bit registers in the high-page register space. Two locations (NVOPT, NVPROT) in the nonvolatile register space in flash memory are copied into corresponding high-page

control registers (FOPT, FPROT) at reset. There is also an 8-byte comparison key in flash memory. Refer to [Table 4-4](#) and [Table 4-5](#) for the absolute address assignments for all flash registers. This section refers to registers and control bits only by their names. A Freescale Semiconductor-provided equate or header file is normally used to translate these names into the appropriate absolute addresses.

## 4.8.1 Flash Clock Divider Register (FCDIV)

Bit 7 of this register is a read-only flag. DIV Bits 6:0 may be read at any time, but can be written only one time. Before any erase or programming operations are possible, write to this register to set the frequency of the clock for the nonvolatile memory system within acceptable limits. [Table 4-8](#) shows the appropriate values for PRDIV8 and DIV for selected bus frequencies.

Figure 4-5. Flash Clock Divider Register (FCDIV)

Table 4-7. FCDIV Register Field Descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 7<br>DIVLD  | <b>Divisor Loaded Status Flag</b> — When set, this read-only status flag indicates that the FCDIV register has been written since reset. Reset clears this bit and the first write to this register causes this bit to become set regardless of the data written.<br>0 FCDIV has not been written since reset; erase and program operations disabled for flash.<br>1 FCDIV has been written since reset; erase and program operations enabled for flash.                                                                                                                                                                                    |
| 6<br>PRDIV8 | <b>Prescale (Divide) Flash Clock by 8</b><br>0 Clock input to the flash clock divider is the bus rate clock.<br>1 Clock input to the flash clock divider is the bus rate clock divided by 8.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 5:0<br>DIV  | <b>Divisor for Flash Clock Divider</b> — The flash clock divider divides the bus rate clock (or the bus rate clock divided by 8 if PRDIV8 = 1) by the value in the 6-bit DIV field plus one. The resulting frequency of the internal flash clock must fall within the range of 200 kHz to 150 kHz for proper flash operations. Program/Erase timing pulses are one cycle of this internal flash clock which corresponds to a range of 5 μs to 6.7 μs. The automated programming logic uses an integer number of these pulses to complete an erase or program operation. See <a href="#">Equation 4-1</a> and <a href="#">Equation 4-2</a> . |

$$\text{if PRDIV8} = 0 \text{ — } f_{\text{CLK}} = f_{\text{Bus}} \div (\text{DIV} + 1) \quad \text{Eqn. 4-1}$$

$$\text{if PRDIV8} = 1 \text{ — } f_{\text{CLK}} = f_{\text{Bus}} \div (8 \times (\text{DIV} + 1)) \quad \text{Eqn. 4-2}$$

[Table 4-8](#) shows the appropriate values for PRDIV8 and DIV for selected bus frequencies.

Table 4-8. Flash Clock Divider Settings

| $f_{\text{Bus}}$ | PRDIV8<br>(Binary) | DIV<br>(Decimal) | $f_{\text{CLK}}$ | Program/Erase Timing Pulse<br>(5 $\mu\text{s}$ Min, 6.7 $\mu\text{s}$ Max) |

## 4.8.2 Flash Options Register (FOPT and NVOPT)

During reset, the contents of the nonvolatile location NVOPT are copied from flash into FOPT. To change the value in this register, erase and reprogram the NVOPT location in flash memory as usual and then issue a new MCU reset.

|   |       |        |   |   |   |   |       |       |
|---|-------|--------|---|---|---|---|-------|-------|
|   | 7     | 6      | 5 | 4 | 3 | 2 | 1     | 0     |
| R | KEYEN | FNORED | 0 | 0 | 0 | 0 | SEC01 | SEC00 |
| W |       |        |   |   |   |   |       |       |

Reset This register is loaded from nonvolatile location NVOPT during reset.

 = Unimplemented or Reserved

Figure 4-6. Flash Options Register (FOPT)

Table 4-9. FOPT Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| R     | 0 | 0 | KEYACC | 0 | 0 | 0 | 0 | 0 |
| W     |   |   |        |   |   |   |   |   |
| Reset | 0 | 0 | 0      | 0 | 0 | 0 | 0 | 0 |

 = Unimplemented or Reserved

**Figure 4-7. Flash Configuration Register (FCNFG)**

**Table 4-11. FCNFG Register Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5<br>KEYACC | <b>Enable Writing of Access Key</b> — This bit enables writing of the backdoor comparison key. For more detailed information about the backdoor key mechanism, refer to <a href="#">Section 4.7, “Security.”</a><br>0 Writes to flash are interpreted as the start of a flash programming or erase command.<br>1 Writes to NVBACKKEY (0xFFB0–0xFFB7) are interpreted as comparison key writes while writes to rest of the flash are ignored. |

### 4.8.4 Flash Protection Register (FPROT and NVPROT)

During reset, the contents of the nonvolatile location NVPROT is copied from flash into FPROT. FPROT can be read at any time. With FPDIS set, all bits are writable, but with FPDIS clear the FPS bits are writable as long as the size of the protected region is being increased. Any FPROT write that attempts to decrease the size of the protected region is ignored.

|   |                    |   |   |   |   |   |   |                      |
|---|--------------------|---|---|---|---|---|---|----------------------|
|   | 7                  | 6 | 5 | 4 | 3 | 2 | 1 | 0                    |
| R | FPS <sup>(1)</sup> |   |   |   |   |   |   | FPDIS <sup>(1)</sup> |
| W |                    |   |   |   |   |   |   |                      |

Reset This register is loaded from nonvolatile location NVPROT during reset.

<sup>1</sup> Background commands can be used to change the contents of these bits in FPROT.

**Figure 4-8. Flash Protection Register (FPROT)**

Table 4-12. FPROT Register Field Descriptions

| Field      | Description                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1<br>FPS | <b>Flash Protect Select Bits</b> — When FPDIS = 0, this 7-bit field determines the ending address of unprotected flash locations at the high address end of the flash. Protected flash locations cannot be erased or programmed. |
| 0<br>FPDIS | <b>Flash Protection Disable</b><br>0 Flash block specified by FPS7:FPS1 is block protected (program and erase not allowed).<br>1 No flash block is protected.                                                                    |

## 4.8.5 Flash Status Register (FSTAT)

Figure 4-9. Flash Status Register (FSTAT)

Table 4-13. FSTAT Register Field Descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>FCBEF  | <b>Flash Command Buffer Empty Flag</b> — The FCBEF bit is used to launch commands. It also indicates that the command buffer is empty so that a new command sequence can be executed when performing burst programming. The FCBEF bit is cleared by writing a 1 to it or when a burst program command is transferred to the array for programming. Only burst program commands can be buffered.<br>0 Command buffer is full (not ready for additional commands).<br>1 A new burst program command can be written to the command buffer. |
| 6<br>FCCF   | <b>Flash Command Complete Flag</b> — FCCF is set automatically when the command buffer is empty and no command is being processed. FCCF is cleared automatically when a new command is started (by writing 1 to FCBEF to register a command). Writing to FCCF has no meaning or effect.<br>0 Command in progress<br>1 All commands complete                                                                                                                                                                                             |
| 5<br>FPVIOL | <b>Protection Violation Flag</b> — FPVIOL is set automatically when a command is written that attempts to erase or program a location in a protected block (the erroneous command is ignored). FPVIOL is cleared by writing a 1 to FPVIOL.<br>0 No protection violation.<br>1 An attempt was made to erase or program a protected location.                                                                                                                                                                                             |

**Table 4-13. FSTAT Register Field Descriptions (continued)**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4<br>FACCERR | <b>Access Error Flag</b> — FACCERR is set automatically when the proper command sequence is not obeyed exactly (the erroneous command is ignored), if a program or erase operation is attempted before the FCDIV register has been initialized, or if the MCU enters stop while a command was in progress. For a more detailed discussion of the exact actions that are considered access errors, see <a href="#">Section 4.6.5, “Access Errors.”</a> FACCERR is cleared by writing a 1 to FACCERR. Writing a 0 to FACCERR has no meaning or effect.<br>0 No access error.<br>1 An access error has occurred. |
| 2<br>FBLANK  | <b>Flash Verified as All Blank (erased) Flag</b> — FBLANK is set automatically at the conclusion of a blank check command if the entire flash array was verified to be erased. FBLANK is cleared by clearing FCBEF to write a new valid command. Writing to FBLANK has no meaning or effect.<br>0 After a blank check command is completed and FCCF = 1, FBLANK = 0 indicates the flash array is not completely erased.<br>1 After a blank check command is completed and FCCF = 1, FBLANK = 1 indicates the flash array is completely erased (all 0xFF).                                                     |

### 4.8.6 Flash Command Register (FCMD)

Only five command codes are recognized in normal user modes as shown in [Table 4-14](#). Refer to [Section 4.6.3, “Program and Erase Command Execution,”](#) for a detailed discussion of flash programming and erase operations.

|       |      |   |   |   |   |   |   |   |
|-------|------|---|---|---|---|---|---|---|
|       | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| W     | FCMD |   |   |   |   |   |   |   |
| Reset | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Figure 4-10. Flash Command Register (FCMD)**

**Table 4-14. Flash Commands**

| Command                     | FCMD | Equate File Label |
|-----------------------------|------|-------------------|
| Blank check                 | 0x05 | mBlank            |
| Byte program                | 0x20 | mByteProg         |
| Byte program — burst mode   | 0x25 | mBurstProg        |
| Page erase (512 bytes/page) | 0x40 | mPageErase        |
| Mass erase (all flash)      | 0x41 | mMassErase        |

All other command codes are illegal and generate an access error.

It is not necessary to perform a blank check command after a mass erase operation. Only blank check is required as part of the security unlocking mechanism.

## Chapter 5

# Resets, Interrupts, and General System Control

### 5.1 Introduction

This section discusses basic reset and interrupt mechanisms and the various sources of reset and interrupt in the MC9S08LG32 series. Some interrupt sources from peripheral modules are discussed in greater detail in other sections of this document. This section gathers basic information about all reset and interrupt sources in one place for easy reference.

### 5.2 Features

Reset and interrupt features include:

- Multiple sources of reset for flexible system configuration and reliable operation
- Reset status register (SRS) to indicate source of most recent reset
- Separate interrupt vector for all modules (reduces polling overhead) (see [Table 5-2](#))

### 5.3 MCU Reset

Resetting the MCU provides a way to start processing from a known set of initial conditions. During reset, most control and status registers are forced to initial values and the program counter is loaded from the reset vector (0xFFFF:0xFFFF). On-chip peripheral modules are disabled and I/O pins are initially configured as general-purpose high-impedance inputs with pullup devices disabled. The I bit in the condition code register (CCR) is set to block maskable interrupts so the user program has a chance to initialize the stack pointer (SP) and system control settings. SP is forced to 0x00FF at reset.

The MC9S08LG32 series has the following sources for reset:

- Power-on reset (POR)
- External pin reset (PIN)
- Computer operating properly (COP) timer
- Illegal opcode detect (IOP)
- Illegal address detect (ILAD)
- Low-voltage detect (LVD)
- Background debug forced reset

Each of these sources, with the exception of the background debug forced reset, has an associated bit in the system reset status register (SRS). The background debug forced reset causes all the bits in the SRS register to clear, and can be detected by all zeros in SRS.

## 5.4 Computer Operating Properly (COP) Watchdog

The COP watchdog is intended to force a system reset when the application software fails to execute as expected. To prevent a system reset from the COP timer (when it is enabled), application software must reset the COP counter periodically. If the application program gets lost and fails to reset the COP counter before it times out, a system reset is generated to force the system back to a known starting point.

After any reset, the COPE becomes set in SOPT1 enabling the COP watchdog (see [Section 5.8.4, “System Options Register 1 \(SOPT1\)”](#), for additional information). If the COP watchdog is not used in an application, it can be disabled by clearing COPE. The COP counter is reset by writing any value to the address of SRS. This write does not affect the data in the read-only SRS. Instead, the act of writing to this address is decoded and sends a reset signal to the COP counter.

The COPCLKS bit in SOPT2 (see [Section 5.8.5, “System Options Register 2 \(SOPT2\)”](#), for additional information) selects the clock source used for the COP timer. The clock source options are either the bus clock or an internal 1 kHz clock source. With each clock source, there is an associated short and long time-out controlled by COPT in SOPT1. [Table 5-1](#) summarizes the control functions of the COPCLKS and COPT bits. The COP watchdog defaults to operation from the 1 kHz clock source and the associated long time-out ( $2^8$  cycles).

**Table 5-1. COP Configuration Options**

| Control Bits |      | Clock Source | COP Overflow Count                 |
|--------------|------|--------------|------------------------------------|
| COPCLKS      | COPT |              |                                    |
| 0            | 0    | ~1 kHz       | $2^5$ cycles (32 ms) <sup>1</sup>  |
| 0            | 1    | ~1 kHz       | $2^8$ cycles (256 ms) <sup>1</sup> |
| 1            | 0    | Bus          | $2^{13}$ cycles                    |
| 1            | 1    | Bus          | $2^{18}$ cycles                    |

<sup>1</sup> Values are shown in this column based on  $t_{LPO} = 1$  ms. See  $t_{LPO}$  in the data sheet for the tolerance of this value.

Even if your application uses the reset default settings of COPE, COPCLKS, and COPT; you must write to the write-once SOPT1 and SOPT2 registers, during reset initialization, to lock in the settings. That way, the settings cannot be changed accidentally if the application program gets lost. The initial writes to SOPT1 and SOPT2 reset the COP counter.

The write to SRS that services (clears) the COP counter must not be placed in an interrupt service routine (ISR) because the ISR could continue to be executed periodically even if the main application program fails.

In background debug mode, the COP counter does not increment.

When the bus clock source is selected, the COP counter does not increment while the system is in stop mode. The COP counter resumes as soon as the MCU exits stop mode.

When the 1 kHz clock source is selected, the COP counter is re-initialized to zero upon entry to stop mode. The COP counter begins from zero after the MCU exits stop mode.

## 5.5 Interrupts

Interrupts provide a way to save the current CPU status and registers, execute an interrupt service routine (ISR), and then restore the CPU status so processing can resume where it left off before the interrupt. Other than the software interrupt (SWI), which is a program instruction, interrupts are caused by hardware events such as an edge on the IRQ pin or a timer-overflow event. The debug module can also generate an SWI under certain circumstances.

If an event occurs in an enabled interrupt source, an associated read-only status flag is set. The CPU does not respond unless the local interrupt enable is a 1 (enabled) and the I bit in the CCR is 0 to allow interrupts. The global interrupt mask (I bit) in the CCR is initially set after reset which prevents all maskable interrupt sources. The user program initializes the stack pointer and performs other system setup before clearing the I bit to allow the CPU to respond to interrupts.

When the CPU receives a qualified interrupt request, it completes the current instruction before responding to the interrupt. The interrupt sequence obeys the same cycle-by-cycle sequence as the SWI instruction and consists of:

- Saving the CPU registers on the stack
- Setting the I bit in the CCR to mask further interrupts
- Fetching the interrupt vector for the highest-priority interrupt that is currently pending
- Filling the instruction queue with the first three bytes of program information starting from the address fetched from the interrupt vector locations

While the CPU is responding to the interrupt, the I bit is automatically set to avoid the possibility of another interrupt interrupting the ISR itself (this is called nesting of interrupts). Normally, the I bit is restored to 0 when the CCR is restored from the value stacked on entry to the ISR. In rare cases, the I bit can be cleared inside an ISR (after clearing the status flag that generated the interrupt) so that other interrupts can be serviced without waiting for the first service routine to finish. This practice is not recommended for anyone other than the most experienced programmers because it can lead to subtle program errors that are difficult to debug.

The interrupt service routine ends with a return-from-interrupt (RTI) instruction which restores the CCR, A, X, and PC registers to their pre-interrupt values by reading the previously saved information from the stack.

### NOTE

For compatibility with M68HC08 devices, the H register is not automatically saved and restored. It is good programming practice to push H onto the stack at the start of the interrupt service routine (ISR) and restore it immediately before the RTI that is used to return from the ISR.

If more than one interrupt is pending when the I bit is cleared, the highest priority source is serviced first (see [Table 5-2](#)).

## 5.5.1 Interrupt Stack Frame

Figure 5-1 shows the contents and organization of a stack frame. Before the interrupt, the stack pointer (SP) points at the next available byte location on the stack. The current values of CPU registers are stored on the stack starting with the low-order byte of the program counter (PCL) and ending with the CCR. After stacking, the SP points at the next available location on the stack. This address is one less than the address where the CCR was saved. The PC value that is stacked is the address of the instruction in the main program that would have executed next if the interrupt had not occurred.

Figure 5-1. Interrupt Stack Frame

When an RTI instruction is executed, these values are recovered from the stack in reverse order. As part of the RTI sequence, the CPU fills the instruction pipeline by reading three bytes of program information, starting from the PC address recovered from the stack.

The status flag corresponding to the interrupt source must be acknowledged (cleared) before returning from the ISR. Typically, the flag is cleared at the beginning of the ISR so that if another interrupt is generated by this same source it is registered so it can be serviced after completion of the current ISR.

## 5.5.2 External Interrupt Request (IRQ) Pin

External interrupts are managed by the IRQ status and control register (IRQSC). When the IRQ function is enabled, synchronous logic monitors the pin for edge-only or edge-and-level events. When the MCU is in stop mode and system clocks are shut down, a separate asynchronous path is used so the IRQ pin can wake the MCU.

### 5.5.2.1 Pin Configuration Options

The IRQ pin enable (IRQPE) control bit in IRQSC must be 1 in order for the IRQ pin to act as the interrupt request (IRQ) input. As an IRQ input, you can choose the polarity of edges or levels detected (IRQEDG), whether the pin detects edges-only or edges and levels (IRQMOD) and whether an event causes an interrupt or only sets the IRQF flag which can be polled by software (IRQIE).

The IRQ pin, when enabled, defaults to use an internal pull device ( $IRQPDD = 0$ ), configured as a pullup or pulldown depending on the polarity chosen. If the user desires to use an external pullup or pulldown, the  $IRQPDD$  can be written to a 1 to turn off the internal device.

BIH and BIL instructions may be used to detect the level on the IRQ pin when the pin is configured to act as the IRQ input.

### 5.5.2.2 Edge and Level Sensitivity

The  $IRQMOD$  control bit reconfigures the detection logic so it detects edge events and pin levels. In the edge and level detection mode, the  $IRQF$  status flag becomes set when an edge is detected (when the IRQ pin changes from the deasserted to the asserted level), but the flag is continuously set (and cannot be cleared) as long as the IRQ pin remains at the asserted level.

### 5.5.2.3 IRQ Initialization

When IRQ is first enabled it is possible to get a false IRQ interrupt flag. To prevent a false interrupt request during IRQ initialization, you must do the following:

1. Mask IRQ interrupt by clearing  $IRQIE$  in  $IRQSC$ .
2. Select the IRQ mode by writing to the  $IRQEDG$ ,  $IRQMOD$  and  $IRQPDD$  bits in  $IRQSC$ .
3. Enable the IRQ pin by setting the  $IRQPE$  bit in  $IRQSC$ .
4. Write to  $IRQACK$  in  $IRQSC$  to clear any false interrupts.
5. Set  $IRQIE$  in  $IRQSC$  to enable interrupts.

## 5.5.3 Interrupt Vectors, Sources, and Local Masks

[Table 5-2](#) provides a summary of all interrupt sources. Higher-priority sources are located toward the bottom of the table. The high-order byte of the address for the interrupt service routine is located at the first address in the vector address column, and the low-order byte of the address for the interrupt service routine is located at the next higher address.

When an interrupt condition occurs, an associated flag bit becomes set. If the associated local interrupt enable is 1, an interrupt request is sent to the CPU. Within the CPU, if the global interrupt mask (I bit in the CCR) is 0, the CPU finishes the current instruction; stack the PCL, PCH, X, A, and CCR CPU registers; set the I bit; and then fetch the interrupt vector for the highest priority pending interrupt. Processing then continues in the interrupt service routine.

Table 5-2. Vector Summary

| Vector Priority                                                             | Vector Number | Address (High/Low)              | Vector Name                                      | Module         | Source                                                              | Enable                           | Description                                                                               |
|-----------------------------------------------------------------------------|---------------|---------------------------------|--------------------------------------------------|----------------|---------------------------------------------------------------------|----------------------------------|-------------------------------------------------------------------------------------------|
| <div> <div>Lowest</div> <div>↑</div> <div>↓</div> <div>Highest</div> </div> | 31 through 27 | 0xFFC0:FFC1 through 0xFFC8:FFC9 | Unused Vector Space (available for user program) |                |                                                                     |                                  |                                                                                           |
|                                                                             | 26            | 0xFFCA:0xFFCB                   | Vrtc                                             | RTC            | RTIF                                                                | RTIE                             | Counter Match                                                                             |
|                                                                             | 25            | 0xFFCC:0xFFCD                   | Vmtim                                            | MTIM           | TOF                                                                 | TOIE                             | Counter Match                                                                             |
|                                                                             | 24            | 0xFFCE:0xFFCF                   | Vtpm2ovf                                         | TPM2           | TOF                                                                 | TO2E                             | TPM2 overflow                                                                             |
|                                                                             | 23            | 0xFFD0:0xFFD1                   | Vtpm2ch5                                         | TPM2           | CH5F                                                                | CH5IE                            | TPM2 channel 5                                                                            |

## 5.6 Low-Voltage Detect (LVD) System

The MC9S08LG32 series includes a system to protect against low voltage conditions to protect memory contents and control MCU system states during supply voltage variations. The system is comprised of a power-on reset (POR) circuit and a LVD circuit. The LVD circuit is enabled when LVDE in SPMSC1. The LVD is disabled upon entering either of the stop modes unless LVDSE is set in SPMSC1. If LVDSE and LVDE are both set, then the MCU enters stop3 instead of stop2, and the current consumption in stop3 with the LVD enabled is greater.

### 5.6.1 Power-On Reset Operation

When power is initially applied to the MCU, or when the supply voltage drops below the power-on reset rearm voltage level,  $V_{POR}$ , the POR circuit causes a reset condition. As the supply voltage rises, the LVD circuit holds the MCU in reset until the supply has risen above the low voltage detection low threshold,  $V_{LVDL}$ . Both the POR bit and the LVD bit in SRS are set following a POR.

### 5.6.2 Low-Voltage Detection (LVD) Reset Operation

The LVD can be configured to generate a reset upon detection of a low voltage condition by setting LVDRE to 1. After an LVD reset has occurred, the LVD system holds the MCU in reset until the supply voltage has risen above the low voltage detection threshold. The LVD bit in the SRS register is set following either an LVD reset or POR.

### 5.6.3 Low-Voltage Warning (LVW) Interrupt Operation

The LVD system has a low voltage warning flag (LVWF) to indicate to you that the supply voltage is approaching, but remains above, the LVD voltage. The LVW has an interrupt associated with it, enabled by setting the LVWIE bit in the SPMSC1 register. If enabled, an LVW interrupt request occurs when the LVWF is set. LVWF is cleared by writing a 1 to the LVWACK bit in SPMSC1 provided the LVW condition no longer exists.

## 5.7 Peripheral Clock Gating

The MC9S08LG32 series includes a clock gating system to manage the bus clock sources to the individual peripherals. Using this system, you can enable or disable the bus clock to each of the peripherals at the clock source, eliminating unnecessary clocks to peripherals which are not in use and thereby reducing the overall run and wait mode currents.

Out of reset, all peripheral clocks are disabled. For lowest possible run or wait currents, user software must disable the clock source to any peripheral not in use. The actual clock is enabled or disabled immediately following the write to the Clock Gating Control registers (SCGC1 and SCGC2). Any peripheral with a gated clock cannot be used unless its clock is enabled. Writing to the registers of a peripheral with a disabled clock has no effect.

## NOTE

User software must disable the peripheral before disabling the clocks to the peripheral. When clocks are re-enabled to a peripheral, the peripheral registers need to be re-initialized by user software.

In stop modes, the bus clock is disabled for all gated peripherals, regardless of the settings in SCGC1 and SCGC2.

## 5.8 Reset, Interrupt, and System Control Registers and Control Bits

One 8-bit register in the direct page register space and fourteen 8-bit registers in the high-page register space are related to reset and interrupt systems.

Refer to [Table 4-2](#) and [Table 4-4](#) in [Chapter 4, “Memory,”](#) for the absolute address assignments for all registers. This section refers to registers and control bits only by their names. A Freescale-provided equate or header file is used to translate these names into the appropriate absolute addresses.

Some control bits in the SOPT1 and SPMSC2 registers are related to modes of operation. Although brief descriptions of these bits are provided here, the related functions are discussed in greater detail in [Chapter 3, “Modes of Operation.”](#)

### 5.8.1 Interrupt Pin Request Status and Control Register (IRQSC)

This direct page register includes status and control bits which are used to configure the IRQ function, report status, and acknowledge IRQ events.

**Figure 5-2. Interrupt Request Status and Control Register (IRQSC)**

**Table 5-3. IRQSC Register Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6<br>IRQPDD | <b>Interrupt Request (IRQ) Pull Device Disable</b> — This read/write control bit is used to disable the internal pullup/pulldown device when the IRQ pin is enabled (IRQPE = 1) allowing for an external device to be used.<br>0 IRQ pull device enabled if IRQPE = 1.<br>1 IRQ pull device disabled if IRQPE = 1.                                                                                                                                                                                                                    |
| 5<br>IRQEDG | <b>Interrupt Request (IRQ) Edge Select</b> — This read/write control bit is used to select the polarity of edges or levels on the IRQ pin that cause IRQF to be set. The IRQMOD control bit determines whether the IRQ pin is sensitive to both edges and levels or only edges. When IRQEDG = 1 and the internal pull device is enabled, the pullup device is reconfigured as an optional pulldown device.<br>0 IRQ is falling edge or falling edge/low-level sensitive.<br>1 IRQ is rising edge or rising edge/high-level sensitive. |

**Table 5-3. IRQSC Register Field Descriptions (continued)**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4<br>IRQPE  | <b>IRQ Pin Enable</b> — This read/write control bit enables the IRQ pin function. When this bit is set the IRQ pin can be used as an interrupt request.<br>0 IRQ pin function is disabled.<br>1 IRQ pin function is enabled.                                                                                                                                                                                                                                            |
| 3<br>IRQF   | <b>IRQ Flag</b> — This read-only status bit indicates when an interrupt request event has occurred.<br>0 No IRQ request.<br>1 IRQ event detected.                                                                                                                                                                                                                                                                                                                       |
| 2<br>IRQACK | <b>IRQ Acknowledge</b> — This write-only bit is used to acknowledge interrupt request events (write 1 to clear IRQF). Writing 0 has no meaning or effect. Reads always return 0. If edge-and-level detection is selected (IRQMOD = 1), IRQF cannot be cleared while the IRQ pin remains at its asserted level.                                                                                                                                                          |
| 1<br>IRQIE  | <b>IRQ Interrupt Enable</b> — This read/write control bit determines whether IRQ events generate an interrupt request.<br>0 Interrupt request when IRQF set is disabled (use polling).<br>1 Interrupt requested whenever IRQF = 1.                                                                                                                                                                                                                                      |
| 0<br>IRQMOD | <b>IRQ Detection Mode</b> — This read/write control bit selects either edge-only detection or edge-and-level detection. The IRQEDG control bit determines the polarity of edges and levels that are detected as interrupt request events. See <a href="#">Section 5.5.2.2, “Edge and Level Sensitivity,”</a> for more details.<br>0 IRQ event on falling edges or rising edges only.<br>1 IRQ event on falling edges and low levels or on rising edges and high levels. |

## 5.8.2 System Reset Status Register (SRS)

This high-page register includes read-only status flags to indicate the source of the most recent reset. When a debug host forces reset by writing 1 to BDFR in the SBDFR register, none of the status bits in SRS is set. Writing any value to this register address clears the COP watchdog timer without affecting the contents of this register. The reset state of these bits depends on what caused the MCU to reset.

|                  | 7                                                           | 6                   | 5                   | 4                   | 3                   | 2 | 1   | 0 |

Figure 5-4. System Background Debug Force Reset Register (SBDFR)

<sup>1</sup> BDFR is writable only through serial background debug commands, not from user programs.

Table 5-5. SBDFR Register Field Descriptions

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>BDFR | <b>Background Debug Force Reset</b> — A serial background command such as WRITE_BYTE can be used to allow an external debug host to force a target system reset. Writing 1 to this bit forces an MCU reset. This bit cannot be written from a user program. To enter user mode, PTC5/BKGD/MS must be high immediately after issuing WRITE_BYTE command. To enter BDM, PTC5/BKGD/MS must be low immediately after issuing WRITE_BYTE command. See the data sheet for more information. |

## 5.8.4 System Options Register 1 (SOPT1)

This high-page register is a write-once register, so only the first write after reset is honored. It can be read at any time. Any subsequent attempt to write to SOPT1 (intentionally or unintentionally) is ignored to avoid accidental changes to these sensitive settings. SOPT1 must be written during the user's reset initialization program to set the desired controls even if the desired settings are the same as the reset settings.

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>COPE   | <b>COP Watchdog Enable</b> — This write-once bit selects whether the COP watchdog is enabled.<br>0 COP watchdog timer disabled.<br>1 COP watchdog timer enabled (force reset on timeout).                                                                                                                                                                                                                                                          |
| 6<br>COPT   | <b>COP Watchdog Timeout</b> — This write-once bit selects the timeout period of the COP. COPT along with COPCLKS in SOPT2 defines the COP timeout period.<br>0 Short timeout period selected.<br>1 Long timeout period selected.                                                                                                                                                                                                                   |
| 5<br>STOPE  | <b>Stop Mode Enable</b> — This write-once bit is used to enable stop mode. If stop mode is disabled and a user program attempts to execute a STOP instruction, an illegal opcode reset is forced.<br>0 Stop mode disabled.<br>1 Stop mode enabled.                                                                                                                                                                                                 |
| 1<br>BKGDPE | <b>Background Debug Mode Pin Enable</b> — This write-once bit when set enables the PTC5/BKGD/MS pin to function as BKGD/MS. When clear, the pin functions as output only GPIO. This pin defaults to the BKGD/MS function following any MCU reset.<br>0 PTC5/BKGD/MS pin functions as PTC5.<br>1 PTC5/BKGD/MS pin functions as BKGD/MS.                                                                                                             |
| 0<br>RSTPE  | <b>RESET Pin Enable</b> — This write-once bit when set enables the PTC6/ <u>RESET</u> pin to function as <u>RESET</u> . When clear, the pin functions as open drain output only GPIO. This pin defaults to its <u>RESET</u> function following an MCU POR or LVD. When RSTPE is set, an internal pullup device is enabled on <u>RESET</u> .<br>0 PTC6/ <u>RESET</u> pin functions as PTC6.<br>1 PTC6/ <u>RESET</u> pin functions as <u>RESET</u> . |

### 5.8.5 System Options Register 2 (SOPT2)

This high-page register contains bits to configure MCU specific features on the MC9S08LG32 series devices.

**Figure 5-6. System Options Register 2 (SOPT2)**

<sup>1</sup> This bit can be written only one time after reset. Additional writes are ignored.

**Table 5-7. SOPT2 Register Field Descriptions**

| Field        | Description                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>COPCLKS | <b>COP Watchdog Clock Select</b> — This write-once bit selects the clock source of the COP watchdog.<br>0 Internal 1 kHz clock is source to COP.<br>1 Bus clock is source to COP. |
| 0<br>SPIFE   | <b>SPI Filter Enable</b> — This bit selects the IFE control of the SPI pins.<br>0 IFE disabled<br>1 IFE enabled                                                                   |

### 5.8.6 System Device Identification Register (SDIDH, SDIDL)

These high-page read-only registers are included so host development systems can identify the HCS08 derivative. This allows the development software to recognize where specific memory blocks, registers, and control bits are located in a target MCU.

Figure 5-7. System Device Identification Register — High (SDIDH)

Table 5-8. SDIDH Register Field Descriptions

| Field           | Description                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:4<br>Reserved | Bits 7:4 are reserved. Reading these bits result in an indeterminate value; writes have no effect.                                                                                                           |
| 3:0<br>ID[11:8] | <b>Part Identification Number</b> — Each derivative in the HCS08 Family has a unique identification number. The MC9S08LG32 is hard coded to the value 0x02A. See also ID bits in <a href="#">Table 5-9</a> . |

| Field          | Description                                                                                                                                                                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>ID[7:0] | <b>Part Identification Number</b> — Each derivative in the HCS08 Family has a unique identification number. The MC9S08LG32 is hard coded to the value 0x02A. See also ID bits in <a href="#">Table 5-8</a> . |

## 5.8.7 System Power Management Status and Control 1 Register (SPMSC1)

This high-page register contains status and control bits to support the low voltage detect function, and to enable the bandgap voltage reference for use by the ADC module. To configure the low voltage detect trip voltage, see Table for the LVDV bit description in SPMSC2.

|              | 7                 | 6      | 5                           | 4                  | 3     | 2                 | 1              | 0    |
|--------------|-------------------|--------|-----------------------------|--------------------|-------|-------------------|----------------|------|
| R            | LVWF <sup>1</sup> | 0      | LVWIE                       | LVDRE <sup>2</sup> | LVDSE | LVDE <sup>2</sup> | 0 <sup>3</sup> | BGBE |
| W            |                   | LVWACK |                             |                    |       |                   |                |      |
| RESET:       | 0                 | 0      | 0                           | 1                  | 1     | 1                 | 0              | 0    |
| POR and LVD: | 0                 | 0      | 0                           | 1                  | 1     | 1                 | 0              | 0    |
|              |                   |        | = Unimplemented or Reserved |                    |       |                   |                |      |

**Figure 5-9. System Power Management Status and Control 1 Register (SPMSC1)**

<sup>1</sup> LVWF is set in the case when V<sub>Supply</sub> transitions below the trip point or after reset and V<sub>Supply</sub> is already below V<sub>LVW</sub>.

<sup>2</sup> Write-once only after any system reset

<sup>3</sup> Bit 1 is a reserved bit that must always be written to 0.

**Table 5-10. SPMSC1 Register Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>LVWF   | <b>Low-Voltage Warning Flag</b> - The LVWF bit indicates the Low-Voltage Warning status.<br>0 Low voltage warning <b>not</b> present.<br>1 Low voltage warning is present or was present.                                                                                                                                           |
| 6<br>LVWACK | <b>Low-Voltage Warning Acknowledge</b><br>The LVWACK bit indicates the Low-Voltage Warning Acknowledge status. Writing a logic 1 to LVWACK clears LVWF to a logic 0 if a low voltage warning is not present.                                                                                                                        |
| 5<br>LVWIE  | <b>Low-Voltage Warning Interrupt Enable</b><br>This bit enables hardware interrupt requests for LVWF..<br>0 Hardware interrupt disabled(use polling).<br>1 Request a hardware interrupt when LVWF=1.                                                                                                                                |
| 4<br>VDRE   | <b>Low-Voltage Detect Reset Enable</b><br>This write-once bit enables LVD events to generate a hardware reset(provided LVDE=1). This bit has no effect if the LVDE bit is a logic 0.<br>0 LVD events do not generate hardware resets.<br>1 Force an MCU reset when an enabled low-voltage detect event occurs.                      |
| 3<br>LVDSE  | <b>Low-Voltage Detect Stop Enable</b><br>Provided LVDE = 1, this read/write bit determines whether the low-voltage detect function operates when the MCU is in stop mode. This bit has no effect if the LVDE bit is a logic 0.<br>0 Low-Voltage detect disabled during stop mode.<br>1 Low-Voltage detect enabled during stop mode. |

Table 5-10. SPMSC1 Register Field Descriptions (continued)

| Field     | Description                                                                                                                                                                                                                 |

## 5.8.9 System Clock Gating Control 1 Register (SCGC1)

This high-page register contains control bits to enable or disable the bus clock to the TPMx, ADC, IIC, MTIM, RTC, and SCIx modules. Gating off the clocks to unused peripherals is used to reduce the MCU's run and wait currents. See [Section 5.7, “Peripheral Clock Gating,”](#) for more information.

### NOTE

User software must disable the peripheral before disabling the clocks to the peripheral. When clocks are re-enabled to a peripheral, the peripheral registers need to be re-initialized by user software.

|        |     |      |      |     |      |     |      |      |
|--------|-----|------|------|-----|------|-----|------|------|

## 5.8.10 System Clock Gating Control 2 Register (SCGC2)

This high-page register contains control bits to enable or disable the bus clock to the IRQ, KBI, LCD, and SPI modules. Gating off the clocks to unused peripherals is used to reduce the MCU's run and wait currents. See [Section 5.7, "Peripheral Clock Gating,"](#) for more information.

### NOTE

User software must disable the peripheral before disabling the clocks to the peripheral. When clocks are re-enabled to a peripheral, the peripheral registers need to be re-initialized by user software.

### 5.8.14 Pin Position Control Register (PINPS4)

This high-page register contains control bits that determine which of the two potential pins is used as the source for the function. The default source is the pin available on 48-pin package.

## Chapter 6

# Parallel Input/Output Control

### 6.1 Introduction

This section explains software controls related to parallel input/output (I/O) and pin control. The MC9S08LG32 has nine parallel I/O ports (PTA-PTI) which include a total of 69 I/O pins, including two output-only pins. See [Chapter 2, “Pins and Connections,”](#) for more information about pin assignments and external hardware considerations of these pins.

Many of these pins are shared with on-chip peripherals such as timer systems, communication systems, or keyboard interrupts, as shown in [Table 2-1](#). The peripheral modules have priority over the general-purpose I/O functions so that when a peripheral is enabled, the I/O functions associated with the shared pins may be disabled.

After reset, the shared peripheral functions are disabled and the pins are configured as inputs (PTxDDn = 0). The pin control functions for each pin are configured as follows: slew rate control enabled (PTxSEn = 1), low drive strength selected (PTxDSn = 0), and internal pullups disabled (PTxPEn = 0).

#### NOTE

All general-purpose I/O pins are not available on all packages. To avoid extra current drain from floating input pins, your reset initialization routine in the application program must either enable on-chip pullup devices or change the direction of unconnected pins to outputs so the pins do not float.

### 6.2 Pins Shared with LCD

Pins that have shared function with the LCD have special behavior based on the state of the VSUPPLY bits in the LCDSUPPLY register. These pins (PTA, PTB, PTC[4:0], PTD, PTE and PTG) can operate as full complementary drive or open drain drive depending on the VSUPPLY bits. When  $V_{LL3}$  is connected to  $V_{DD}$  externally, VSUPPLY = 11, FCDEN = 1, and RVEN = 0; the pins operate as full complementary drive. For all other VSUPPLY modes, the GPIO shared with LCD operates as open drain.

### 6.3 Port Data and Data Direction

Reading and writing of parallel I/Os are performed through the port data registers (PTxDn). The direction, either input or output, is controlled through the port data direction registers (PTxDDn). The parallel I/O port function for an individual pin is illustrated in the block diagram shown in [Figure 6-1](#).

The data direction control bit (PTxDDn) determines whether the output buffer or the input buffer for the associated pin is enabled. When a shared digital function is enabled for a pin, the output buffer is controlled

by the shared function. However, the data direction register bit continues to control the source for reads of the port data register.

When a shared analog function is enabled for a pin, both the input and output buffers are disabled. A value of 0 is read for any port data bit where the bit is an input ( $PTxDDn = 0$ ) and the input buffer is disabled. In general, whenever a pin is shared with both an alternate digital function and an analog function, the analog function has priority such that if both the digital and analog functions are enabled, the analog function controls the pin.

It is good programming practice to write to the port data register before changing the direction of a port pin so it becomes an output. This ensures that the pin is not driven momentarily with an old data value that happen to be in the port data register.

Figure 6-1. Parallel I/O Block Diagram

## 6.4 Pullup, Slew Rate, and Drive Strength

Associated with the parallel I/O ports is a set of registers located in the high-page register space that operates independently of the parallel I/O registers. These registers are used to control pullups, slew rate, and drive strength for the pins and can be used in conjunction with the peripheral functions on these pins.

### 6.4.1 Port Internal Pullup Enable

For all GPIOs, set the corresponding bit in the pullup enable register ( $PTxPEN$ ) to enable an internal pullup resistor for each port pin. Typically, GPIO internal pullups are disabled when in output mode. However, for GPIO that are muxed with LCD pins, the internal pullup is not disabled when in open drain, output mode. Similarly the internal pullup for GPIO muxed with open drain RESET pin is not disabled in the output mode.

The pullup device is disabled if the pin is controlled by an analog function regardless of the state of the corresponding pullup enable register bit.

### 6.4.2 Port Slew Rate Enable

Slew rate control can be enabled for each port pin by setting the corresponding bit in the slew rate control register (PTxSEn). When enabled, slew control limits the rate at which an output can transition to reduce EMC emissions. Slew rate control has no effect on pins that are configured as inputs.

### 6.4.3 Port Drive Strength Select

An output pin can be configured for high-output drive strength by setting the corresponding bit in the drive strength select register (PTxDSn). When high drive is selected, a pin is capable of sourcing and sinking greater current. Even though every I/O pin can be selected as high drive, you must ensure that the total current source and sink limits for the MCU are not exceeded. Drive strength selection is intended to affect the DC behavior of I/O pins. However, the AC behavior is also affected. High drive allows a pin to drive a greater load with the same switching speed as a low drive enabled pin into a smaller load. Because of this, the EMC emissions may be affected by enabling pins as high drive.

## 6.5 Open Drain Operation

For most cases, port pins that share functions with the LCD operate as open drain outputs. As an open drain output, the output high of the pin is dependent upon the pullup resistor. The pullup resistor can be an internal resistor enabled by the PTxPEx bit or an external resistor.

- The value of the internal resistor can be in the range of 17.5 to 52.5 k $\Omega$
- The value of an external resistor must be carefully selected to ensure it supports the output loads that are being driven.

## 6.6 Pin Behavior in Stop Modes

Pin behavior following execution of a STOP instruction depends on the stop mode that is entered. An explanation of pin behavior for the various stop modes follows:

- Stop2 mode is a partial power-down mode, whereby I/O latches are maintained in their pre-STOP instruction state. CPU register status and the state of I/O registers must be saved in RAM before the STOP instruction is executed to place the MCU in stop2 mode. Upon recovery from stop2 mode, before accessing any I/O, you must examine the state of the PPDF bit in the SPMSC2 register. If the PPDF bit is 0, I/O must be initialized as if a power-on reset had occurred. If the PPDF bit is 1, I/O register states must be restored from the values saved in RAM before the STOP instruction was executed. Peripherals may require initialization or restoration to their pre-stop condition. You must then write a 1 to the PPDACK bit in the SPMSC2 register. Access to I/O is again permitted in the user application program.
- If the LCD module is configured to operate in Stop modes, the drive mode of the GPIO shared with LCD is retained upon stop recovery.

- In stop3 mode, all I/O is maintained because internal logic circuitry stays powered up. Upon recovery, normal I/O function is available to the user.

## 6.7 Parallel I/O and Pin Control Registers

This section provides information about the registers associated with the parallel I/O ports. The data and data direction registers are located in page zero of the memory map. The pullup, slew rate, and drive strength control registers are located in the high-page section of the memory map.

Refer to tables in [Chapter 4, “Memory,”](#) for the absolute address assignments for all parallel I/O and their pin control registers. This section refers to registers and control bits only by their names. A Freescale Semiconductor-provided equate or header file is normally to translate these names into the appropriate absolute addresses.

### 6.7.1 Port A Registers

Port A is controlled by the registers listed below. All the pins of port A are shared with LCD. These pins have special behavior as explained in [Section 6.2](#).

### 6.7.1.1 Port A Data Register (PTAD)

Figure 6-2. Port A Data Register (PTAD)

Table 6-1. PTAD Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTAD[7:0] | <b>Port A Data Register Bits</b> — For port A pins that are inputs, reads return the logic level on the pin. For port A pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For port A pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTAD to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled. |

### 6.7.1.2 Port A Data Direction Register (PTADD)

Figure 6-3. Port A Data Direction Register (PTADD)

Table 6-2. PTADD Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTADD[7:0] | <b>Data Direction for Port A Bits</b> — These read/write bits control the direction of port A pins and what is read for PTAD reads.<br>0 Input (output driver disabled) and reads return the pin value.<br>1 Output driver enabled for port A bit n and PTAD reads return the contents of PTADn. |

Figure 6-11. Drive Strength Selection for Port B Register (PTBDS)

Table 6-10. PTBDS Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTBDS[7:0] | <b>Output Drive Strength Selection for Port B Bits</b> — Each of these control bits selects between low and high output drive for the associated PTB pin. For Port B pins that are configured as inputs, these bits have no effect.<br>0 Low output drive strength selected for Port B bit n.<br>1 High output drive strength selected for Port B bit n. |

### 6.7.3 Port C Registers

Port C is controlled by the registers listed below. PTC[4:0] are shared with LCD. These pins have special behavior as explained in [Section 6.2](#). PTC[5] is a output only pin. PTC[6] is a output only pin with open drain drive and internal pull up.

#### 6.7.3.1 Port C Data Register (PTCD)

Figure 6-12. Port C Data Register (PTCD)

Table 6-11. PTCD Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0<br>PTCD[6:0] | <b>Port C Data Register Bits</b> — For Port C pins that are inputs, reads return the logic level on the pin. For Port C pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For Port C pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTCD to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled. |

#### 6.7.3.2 Port C Data Direction Register (PTCDD)

Figure 6-13. Port C Data Direction Register (PTCDD)

Table 6-12. PTCDD Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0<br>PTCDD[6:0] | <b>Data Direction for Port C Bits</b> — These read/write bits control the direction of Port C pins and what is read for PTCD reads. <ul style="list-style-type: none"> <li>0 Input (output driver disabled) and reads return the pin value.</li> <li>1 Output driver enabled for Port C bit n and PTCD reads return the contents of PTCDn.</li> </ul> |

### 6.7.3.3 Port C Pull Enable Register (PTCPE)

Figure 6-14. Internal Pull Enable for Port C Register (PTCPE)

Table 6-13. PTCPE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0<br>PTCPE[6:0] | <b>Internal Pull Enable for Port C Bits</b> — Each of these control bits determines if the internal pullup or pulldown device is enabled for the associated PTC pin. For Port C pins that are configured as outputs, these bits have no effect and the internal pull devices are disabled.<br>0 Internal pullup device disabled for Port C bit n.<br>1 Internal pullup device enabled for Port C bit n. |

### 6.7.3.4 Port C Slew Rate Enable Register (PTCSE)

Figure 6-15. Slew Rate Enable for Port C Register (PTCSE)

Table 6-14. PTCSE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0<br>PTCSE[6:0] | <b>Output Slew Rate Enable for Port C Bits</b> — Each of these control bits determines if the output slew rate control is enabled for the associated PTC pin. For Port C pins that are configured as inputs, these bits have no effect.<br>0 Output slew rate control disabled for Port C bit n.<br>1 Output slew rate control enabled for Port C bit n. |

# 6.7.6 Port F Registers

Port F is controlled by the registers listed below.

## 6.7.6.1 Port F Data Register (PTFD)

Figure 6-27. Port F Data Register (PTFD)

Table 6-26. PTFD Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTFD[7:0] | <b>Port F Data Register Bits</b> — For Port F pins that are inputs, reads return the logic level on the pin. For Port F pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For Port F pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTFD to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled. |

## 6.7.6.2 Port F Data Direction Register (PTFDD)

Figure 6-28. Port F Data Direction Register (PTFDD)

Table 6-27. PTFDD Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTFDD[7:0] | <b>Data Direction for Port F Bits</b> — These read/write bits control the direction of Port F pins and what is read for PTFD reads.<br>0 Input (output driver disabled) and reads return the pin value.<br>1 Output driver enabled for Port F bit n and PTFD reads return the contents of PTFDn. |

### 6.7.6.3 Port F Pull Enable Register (PTFPE)

Figure 6-29. Internal Pull Enable for Port F Register (PTFPE)

Table 6-28. PTFPE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTFPE[7:0] | <b>Internal Pull Enable for Port F Bits</b> — Each of these control bits determines if the internal pullup or pulldown device is enabled for the associated PTF pin. For Port F pins that are configured as outputs, these bits have no effect and the internal pull devices are disabled.<br>0 Internal pullup device disabled for Port F bit n.<br>1 Internal pullup device enabled for Port F bit n. |

### 6.7.6.4 Port F Slew Rate Enable Register (PTFSE)

Figure 6-30. Slew Rate Enable for Port F Register (PTFSE)

Table 6-29. PTFSE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTFSE[7:0] | <b>Output Slew Rate Enable for Port F Bits</b> — Each of these control bits determines if the output slew rate control is enabled for the associated PTF pin. For Port F pins that are configured as inputs, these bits have no effect.<br>0 Output slew rate control disabled for Port F bit n.<br>1 Output slew rate control enabled for Port F bit n. |

### 6.7.6.5 Port F Drive Strength Selection Register (PTFDS)

Figure 6-31. Drive Strength Selection for Port F Register (PTFDS)

Table 6-30. PTFDS Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTFDS[7:0] | <b>Output Drive Strength Selection for Port F Bits</b> — Each of these control bits selects between low and high output drive for the associated PTF pin. For Port F pins that are configured as inputs, these bits have no effect.<br>0 Low output drive strength selected for Port F bit n.<br>1 High output drive strength selected for Port F bit n. |

## 6.7.7 Port G Registers

Port G is controlled by the registers listed below. All Port G pins are shared with LCD. These pins have special behavior as explained in [Section 6.2](#).

### 6.7.7.1 Port G Data Register (PTGD)

Figure 6-32. Port G Data Register (PTGD)

Table 6-31. PTGD Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTGD[7:0] | <b>Port G Data Register Bits</b> — For Port G pins that are inputs, reads return the logic level on the pin. For Port G pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For Port G pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTGD to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled. |

### 6.7.7.2 Port G Data Direction Register (PTGDD)

Figure 6-33. Port G Data Direction Register (PTGDD)

Table 6-32. PTGDD Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTGDD[7:0] | <b>Data Direction for Port G Bits</b> — These read/write bits control the direction of Port G pins and what is read for PTGD reads.<br>0 Input (output driver disabled) and reads return the pin value.<br>1 Output driver enabled for Port G bit n and PTGD reads return the contents of PTGDn. |

### 6.7.7.3 Port G Pull Enable Register (PTGPE)

Figure 6-34. Internal Pull Enable for Port G Register (PTGPE)

Table 6-33. PTGPE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Figure 6-35. Slew Rate Enable for Port G Register (PTGSE)

Table 6-34. PTGSE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTGSE[7:0] | <b>Output Slew Rate Enable for Port G Bits</b> — Each of these control bits determines if the output slew rate control is enabled for the associated PTG pin. For Port G pins that are configured as inputs, these bits have no effect.<br>0 Output slew rate control disabled for Port G bit n.<br>1 Output slew rate control enabled for Port G bit n. |

### 6.7.7.5 Port G Drive Strength Selection Register (PTGDS)

Figure 6-36. Drive Strength Selection for Port G Register (PTGDS)

Table 6-35. PTGDS Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTGDS[7:0] | <b>Output Drive Strength Selection for Port G Bits</b> — Each of these control bits selects between low and high output drive for the associated PTG pin. For Port G pins that are configured as inputs, these bits have no effect.<br>0 Low output drive strength selected for Port G bit n.<br>1 High output drive strength selected for Port G bit n. |

# 6.7.8 Port H Registers

Port H is controlled by the registers listed below.

## 6.7.8.1 Port H Data Register (PTHD)

Figure 6-37. Port H Data Register (PTHD)

Table 6-36. PTHD Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTHD[7:0] | <b>Port H Data Register Bits</b> — For Port H pins that are inputs, reads return the logic level on the pin. For Port H pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For Port H pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTHD to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled. |

## 6.7.8.2 Port H Data Direction Register (PTHDD)

Figure 6-38. Port H Data Direction Register (PTHDD)

Table 6-37. PTHDD Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTHDD[7:0] | <b>Data Direction for Port H Bits</b> — These read/write bits control the direction of Port H pins and what is read for PTHD reads.<br>0 Input (output driver disabled) and reads return the pin value.<br>1 Output driver enabled for Port H bit n and PTHD reads return the contents of PTHDn. |

### 6.7.8.3 Port H Pull Enable Register (PTHPE)

Figure 6-39. Internal Pull Enable for Port H Register (PTHPE)

Table 6-38. PTHPE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTHPE[7:0] | <b>Internal Pull Enable for Port H Bits</b> — Each of these control bits determines if the internal pullup or pulldown device is enabled for the associated PTH pin. For Port H pins that are configured as outputs, these bits have no effect and the internal pull devices are disabled.<br>0 Internal pullup device disabled for Port H bit n.<br>1 Internal pullup device enabled for Port H bit n. |

### 6.7.8.4 Port H Slew Rate Enable Register (PTHSE)

Figure 6-40. Slew Rate Enable for Port H Register (PTHSE)

Table 6-39. PTHSE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTHSE[7:0] | <b>Output Slew Rate Enable for Port H Bits</b> — Each of these control bits determines if the output slew rate control is enabled for the associated PTH pin. 6.7.8.5 Port H Drive Strength Selection Register (PTHDS)

Figure 6-41. Drive Strength Selection for Port H Register (PTHDS)

Table 6-40. PTHDS Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTHDS[7:0] | <b>Output Drive Strength Selection for Port H Bits</b> — Each of these control bits selects between low and high output drive for the associated PTH pin. For Port H pins that are configured as inputs, these bits have no effect.<br>0 Low output drive strength selected for Port H bit n.<br>1 High output drive strength selected for Port H bit n. |

## 6.7.9 Port I Registers

The following registers control the Port I.

### 6.7.9.1 Port I Data Register (PTID)

Figure 6-42. Port I Data Register (PTID)

Table 6-41. PTID Register Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5:0<br>PTID[5:0] | <b>Port I Data Register Bits</b> — For Port I pins that are inputs, reads return the logic level on the pin. For Port I pins that are configured as outputs, reads return the last value written to this register. Writes are latched into all bits of this register. For Port I pins that are configured as outputs, the logic level is driven out the corresponding MCU pin. Reset forces PTID to all 0s, but these 0s are not driven out the corresponding pins because reset also configures all port pins as high-impedance inputs with pullups disabled. |

### 6.7.9.2 Port I Data Direction Register (PTIDD)

Figure 6-43. Port I Data Direction Register (PTIDD)

Table 6-42. PTIDD Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5:0<br>PTIDD[5:0] | <b>Data Direction for Port I Bits</b> — These read/write bits control the direction of Port I pins and what is read for PTID reads.<br>0 Input (output driver disabled) and reads return the pin value.<br>1 Output driver enabled for Port I bit n and PTID reads return the contents of PTIDn. |

### 6.7.9.3 Port I Pull Enable Register (PTIPE)

Figure 6-44. Internal Pull Enable for Port I Register (PTIPE)

Table 6-43. PTIPE Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5:0<br>PTIPE[5:0] | <b>Internal Pull Enable for Port I Bits</b> — Each of these control bits determines if the internal pullup or pulldown device is enabled for the associated PTI pin. 6.7.9.5 Port I Drive Strength Selection Register (PTIDS)

Figure 6-46. Drive Strength Selection for Port I Register (PTIDS)

Table 6-45. PTIDS Register Field Descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>PTIDS[7:0] | <b>Output Drive Strength Selection for Port I Bits</b> — Each of these control bits selects between low and high output drive for the associated PTI pin. For Port I pins that are configured as inputs, these bits have no effect.<br>0 Low output drive strength selected for Port I bit n.<br>1 High output drive strength selected for Port I bit n. |

## Chapter 7

# Keyboard Interrupt (S08KBIV2)

### 7.1 Introduction

The keyboard interrupt KBI module provides up to eight independently-enabled, external interrupt sources.

#### 7.1.1 Module Configuration

The KBI module pins, KBI<sub>n</sub> can be repositioned under software control using KBI0, KBI1, KBI2, KBI3, KBI4, KBI5, KBI6, and KBI7 bits in PINPS1 register as shown in [Table 7-1](#). KBI0, KBI1, KBI2, KBI3, KBI4, KBI5, KBI6, and KBI7 bits in PINPS1 register selects which general-purpose I/O ports are associated with KBI operation.

**Table 7-1. KBI Position Options**

| KBI <sub>n</sub> in PINPS1 | Port Pin for KBI7 | Port Pin for KBI6 | Port Pin for KBI5 | Port Pin for KBI4 |
|----------------------------|-------------------|-------------------|-------------------|-------------------|
| 0 (default)                | PTA6              | PTA5              | PTA4              | PTA3              |
| 1                          | PTH3              | PTH2              | PTH1              | PTH0              |

| KBI <sub>n</sub> in PINPS1 | Port Pin for KBI3 | Port Pin for KBI2 | Port Pin for KBI1 | Port Pin for KBI0 |
|----------------------------|-------------------|-------------------|-------------------|-------------------|
| 0 (default)                | PTF0              | PTF5              | PTF4              | PTF3              |
| 1                          | PTH5              | PTH4              | PTH7              | PTH6              |

#### 7.1.2 KBI Clock Gating

The bus clock to the KBI can be gated on and off using the KBI bit in SCGC2. This bit is clear after any reset, which disables the bus clock to this module. To conserve power, this bit can be cleared to disable the clock to this module when not in use. For more details, see [Section 5.7, “Peripheral Clock Gating.”](#)

Figure 7-1. MC9S08LG32 Series Block Diagram Highlighting KBI Block and Pins

### 7.1.3 Features

The KBI features include:

- Up to eight keyboard interrupt pins with individual pin enable bits.
- Each keyboard interrupt pin is programmable as falling edge (or rising edge) only, or both falling edge and low level (or both rising edge and high level) interrupt sensitivity.
- One software enabled keyboard interrupt.
- Exit from low-power modes.

### 7.1.4 Modes of Operation

This section defines the KBI operation in wait, stop, and background debug modes.

#### 7.1.4.1 KBI in Wait Mode

The KBI continues to operate in wait mode if enabled before executing the WAIT instruction. Therefore, an enabled KBI pin ( $KBPEx = 1$ ) can be used to bring the MCU out of wait mode if the KBI interrupt is enabled ( $KBIE = 1$ ).

#### 7.1.4.2 KBI in Stop Modes

The KBI operates asynchronously in stop3 mode if enabled before executing the STOP instruction. Therefore, an enabled KBI pin ( $KBPEx = 1$ ) can be used to bring the MCU out of stop3 mode if the KBI interrupt is enabled ( $KBIE = 1$ ).

During stop2 mode, the KBI is disabled. In some systems, the pins associated with the KBI may be sources of wakeup from stop2, see the stop modes section in the [Chapter 3, “Modes of Operation.”](#) Upon wakeup from stop2 mode, the KBI module will be in the reset state.

#### 7.1.4.3 KBI in Active Background Mode

When the microcontroller is in active background mode, the KBI will continue to operate normally.

### 7.1.5 Block Diagram

The block diagram for the keyboard interrupt module is shown [Figure 7-2](#).

Figure 7-2. KBI Block Diagram

## 7.2 External Signal Description

The KBI input pins can be used to detect either falling edges, or both falling edge and low level interrupt requests. The KBI input pins can also be used to detect either rising edges, or both rising edge and high level interrupt requests.

The signal properties of KBI are shown in [Table 7-2](#).

Table 7-2. Signal Properties

| Signal | Function                | I/O |
|--------|-------------------------|-----|
| KBIPn  | Keyboard interrupt pins | I   |

## 7.3 Register Definition

The KBI includes three registers:

- An 8-bit pin status and control register.
- An 8-bit pin enable register.
- An 8-bit edge select register.

Refer to the direct-page register summary in [Chapter 4, “Memory,”](#) for the absolute address assignments for all KBI registers. This section refers to registers and control bits only by their names.

Some MCUs may have more than one KBI, so register names include placeholder characters to identify which KBI is being referenced.

### 7.3.1 KBI Status and Control Register (KBISC)

KBISC contains the status flag and control bits, which are used to configure the KBI.

Figure 7-3. KBI Status and Control Register

Table 7-3. KBISC Register Field Descriptions

| Field      | Description                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:4        | Unused register bits, always read 0.                                                                                                                                                                          |
| 3<br>KBF   | <b>Keyboard Interrupt Flag</b> — KBF indicates when a keyboard interrupt is detected. Writes have no effect on KBF.<br>0 No keyboard interrupt detected.<br>1 Keyboard interrupt detected.                    |
| 2<br>KBACK | <b>Keyboard Acknowledge</b> — Writing a 1 to KBACK is part of the flag clearing mechanism. KBACK always reads as 0.                                                                                           |
| 1<br>KBIE  | <b>Keyboard Interrupt Enable</b> — KBIE determines whether a keyboard interrupt is requested.<br>0 Keyboard interrupt request not enabled.<br>1 Keyboard interrupt request enabled.                           |
| 0<br>KBMOD | <b>Keyboard Detection Mode</b> — KBMOD (along with the KBEDG bits) controls the detection mode of the keyboard interrupt pins.<br>0 Keyboard detects edges only.<br>1 Keyboard detects both edges and levels. |

### 7.3.2 KBI Pin Enable Register (KBIPE)

KBIPE contains the pin enable control bits.

Figure 7-4. KBI Pin Enable Register

Table 7-4. KBIPE Register Field Descriptions

| Field         | Description                                                                                                                                                                                |

## 7.4 Functional Description

This on-chip peripheral module is called a keyboard interrupt (KBI) module because originally it was designed to simplify the connection and use of row-column matrices of keyboard switches. However, these inputs are also useful as extra external interrupt inputs and as an external means of waking the MCU from stop or wait low-power modes.

The KBI module allows up to eight pins to act as additional interrupt sources. Writing to the KBIPEn bits in the keyboard interrupt pin enable register (KBIPEn) independently enables or disables each KBI pin. Each KBI pin can be configured as edge sensitive or edge and level sensitive based on the KBMOD bit in the keyboard interrupt status and control register (KBISC). Edge sensitive can be software programmed to be either falling or rising; the level can be either low or high. The polarity of the edge or edge and level sensitivity is selected using the KBEDGn bits in the keyboard interrupt edge select register (KBIES).

Synchronous logic is used to detect edges. Prior to detecting an edge, enabled keyboard inputs must be at the deasserted logic level. A falling edge is detected when an enabled keyboard input signal is seen as a logic 1 (the deasserted level) during one bus cycle and then a logic 0 (the asserted level) during the next cycle. A rising edge is detected when the input signal is seen as a logic 0 during one bus cycle and then a logic 1 during the next cycle.

### 7.4.1 Edge Only Sensitivity

A valid edge on an enabled KBI pin will set KBF in KBISC. If KBIE in KBISC is set, an interrupt request will be presented to the CPU. Clearing of KBF is accomplished by writing a 1 to KBACK in KBISC.

### 7.4.2 Edge and Level Sensitivity

A valid edge or level on an enabled KBI pin will set KBF in KBISC. If KBIE in KBISC is set, an interrupt request will be presented to the CPU. Clearing of KBF is accomplished by writing a 1 to KBACK in KBISC provided all enabled keyboard inputs are at their deasserted levels. KBF will remain set if any enabled KBI pin is asserted while attempting to clear by writing a 1 to KBACK.

### 7.4.3 KBI Pullup/Pulldown Resistors

The KBI pins can be configured to use an internal pullup/pulldown resistor using the associated I/O port pullup enable register. If an internal resistor is enabled, the KBIES register is used to select whether the resistor is a pullup ( $KBEDG_n = 0$ ) or a pulldown ( $KBEDG_n = 1$ ).

### 7.4.4 KBI Initialization

When a keyboard interrupt pin is first enabled it is possible to get a false keyboard interrupt flag. To prevent a false interrupt request during keyboard initialization, the user must do the following:

1. Mask keyboard interrupts by clearing KBIE in KBISC.
2. Enable the KBI polarity by setting the appropriate KBEDG<sub>n</sub> bits in KBIES.
3. If using internal pullup/pulldown device, configure the associated pullup enable bits in PTxPE.
4. Enable the KBI pins by setting the appropriate KBIPEn bits in KBIPE.
5. Write to KBACK in KBISC to clear any false interrupts.
6. Set KBIE in KBISC to enable interrupts.

## Chapter 8

# Central Processor Unit (S08CPUV5)

### 8.1 Introduction

This section provides summary information about the registers, addressing modes, and instruction set of the CPU of the HCS08 Family. For a more detailed discussion, refer to the *HCS08 Family Reference Manual, volume 1*, Freescale Semiconductor document order number HCS08RMV1/D.

The HCS08 CPU is fully source- and object-code-compatible with the M68HC08 CPU. Several instructions and enhanced addressing modes were added to improve C compiler efficiency and to support a new background debug system which replaces the monitor mode of earlier M68HC08 microcontrollers (MCU).

#### 8.1.1 Features

Features of the HCS08 CPU include:

- Object code fully upward-compatible with M68HC05 and M68HC08 Families
- All registers and memory are mapped to a single 64 KB address space
- 16-bit stack pointer (any size stack anywhere in 64 KB CPU address space)
- 16-bit index register (H:X) with powerful indexed addressing modes
- 8-bit accumulator (A)
- Many instructions treat X as a second general-purpose 8-bit register
- Seven addressing modes:
  - Inherent — Operands in internal registers
  - Relative — 8-bit signed offset to branch destination
  - Immediate — Operand in next object code byte(s)
  - Direct — Operand in memory at 0x0000–0x00FF
  - Extended — Operand anywhere in 64 KB address space
  - Indexed relative to H:X — Five submodes including auto increment
  - Indexed relative to SP — Improves C efficiency dramatically
- Memory-to-memory data move instructions with four address mode combinations
- Overflow, half-carry, negative, zero, and carry condition codes support conditional branching on the results of signed, unsigned, and binary-coded decimal (BCD) operations
- Efficient bit manipulation instructions
- Fast 8-bit by 8-bit multiply and 16-bit by 8-bit divide instructions
- Stop and Wait instructions to invoke low-power operating modes

## 8.2 Programmer's Model and CPU Registers

Figure 8-1 shows the five CPU registers. CPU registers are not part of the memory map.

Figure 8-1. CPU Registers

### 8.2.1 Accumulator (A)

The A accumulator is a general-purpose 8-bit register. One operand input to the arithmetic logic unit (ALU) is connected to the accumulator and the ALU results are often stored into the A accumulator after arithmetic and logical operations. The accumulator can be loaded from memory using various addressing modes to specify the address where the loaded data comes from, or the contents of A can be stored to memory using various addressing modes to specify the address where data from A will be stored.

Reset has no effect on the contents of the A accumulator.

### 8.2.2 Index Register (H:X)

This 16-bit register is actually two separate 8-bit registers (H and X), which often work together as a 16-bit address pointer where H holds the upper byte of an address and X holds the lower byte of the address. All indexed addressing mode instructions use the full 16-bit value in H:X as an index reference pointer; however, for compatibility with the earlier M68HC05 Family, some instructions operate only on the low-order 8-bit half (X).

Many instructions treat X as a second general-purpose 8-bit register that can be used to hold 8-bit data values. X can be cleared, incremented, decremented, complemented, negated, shifted, or rotated. Transfer instructions allow data to be transferred from A or transferred to A where arithmetic and logical operations can then be performed.

For compatibility with the earlier M68HC05 Family, H is forced to 0x00 during reset. Reset has no effect on the contents of X.

### 8.2.3 Stack Pointer (SP)

This 16-bit address pointer register points at the next available location on the automatic last-in-first-out (LIFO) stack. The stack may be located anywhere in the 64 KB address space that has RAM and can be any size up to the amount of available RAM. The stack is used to automatically save the return address for subroutine calls, the return address and CPU registers during interrupts, and for local variables. The AIS (add immediate to stack pointer) instruction adds an 8-bit signed immediate value to SP. This is most often used to allocate or deallocate space for local variables on the stack.

SP is forced to 0x00FF at reset for compatibility with the earlier M68HC05 Family. HCS08 programs normally change the value in SP to the address of the last location (highest address) in on-chip RAM during reset initialization to free up direct page RAM (from the end of the on-chip registers to 0x00FF).

The RSP (reset stack pointer) instruction was included for compatibility with the M68HC05 Family and is seldom used in new HCS08 programs because it only affects the low-order half of the stack pointer.

### 8.2.4 Program Counter (PC)

The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched.

During normal program execution, the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, interrupt, and return operations load the program counter with an address other than that of the next sequential location. This is called a change-of-flow.

During reset, the program counter is loaded with the reset vector that is located at 0xFFFFE and 0xFFFF. The vector stored there is the address of the first instruction that will be executed after exiting the reset state.

### 8.2.5 Condition Code Register (CCR)

The 8-bit condition code register contains the interrupt mask (I) and five flags that indicate the results of the instruction just executed. Bits 6 and 5 are set permanently to 1. The following paragraphs describe the functions of the condition code bits in general terms. For a more detailed explanation of how each instruction sets the CCR bits, refer to the *HCS08 Family Reference Manual, volume 1*, Freescale Semiconductor document order number HCS08RMv1.

Figure 8-2. Condition Code Register

Table 8-1. CCR Register Field Descriptions

| Field  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>V | <b>Two's Complement Overflow Flag</b> — The CPU sets the overflow flag when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow flag.<br>0 No overflow<br>1 Overflow                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 4<br>H | <b>Half-Carry Flag</b> — The CPU sets the half-carry flag when a carry occurs between accumulator bits 3 and 4 during an add-without-carry (ADD) or add-with-carry (ADC) operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations. The DAA instruction uses the states of the H and C condition code bits to automatically add a correction value to the result from a previous ADD or ADC on BCD operands to correct the result to a valid BCD value.<br>0 No carry between bits 3 and 4<br>1 Carry between bits 3 and 4                                                                                                                                    |
| 3<br>I | <b>Interrupt Mask Bit</b> — When the interrupt mask is set, all maskable CPU interrupts are disabled. CPU interrupts are enabled when the interrupt mask is cleared. When a CPU interrupt occurs, the interrupt mask is set automatically after the CPU registers are saved on the stack, but before the first instruction of the interrupt service routine is executed.<br>Interrupts are not recognized at the instruction boundary after any instruction that clears I (CLI or TAP). This ensures that the next instruction after a CLI or TAP will always be executed without the possibility of an intervening interrupt, provided I was set.<br>0 Interrupts enabled<br>1 Interrupts disabled |
| 2<br>N | <b>Negative Flag</b> — The CPU sets the negative flag when an arithmetic operation, logic operation, or data manipulation produces a negative result, setting bit 7 of the result. Simply loading or storing an 8-bit or 16-bit value causes N to be set if the most significant bit of the loaded or stored value was 1.<br>0 Non-negative result<br>1 Negative result                                                                                                                                                                                                                                                                                                                             |
| 1<br>Z | <b>Zero Flag</b> — The CPU sets the zero flag when an arithmetic operation, logic operation, or data manipulation produces a result of 0x00 or 0x0000. Simply loading or storing an 8-bit or 16-bit value causes Z to be set if the loaded or stored value was all 0s.<br>0 Non-zero result<br>1 Zero result                                                                                                                                                                                                                                                                                                                                                                                        |
| 0<br>C | <b>Carry/Borrow Flag</b> — The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some instructions — such as bit test and branch, shift, and rotate — also clear or set the carry/borrow flag.<br>0 No carry out of bit 7<br>1 Carry out of bit 7                                                                                                                                                                                                                                                                                                                                       |

## 8.3 Addressing Modes

Addressing modes define the way the CPU accesses operands and data. In the HCS08, memory, status and control registers, and input/output (I/O) ports share a single 64 KB CPU address space. This arrangement means that the same instructions that access variables in RAM can also be used to access I/O and control registers or nonvolatile program space.

Some instructions use more than one addressing mode. For instance, move instructions use one addressing mode to specify the source operand and a second addressing mode to specify the destination address. Instructions such as BRCLR, BRSET, CBEQ, and DBNZ use one addressing mode to specify the location of an operand for a test and then use relative addressing mode to specify the branch destination address when the tested condition is true. For BRCLR, BRSET, CBEQ, and DBNZ, the addressing mode listed in the instruction set tables is the addressing mode needed to access the operand to be tested, and relative addressing mode is implied for the branch destination.

### 8.3.1 Inherent Addressing Mode (INH)

In this addressing mode, operands needed to complete the instruction (if any) are located within CPU registers so the CPU does not need to access memory to get any operands.

### 8.3.2 Relative Addressing Mode (REL)

Relative addressing mode is used to specify the destination location for branch instructions. A signed 8-bit offset value is located in the memory location immediately following the opcode. During execution, if the branch condition is true, the signed offset is sign-extended to a 16-bit value and is added to the current contents of the program counter, which causes program execution to continue at the branch destination address.

### 8.3.3 Immediate Addressing Mode (IMM)

In immediate addressing mode, the operand needed to complete the instruction is included in the object code immediately following the instruction opcode in memory. In the case of a 16-bit immediate operand, the high-order byte is located in the next memory location after the opcode, and the low-order byte is located in the next memory location after that.

### 8.3.4 Direct Addressing Mode (DIR)

In direct addressing mode, the instruction includes the low-order eight bits of an address in the direct page (0x0000–0x00FF). During execution a 16-bit address is formed by concatenating an implied 0x00 for the high-order half of the address and the direct address from the instruction to get the 16-bit address where the desired operand is located. This is faster and more memory efficient than specifying a complete 16-bit address for the operand.

### 8.3.5 Extended Addressing Mode (EXT)

In extended addressing mode, the full 16-bit address of the operand is located in the next two bytes of program memory after the opcode (high byte first).

### 8.3.6 Indexed Addressing Mode

Indexed addressing mode has seven variations including five that use the 16-bit H:X index register pair and two that use the stack pointer as the base reference.

#### 8.3.6.1 Indexed, No Offset (IX)

This variation of indexed addressing uses the 16-bit value in the H:X index register pair as the address of the operand needed to complete the instruction.

#### 8.3.6.2 Indexed, No Offset with Post Increment (IX+)

This variation of indexed addressing uses the 16-bit value in the H:X index register pair as the address of the operand needed to complete the instruction. The index register pair is then incremented ( $H:X = H:X + 0x0001$ ) after the operand has been fetched. This addressing mode is only used for MOV and CBEQ instructions.

#### 8.3.6.3 Indexed, 8-Bit Offset (IX1)

This variation of indexed addressing uses the 16-bit value in the H:X index register pair plus an unsigned 8-bit offset included in the instruction as the address of the operand needed to complete the instruction.

#### 8.3.6.4 Indexed, 8-Bit Offset with Post Increment (IX1+)

This variation of indexed addressing uses the 16-bit value in the H:X index register pair plus an unsigned 8-bit offset included in the instruction as the address of the operand needed to complete the instruction. The index register pair is then incremented ( $H:X = H:X + 0x0001$ ) after the operand has been fetched. This addressing mode is used only for the CBEQ instruction.

#### 8.3.6.5 Indexed, 16-Bit Offset (IX2)

This variation of indexed addressing uses the 16-bit value in the H:X index register pair plus a 16-bit offset included in the instruction as the address of the operand needed to complete the instruction.

#### 8.3.6.6 SP-Relative, 8-Bit Offset (SP1)

This variation of indexed addressing uses the 16-bit value in the stack pointer (SP) plus an unsigned 8-bit offset included in the instruction as the address of the operand needed to complete the instruction.

### 8.3.6.7 SP-Relative, 16-Bit Offset (SP2)

This variation of indexed addressing uses the 16-bit value in the stack pointer (SP) plus a 16-bit offset included in the instruction as the address of the operand needed to complete the instruction.

## 8.4 Special Operations

The CPU performs a few special operations that are similar to instructions but do not have opcodes like other CPU instructions. In addition, a few instructions such as STOP and WAIT directly affect other MCU circuitry. This section provides additional information about these operations.

### 8.4.1 Reset Sequence

Reset can be caused by a power-on-reset (POR) event, internal conditions such as the COP (computer operating properly) watchdog, or by assertion of an external active-low reset pin. When a reset event occurs, the CPU immediately stops whatever it is doing (the MCU does not wait for an instruction boundary before responding to a reset event). For a more detailed discussion about how the MCU recognizes resets and determines the source, refer to [Chapter 5, “Resets, Interrupts, and General System Control.”](#)

The reset event is considered concluded when the sequence to determine whether the reset came from an internal source is done and when the reset pin is no longer asserted. At the conclusion of a reset event, the CPU performs a 6-cycle sequence to fetch the reset vector from 0xFFFFE and 0xFFFF and to fill the instruction queue in preparation for execution of the first program instruction.

### 8.4.2 Interrupt Sequence

When an interrupt is requested, the CPU completes the current instruction before responding to the interrupt. At this point, the program counter is pointing at the start of the next instruction, which is where the CPU should return after servicing the interrupt. The CPU responds to an interrupt by performing the same sequence of operations as for a software interrupt (SWI) instruction, except the address used for the vector fetch is determined by the highest priority interrupt that is pending when the interrupt sequence started.

The CPU sequence for an interrupt is:

1. Store the contents of PCL, PCH, X, A, and CCR on the stack, in that order.
2. Set the I bit in the CCR.
3. Fetch the high-order half of the interrupt vector.
4. Fetch the low-order half of the interrupt vector.
5. Delay for one free bus cycle.
6. Fetch three bytes of program information starting at the address indicated by the interrupt vector to fill the instruction queue in preparation for execution of the first instruction in the interrupt service routine.

After the CCR contents are pushed onto the stack, the I bit in the CCR is set to prevent other interrupts while in the interrupt service routine. Although it is possible to clear the I bit with an instruction in the

interrupt service routine, this would allow nesting of interrupts (which is not recommended because it leads to programs that are difficult to debug and maintain).

For compatibility with the earlier M68HC05 MCUs, the high-order half of the H:X index register pair (H) is not saved on the stack as part of the interrupt sequence. The user must use a PSHH instruction at the beginning of the service routine to save H and then use a PULH instruction just before the RTI that ends the interrupt service routine. It is not necessary to save H if you are certain that the interrupt service routine does not use any instructions or auto-increment addressing modes that might change the value of H.

The software interrupt (SWI) instruction is like a hardware interrupt except that it is not masked by the global I bit in the CCR and it is associated with an instruction opcode within the program so it is not asynchronous to program execution.

### 8.4.3 Wait Mode Operation

The WAIT instruction enables interrupts by clearing the I bit in the CCR. It then halts the clocks to the CPU to reduce overall power consumption while the CPU is waiting for the interrupt or reset event that will wake the CPU from wait mode. When an interrupt or reset event occurs, the CPU clocks will resume and the interrupt or reset event will be processed normally.

If a serial BACKGROUND command is issued to the MCU through the background debug interface while the CPU is in wait mode, CPU clocks will resume and the CPU will enter active background mode where other serial background commands can be processed. This ensures that a host development system can still gain access to a target MCU even if it is in wait mode.

### 8.4.4 Stop Mode Operation

Usually, all system clocks, including the crystal oscillator (when used), are halted during stop mode to minimize power consumption. In such systems, external circuitry is needed to control the time spent in stop mode and to issue a signal to wake up the target MCU when it is time to resume processing. Unlike the earlier M68HC05 and M68HC08 MCUs, the HCS08 can be configured to keep a minimum set of clocks running in stop mode. This optionally allows an internal periodic signal to wake the target MCU from stop mode.

When a host debug system is connected to the background debug pin (BKGD) and the ENBDM control bit has been set by a serial command through the background interface (or because the MCU was reset into active background mode), the oscillator is forced to remain active when the MCU enters stop mode. In this case, if a serial BACKGROUND command is issued to the MCU through the background debug interface while the CPU is in stop mode, CPU clocks will resume and the CPU will enter active background mode where other serial background commands can be processed. This ensures that a host development system can still gain access to a target MCU even if it is in stop mode.

Recovery from stop mode depends on the particular HCS08 and whether the oscillator was stopped in stop mode. Refer to [Chapter 3, “Modes of Operation,”](#) for more details.

### 8.4.5 BGND Instruction

The BGND instruction is new to the HCS08 compared to the M68HC08. BGND would not be used in normal user programs because it forces the CPU to stop processing user instructions and enter the active background mode. The only way to resume execution of the user program is through reset or by a host debug system issuing a GO, TRACE1, or TAGGO serial command through the background debug interface.

Software-based breakpoints can be set by replacing an opcode at the desired breakpoint address with the BGND opcode. When the program reaches this breakpoint address, the CPU is forced to active background mode rather than continuing the user program.

## 8.5 HCS08 Instruction Set Summary

### Instruction Set Summary Nomenclature

The nomenclature listed here is used in the instruction descriptions in [Figure 8-2](#).

#### Operators

- ( ) = Contents of register or memory location shown inside parentheses
- $\leftarrow$  = Is loaded with (read: “gets”)
- & = Boolean AND
- | = Boolean OR
- $\oplus$  = Boolean exclusive-OR
- $\times$  = Multiply
- $\div$  = Divide
- :
- + = Add
- = Negate (two’s complement)

#### CPU registers

- A = Accumulator
- CCR = Condition code register
- H = Index register, higher order (most significant) 8 bits
- X = Index register, lower order (least significant) 8 bits
- PC = Program counter
- PCH = Program counter, higher order (most significant) 8 bits
- PCL = Program counter, lower order (least significant) 8 bits
- SP = Stack pointer

#### Memory and addressing

- M = A memory location or absolute data, depending on addressing mode
- M:M + 0x0001 = A 16-bit value in two consecutive memory locations. The higher-order (most significant) 8 bits are located at the address of M, and the lower-order (least significant) 8 bits are located at the next higher sequential address.

#### Condition code register (CCR) bits

- V = Two’s complement overflow indicator, bit 7
- H = Half carry, bit 4
- I = Interrupt mask, bit 3
- N = Negative indicator, bit 2
- Z = Zero indicator, bit 1
- C = Carry/borrow, bit 0 (carry out of bit 7)

### CCR activity notation

- = Bit not affected
- 0 = Bit forced to 0
- 1 = Bit forced to 1
- = Bit set or cleared according to results of operation
- U = Undefined after the operation

### Machine coding notation

- dd = Low-order 8 bits of a direct address 0x0000–0x00FF (high byte assumed to be 0x00)
- ee = Upper 8 bits of 16-bit offset
- ff = Lower 8 bits of 16-bit offset or 8-bit offset
- ii = One byte of immediate data
- jj = High-order byte of a 16-bit immediate data value
- kk = Low-order byte of a 16-bit immediate data value
- hh = High-order byte of 16-bit extended address
- ll = Low-order byte of 16-bit extended address
- rr = Relative offset

### Source form

Everything in the source forms columns, except expressions in italic characters, is literal information that must appear in the assembly source file exactly as shown. The initial 3- to 5-letter mnemonic is always a literal expression. All commas, pound signs (#), parentheses, and plus signs (+) are literal characters.

- n — Any label or expression that evaluates to a single integer in the range 0–7
- opr8i — Any label or expression that evaluates to an 8-bit immediate value
- opr16i — Any label or expression that evaluates to a 16-bit immediate value
- opr8a — Any label or expression that evaluates to an 8-bit value. The instruction treats this 8-bit value as the low order 8 bits of an address in the direct page of the 64 KB address space (0x00xx).
- opr16a — Any label or expression that evaluates to a 16-bit value. The instruction treats this value as an address in the 64 KB address space.
- opr8 — Any label or expression that evaluates to an unsigned 8-bit value, used for indexed addressing
- opr16 — Any label or expression that evaluates to a 16-bit value. Because the HCS08 has a 16-bit address bus, this can be either a signed or an unsigned value.
- rel — Any label or expression that refers to an address that is within –128 to +127 locations from the next address after the last byte of object code for the current instruction. The assembler will calculate the 8-bit signed offset and include it in the object code for this instruction.

### Address modes

- INH = Inherent (no operands)

IMM = 8-bit or 16-bit immediate

DIR = 8-bit direct

EXT = 16-bit extended

IX = 16-bit indexed no offset

IX+ = 16-bit indexed no offset, post increment (CBEQ and MOV only)

IX1 = 16-bit indexed with 8-bit offset from H:X

IX1+ = 16-bit indexed with 8-bit offset, post increment (CBEQ only)

IX2 = 16-bit indexed with 16-bit offset from H:X

REL = 8-bit relative offset

SP1 = Stack pointer with 8-bit offset

SP2 = Stack pointer with 16-bit offset

Table 8-2 provides a summary of the HCS08 instruction set in all possible addressing modes. The table shows operand construction, execution time in internal bus clock cycles, and cycle-by-cycle details for each addressing mode variation of each instruction.

Table 8-2. Instruction Set Summary (Sheet 1 of 10)

## Chapter 9

# LCD Module (S08LCDLPV1)

### 9.1 Introduction

On the MC9S08LG32 series, the LCD module (LCD) controls 45 LCD pins to generate the waveforms necessary to drive a liquid crystal display. On the 80-pin package, the 45 LCD pins can be used to generate 4x41 or 8x37 configuration. On the 64-pin package, the 37 LCD pins can be used to generate 4x33 or 8x29 configuration. On the 48-pin package, there are 29 LCD pins available for driving 4x25 or 8x21 configurations.

#### NOTE

1. All references to  $V_{LL3}$  also applies to  $V_{LL3\_2}$  in this chapter.
2. For MC9S08LG32 series MCUs, the devices working at  $-40\text{ }^{\circ}\text{C}$  to  $85\text{ }^{\circ}\text{C}$  temperature range have the change pump feature only, whereas devices working at  $-40\text{ }^{\circ}\text{C}$  to  $105\text{ }^{\circ}\text{C}$  do not have this feature. For higher temperatures ( $-40\text{ }^{\circ}\text{C}$  to  $105\text{ }^{\circ}\text{C}$ ) register bias in high gain mode is recommended. For more details, see *AN3802 – Interfacing LCD with MC9S08LG32*.

#### 9.1.1 LCD Clock Sources

The LCD module on MC9S08LG32 series can be clocked from the OSCOUT or the ICSIRCLK (ALTCLK). See [Section 1.3, “System Clock Distribution,”](#) for more information.

#### 9.1.2 LCD Modes of Operation

The LCD module can be configured to operate in stop modes by setting the LCDSTP bit. All clock sources are available in all modes except stop2. In stop2 mode, only OSCOUT is available.

#### 9.1.3 LCD Status after Stop2 Wakeup

The LCD control registers is set to their default state. These registers must be re-initialized before setting the PPDACK. The contents of the LCD data registers (LCD waveform, LCD pin enable, and LCD backplane enable) are retained.

#### 9.1.4 LCD Clock Gating

The bus clock to the LCD can be gated on and off using the LCD bit in SCGC2. This bit is clear after any reset that disables the bus clock to this module. To conserve power, the LCD bit can be cleared to disable the clock to this module when not in use. For more details, see [Section 5.7, “Peripheral Clock Gating.”](#)

Figure 9-1. MC9S08LG32 Series Block Diagram Highlighting LCD Block and Pins

### 9.1.5 Features

The LCD module driver features include:

- LCD waveforms functional in wait, stop2 and stop3 low-power modes
- 45 LCD (LCD[44:0]) pins with selectable frontplane/backplane configuration
  - Generate up to 44 frontplane signals
  - Generate up to 8 backplanes signals
- Programmable LCD frame frequency
- Programmable blink modes and frequency
  - All segments blank during blink period
  - Alternate display for each LCD segment in x4 or less mode
  - Blink operation in low-power modes
- Programmable LCD power supply switch, making it an ideal solution for battery-powered and board-level applications
  - Charge pump requires only four external capacitors
  - Internal LCD power using  $V_{DD}$  (1.8 to 3.6 V)
  - External  $V_{LL3}$  power supply option (3V)
- Integrated charge pump for generating LCD bias voltages
  - Hardware configurable to drive 3 V or 5 V LCD panels
  - On-chip generation of bias voltages
- Waveform storage registers LCDWF
- Backplane reassignment to assist in vertical scrolling on dot-matrix displays
- Software configurable LCD frame frequency interrupt
- Internal ADC channels are connected to  $V_{LL1}$  to monitor their magnitudes. This feature allows software to adjust the contrast.

### 9.1.6 Modes of Operation

The LCD module supports the following operation modes:

**Table 9-1. LCD-Module Operation Modes**

| Mode  | Operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stop2 | <p>Depending on the state of the LCDSTP bit, the LCD module can operate an LCD panel in stop2 mode. If LCDSTP = 1, LCD module clock generation is turned off and the LCD module enters a power conservation state and is disabled. If LCDSTP = 0, the LCD module can operate an LCD panel in stop2, and the LCD module continues to display the current LCD panel contents based on the LCD operation prior to the stop2 event.</p> <p>If the LCD is enabled in stop2, the selected LCD clock source, OSCOUT, must be enabled to operate in stop2.</p> <p>The LCD frame interrupt does not cause the MCU to exit stop2.</p>           |
| Stop3 | <p>Depending on the state of the LCDSTP bit, the LCD module can operate an LCD panel in stop3 mode. If LCDSTP = 1, LCD module clock generation is turned off and the LCD module enters a power conservation state and is disabled. If LCDSTP = 0, the LCD module can operate an LCD panel in stop3, and the LCD module continues displaying the current LCD panel contents based on the LCD operation prior to the stop3 event.</p> <p>If the LCD is enabled in stop3, the selected LCD clock source, OSCOUT, must be enabled to operate in stop3.</p> <p>In stop3 mode, the LCD frame interrupt can cause the MCU to exit stop3.</p> |
| Wait  | <p>Depending on the configuration, the LCD module can operate an LCD panel in wait mode. If LCDWAI = 1, the LCD module clock generation is turned off and the LCD module enters a power-conservation state and is disabled. If LCDWAI = 0, the LCD module can operate an LCD panel in wait, and the LCD module continues displaying the current LCD panel contents base on the LCDWF registers.</p> <p>In wait mode, the LCD frame interrupt can cause the MCU to exit wait.</p>                                                                                                                                                      |

Stop2 provides the lowest power consumption state where the LCD module is functional. To operate the LCD in stop2 mode, use an external crystal.

### 9.1.7 Block Diagram

Figure 9-2 is a block diagram of the LCD module.

Figure 9-2. LCD Driver Block Diagram

## 9.2 External Signal Description

The LCD module has several external pins dedicated to power supply and LCD frontplane/backplane signaling. The LCD module can be configured to support eight backplane signals. The table below itemizes all the LCD external pins. See the [Chapter 2, “Pins and Connections,”](#) for device-specific pin configurations.

Table 9-2. Signal Properties

| Name                        | Port                                                   | Function                                                                                                           | Reset State    |
|-----------------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|----------------|
| 45 LCD frontplane/backplane | LCD[44:0]                                              | Switchable frontplane/backplane driver that connects directly to the display<br>LCD[44:0] can operate as GPIO pins | High impedance |
| LCD bias voltages           | $V_{LL1}$ ,<br>$V_{LL2}$ ,<br>$V_{LL3}$ , $V_{LL3\_2}$ | LCD bias voltages                                                                                                  | —              |
| LCD charge pump capacitance | $V_{cap1}$ , $V_{cap2}$                                | Charge pump capacitor pins                                                                                         | —              |

### 9.2.1 LCD[44:0]

When LCD functionality is enabled by the PEN[44:0] bits in the LCDPEN registers, the corresponding LCD[44:0] pin will generate a frontplane or backplane waveform depending on the configuration of the backplane-enable bit field (BPEN[44:0]).

### 9.2.2 $V_{LL1}$ , $V_{LL2}$ , $V_{LL3}$

$V_{LL1}$ ,  $V_{LL2}$ , and  $V_{LL3}$  are bias voltages for the LCD module driver waveforms which can be internally generated using the internal charge pump (when enabled). The charge pump can also be configured to accept  $V_{LL3}$  as an input and generate  $V_{LL1}$  and  $V_{LL2}$ . Refer to VSUPPLY[1:0] bits explanation.

On 64 and 80 pin packages  $V_{LL3}$  and  $V_{LL3\_2}$  pins provide the  $V_{LL3}$  supply to the LCD controller.

### 9.2.3 $V_{cap1}$ , $V_{cap2}$

The charge pump capacitor is used to transfer charge from the input supply to the regulated output. A ceramic capacitor is recommended.

## 9.3 Register Definition

This section consists of register descriptions. Each description includes a standard register diagram. Details of register bit and field function follow the register diagrams, in bit order.

### 9.3.1 LCD Control Register 0 (LCDC0)

Figure 9-3. LCD Control Register 0 (LCDC0)

Read: anytime

Write: LCDEN anytime. Do not change SOURCE, LCLK, or DUTY while LCDEN = 1.

**Table 9-3. LCDC0 Field Descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 9.3.7 LCD Pin Enable Registers 0–5 (LCDPEN0–LCDPEN5)

When LCDEN = 1, these bits enable the corresponding LCD pin for LCD operation.

These registers should only be written with instructions that perform byte writes, using instructions that perform word writes will lead to invalid data being placed in the register. Initialize these registers before enabling the LCD module. Exiting stop2 mode does not require reinitializing the LCDPEN registers.

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 44:0<br>PEN[44:0] | <p><b>LCD Pin Enable</b> — The PEN[44:0] bit enables the LCD[44:0] pin for LCD operation. Each LCD[44:0] pin can be configured as a backplane or a frontplane based on the corresponding BPEN[n] bit in the Backplane Enable Register (LCDBPEN[5:0]). If LCDEN = 0, these bits have no effect on the state of the I/O pins. Set PEN[44:0] bits before LCDEN is set.</p> <p>0 LCD operation disabled on LCDnn.<br/>1 LCD operation enabled on LCDnn.</p> |

### 9.3.8 Backplane Enable Registers 0–5 (BPEN0–BPEN5)

When LCDPEN[n] = 1, these bits configure the corresponding LCD pin to operate as an LCD backplane or an LCD frontplane. Most applications set a maximum of eight of these bits. Initialize these registers before enabling the LCD module. Exiting stop2 mode does not require reinitializing the LCDBPEN registers.

These registers should only be written with instructions that perform byte writes, using instructions that perform word writes will lead to invalid data being placed in the register.

| 44:0<br>BPEN[44:0] | <b>Backplane Enable</b> — The BPEN[44:0] bit configures the LCD[44:0] pin to operate as an LCD backplane or LCD frontplane. If LCDEN = 0, these bits have no effect on the state of the I/O pins. It is recommended to set BPEN[44:0] bits before LCDEN is set.<br>0 Frontplane operation enabled on LCD[n].<br>1 Backplane operation enabled on LCD[n]. |

### 9.3.9 LCD Waveform Registers (LCDWF[44:0])

For an LCD pin configured as a frontplane, the LCDWF registers control the on/off state for frontplane segments. Each frontplane segment is associated with a backplane phase (A-H).

For an LCD pin configured as a backplane, the LCDWF registers controls the phase (A-H) in which the associated backplane pin is active.

After reset, the LCDWF contents are indeterminate as indicated by [Figure 9-11](#). Exiting stop2 mode does not require reinitializing the LCDWF registers.

|                |       | 7                         | 6        | 5        | 4        | 3        | 2        | 1        | 0        |

## 9.4 Functional Description

This section provides a complete functional description of the LCD block, detailing the operation of the design from the end-user perspective.

Before enabling the LCD module by asserting the LCDEN bit in the LCDC0 register, configure the LCD module based on the end application requirements. Out of reset, the LCD module is configured with default settings, but these settings are not optimal for every application.

The LCD module provides several versatile configuration settings and options to support varied implementation requirements, including:

- Frame frequency

- Duty cycle (number of backplanes)
- Backplane assignment (which LCD[44:0] pins operate as backplanes)
- Frame frequency interrupt enable
- Blinking frequency and options
- Power-supply configurations

The LCD module also provides an LCD pin enable control. Setting the LCD pin enable bit (PEN[x] in the LCDPEN[y] register) for a particular LCD[y] pin enables the LCD module functionality of that pin once the LCDEN bit is set. When the BPEN[x] bit in the LCDBPEN[y] is set, the associated pin operates as a backplane. The LCDWF registers can then activate (display) the corresponding LCD segments on an LCD panel.

The LCDWF registers control the on/off state for the segments controlled by the LCD pins defined as front planes and the active phase for the backplanes. Blank display modes do not use the data from the LCDWF registers. When using the LCDWF register for frontplane operation, writing a 0 turns the segment off.

For pins enabled as backplane, the phase of the backplane (A-H) is assigned by the LCDWF register for the corresponding backplane pin. For a detailed description of LCD module operation for a basic seven-segment LCD display, see [Section 9.6.1, “LCD Seven Segment Example Description.”](#)

## 9.4.1 LCD Driver Description

The LCD module driver has 8 modes of operation:

- 1/1 duty (1 backplane) (Phase A), 1/3 bias (4 voltage levels)
- 1/2 duty (2 backplanes) (Phase A, B), 1/3 bias (4 voltage levels)
- 1/3 duty (3 backplanes) (Phase A, B, C), 1/3 bias (4 voltage levels)
- 1/4 duty (4 backplanes) (Phase A, B, C, D), 1/3 bias (4 voltage levels)
- 1/5 duty (5 backplanes) (Phase A, B, C, D, E), 1/3 bias (4 voltage levels)
- 1/6 duty (6 backplanes) (Phase A, B, C, D, E, F), 1/3 bias (4 voltage levels)
- 1/7 duty (7 backplanes) (Phase A, B, C, D, E, F, G), 1/3 bias (4 voltage levels)
- 1/8 duty (8 backplanes) (Phase A, B, C, D, E, F, G, H), 1/3 bias (4 voltage levels)

All modes are 1/3 bias. These modes of operation are described in more detail in the following sections.

### 9.4.1.1 LCD Duty Cycle

The denominator of the duty cycle indicates the number of LCD panel segments capable of being driven by each individual frontplane output driver. Depending on the duty cycle, the LCD waveform drive can be categorized as static or multiplexed.

In static-driving method, the LCD is driven with two square waveforms. The static-driving method is the most basic method to drive an LCD panel, but because each frontplane driver can drive only one LCD segment, static driving limits the LCD segments that can be driven with a given number of frontplane pins. In static mode, only one backplane is required.

In multiplexed mode, the LCD waveforms are multi-level and depend on the bias mode. Multiplex mode, depending on the number of backplanes, can drive multiple LCD segments with a single frontplane driver. This reduces the number of driver circuits and connections to LCD segments. For multiplex mode operation, at least two backplane drivers are needed. The LCD module is optimized for multiplex mode.

The duty cycle indicates the amount of time the LCD panel segment is energized during each LCD module frame cycle. The denominator of the duty cycle indicates the number of backplanes that are being used to drive an LCD panel.

The duty cycle is used by the backplane phase generator to set the phase outputs. The phase outputs A-H are driven according to the sequence shown below. The sequence is repeated at the LCD frame frequency. The duty cycle is configured using the DUTY[2:0] bit field in the LCDC0 register, as shown in [Table 9-11](#).

**Table 9-11. LCD Module Duty Cycle Modes**

| Duty | LCDC0 Register |       |       | Number of Backplanes | Phase Sequence  |
|------|----------------|-------|-------|----------------------|-----------------|
|      | DUTY2          | DUTY1 | DUTY0 |                      |                 |
| 1/1  | 0              | 0     | 0     | 1                    | A               |
| 1/2  | 0              | 0     | 1     | 2                    | A B             |
| 1/3  | 0              | 1     | 0     | 3                    | A B C           |
| 1/4  | 0              | 1     | 1     | 4                    | A B C D         |
| 1/5  | 1              | 0     | 0     | 5                    | A B C D E       |
| 1/6  | 1              | 0     | 1     | 6                    | A B C D E F     |
| 1/7  | 1              | 1     | 0     | 7                    | A B C D E F G   |
| 1/8  | 1              | 1     | 1     | 8                    | A B C D E F G H |

### 9.4.1.2 LCD Bias

Because a single frontplane driver is configured to drive more and more individual LCD segments, 3 voltage levels are required to generate the appropriate waveforms to drive the segment. The LCD module is designed to operate using the 1/3 bias mode.

### 9.4.1.3 LCD Module Base Clock and Frame Frequency

The LCD module is optimized to operate using a 32.768 kHz clock input. Two clock sources are available to the LCD module, which are selectable by configuring the SOURCE bit in the LCDC0 register. The two clock sources include:

- External crystal — OSCOUT (SOURCE = 0)
- Alternate clock (SOURCE = 1)

[Figure 9-12](#) shows the LCD clock tree. The clock tree shows the two possible clock sources and the LCD frame frequency and blink frequency clock source. The LCD blink frequency is discussed in [Section 9.4.3.2, “Blink Frequency.”](#)

Figure 9-12. LCD Clock Tree

An external 32.768 kHz clock input is required to achieve lowest power consumption.

The value of LCDCLK is important because it is used to generate the LCD module frame frequency. Equation 9-1 provides an expression for the LCD module frame frequency calculation.

The LCD module frame frequency is a function of the LCD module duty cycle as shown in Equation 9-1. Table 9-13 and Table 9-12 show LCD module frame frequency calculations that consider several possible LCD module configurations of LCLK[2:0] and DUTY[2:0].

The LCD module frame frequency is defined as the number of times the LCD segments are energized per second. The LCD module frame frequency must be selected to prevent the LCD display from flickering (LCD module frame frequency is too low) or ghosting (LCD module frame frequency is too high). To avoid these issues, an LCD module frame frequency in the range of 28 to 58 Hz is required. LCD module frame frequencies less than 28 Hz or greater than 58 Hz are out of specification, and so are invalid. Selecting lower values for the LCD base and frame frequency results in lower current consumption for the LCD module.

The LCD module base clock frequency is the LCD module frame frequency multiplied by the number of backplane phases that are being generated. The number of backplane phases is selected using the DUTY[2:0] bits. The LCD module base clock is used by the backplane sequencer to generate the LCD waveform data for the enabled phases (A-H).

**Table 9-12. LCD Module Frame Frequency Calculations<sup>1</sup>**

| Duty Cycle | 1/1  | 1/2  | 1/3  | 1/4  | 1/5  | 1/6  | 1/7  | 1/8  |
|------------|------|------|------|------|------|------|------|------|

### 9.4.1.4 LCD Waveform Examples

This section shows the timing examples of the LCD output waveforms for the several modes of operation. As shown in [Table 9-14](#), all examples use 1/3 bias mode.

**Table 9-14. Configurations for Example LCD Waveforms**

|           | Bias Mode | DUTY[2:0] | Duty Cycle |
|-----------|-----------|-----------|------------|
| Example 1 | 1/3       | 001       | 1/2        |
| Example 2 |           | 011       | 1/4        |
| Example 3 |           | 111       | 1/8        |

#### 9.4.1.4.1 1/2 Duty Multiplexed with 1/3 Bias Mode (Low-power Waveform)

Duty=1/2:DUTY[2:0] = 001

LCD pin 0 (LCD[0]) and LCD pin 1, LCD[1] enabled as backplanes:

BPEN0 = 1 and BPEN1 = 1 in the LCDBPEN0

LCD[0] assigned to Phase A: LCDWF0 = 0x01

LCD[1] assigned to Phase B: LCDWF1 = 0x02

Figure 9-13. 1/2 Duty and 1/3 Bias (Low-Power Waveform)

#### 9.4.1.4.2 1/4 Duty Multiplexed with 1/3 Bias Mode (Low-power Waveform)

Duty = 1/4: DUTY[2:0] = 011

LCD pins 0 – 3 enabled as backplanes: LCDBPEN0 = 0x0F

LCD[0] assigned to Phase A: LCDWF0 = 0x01

LCD[1] assigned to Phase B: LCDWF1 = 0x02

LCD[2] assigned to Phase C: LCDWF2 = 0x04

LCD[3] assigned to Phase D: LCDWF3 = 0x08

Figure 9-14. 1/4 Duty and 1/3 Bias (Low-Power Waveform)

#### 9.4.1.4.3 1/8 Duty Multiplexed with 1/3 Bias Mode (Low-power Waveform)

Duty = 1/8: DUTY[2:0] = 111

LCD pins 0 – 7 enabled as backplanes: LCDBPEN0 = 0xFF

LCD[0] assigned to Phase A: LCDWF0 = 0x01

LCD[1] assigned to Phase B: LCDWF1 = 0x02

LCD[2] assigned to Phase C: LCDWF2 = 0x04

LCD[3] assigned to Phase D: LCDWF3 = 0x08

LCD[4] assigned to Phase E: LCDWF4 = 0x10

LCD[5] assigned to Phase F: LCDWF5 = 0x20

LCD[6] assigned to Phase G: LCDWF6 = 0x40

LCD[7] assigned to Phase H: LCDWF7 = 0x80

Figure 9-15. 1/8 Duty and 1/3 Bias (Low-power Waveform)

### 9.4.2 LCDWF Registers

For a segment on the LCD panel to be displayed, data must be written to the LCDWF registers. For LCD pins enabled as frontplanes, each bit in the LCDWF registers corresponds to a segment on an LCD panel. The different phases A-H represent the different backplanes of the LCD panel. The selected LCD duty cycle controls the number of implemented phases. Refer to [Table 9-11](#) for normal LCD operation the phases follow the sequence shown.

For LCD pins enabled as a backplane, the LCDWF assigns the phase in which the backplane pin is active. This is how backplane assignment is done.

An example of normal operation follows: enable LCD pin 0 to operate as backplane 0. Enable the LCD pin 0 by setting PEN0 bit in the LCDPEN0 register. Configure LCD pin 0 as a backplane pin by setting the BPEN0 bit in the LCDBPEN0 register. Finally, the BPALCD0 bit in the LCDWF0 is set to associate LCD pin 0 with backplane phase A. This will configure LCD0 to operate as a backplane that is active in Phase A.

For LCD pins enabled as a frontplane, writing a 1 to a given LCDWF location results in the corresponding display segment being driven with the differential root mean square (RMS) voltage necessary to turn the segment on during the phase selected. Writing a 0 to a given location results in the corresponding display segment being driven with the differential RMS voltage necessary to turn the segment off during the phase selected.

### 9.4.3 LCD Display Modes

The LCD module can be configured to implement several different display modes. The bits ALT and BLANK in the LCD-blink-control register (LCDBCTL) configure the different display modes. In normal display mode (default), LCD segments are controlled by the data placed in the LCDWF registers, as described in [Section 9.4.2, “LCDWF Registers.”](#) For blank-display mode, the LCDWF data is bypassed and the frontplane and backplane pins are configured to clear all segments.

For alternate-display mode, the backplane sequence is modified for duty cycles of 1/4, 1/3, 1/2, and 1/1. For four backplanes or less, the backplane sequence is modified as shown below. The altered sequence allows two complete displays to be placed in the LCDWF registers. The first display is placed in phases A-D and the second in phases E-H in the case of four backplanes. If the LCD duty cycle is five backplanes or greater, the ALT bit is ignored and creates a blank display. Refer to [Table 9-16](#) for additional information.

Using the alternate display function an inverse display can be accomplished for x4 mode and less by placing inverse data in the alternate phases of the LCDWF registers.

**Table 9-15. Alternate Display Backplane Sequence**

| Duty | Backplane Sequence | Alt. Backplane Sequence |
|------|--------------------|-------------------------|
| 1/1  | A                  | E                       |
| 1/2  | A B                | E F                     |

Table 9-15. Alternate Display Backplane Sequence (continued)

| Duty | Backplane Sequence | Alt. Backplane Sequence |
|------|--------------------|-------------------------|
| 1/3  | A B C              | E F G                   |
| 1/4  | A B C D            | E F G H                 |

### 9.4.3.1 LCD Blink Modes

The blink mode is used as a means of alternating among different LCD display modes at a defined frequency. The LCD module can be configured to implement two blink modes. The BMODE bit in the LCD-blink-control register (LCDBCTL) configures the different blink modes. Blink modes are activated by setting the BLINK bit in the LCDBCTL register. If BLINK = 0, the LCD module operates normally as described [Section 9.4.3, “LCD Display Modes.”](#) If BLINK = 1, BMODE bit configures the blinking operation. During a blink, the display data driven by the LCD module changes to the mode selected by the BMODE bit. The BMODE bit selects two different blink modes, blank and alternate modes operate in the same way, as defined in [Section 9.4.3, “LCD Display Modes.”](#) The table below shows the interaction between display modes and blink modes. If the LCD duty cycle is five backplanes or greater, BMODE = 1 is ignored and will revert to create a blank display during the blink period.

Table 9-16. Display Mode Interaction

| BLANK | ALT | BMODE | LCD Duty | BLINK = 1         |                   |
|-------|-----|-------|----------|-------------------|-------------------|
|       |     |       |          | Normal Period     | Blink Period      |

| 1     | X   | 1     | 1-4      | Blank Display     | Alternate display |
| 0     | X   | X     | 5-8      | Normal Display    | Blank Display     |
| 1     | X   | X     | 5-8      | Blank Display     | Blank Display     |

### 9.4.3.2 Blink Frequency

The LCD clock is the basis for the calculation of the LCD module blink frequency. The LCD module blink frequency is equal to the LCD clock (LCDCLK) divided by the factor selected by the BRATE[2:0] bits. [Table 9-17](#) shows LCD module blink frequency calculations for all values of BRATE[2:0] at a few common LCDCLK selections.

**Table 9-17. Blink Frequency Calculations**  
(Blink Rate = LCD Clock(Hz) ÷ Blink Divider)

| BRATE[2:0] | 0                    | 1    | 2     | 3    | 4   | 5   | 6   | 7    |
|------------|----------------------|------|-------|------|-----|-----|-----|------|
|            |                      |      |       |      |     |     |     |      |
| LCD Clock  | Blink Frequency (Hz) |      |       |      |     |     |     |      |
| 30 khz     | 7.32                 | 3.66 | 1.831 | .916 | .46 | .23 | .11 | .06  |
| 32.768 khz | 8                    | 4    | 2     | 1    | .5  | .25 | .13 | .06  |
| 39.063 khz | 9.54                 | 4.77 | 2.38  | 1.19 | .6  | .30 | .15 | .075 |

#### 9.4.4 LCD Charge Pump, Voltage Divider, and Power Supply Operation

This section describes the LCD charge pump, voltage divider, and LCD power supply configuration options. [Figure 9-16](#) provides a block diagram for the LCD charge pump and the resistor divider network. For charge pump option please refer to Note 2 at start of chapter.

The LCD bias voltages ( $V_{LL1}$ ,  $V_{LL2}$  and  $V_{LL3}$ ) can be generated by the LCD charge pump or a resistor divider network that is connected using the CPSEL bit. The input source to the LCD charge pump is controlled by the VSUPPLY[1:0] bit field.

VSUPPLY[1:0] indicates the state of internal signals used to configure power switches as shown in the table in [Figure 9-16](#). The block diagram in [Figure 9-16](#) illustrates several potential operational modes for the LCD module including configuration of the LCD module power supply source using  $V_{DD}$  or an external supply on the  $V_{LL3}/V_{LL3\_2}$  pins.

Upon Reset the VSUPPLY[1:0] bits are configured to connect  $V_{LL3}$  to  $V_{DD}$ . This configuration should be changed to match the application requirements before the LCD module is enabled.

Figure 9-16. LCD Charge Pump and Voltage Divider Block Diagram

**NOTE:**

The charge pump is optimized for 1/3 bias mode operation only.

During the first 16 timebase clock cycles after the LCDPEN bit is set, all the LCD frontplane and backplane outputs are disabled, regardless of the state of the LCDEN bit.

The charge pump requires external capacitance for its operation. To provide this external capacitance, the  $V_{cap1}$  and  $V_{cap2}$  external pins are provided. It is recommended that a ceramic capacitor be used. Proper orientation is imperative when using a polarized capacitor. The recommended value for the external capacitor is 0.1  $\mu$ F.

#### 9.4.4.1 LCD Charge Pump and Voltage Divider

Using the voltage divider and charge pump, the LCD module can be used to generate various voltages. This LCD module configurability makes the LCD module compatible with both 3 V or 5 V LCD glass.

#### 9.4.4.1.1 CPSEL: LCD Charge Pump or Resistor Bias Enable

The CPSEL bit in the LCDSUPPLY register selects the charge pump. When the charge pump is selected (CPSEL = 1),  $V_{LL1}$ ,  $V_{LL2}$ , and  $V_{LL3}$  can be generated internally or  $V_{LL1}$  and  $V_{LL2}$  can be generated from supplied  $V_{LL3}$ .

When the charge pump is unselected (CPSEL = 0),  $V_{LL3}$  must be supplied and  $V_{LL1}$ ,  $V_{LL2}$  are generated by a resistor bias network.

#### 9.4.4.2 LCD Power Supply and Voltage Buffer Configuration

The LCD bias voltages can be internally derived from  $V_{DD}$ , or externally derived from a voltage source (must not exceed  $V_{DD}$ ) connected to  $V_{LL3}$ . Table 9-19 provides a more detailed description of the power state of the LCD module which depends on the configuration of the VSUPPLY[1:0] and CPSEL bits.

Table 9-19 shows all possible configurations of the LCD Power Supply. All other combinations of the configuration bits above are not permissible LCD power supply modes and should be avoided.

**Table 9-19. LCD Power Supply Options**

| LCD Operational State                                                                                                          | LCD Power Supply Configuration                                                                                                                                    | VSUPPLY[1:0] | CPSEL |

Table 9-19. LCD Power Supply Options (continued)

| LCD Operational State                                                                                                           | LCD Power Supply Configuration                                                                                                                             | VSUPPLY[1:0] | CPSEL |
|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|-------|
| $V_{LL3}$ is driven externally for 3 V LCD Glass operation.<br><br>Resistor Bias Network enabled.                               | For 3 V glass operation $V_{LL3}$ must equal 3 V.<br><br>Charge pump is disabled.<br><br>Resistor Bias network is used to create $V_{LL1}$ and $V_{LL2}$   | 11           | 0     |
| $V_{LL3}$ is driven externally for 5 V LCD Glass operation. Resistor Bias network enabled.<br><br>$V_{LL3}$ must equal $V_{DD}$ | For 5 V glass operation $V_{LL3}$ must equal 5 V.<br><br>Charge pump is disabled.<br><br>Resistor Bias network is used to create $V_{LL1}$ and $V_{LL2}$ . | 11           | 0     |

#### 9.4.4.2.1 LCD External Power Supply, VSUPPLY[1:0] = 11

When VSUPPLY[1:0] = 11, powersw1, and powersw2 are deasserted.  $V_{DD}$  is not available to power the LCD module internally, so the LCD module requires an external power source for  $V_{LL1}$ ,  $V_{LL2}$ , and  $V_{LL3}$  when the charge pump is disabled.

If the charge pump is enabled, external power must be applied to  $V_{LL3}$ . With this configuration, the charge pump will generate the other LCD bias voltages  $V_{LL1}$  and  $V_{LL2}$ .

#### 9.4.4.2.2 LCD Internal Power Supply, VSUPPLY[1:0] = 00 or 01

$V_{DD}$  is used as the LCD module power supply when VSUPPLY[1:0] = 00 or 11 (Table 9-20). Table 9-20 provides recommendations regarding configuration of the VSUPPLY[1:0] bit field when using both 3 V and 5 V LCD panels.

Table 9-20.  $V_{DD}$  Switch Option

| VSUPPLY[1:0] | $V_{DD}$ Switch Option               | Recommend Use for 3-V LCD Panels                                                                                                                                                   | Recommend Use for 5-V LCD Panels                                                                                                                                                         |
|--------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00           | $V_{LL2}$ is generated from $V_{DD}$ | <ul style="list-style-type: none"> <li><math>V_{LL1} = 1\text{ V}</math></li> <li><math>V_{DD} = V_{LL2} = 2\text{ V}</math></li> <li><math>V_{LL3} = 3\text{ V}</math></li> </ul> | <ul style="list-style-type: none"> <li><math>V_{LL1} = 1.67\text{ V}</math></li> <li><math>V_{DD} = V_{LL2} = 3.3\text{ V}</math></li> <li><math>V_{LL3} = 5\text{ V}</math></li> </ul>  |
| 01           | $V_{LL3}$ is generated from $V_{DD}$ | <ul style="list-style-type: none"> <li><math>V_{LL1} = 1\text{ V}</math></li> <li><math>V_{LL2} = 2\text{ V}</math></li> <li><math>V_{DD} = V_{LL3} = 3\text{ V}</math></li> </ul> | <ul style="list-style-type: none"> <li><math>V_{LL1} = 1.67\text{ V}</math></li> <li><math>V_{LL2} = 3.33\text{ V}</math></li> <li><math>V_{DD} = V_{LL3} = 5\text{ V}</math></li> </ul> |

### 9.4.5 Resets

During a reset, the LCD module system is configured in the default mode. The default mode includes the following settings:

- LCDEN is cleared, thereby forcing all frontplane and backplane driver outputs to the high impedance state.
- 1/4 duty
- 1/3 bias
- LCLK[2:0], VSUPPLY[1:0], CPSEL and BRATE[2:0] revert to their reset values

### 9.4.6 Interrupts

When an LCD module frame-frequency interrupt event occurs, the LCDIF bit in the LCDS register is asserted. The LCDIF bit remains asserted until software clears the LCD-module-frame-frequency interrupt. The interrupt can be cleared by software writing a 1 to the LCDIF bit.

If both the LCDIF bit in the LCDS register and the LCDIEN bit in the LCDC1 register are set, an LCD interrupt signal asserts.

## 9.5 Initialization Section

This section provides a recommended initialization sequence for the LCD module and also includes initialization examples for several LCD application scenarios.

### 9.5.1 Initialization Sequence

The below list provides a recommended initialization sequence for the LCD module.

You must write to all LCDPEN, LCDBPEN, and LCDWF registers to initialize their values after a reset.

1. LCDC0 register
  - a) Configure LCD clock source (SOURCE bit).
2. LCDSUPPLY register
  - a) Enable charge pump (CPSEL bit).
  - b) Configure charge pump clock (LADJ[1:0]).
  - c) Configure LCD power supply (VSUPPLY[1:0]).
3. LCDC1 register
  - a) Configure LCD frame frequency interrupt (LCDIEN bit).
  - b) Configure LCD behavior in low-power mode (LCDWAI and LCDSTP bits).
4. LCDC0 register
  - a) Configure LCD duty cycle (DUTY[2:0]).
  - b) Select and configure LCD frame frequency (LCLK[2:0]).
5. LCDBCTL register
  - a) Configure display mode (ALT and BLANK bits).
  - b) Configure blink mode (BMODE).
  - c) Configure blink frequency (BRATE[2:0]).

6. LCDPEN[5:0] register
  - a) Enable LCD module pins (PEN[44:0] bits).
7. LCDBPEN[5:0]
  - a) Enable LCD pins to operate as an LCD backplane (BPEN[44:0]).
8. LCDC0 register
  - a) Enable LCD module (LCDEN bit).

## 9.5.2 Initialization Examples

This section provides initialization information for LCD configuration. Each example details the register and bit-field values required to achieve the appropriate LCD configuration for a given LCD application scenario. The table below lists each example and the setup requirements.

**Table 9-21. LCD Application Scenario**

| Example | Operating Voltage, $V_{DD}$ | LCD Clock Source    | LCD Glass Operating Voltage | Required LCD segments | LCD Frame Rate | Blinking Mode/Rate | Behavior in WAIT/STOP modes | LCD Power Input             |
|---------|-----------------------------|---------------------|-----------------------------|-----------------------|----------------|--------------------|-----------------------------|-----------------------------|
| 1       | 5.0 V                       | External 32.768 kHz | 5 V                         | 128                   | 30 Hz          | None               | WAIT: on<br>STOP: on        | Power via $V_{LL3}$ (CPump) |
| 2       | 3.6 V                       | Internal 39.063 kHz | 3 V                         | 100                   | 50 Hz          | Alternate 0.5 Hz   | WAIT: on<br>STOP: off       | Power via $V_{DD}$          |
| 3       | 5.0 V                       | External 32.768 kHz | 5 V                         | 168                   | 30 Hz          | Blank 2.0 Hz       | WAIT: off<br>STOP: off      | Power via $V_{LL3}$ (RBias) |

These examples illustrate the flexibility of the LCD module to be configured to meet a wide range of application requirements including:

- Clock inputs/sources
- LCD power supply
- LCD glass operating voltage
- LCD segment count
- Varied blink modes/frequencies
- LCD frame rate

### 9.5.2.1 Initialization Example 1

**Table 9-22. LCD Setup Requirements for Example 1**

| Example | Operating Voltage, $V_{DD}$ | LCD Clock Source | LCD Glass Operating Voltage | Required LCD segments | LCD Frame Rate | Blinking Mode/Rate | Behavior in STOP and WAIT modes | LCD Power Input |
|---------|-----------------------------|------------------|-----------------------------|-----------------------|----------------|--------------------|---------------------------------|-----------------|
|---------|-----------------------------|------------------|-----------------------------|-----------------------|----------------|--------------------|---------------------------------|-----------------|

**Table 9-22. LCD Setup Requirements for Example 1**

|   |       |                        |     |     |       |      |                      |                                          |
|---|-------|------------------------|-----|-----|-------|------|----------------------|------------------------------------------|
| 1 | 5.0 V | External<br>32.768 kHz | 5 V | 128 | 30 Hz | None | WAIT: on<br>STOP: on | Power via<br>V <sub>LL3</sub><br>(CPump) |
|---|-------|------------------------|-----|-----|-------|------|----------------------|------------------------------------------|

The table below lists the setup values required to initialize the LCD as specified by Example 1:

**Table 9-23. Initialization Register Values for Example 1**

| Register              | bit or<br>bit field                                                          | Binary<br>Value                                                                              | Comment                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LCDSUPPLY<br>1-00--11 | CPSEL                                                                        | 1                                                                                            | Enable charge pump                                                                                                                                                                                                               |
|                       | LADJ[1:0]                                                                    | 00                                                                                           | Configure LCD charge pump clock source                                                                                                                                                                                           |
|                       | VSUPPLY[1:0]                                                                 | 11                                                                                           | When VSUPPLY[1:0] = 11, the LCD must be externally powered via V <sub>LL3</sub> (see <a href="#">Table 9-19</a> ). For 5V glass, the nominal value of V <sub>LL3</sub> should be 5V.                                             |

### 9.5.2.2 Initialization Example 2

Example 2 LCD setup requirements are reiterated in the table below:

| Example | Operating Voltage, $V_{DD}$ | LCD Clock Source    | LCD Glass Operating Voltage | Required LCD segments | LCD Frame Rate | Blinking Mode/Rate | Behavior in STOP3 and WAIT modes | LCD Power Input    |
|---------|-----------------------------|---------------------|-----------------------------|-----------------------|----------------|--------------------|----------------------------------|--------------------|
| 2       | 3.6 V                       | Internal 39.063 kHz | 3 V                         | 100                   | 50 Hz          | Alternate 0.5 Hz   | WAIT: on<br>STOP: off            | Power via $V_{DD}$ |

The table below lists the required setup values required to initialize the LCD as specified by Example 2:

**Table 9-24. Initialization Register Values for Example 2**

### 9.5.2.3 Initialization Example 3

Example 3 LCD setup requirements are reiterated in the table below:

| Example | Operating Voltage, $V_{DD}$ | LCD Clock Source    | LCD Glass Operating Voltage | Required LCD segments | LCD Frame Rate | Blinking Mode/Rate | Behavior in STOP3 and WAIT modes | LCD Power Input             |
|---------|-----------------------------|---------------------|-----------------------------|-----------------------|----------------|--------------------|----------------------------------|-----------------------------|
| 3       | 5.0 V                       | External 32.768 kHz | 5 V                         | 168                   | 30 Hz          | Blank 2.0 Hz       | WAIT: off<br>STOP: off           | Power via $V_{LL3}$ (RBias) |

The table below lists the required setup values required to initialize the LCD as specified by Example 3:

**Table 9-25. Initialization Register Values for Example 3**

| Register              | bit or bit field | Binary Value | Comment                                                                                                             |
|-----------------------|------------------|--------------|---------------------------------------------------------------------------------------------------------------------|
| LCDSUPPLY<br>0-00--11 | CPSEL            | 0            | Disable charge pump, Resistor network selected.                                                                     |
|                       | LADJ[1:0]        | 00           | Configure LCD charge pump clock source                                                                              |
|                       | VSUPPLY[1:0]     | 11           | When VSUPPLY[1:0] = 11, the LCD powered via $V_{LL3}$ (see <a href="#">Table 9-19</a> ).                            |

## 9.6 Application Information

[Figure 9-16](#) is a programmer's model of the LCD module. The programmer's model groups the LCD module register bit and bit field into functional groups. The model is a high-level illustration of the LCD module showing the module's functional hierarchy including initialization and runtime control.

Figure 9-17. LCD Programmer's Model Diagram

### 9.6.1 LCD Seven Segment Example Description

A description of the connection between the LCD module and a seven segment LCD character is illustrated below to provide a basic example for a 1/3 duty cycle LCD implementation. The example uses three backplane pins (LCD[3], LCD[4] and LCD[5] and 3 frontplane pins (LCD[0], LCD[1], and LCD[2]).

LCDWF contents and output waveforms are also shown. Output waveforms are illustrated in Figure 9-18 and Figure 9-19.

The above segment assignments are provided by the specification for the LCD glass for this example. For this LCD Module any of the LCD pins can be configured to be Frontplane 0-2 or Backplane 0-2. For this example we will set LCD[0] as FP0, LCD[1] as FP1, and LCD[2] as FP2. For this example we will set LCD[3] as BP0, LCD[4] as BP1 and LCD[5] as BP2.

Backplane assignment is done in the LCDWF register as shown below:

|        |   |   |   |   |   |   |   |   |
|--------|---|---|---|---|---|---|---|---|
| LCDWF3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| LCDWF4 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| LCDWF5 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |

With the above conditions the segment assignment is shown below:

|        |   |   |   |   |   |   |   |   |
|--------|---|---|---|---|---|---|---|---|
| LCDWF0 | - | - | - | - | - | e | f | - |
| LCDWF1 | - | - | - | - | - | d | g | a |
| LCDWF2 | - | - | - | - | - | - | c | b |

To display the character "4": LCDWF0 = XXXXX01X, LCDWF1 = XXXXX010, LCDWF2 =XXXXXX11

|        |   |   |   |   |   |   |   |   |
|--------|---|---|---|---|---|---|---|---|
| LCDWF0 | X | X | X | X | X | 0 | 1 | X |
| LCDWF1 | X | X | X | X | X | 0 | 1 | 0 |
| LCDWF2 | X | X | X | X | X | X | 1 | 1 |

X = don't care

Figure 9-18. Waveform Output from LCDWF Registers

### 9.6.1.1 LCD Module Waveforms

Figure 9-19. LCD Waveforms

### 9.6.1.2 Segment On Driving Waveform

The voltage waveform across the “f” segment of the LCD (between LCD[4]/BP1 and LCD[0]/FP0) is illustrated in Figure 9-20. As shown in the waveform, the voltage level reaches the value  $V_3$  therefore the segment will be on.

Figure 9-20. “f” Segment Voltage Waveform

### 9.6.1.3 Segment Off Driving Waveform

The voltage waveform across the “e” segment of the LCD (between LCD[5]/BP2 and LCD[0]/FP0) is illustrated in Figure 9-21. As shown in the waveform, the voltage does not reach the voltage  $V_3$  threshold therefore the segment will be off.

Figure 9-21. “e” Segment Voltage Waveform

## 9.6.2 LCD Contrast Control

Contrast control for the LCD module is achieved when the LCD power supply is adjusted above and below the LCD threshold voltage. The LCD threshold voltage is the nominal voltage required to energize the LCD segments. For 3 V LCD glass, the LCD threshold voltage is 3 V; while for 5 V LCD glass it is 5 V. By increasing the value of the LCD voltage, the energized segments on the LCD glass will become more opaque. Decreasing the value of the LCD voltage makes the energized segments on the LCD glass become more transparent. The LCD power supply can be adjusted to facilitate contrast control by using external components like a variable resistor. Figure 9-22 shows two circuits that can be used to implement contrast control.

Increasing the value of the LCD voltage will cause the energized segments on the LCD glass to become more opaque. Decreasing the value of the LCD voltage makes the energized segments on the LCD glass more transparent.

**NOTE:**

Contrast control configuration when LCD is powered using external  $V_{LL3}$

This is the recommended configuration for contrast control.

**NOTE:**

Contrast control configuration when LCD is powered using internal  $V_{DD}$

**Figure 9-22. Power Connections for Contrast Control**

### 9.6.3 Stop Mode Recovery

When the MCU recovers from stop2 mode a reset sequence is initiated. All Control Registers should be re-written before the stop2 recovery acknowledge bit is set. The Registers LCDBPEN, LCDPEN and the LCDWF retain their values upon stop2 recovery and do not need to be re-written.

## Chapter 10

# Analog-to-Digital Converter (S08ADC12V1)

### 10.1 Introduction

The 12-bit analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

Figure 10-1 shows the MC9S08LG32 series with the ADC module highlighted.

#### 10.1.1 ADC shared with LCD

PTA2/SDA/ADC0/LCD23, PTA3/KBI4/TX2/ADC1/LCD24, PTA4/KBI5/RX2/ADC2/LCD25, PTA5/KBI6/TPM2CH0/ADC3/LCD26, PTA6/KBI7/TPM2CH1/ADC4/LCD27 and PTA7/TPMCLK/ADC5/LCD28 share ADC functionality with LCD pins. To avoid the possibility of placing a voltage greater than  $V_{DD}$  on an ADC input, LCD functionality must be disabled for these pins to operate as ADC pins.

As ADC inputs, these pins operate just like other ADC pins. If the ADC channel input channel voltage is more than the LCD reference voltage ( $V_{MCU}$  or  $V_{LL3}$ ) then there would be some leakage through the ADC input.

#### 10.1.2 ADC Reference and Supply Voltage

For MC9S08LG32 series devices, the ADC reference inputs ( $V_{REFH}$  and  $V_{REFL}$ ) are shorted with the ADC supply ( $V_{DDA}$  and  $V_{SSA}$ ). The ADC supply must be within  $\pm 100$  mV of main supply  $V_{DD}$ , otherwise there would be some leakage through the  $V_{DDA}$  pad.

#### 10.1.3 ADC Clock Gating

The bus clock to the ADC can be gated on and off using the ADC bit in SCGC1. This bit is cleared after any reset, which disables the bus clock to this module. To conserve power, the ADC bit can be cleared to disable the clock to this module when not in use. See [Section 5.7, “Peripheral Clock Gating,”](#) for more details.

Figure 10-1. MC9S08LG32 Series Block Diagram Highlighting ADC Block and Pins

### 10.1.4 Module Configurations

This section provides device-specific information for configuring the ADC on MC9S08LG32 series.

### 10.1.4.1 Configurations for Low Power Modes

The ADC, if enabled in stop3 mode, must be configured to use the asynchronous clock source, ADACK, to meet the ADC minimum frequency requirements.

### 10.1.4.2 Channel Assignments

The ADC channel assignments for the MC9S08LG32 series devices are shown in [Table 10-1](#). Reserved channels convert to an unknown value.

**Table 10-1. ADC Channel Assignment**

| ADCH  | Channel | Input      | Pin Control | ADCH  | Channel           | Input                           | Pin Control |
|-------|---------|------------|-------------|-------|-------------------|---------------------------------|-------------|
| 00000 | AD0     | PTA2/ADP0  | ADPC0       | 10000 | AD16              | Reserved                        | N/A         |
| 00001 | AD1     | PTA3/ADP1  | ADPC1       | 10001 | AD17              | Reserved                        | N/A         |
| 00010 | AD2     | PTA4/ADP2  | ADPC2       | 10010 | AD18              | Reserved                        | N/A         |
| 00011 | AD3     | PTA5/ADP3  | ADPC3       | 10011 | AD19              | Reserved                        | N/A         |
| 00100 | AD4     | PTA6/ADP4  | ADPC4       | 10100 | AD20              | Reserved                        | N/A         |
| 00101 | AD5     | PTA7/ADP5  | ADPC5       | 10101 | AD21              | V <sub>LL2</sub>                | N/A         |
| 00110 | AD6     | PTH0/ADP6  | ADPC6       | 10110 | AD22              | V <sub>LL1</sub>                | N/A         |
| 00111 | AD7     | PTH1/ADP7  | ADPC7       | 10111 | AD23              | Reserved                        | N/A         |
| 01000 | AD8     | PTH2/ADP8  | ADPC8       | 11000 | AD24              | Reserved                        | N/A         |
| 01001 | AD9     | PTH3/ADP9  | ADPC9       | 11001 | AD25              | Reserved                        | N/A         |
| 01010 | AD10    | PTH4/ADP10 | ADPC10      | 11010 | AD26              | Temperature Sensor <sup>1</sup> | N/A         |
| 01011 | AD11    | PTH5/ADP11 | ADPC11      | 11011 | AD27              | Internal Bandgap                | N/A         |
| 01100 | AD12    | PTF0/ADP12 | ADPC12      | 11100 | —                 | Reserved                        | N/A         |
| 01101 | AD13    | PTF1/ADP13 | ADPC13      | 11101 | V <sub>REFH</sub> | V <sub>REFH</sub>               | N/A         |
| 01110 | AD14    | PTF2/ADP14 | ADPC14      | 11110 | V <sub>REFL</sub> | V <sub>REFL</sub>               | N/A         |
| 01111 | AD15    | PTH6/ADP15 | ADPC15      | 11111 | Module Disabled   | None                            | N/A         |

<sup>1</sup> For information, see [Section 10.1.4.5, “Temperature Sensor.”](#)

#### NOTE

Selecting the internal bandgap channel requires BGBE = 1 in SPMSC1, see [Section 5.8.7, “System Power Management Status and Control 1 Register \(SPMSC1\),”](#) for more details. For value of bandgap voltage reference, see *MC9S08LG32 Data Sheet*.

### 10.1.4.3 Alternate Clock

The ADC is capable of performing conversions using the MCU bus clock, the bus clock divided by two, the local asynchronous clock (ADACK) within the module, or the alternate clock (ALTCLK). The

ALTCLK on the MC9S08LG32 series is connected to the ICSERCLK. See [Chapter 11, “Internal Clock Source \(S08ICSV3\),”](#) for more information.

#### 10.1.4.4 Hardware Trigger

The RTC can be enabled as a hardware trigger for the ADC module by setting the ADTRG bit in the ADCSC2 register. When enabled, the ADC will be triggered every time a RTC overflow condition occurs. The RTC overflow interrupt does not have to be enabled to trigger the ADC.

The RTC can be configured to cause a hardware trigger in MCU run, wait, and stop3.

#### 10.1.4.5 Temperature Sensor

The ADC module includes a temperature sensor whose output is connected to one of the ADC analog channel inputs. [Equation 10-1](#) provides an approximate transfer function of the temperature sensor.

$$\text{Temp} = 25 - ((V_{\text{TEMP}} - V_{\text{TEMP25}}) \div m) \quad \text{Eqn. 10-1}$$

where:

- $V_{\text{TEMP}}$  is the voltage of the temperature sensor channel at the ambient temperature.
- $V_{\text{TEMP25}}$  is the voltage of the temperature sensor channel at 25 °C.
- $m$  is the hot or cold voltage versus temperature slope in V/°C.

For temperature calculations, use the  $V_{\text{TEMP25}}$  and  $m$  values in the *MC9S08LG32 Data Sheet*.

In application code, you read the temperature sensor channel, calculate  $V_{\text{TEMP}}$ , and compare it to  $V_{\text{TEMP25}}$ . If  $V_{\text{TEMP}}$  is greater than  $V_{\text{TEMP25}}$  the cold slope value is applied in [Equation 10-1](#). If  $V_{\text{TEMP}}$  is less than  $V_{\text{TEMP25}}$  the hot slope value is applied in [Equation 10-1](#).

## 10.1.5 Features

Features of the ADC module include:

- Linear successive approximation algorithm with 12-bit resolution
- Up to 28 analog inputs
- Output formatted in 12-, 10-, or 8-bit right-justified unsigned format
- Single or continuous conversion (automatic return to idle after single conversion)
- Configurable sample time and conversion speed/power
- Conversion complete flag and interrupt
- Input clock selectable from up to four sources
- Operation in wait or stop3 modes for lower noise operation
- Asynchronous clock source for lower noise operation
- Selectable asynchronous hardware conversion trigger
- Automatic compare with interrupt for less-than, or greater-than or equal-to, programmable value
- Temperature sensor

## 10.1.6 ADC Module Block Diagram

Figure 10-2 provides a block diagram of the ADC module.

Figure 10-2. ADC Block Diagram

## 10.2 External Signal Description

The ADC module supports up to 28 separate analog inputs. It also requires four supply/reference/ground connections.

Table 10-2. Signal Properties

| Name              | Function               |
|-------------------|------------------------|
| AD27–AD0          | Analog Channel inputs  |
| V <sub>REFH</sub> | High reference voltage |
| V <sub>REFL</sub> | Low reference voltage  |
| V <sub>DDA</sub>  | Analog power supply    |
| V <sub>SSA</sub>  | Analog ground          |

### 10.2.1 Analog Power ( $V_{DDA}$ )

The ADC analog portion uses  $V_{DDA}$  as its power connection. In some packages,  $V_{DDA}$  is connected internally to  $V_{DD}$ . If externally available, connect the  $V_{DDA}$  pin to the same voltage potential as  $V_{DD}$ . External filtering may be necessary to ensure clean  $V_{DDA}$  for good results.

### 10.2.2 Analog Ground ( $V_{SSA}$ )

The ADC analog portion uses  $V_{SSA}$  as its ground connection. In some packages,  $V_{SSA}$  is connected internally to  $V_{SS}$ . If externally available, connect the  $V_{SSA}$  pin to the same voltage potential as  $V_{SS}$ .

### 10.2.3 Voltage Reference High ( $V_{REFH}$ )

$V_{REFH}$  is the high reference voltage for the converter. In some packages,  $V_{REFH}$  is connected internally to  $V_{DDA}$ . If externally available,  $V_{REFH}$  may be connected to the same potential as  $V_{DDA}$  or may be driven by an external source between the minimum  $V_{DDA}$  spec and the  $V_{DDA}$  potential ( $V_{REFH}$  must never exceed  $V_{DDA}$ ).

### 10.2.4 Voltage Reference Low ( $V_{REFL}$ )

$V_{REFL}$  is the low-reference voltage for the converter. In some packages,  $V_{REFL}$  is connected internally to  $V_{SSA}$ . If externally available, connect the  $V_{REFL}$  pin to the same voltage potential as  $V_{SSA}$ .

### 10.2.5 Analog Channel Inputs (ADx)

The ADC module supports up to 28 separate analog inputs. An input is selected for conversion through the ADCH channel select bits.

## 10.3 Register Definition

These memory-mapped registers control and monitor operation of the ADC:

- Status and control register, ADCSC1
- Status and control register, ADCSC2
- Data result registers, ADCRH and ADCRL
- Compare value registers, ADCCVH and ADCCVL
- Configuration register, ADCCFG
- Pin control registers, APCTL1, APCTL2, APCTL3

### 10.3.1 Status and Control Register 1 (ADCSC1)

This section describes the function of the ADC status and control register (ADCSC1). Writing ADCSC1 aborts the current conversion and initiates a new conversion (if the ADCH bits are equal to a value other than all 1s).

**Figure 10-3. Status and Control Register (ADCSC1)**

**Table 10-3. ADCSC1 Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>COCO   | Conversion Complete Flag. The COCO flag is a read-only bit set each time a conversion is completed when the compare function is disabled (ACFE = 0). When the compare function is enabled (ACFE = 1), the COCO flag is set upon completion of a conversion only if the compare result is true. This bit is cleared when ADCSC1 is written or when ADCRL is read.<br>0 Conversion not completed<br>1 Conversion completed                                                                                                                                                                                                                                                                                                                  |
| 6<br>AIEN   | Interrupt Enable AIEN enables conversion complete interrupts. When COCO becomes set while AIEN is high, an interrupt is asserted.<br>0 Conversion complete interrupt disabled<br>1 Conversion complete interrupt enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 5<br>ADCO   | Continuous Conversion Enable. ADCO enables continuous conversions.<br>0 One conversion following a write to the ADCSC1 when software triggered operation is selected, or one conversion following assertion of ADHWT when hardware triggered operation is selected.<br>1 Continuous conversions initiated following a write to ADCSC1 when software triggered operation is selected. Continuous conversions are initiated by an ADHWT event when hardware triggered operation is selected.                                                                                                                                                                                                                                                |
| 4:0<br>ADCH | Input Channel Select. The ADCH bits form a 5-bit field that selects one of the input channels. The input channels are detailed in <a href="#">Table 10-4</a> .<br>The successive approximation converter subsystem is turned off when the channel select bits are all set. This feature allows for explicit disabling of the ADC and isolation of the input channel from all sources. Terminating continuous conversions this way prevents an additional, single conversion from being performed. It is not necessary to set the channel select bits to all ones to place the ADC in a low-power state when continuous conversions are not enabled because the module automatically enters a low-power state when a conversion completes. |

**Table 10-4. Input Channel Select**

| ADCH        | Input Select      |
|-------------|-------------------|
| 00000–01111 | AD0–15            |
| 10000–11011 | AD16–27           |
| 11100       | Reserved          |
| 11101       | V <sub>REFH</sub> |
| 11110       | V <sub>REFL</sub> |
| 11111       | Module disabled   |

### 10.3.2 Status and Control Register 2 (ADCSC2)

The ADCSC2 register controls the compare function, conversion trigger, and conversion active of the ADC module.

**Figure 10-4. Status and Control Register 2 (ADCSC2)**

<sup>1</sup> Bits 1 and 0 are reserved bits that must always be written to 0.

**Table 10-5. ADCSC2 Register Field Descriptions**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>ADACT | Conversion Active. Indicates that a conversion is in progress. ADACT is set when a conversion is initiated and cleared when a conversion is completed or aborted.<br>0 Conversion not in progress<br>1 Conversion in progress                                                                                                                                                                                                                                                 |
| 6<br>ADTRG | Conversion Trigger Select. Selects the type of trigger used for initiating a conversion. Two types of triggers are selectable: software trigger and hardware trigger. When software trigger is selected, a conversion is initiated following a write to ADCSC1. When hardware trigger is selected, a conversion is initiated following the assertion of the ADHWT input.<br>0 Software trigger selected<br>1 Hardware trigger selected                                        |
| 5<br>ACFE  | Compare Function Enable. Enables the compare function.<br>0 Compare function disabled<br>1 Compare function enabled                                                                                                                                                                                                                                                                                                                                                           |
| 4<br>ACFGT | Compare Function Greater Than Enable. Configures the compare function to trigger when the result of the conversion of the input being monitored is greater than or equal to the compare value. The compare function defaults to triggering when the result of the compare of the input being monitored is less than the compare value.<br>0 Compare triggers when input is less than compare value<br>1 Compare triggers when input is greater than or equal to compare value |

### 10.3.3 Data Result High Register (ADCRH)

In 12-bit operation, ADCRH contains the upper four bits of the result of a 12-bit conversion. In 10-bit mode, ADCRH contains the upper two bits of the result of a 10-bit conversion. When configured for 10-bit mode, ADR[11:10] are cleared. When configured for 8-bit mode, ADR[11:8] are cleared.

In 12-bit and 10-bit mode, ADCRH is updated each time a conversion completes except when automatic compare is enabled and the compare condition is not met. When a compare event does occur, the value is the addition of the conversion result and the two's complement of the compare value. In 12-bit and 10-bit mode, reading ADCRH prevents the ADC from transferring subsequent conversion results into the result registers until ADCRL is read. If ADCRL is not read until after the next conversion is completed, the intermediate conversion result is lost. In 8-bit mode, there is no interlocking with ADCRL.

If the MODE bits are changed, any data in ADCRH becomes invalid.

|        |   |   |   |   |       |       |      |      |
|--------|---|---|---|---|-------|-------|------|------|
|        | 7 | 6 | 5 | 4 | 3     | 2     | 1    | 0    |
| R      | 0 | 0 | 0 | 0 | ADR11 | ADR10 | ADR9 | ADR8 |
| W      |   |   |   |   |       |       |      |      |
| Reset: | 0 | 0 | 0 | 0 | 0     | 0     | 0    | 0    |

Figure 10-5. Data Result High Register (ADCRH)

### 10.3.4 Data Result Low Register (ADCRL)

ADCRL contains the lower eight bits of the result of a 12-bit or 10-bit conversion, and all eight bits of an 8-bit conversion. This register is updated each time a conversion completes except when automatic compare is enabled and the compare condition is not met. In 12-bit and 10-bit mode, reading ADCRH prevents the ADC from transferring subsequent conversion results into the result registers until ADCRL is read. If ADCRL is not read until the after next conversion is completed, the intermediate conversion results are lost. In 8-bit mode, there is no interlocking with ADCRH. If the MODE bits are changed, any data in ADCRL becomes invalid.

|        |      |      |      |      |      |      |      |      |
|--------|------|------|------|------|------|------|------|------|
|        | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| R      | ADR7 | ADR6 | ADR5 | ADR4 | ADR3 | ADR2 | ADR1 | ADR0 |
| W      |      |      |      |      |      |      |      |      |
| Reset: | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |

Figure 10-6. Data Result Low Register (ADCRL)

### 10.3.5 Compare Value High Register (ADCCVH)

In 12-bit mode, the ADCCVH register holds the upper four bits of the 12-bit compare value. When the compare function is enabled, these bits are compared to the upper four bits of the result following a conversion in 12-bit mode.

|        |   |   |   |   |        |        |       |       |
|--------|---|---|---|---|--------|--------|-------|-------|
|        | 7 | 6 | 5 | 4 | 3      | 2      | 1     | 0     |
| R      | 0 | 0 | 0 | 0 | ADCV11 | ADCV10 | ADCV9 | ADCV8 |
| W      |   |   |   |   |        |        |       |       |
| Reset: | 0 | 0 | 0 | 0 | 0      | 0      | 0     | 0     |

Figure 10-7. Compare Value High Register (ADCCVH)

In 10-bit mode, the ADCCVH register holds the upper two bits of the 10-bit compare value (ADCV[9:8]). These bits are compared to the upper two bits of the result following a conversion in 10-bit mode when the compare function is enabled.

In 8-bit mode, ADCCVH is not used during compare.

### 10.3.6 Compare Value Low Register (ADCCVL)

This register holds the lower 8 bits of the 12-bit or 10-bit compare value or all 8 bits of the 8-bit compare value. When the compare function is enabled, bits ADCV[7:0] are compared to the lower 8 bits of the result following a conversion in 12-bit, 10-bit or 8-bit mode.

Figure 10-8. Compare Value Low Register(ADCCVL)

### 10.3.7 Configuration Register (ADCCFG)

ADCCFG selects the mode of operation, clock source, clock divide, and configures for low-power and long sample time.

Figure 10-9. Configuration Register (ADCCFG)

Table 10-6. ADCCFG Register Field Descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>ADLPC  | Low-Power Configuration. ADLPC controls the speed and power configuration of the successive approximation converter. This optimizes power consumption when higher sample rates are not required.<br>0 High speed configuration<br>1 Low-power configuration:The power is reduced at the expense of maximum clock speed.                                                                                                                         |
| 6:5<br>ADIV | Clock Divide Select. ADIV selects the divide ratio used by the ADC to generate the internal clock ADCK. <a href="#">Table 10-7</a> shows the available clock configurations.                                                                                                                                                                                                                                                                    |
| 4<br>ADLSMP | Long Sample Time Configuration. ADLSMP selects between long and short sample time. This adjusts the sample period to allow higher impedance inputs to be accurately sampled or to maximize conversion speed for lower impedance inputs. Longer sample times can also be used to lower overall power consumption when continuous conversions are enabled if high conversion rates are not required.<br>0 Short sample time<br>1 Long sample time |

**Table 10-6. ADCCFG Register Field Descriptions (continued)**

| 11     | Asynchronous clock (ADACK) |

### 10.3.8 Pin Control 1 Register (APCTL1)

The pin control registers disable the I/O port control of MCU pins used as analog inputs. APCTL1 is used to control the pins associated with channels 0–7 of the ADC module.

**Figure 10-10. Pin Control 1 Register (APCTL1)**

**Table 10-10. APCTL1 Register Field Descriptions**

| Field      | Description                                                                                                                               |

## 10.4 Functional Description

The ADC module is disabled during reset or when the ADCH bits are all high. The module is idle when a conversion has completed and another conversion has not been initiated. When idle, the module is in its lowest power state.

The ADC can perform an analog-to-digital conversion on any of the software selectable channels. In 12-bit and 10-bit mode, the selected channel voltage is converted by a successive approximation algorithm into a 12-bit digital result. In 8-bit mode, the selected channel voltage is converted by a successive approximation algorithm into a 9-bit digital result.

When the conversion is completed, the result is placed in the data registers (ADCRH and ADCRL). In 10-bit mode, the result is rounded to 10 bits and placed in the data registers (ADCRH and ADCRL). In 8-bit mode, the result is rounded to 8 bits and placed in ADCRL. The conversion complete flag (COCO) is then set and an interrupt is generated if the conversion complete interrupt has been enabled (AIEN = 1).

The ADC module has the capability of automatically comparing the result of a conversion with the contents of its compare registers. The compare function is enabled by setting the ACFE bit and operates with any of the conversion modes and configurations.

### 10.4.1 Clock Select and Divide Control

One of four clock sources can be selected as the clock source for the ADC module. This clock source is then divided by a configurable value to generate the input clock to the converter (ADCK). The clock is selected from one of the following sources by means of the ADICLK bits.

- The bus clock, which is equal to the frequency at which software is executed. This is the default selection following reset.
- The bus clock divided by two. For higher bus clock rates, this allows a maximum divide by 16 of the bus clock.
- ALTCLK, as defined for this MCU (See module section introduction).
- The asynchronous clock (ADACK). This clock is generated from a clock source within the ADC module. When selected as the clock source, this clock remains active while the MCU is in wait or stop3 mode and allows conversions in these modes for lower noise operation.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC do not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by the ADIV bits and can be divide-by 1, 2, 4, or 8.

### 10.4.2 Input Select and Pin Control

The pin control registers (APCTL3, APCTL2, and APCTL1) disable the I/O port control of the pins used as analog inputs. When a pin control register bit is set, the following conditions are forced for the associated MCU pin:

- The output buffer is forced to its high impedance state.
- The input buffer is disabled. A read of the I/O port returns a zero for any pin with its input buffer disabled.
- The pullup is disabled.

### 10.4.3 Hardware Trigger

The ADC module has a selectable asynchronous hardware conversion trigger, ADHWT, that is enabled when the ADTRG bit is set. This source is not available on all MCUs. Consult the module introduction for information on the ADHWT source specific to this MCU.

When ADHWT source is available and hardware trigger is enabled (ADTRG=1), a conversion is initiated on the rising edge of ADHWT. If a conversion is in progress when a rising edge occurs, the rising edge is ignored. In continuous convert configuration, only the initial rising edge to launch continuous conversions is observed. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

### 10.4.4 Conversion Control

Conversions can be performed in 12-bit mode, 10-bit mode, or 8-bit mode as determined by the MODE bits. Conversions can be initiated by a software or hardware trigger. In addition, the ADC module can be

configured for low-power operation, long sample time, continuous conversion, and automatic compare of the conversion result to a software determined compare value.

#### 10.4.4.1 Initiating Conversions

A conversion is initiated:

- Following a write to ADCSC1 (with ADCH bits not all 1s) if software triggered operation is selected.
- Following a hardware trigger (ADHWT) event if hardware triggered operation is selected.
- Following the transfer of the result to the data registers when continuous conversion is enabled.

If continuous conversions are enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation, continuous conversions begin after ADCSC1 is written and continue until aborted. In hardware triggered operation, continuous conversions begin after a hardware trigger event and continue until aborted.

#### 10.4.4.2 Completing Conversions

A conversion is completed when the result of the conversion is transferred into the data result registers, ADCRH and ADCRL. This is indicated by the setting of COCO. An interrupt is generated if AIEN is high at the time that COCO is set.

A blocking mechanism prevents a new result from overwriting previous data in ADCRH and ADCRL if the previous data is in the process of being read while in 12-bit or 10-bit MODE (the ADCRH register has been read but the ADCRL register has not). When blocking is active, the data transfer is blocked, COCO is not set, and the new result is lost. In the case of single conversions with the compare function enabled and the compare condition false, blocking has no effect and ADC operation is terminated. In all other cases of operation, when a data transfer is blocked, another conversion is initiated regardless of the state of ADCO (single or continuous conversions enabled).

If single conversions are enabled, the blocking mechanism could result in several discarded conversions and excess power consumption. To avoid this issue, the data registers must not be read after initiating a single conversion until the conversion completes.

#### 10.4.4.3 Aborting Conversions

Any conversion in progress is aborted when:

- A write to ADCSC1 occurs (the current conversion will be aborted and a new conversion will be initiated, if ADCH are not all 1s).
- A write to ADCSC2, ADCCFG, ADCCVH, or ADCCVL occurs. This indicates a mode of operation change has occurred and the current conversion is therefore invalid.
- The MCU is reset.
- The MCU enters stop mode with ADACK not enabled.

When a conversion is aborted, the contents of the data registers, ADCRH and ADCRL, are not altered. However, they continue to be the values transferred after the completion of the last successful conversion. If the conversion was aborted by a reset, ADCRH and ADCRL return to their reset states.

#### 10.4.4.4 Power Control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source, the ADACK clock generator is also enabled.

Power consumption when active can be reduced by setting ADLPC. This results in a lower maximum value for  $f_{ADCK}$  (see the electrical specifications).

#### 10.4.4.5 Sample Time and Total Conversion Time

The total conversion time depends on the sample time (as determined by ADLSMP), the MCU bus frequency, the conversion mode (8-bit, 10-bit or 12-bit), and the frequency of the conversion clock ( $f_{ADCK}$ ). After the module becomes active, sampling of the input begins. ADLSMP selects between short (3.5 ADCK cycles) and long (23.5 ADCK cycles) sample times. When sampling is complete, the converter is isolated from the input channel and a successive approximation algorithm is performed to determine the digital value of the analog signal. The result of the conversion is transferred to ADCRH and ADCRL upon completion of the conversion algorithm.

If the bus frequency is less than the  $f_{ADCK}$  frequency, precise sample time for continuous conversions cannot be guaranteed when short sample is enabled (ADLSMP=0). If the bus frequency is less than 1/11th of the  $f_{ADCK}$  frequency, precise sample time for continuous conversions cannot be guaranteed when long sample is enabled (ADLSMP=1).

The maximum total conversion time for different conditions is summarized in [Table 10-13](#).

**Table 10-13. Total Conversion Time vs. Control Conditions**

| Conversion Type                                                    | ADICLK | ADLSMP | Max Total Conversion Time                |
|--------------------------------------------------------------------|--------|--------|------------------------------------------|
| Single or first continuous 8-bit                                   | 10     | 0      | 20 ADCK cycles + 5 bus clock cycles      |
| Single or first continuous 10-bit or 12-bit                        | 10     | 0      | 23 ADCK cycles + 5 bus clock cycles      |
| Single or first continuous 8-bit                                   | 10     | 1      | 40 ADCK cycles + 5 bus clock cycles      |
| Single or first continuous 10-bit or 12-bit                        | 10     | 1      | 43 ADCK cycles + 5 bus clock cycles      |
| Single or first continuous 8-bit                                   | 11     | 0      | 5 $\mu$ s + 20 ADCK + 5 bus clock cycles |
| Single or first continuous 10-bit or 12-bit                        | 11     | 0      | 5 $\mu$ s + 23 ADCK + 5 bus clock cycles |
| Single or first continuous 8-bit                                   | 11     | 1      | 5 $\mu$ s + 40 ADCK + 5 bus clock cycles |
| Single or first continuous 10-bit or 12-bit                        | 11     | 1      | 5 $\mu$ s + 43 ADCK + 5 bus clock cycles |
| Subsequent continuous 8-bit;<br>$f_{BUS} \geq f_{ADCK}$            | xx     | 0      | 17 ADCK cycles                           |
| Subsequent continuous 10-bit or 12-bit;<br>$f_{BUS} \geq f_{ADCK}$ | xx     | 0      | 20 ADCK cycles                           |
| Subsequent continuous 8-bit;<br>$f_{BUS} \geq f_{ADCK}/11$         | xx     | 1      | 37 ADCK cycles                           |

**Table 10-13. Total Conversion Time vs. Control Conditions** (continued)

| Conversion Type                                                                     | ADICLK | ADLSMP | Max Total Conversion Time |
|-------------------------------------------------------------------------------------|--------|--------|---------------------------|
| Subsequent continuous 10-bit or 12-bit;<br>$f_{\text{BUS}} \geq f_{\text{ADCK}}/11$ | xx     | 1      | 40 ADCK cycles            |

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by the ADICLK bits, and the divide ratio is specified by the ADIV bits. For example, in 10-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 8 MHz, then the conversion time for a single conversion is:

$$\text{Conversion time} = \frac{23 \text{ ADCK Cyc}}{8 \text{ MHz}} + \frac{5 \text{ bus Cyc}}{8 \text{ MHz}} = 3.5 \mu\text{s}$$

Number of bus cycles = 28 cycles

#### NOTE

The ADCK frequency must be between  $f_{\text{ADCK}}$  minimum and  $f_{\text{ADCK}}$  maximum to meet ADC specifications.

### 10.4.5 Automatic Compare Function

The compare function can be configured to check for an upper or lower limit. After the input is sampled and converted, the result is added to the two's complement of the compare value (ADCCVH and ADCCVL). When comparing to an upper limit (ACFGT = 1), if the result is greater-than or equal-to the compare value, COCO is set. When comparing to a lower limit (ACFGT = 0), if the result is less than the compare value, COCO is set. The value generated by the addition of the conversion result and the two's complement of the compare value is transferred to ADCRH and ADCRL.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, COCO is not set and no data is transferred to the result registers. An ADC interrupt is generated upon the setting of COCO if the ADC interrupt is enabled (AIEN = 1).

#### NOTE

The compare function can monitor the voltage on a channel while the MCU is in wait or stop3 mode. The ADC interrupt wakes the MCU when the compare condition is met.

### 10.4.6 MCU Wait Mode Operation

Wait mode is a lower power-consumption standby mode from which recovery is fast because the clock sources remain active. If a conversion is in progress when the MCU enters wait mode, it continues until completion. Conversions can be initiated while the MCU is in wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two, and ADACK are available as conversion clock sources while in wait mode. The use of ALTCLK as the conversion clock source in wait is dependent on the definition of

ALTCLK for this MCU. Consult the module introduction for information on ALTCLK specific to this MCU.

A conversion complete event sets the COCO and generates an ADC interrupt to wake the MCU from wait mode if the ADC interrupt is enabled (AIEN = 1).

## 10.4.7 MCU Stop3 Mode Operation

Stop mode is a low-power-consumption standby mode during which most or all clock sources on the MCU are disabled.

### 10.4.7.1 Stop3 Mode With ADACK Disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its idle state. The contents of ADCRH and ADCRL are unaffected by stop3 mode. After exiting from stop3 mode, a software or hardware trigger is required to resume conversions.

### 10.4.7.2 Stop3 Mode With ADACK Enabled

If ADACK is selected as the conversion clock, the ADC continues operation during stop3 mode. For guaranteed ADC operation, the MCU's voltage regulator must remain active during stop3 mode. Consult the module introduction for configuration information for this MCU.

If a conversion is in progress when the MCU enters stop3 mode, it continues until completion. Conversions can be initiated while the MCU is in stop3 mode by means of the hardware trigger or if continuous conversions are enabled.

A conversion complete event sets the COCO and generates an ADC interrupt to wake the MCU from stop3 mode if the ADC interrupt is enabled (AIEN = 1).

#### NOTE

The ADC module can wake the system from low-power stop and cause the MCU to begin consuming run-level currents without generating a system level interrupt. To prevent this scenario, software should ensure the data transfer blocking mechanism (discussed in [Section 10.4.4.2, “Completing Conversions”](#)) is cleared when entering stop3 and continuing ADC conversions.

## 10.4.8 MCU Stop2 Mode Operation

The ADC module is automatically disabled when the MCU enters stop2 mode. All module registers contain their reset values following exit from stop2. Therefore, the module must be re-enabled and re-configured following exit from stop2.

## 10.5 Initialization Information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. You can configure the module for 8-, 10-, or 12-bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options. Refer to [Table 10-7](#), [Table 10-8](#), and [Table 10-9](#) for information used in this example.

### NOTE

Hexadecimal values designated by a preceding 0x, binary values designated by a preceding %, and decimal values have no preceding character.

### 10.5.1 ADC Module Initialization Example

#### 10.5.1.1 Initialization Sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is as follows:

1. Update the configuration register (ADCCFG) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
2. Update status and control register 2 (ADCSC2) to select the conversion trigger (hardware or software) and compare function options, if enabled.
3. Update status and control register 1 (ADCSC1) to select whether conversions will be continuous or completed only once, and to enable or disable conversion complete interrupts. The input channel on which conversions will be performed is also selected here.

#### 10.5.1.2 Pseudo-Code Example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low-power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

**ADCCFG = 0x98 (%10011000)**

|         |        |    |                                                       |
|---------|--------|----|-------------------------------------------------------|
| Bit 7   | ADLPC  | 1  | Configures for low-power (lowers maximum clock speed) |
| Bit 6:5 | ADIV   | 00 | Sets the ADCK to the input clock ÷ 1                  |
| Bit 4   | ADLSMP | 1  | Configures for long sample time                       |
| Bit 3:2 | MODE   | 10 | Sets mode at 10-bit conversions                       |
| Bit 1:0 | ADICLK | 00 | Selects bus clock as input clock source               |

**ADCSC2 = 0x00 (%00000000)**

|         |       |    |                                                          |
|---------|-------|----|----------------------------------------------------------|
| Bit 7   | ADACT | 0  | Flag indicates if a conversion is in progress            |
| Bit 6   | ADTRG | 0  | Software trigger selected                                |
| Bit 5   | ACFE  | 0  | Compare function disabled                                |
| Bit 4   | ACFGT | 0  | Not used in this example                                 |
| Bit 3:2 |       | 00 | Reserved, always reads zero                              |
| Bit 1:0 |       | 00 | Reserved for Freescale's internal use; always write zero |

### ADCSC1 = 0x41 (%01000001)

|         |      |       |                                                         |
|---------|------|-------|---------------------------------------------------------|
| Bit 7   | COCO | 0     | Read-only flag which is set when a conversion completes |
| Bit 6   | AIEN | 1     | Conversion complete interrupt enabled                   |
| Bit 5   | ADCO | 0     | One conversion only (continuous conversions disabled)   |
| Bit 4:0 | ADCH | 00001 | Input channel 1 selected as ADC input channel           |

### ADCRH/L = 0xxx

Holds results of conversion. Read high byte (ADCRH) before low byte (ADCRL) so that conversion data cannot be overwritten with data from the next conversion.

### ADCCVH/L = 0xxx

Holds compare value when compare function enabled

### APCTL1=0x02

AD1 pin I/O control disabled. All other AD pins remain general purpose I/O pins

### APCTL2=0x00

All other AD pins remain general purpose I/O pins

**Figure 10-13. Initialization Flowchart for Example**

## 10.6 Application Information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

### 10.6.1 External Pins and Routing

The following sections discuss the external pins associated with the ADC module and how they should be used for best results.

#### 10.6.1.1 Analog Supply Pins

The ADC module has analog power and ground supplies ( $V_{DDA}$  and  $V_{SSA}$ ) available as separate pins on some devices.  $V_{SSA}$  is shared on the same pin as the MCU digital  $V_{SS}$  on some devices. On other devices,  $V_{SSA}$  and  $V_{DDA}$  are shared with the MCU digital supply pins. In these cases, there are separate pads for the analog supplies bonded to the same pin as the corresponding digital supply so that some degree of isolation between the supplies is maintained.

When available on a separate pin, both  $V_{DDA}$  and  $V_{SSA}$  must be connected to the same voltage potential as their corresponding MCU digital supply ( $V_{DD}$  and  $V_{SS}$ ) and must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

If separate power supplies are used for analog and digital power, the ground connection between these supplies must be at the  $V_{SSA}$  pin. This should be the only ground connection between these supplies if possible. The  $V_{SSA}$  pin makes a good single point ground location.

#### 10.6.1.2 Analog Reference Pins

In addition to the analog supplies, the ADC module has connections for two reference voltage inputs. The high reference is  $V_{REFH}$ , which may be shared on the same pin as  $V_{DDA}$  on some devices. The low reference is  $V_{REFL}$ , which may be shared on the same pin as  $V_{SSA}$  on some devices.

When available on a separate pin,  $V_{REFH}$  may be connected to the same potential as  $V_{DDA}$ , or may be driven by an external source between the minimum  $V_{DDA}$  spec and the  $V_{DDA}$  potential ( $V_{REFH}$  must never exceed  $V_{DDA}$ ). When available on a separate pin,  $V_{REFL}$  must be connected to the same voltage potential as  $V_{SSA}$ .  $V_{REFH}$  and  $V_{REFL}$  must be routed carefully for maximum noise immunity and bypass capacitors placed as near as possible to the package.

AC current in the form of current spikes required to supply charge to the capacitor array at each successive approximation step is drawn through the  $V_{REFH}$  and  $V_{REFL}$  loop. The best external component to meet this current demand is a 0.1  $\mu$ F capacitor with good high frequency characteristics. This capacitor is connected between  $V_{REFH}$  and  $V_{REFL}$  and must be placed as near as possible to the package pins. Resistance in the path is not recommended because the current causes a voltage drop that could result in conversion errors. Inductance in this path must be minimum (parasitic only).

### 10.6.1.3 Analog Input Pins

The external analog inputs are typically shared with digital I/O pins on MCU devices. The pin I/O control is disabled by setting the appropriate control bit in one of the pin control registers. Conversions can be performed on inputs without the associated pin control register bit set. It is recommended that the pin control register bit always be set when using a pin as an analog input. This avoids problems with contention because the output buffer is in its high impedance state and the pullup is disabled. Also, the input buffer draws DC current when its input is not at  $V_{DD}$  or  $V_{SS}$ . Setting the pin control register bits for all pins used as analog inputs should be done to achieve lowest operating current.

Empirical data shows that capacitors on the analog inputs improve performance in the presence of noise or when the source impedance is high. Use of 0.01  $\mu\text{F}$  capacitors with good high-frequency characteristics is sufficient. These capacitors are not necessary in all cases, but when used they must be placed as near as possible to the package pins and be referenced to  $V_{SSA}$ .

For proper conversion, the input voltage must fall between  $V_{REFH}$  and  $V_{REFL}$ . If the input is equal to or exceeds  $V_{REFH}$ , the converter circuit converts the signal to 0xFFF (full scale 12-bit representation), 0x3FF (full scale 10-bit representation) or 0xFF (full scale 8-bit representation). If the input is equal to or less than  $V_{REFL}$ , the converter circuit converts it to 0x000. Input voltages between  $V_{REFH}$  and  $V_{REFL}$  are straight-line linear conversions. There is a brief current associated with  $V_{REFL}$  when the sampling capacitor is charging. The input is sampled for 3.5 cycles of the ADCK source when ADLSMP is low, or 23.5 cycles when ADLSMP is high.

For minimal loss of accuracy due to current injection, pins adjacent to the analog input pins should not be transitioning during conversions.

## 10.6.2 Sources of Error

Several sources of error exist for A/D conversions. These are discussed in the following sections.

### 10.6.2.1 Sampling Error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Given the maximum input resistance of approximately 7k $\Omega$  and input capacitance of approximately 5.5 pF, sampling to within 1/4LSB (at 12-bit resolution) can be achieved within the minimum sample window (3.5 cycles @ 8 MHz maximum ADCK frequency) provided the resistance of the external analog source ( $R_{AS}$ ) is kept below 2 k $\Omega$ .

Higher source resistances or higher-accuracy sampling is possible by setting ADLSMP (to increase the sample window to 23.5 cycles) or decreasing ADCK frequency to increase sample time.

### 10.6.2.2 Pin Leakage Error

Leakage on the I/O pins can cause conversion error if the external analog source resistance ( $R_{AS}$ ) is high. If this error cannot be tolerated by the application, keep  $R_{AS}$  lower than  $V_{DDA} / (2^N \cdot I_{LEAK})$  for less than 1/4LSB leakage error ( $N = 8$  in 8-bit, 10 in 10-bit or 12 in 12-bit mode).

### 10.6.2.3 Noise-Induced Errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1  $\mu\text{F}$  low-ESR capacitor from  $V_{\text{REFH}}$  to  $V_{\text{REFL}}$ .
- There is a 0.1  $\mu\text{F}$  low-ESR capacitor from  $V_{\text{DDA}}$  to  $V_{\text{SSA}}$ .
- If inductive isolation is used from the primary supply, an additional 1  $\mu\text{F}$  capacitor is placed from  $V_{\text{DDA}}$  to  $V_{\text{SSA}}$ .
- $V_{\text{SSA}}$  (and  $V_{\text{REFL}}$ , if connected) is connected to  $V_{\text{SS}}$  at a quiet point in the ground plane.
- Operate the MCU in wait or stop3 mode before initiating (hardware triggered conversions) or immediately after initiating (hardware or software triggered conversions) the ADC conversion.
  - For software triggered conversions, immediately follow the write to ADCSC1 with a wait instruction or stop instruction.
  - For stop3 mode operation, select ADACK as the clock source. Operation in stop3 reduces  $V_{\text{DD}}$  noise but increases effective conversion time due to stop recovery.
- There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive  $V_{\text{DD}}$  noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in wait or stop3 or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:

- Place a 0.01  $\mu\text{F}$  capacitor ( $C_{\text{AS}}$ ) on the selected input channel to  $V_{\text{REFL}}$  or  $V_{\text{SSA}}$  (this improves noise issues, but affects the sample rate based on the external analog source resistance).
- Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.
- Reduce the effect of synchronous noise by operating off the asynchronous clock (ADACK) and averaging. Noise that is synchronous to ADCK cannot be averaged out.

### 10.6.2.4 Code Width and Quantization Error

The ADC quantizes the ideal straight-line transfer function into 4096 steps (in 12-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 8, 10 or 12), defined as 1LSB, is:

$$1 \text{ lsb} = (V_{\text{REFH}} - V_{\text{REFL}}) / 2^N \quad \text{Eqn. 10-2}$$

There is an inherent quantization error due to the digitization of the result. For 8-bit or 10-bit conversions the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual transfer function. Therefore, the quantization error will be  $\pm 1/2$  lsb in 8- or 10-bit mode. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 lsb and the code width of the last (0xFF or 0x3FF) is 1.5 lsb.

For 12-bit conversions the code transitions only after the full code width is present, so the quantization error is  $-1$  lsb to  $0$  lsb and the code width of each step is  $1$  lsb.

### 10.6.2.5 Linearity Errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system should be aware of them because they affect overall accuracy. These errors are:

- Zero-scale error ( $E_{ZS}$ ) (sometimes called offset) — This error is defined as the difference between the actual code width of the first conversion and the ideal code width ( $1/2$  lsb in 8-bit or 10-bit modes and  $1$  lsb in 12-bit mode). If the first conversion is  $0x001$ , the difference between the actual  $0x001$  code width and its ideal ( $1$  lsb) is used.
- Full-scale error ( $E_{FS}$ ) — This error is defined as the difference between the actual code width of the last conversion and the ideal code width ( $1.5$  lsb in 8-bit or 10-bit modes and  $1$  LSB in 12-bit mode). If the last conversion is  $0x3FE$ , the difference between the actual  $0x3FE$  code width and its ideal ( $1$  LSB) is used.
- Differential non-linearity (DNL) — This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.
- Integral non-linearity (INL) — This error is defined as the highest-value the (absolute value of the) running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.
- Total unadjusted error (TUE) — This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

### 10.6.2.6 Code Jitter, Non-Monotonicity, and Missing Codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes.

Code jitter is when, at certain points, a given input voltage converts to one of two values when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than the transition voltage, the converter yields the lower code (and vice-versa). However, even small amounts of system noise can cause the converter to be indeterminate (between two codes) for a range of input voltages around the transition voltage. This range is normally around  $\pm 1/2$  lsb in 8-bit or 10-bit mode, or around  $2$  lsb in 12-bit mode, and increases with noise.

This error may be reduced by repeatedly sampling the input and averaging the result. Additionally the techniques discussed in [Section 10.6.2.3, “Noise-Induced Errors.”](#) reduces this error.

Non-monotonicity is defined as when, except for code jitter, the converter converts to a lower code for a higher input voltage. Missing codes are those values never converted for any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing codes.

## Chapter 11

# Internal Clock Source (S08ICSV3)

### 11.1 Introduction

The internal clock source (ICS) module provides clock source choices for the MCU. The module contains a frequency-locked loop (FLL) as a clock source that is controllable by either an internal or an external reference clock. The module can provide this FLL clock or either of the internal or external reference clocks as a source for the MCU system clock. There are also signals provided to control a low-power oscillator (XOSC) module to allow the use of an external crystal/resonator as the external reference clock.

Whichever clock source is chosen for ICSOUT, it is passed through a reduced bus divider (BDIV) which allows a lower final output clock frequency to be derived.

#### NOTE

The ICS on the MC9S08LG32 series is configured to support only the low and mid range DCO, therefore the DRS[1] and DRST[1] bits in ICSSC have no effect. The FLL will only multiply the reference clock by 512/1024 or 608/1216 depending on the state of the DMX32 bit.

Figure 11-1 shows the MC9S08LG32 series block diagram with the ICS block highlighted.

During user modes, the trim registers of ICS are automatically loaded with factory programmed values. During debug modes, the trim registers of ICS default to predefined values (see [Section 11.3.3, “ICS Trim Register \(ICSTRM\)”](#) and [Section 11.3.4, “ICS Status and Control \(ICSSC\)”](#)). To get trimmed clock values in debug mode, the user can follow the steps as described in [Section 4.4.1, “Reserved Flash Locations.”](#)

Figure 11-1. MC9S08LG32 Series Block Diagram Highlighting ICS Block and Pins

### 11.1.1 Features

Key features of the ICS module are:

- Frequency-locked loop (FLL) is trimmable for accuracy
- Internal or external reference clocks can be used to control the FLL
- Reference divider is provided for external clock
- Internal reference clock has 9 trim bits available
- Internal or external reference clocks can be selected as the clock source for the MCU
- Whichever clock is selected as the source can be divided down
  - 2 bit select for clock divider is provided
    - Allowable dividers are: 1, 2, 4, 8
- Control signals for a low-power oscillator clock generator (OSCOUT) as the ICS external reference clock are provided
  - HGO, RANGE, EREFS, ERCLKEN, EREFSTEN
- FLL Engaged Internal mode is automatically selected out of reset
- BDC clock is provided as a constant divide by 2 of the low range DCO output
- Three selectable digitally controlled oscillators (DCO) optimized for different frequency ranges.
- Option to maximize output frequency for a 32768 Hz external reference clock source.

### 11.1.2 Block Diagram

Figure 11-2 is the ICS block diagram.

There are seven modes of operation for the ICS: FEI, FEE, FBI, FBILP, FBE, FBELP, and stop.

In FLL engaged internal mode, which is the default mode, the ICS supplies a clock derived from the FLL which is controlled by the internal reference clock. The BDC clock is supplied from the FLL.

In FLL engaged external mode, the ICS supplies a clock derived from the FLL which is controlled by an external reference clock source. The BDC clock is supplied from the FLL.

In FLL bypassed internal mode, the FLL is enabled and controlled by the internal reference clock, but is bypassed. The ICS supplies a clock derived from the internal reference clock. The BDC clock is supplied from the FLL.

### 11.1.3.4 FLL Bypassed Internal Low Power (FBILP)

In FLL bypassed internal low-power mode, the FLL is disabled and bypassed, and the ICS supplies a clock derived from the internal reference clock. The BDC clock is not available.

### 11.1.3.5 FLL Bypassed External (FBE)

In FLL bypassed external mode, the FLL is enabled and controlled by an external reference clock, but is bypassed. The ICS supplies a clock derived from the external reference clock source. The BDC clock is supplied from the FLL.

### 11.1.3.6 FLL Bypassed External Low Power (FBELP)

In FLL bypassed external low-power mode, the FLL is disabled and bypassed, and the ICS supplies a clock derived from the external reference clock. The BDC clock is not available.

### 11.1.3.7 Stop (STOP)

In stop mode the FLL is disabled and the internal reference clock (ICSIRCLK) and XOSC output clock (OSCOU) can be selected to be enabled or disabled. The BDC clock is not available and the ICS does not provide an MCU clock source.

#### NOTE

The DCO frequency changes from the pre-stop value to its reset value and the FLL will need to re-acquire the lock before the frequency is stable. Timing sensitive operations should wait for the FLL acquisition time,  $t_{Acquire}$ , before executing.

## 11.2 External Signal Description

There are no ICS signals that connect off chip.

## 11.3 Register Definition

Figure 11-1 is a summary of ICS registers.

Table 11-1. ICS Register Summary

| Name   |   | 7    | 6 | 5     | 4   | 3  | 2     | 1       | 0        |
|--------|---|------|---|-------|-----|----|-------|---------|----------|

### 11.3.3 ICS Trim Register (ICSTRM)

Reset: Note: TRIM is loaded during reset from a factory programmed location when not in BDM mode. If in a BDM mode, a default value of 0x80 is loaded.

Figure 11-5. ICS Trim Register (ICSTRM)

**Table 11-5. ICS Trim Register Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>TRIM | <p><b>ICS Trim Setting</b> — The TRIM bits control the internal reference clock frequency by controlling the internal reference clock period. The bits' effect are binary weighted (i.e., bit 1 will adjust twice as much as bit 0). Increasing the binary value in TRIM will increase the period, and decreasing the value will decrease the period.</p> <p>An additional fine trim bit is available in ICSSC as the FTRIM bit.</p> |

### 11.3.4 ICS Status and Control (ICSSC)

**Figure 11-6. ICS Status and Control Register (ICSSC)**

<sup>1</sup> FTRIM is loaded during reset from a factory programmed location when not in any BDM mode. If in a BDM mode, FTRIM gets loaded with a value of 1'b0.

**Table 11-6. ICS Status and Control Register Field Descriptions**

| Field                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

<sup>1</sup> Refer to NOTE in [Section 11.1, "Introduction."](#)

Table 11-7. DCO frequency range<sup>1</sup>

| DRS | DMX32    | Reference range     | FLL factor | DCO range   |
|-----|----------|---------------------|------------|-------------|
| 00  | 0        | 31.25 - 39.0625 kHz | 512        | 16 - 20 MHz |
|     | 1        | 32.768 kHz          | 608        | 19.92 MHz   |
| 01  | 0        | 31.25 - 39.0625 kHz | 1024       | 32 - 40 MHz |
|     | 1        | 32.768 kHz          | 1216       | 39.85 MHz   |
| 10  | 0        | 31.25 - 39.0625 kHz | 1536       | 48 - 60 MHz |
|     | 1        | 32.768 kHz          | 1824       | 59.77 MHz   |
| 11  | Reserved |                     |            |             |

<sup>1</sup> The resulting bus clock frequency should not exceed the maximum specified bus clock frequency of the device.

## 11.4 Functional Description

### 11.4.1 Operational Modes

Figure 11-7. Clock Switching Modes

The seven states of the ICS are shown as a state diagram and are described below. The arrows indicate the allowed movements between the states.

#### 11.4.1.1 FLL Engaged Internal (FEI)

FLL engaged internal (FEI) is the default mode of operation and is entered when all the following conditions occur:

- CLKS bits are written to 00.
- IREFS bit is written to 1.

In FLL engaged internal mode, the ICSOUT clock is derived from the FLL clock, which is controlled by the internal reference clock. The FLL loop will lock the frequency to the FLL factor times the internal reference frequency. The ICSLCLK is available for BDC communications, and the internal reference clock is enabled.

### 11.4.1.2 FLL Engaged External (FEE)

The FLL engaged external (FEE) mode is entered when all the following conditions occur:

- CLKS bits are written to 00.
- IREFS bit is written to 0.
- RDIV bits are written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz.

In FLL engaged external mode, the ICSOUT clock is derived from the FLL clock which is controlled by the external reference clock source. The FLL loop will lock the frequency to the FLL factor times the external reference frequency, as selected by the RDIV bits. The ICSLCLK is available for BDC communications, and the external reference clock is enabled.

### 11.4.1.3 FLL Bypassed Internal (FBI)

The FLL bypassed internal (FBI) mode is entered when all the following conditions occur:

- CLKS bits are written to 01.
- IREFS bit is written to 1.
- BDM mode is active or LP bit is written to 0.

In FLL bypassed internal mode, the ICSOUT clock is derived from the internal reference clock. The FLL clock is controlled by the internal reference clock, and the FLL loop will lock the FLL frequency to the FLL factor times the internal reference frequency. The ICSLCLK will be available for BDC communications, and the internal reference clock is enabled.

### 11.4.1.4 FLL Bypassed Internal Low Power (FBILP)

The FLL bypassed internal low-power (FBILP) mode is entered when all the following conditions occur:

- CLKS bits are written to 01
- IREFS bit is written to 1.
- BDM mode is not active and LP bit is written to 1

In FLL bypassed internal low-power mode, the ICSOUT clock is derived from the internal reference clock and the FLL is disabled. The ICSLCLK will be not be available for BDC communications, and the internal reference clock is enabled.

### 11.4.1.5 FLL Bypassed External (FBE)

The FLL bypassed external (FBE) mode is entered when all the following conditions occur:

- CLKS bits are written to 10.
- IREFS bit is written to 0.
- RDIV bits are written to divide external reference clock to be within the range of 31.25 kHz to 39.0625 kHz.
- BDM mode is active or LP bit is written to 0.

In FLL bypassed external mode, the ICSOUT clock is derived from the external reference clock source. The FLL clock is controlled by the external reference clock, and the FLL loop will lock the FLL frequency to the FLL factor times the external reference frequency, as selected by the RDIV bits, so that the ICSLCLK will be available for BDC communications, and the external reference clock is enabled.

#### 11.4.1.6 FLL Bypassed External Low Power (FBELP)

The FLL bypassed external low-power (FBELP) mode is entered when all the following conditions occur:

- CLKS bits are written to 10.
- IREFS bit is written to 0.
- BDM mode is not active and LP bit is written to 1.

In FLL bypassed external low-power mode, the ICSOUT clock is derived from the external reference clock source and the FLL is disabled. The ICSLCLK will be not be available for BDC communications. The external reference clock source is enabled.

#### 11.4.1.7 Stop

Stop mode is entered whenever the MCU enters a STOP state. In this mode, all ICS clock signals are static except in the following cases:

ICSIRCLK will be active in stop mode when all the following conditions occur:

- IRCLKEN bit is written to 1
- IREFSTEN bit is written to 1

OSCOOUT will be active in stop mode when all the following conditions occur:

- ERCLKEN bit is written to 1
- EREFSTEN bit is written to 1

### 11.4.2 Mode Switching

The IREF bit can be changed at anytime, but the actual switch to the newly selected clock is shown by the IREFST bit. When switching between FLL engaged internal (FEI) and FLL engaged external (FEE) modes, the FLL will begin locking again after the switch is completed.

The CLKS bits can also be changed at anytime, but the actual switch to the newly selected clock is shown by the CLKST bits. If the newly selected clock is not available, the previous clock will remain selected.

The DRS bits can be changed at anytime except when LP bit is 1. If the DRS bits are changed while in FLL engaged internal (FEI) or FLL engaged external (FEE), the bus clock remains at the previous DCO range until the new DCO starts. When the new DCO starts the bus clock switches to it. After switching to the new DCO the FLL remains unlocked for several reference cycles. Once the selected DCO startup time is over, the FLL is locked. The completion of the switch is shown by the DRST bits.

### 11.4.3 Bus Frequency Divider

The BDIV bits can be changed at anytime and the actual switch to the new frequency will occur immediately.

### 11.4.4 Low Power Bit Usage

The low-power bit (LP) is provided to allow the FLL to be disabled and thus conserve power when it is not being used. The DRS bits can not be written while LP bit is 1.

However, in some applications it may be desirable to allow the FLL to be enabled and to lock for maximum accuracy before switching to an FLL engaged mode. Do this by writing the LP bit to 0.

### 11.4.5 DCO Maximum Frequency with 32.768 kHz Oscillator

The FLL has an option to change the clock multiplier for the selected DCO range such that it results in the maximum bus frequency with a common 32.768 kHz crystal reference clock.

### 11.4.6 Internal Reference Clock

When IRCLKEN is set the internal reference clock signal will be presented as ICSIRCLK, which can be used as an additional clock source. The ICSIRCLK frequency can be re-targeted by trimming the period of the internal reference clock. This can be done by writing a new value to the TRIM bits in the ICSTRM register. Writing a larger value will slow down the ICSIRCLK frequency, and writing a smaller value to the ICSTRM register will speed up the ICSIRCLK frequency. The TRIM bits will effect the ICSOUT frequency if the ICS is in FLL engaged internal (FEI), FLL bypassed internal (FBI), or FLL bypassed internal low-power (FBILP) mode.

Until ICSIRCLK is trimmed, programming low reference divider (RDIV) factors may result in ICSOUT frequencies that exceed the maximum chip-level frequency and violate the chip-level clock timing specifications (see [Chapter 1, “Device Overview”](#)).

If IREFSTEN is set and the IRCLKEN bit is written to 1, the internal reference clock will keep running during stop mode in order to provide a fast recovery upon exiting stop.

All MCU devices are factory programmed with a trim value in a reserved memory location. This value is uploaded to the ICSTRM register and ICS FTRIM register during any reset initialization. For finer precision, the user can trim the internal oscillator in the application and set the FTRIM bit accordingly.

### 11.4.7 External Reference Clock

The ICS module supports an external reference clock with frequencies between 31.25 kHz to 40 MHz in all modes. When the ERCLKEN is set, the external reference clock signal will be presented as ICSECLK, which can be used as an additional clock source in run mode. When IREFS = 1, the external reference clock will not be used by the FLL and will only be used as ICSECLK. In these modes, the frequency can be equal to the maximum frequency the chip-level timing specifications will support (see [Chapter 1, “Device Overview”](#)).

If EREFSTEN is set and the ERCLKEN bit is written to 1, the external reference clock source (OSCOUT) will keep running during stop mode in order to provide a fast recovery upon exiting stop.

### 11.4.8 Fixed Frequency Clock

The ICS presents the divided FLL reference clock as ICSFFCLK for use as an additional clock source. ICSFFCLK frequency must be no more than 1/4 of the ICSOUT frequency to be valid. Because of this requirement, in bypass modes the ICSFFCLK is valid only in bypass external modes (FBE and FBELP) for the following combinations of BDIV, RDIV, and RANGE values:

- RANGE = 1
- BDIV = 00 (divide by 1), RDIV  $\geq$  010
- BDIV = 01 (divide by 2), RDIV  $\geq$  011
- BDIV = 10 (divide by 4), RDIV  $\geq$  100
- BDIV = 11 (divide by 8), RDIV  $\geq$  101

### 11.4.9 Local Clock

The ICS presents the low range DCO output clock divided by two as ICSLCLK for use as a clock source for BDC communications. ICSLCLK is not available in FLL bypassed internal low-power (FBILP) and FLL bypassed external low-power (FBELP) modes.

## Chapter 12

# Inter-Integrated Circuit (S08IICV2)

### 12.1 Introduction

The inter-integrated circuit (IIC) provides a method of communication between a number of devices. The interface is designed to operate up to 100 kbps with maximum bus loading and timing. The device is capable of operating at higher baud rates, up to a maximum of clock/20, with reduced bus loading. The maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF.

#### NOTE

- MC9S08LG32 series of MCUs include only one IIC module, therefore assume IICxA, IICxF, IICxC1, IICxS, IICxD, and IICxC2 register definitions as IIC0A, IIC0F, IIC0C1, IIC0S, IIC0D, and IIC0C2.
- The SDA and SCL must not be driven above  $V_{DD}$ . These pins are pseudo open-drain and contain a protection diode to  $V_{DD}$ .

#### 12.1.1 Module Configuration

The IIC module pins, SDA and SCL can be repositioned under software control using SDA and SCL bits in PINPS3 as shown in [Table 12-1](#). SDA and SCL bits in PINPS3 selects which general-purpose I/O ports are associated with IIC operation.

**Table 12-1. IIC Position Options**

| SDA/SCL in PINPS3 | Port Pin for SDA | Port Pin for SCL |
|-------------------|------------------|------------------|
| 0 (default)       | PTA2             | PTA1             |
| 1                 | PTI4             | PTI5             |

#### 12.1.2 IIC Clock Gating

The bus clock to the IIC can be gated on and off using the IIC bit in SCGC1. This bit is cleared after any reset, which disables the bus clock to this module. To conserve power, the IIC bit can be cleared to disable the clock to this module when not in use. See [Section 5.7, “Peripheral Clock Gating,”](#) for details.

Figure 12-1. MC9S08LG32 Series Block Diagram Highlighting IIC Block and Pins

### 12.1.3 Features

The IIC includes these distinctive features:

- Compatible with IIC bus standard
- Multi-master operation
- Software programmable for one of 64 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Arbitration lost interrupt with automatic mode switching from master to slave
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- General call recognition
- 10-bit address extension

### 12.1.4 Modes of Operation

A brief description of the IIC in the various MCU modes is given here.

- **Run mode** — This is the basic mode of operation. To conserve power in this mode, disable the module.
- **Wait mode** — The module continues to operate while the MCU is in wait mode and can provide a wake-up interrupt.
- **Stop mode** — The IIC is inactive in stop3 mode for reduced power consumption. The stop instruction does not affect IIC register states. Stop2 resets the register contents.

### 12.1.5 Block Diagram

[Figure 12-2](#) is a block diagram of the IIC.

Figure 12-2. IIC Functional Block Diagram

## 12.2 External Signal Description

This section describes each user-accessible pin signal.

### 12.2.1 SCL — Serial Clock Line

The bidirectional SCL is the serial clock line of the IIC system.

### 12.2.2 SDA — Serial Data Line

The bidirectional SDA is the serial data line of the IIC system.

## 12.3 Register Definition

This section consists of the IIC register descriptions in address order.

Refer to the direct-page register summary in [Chapter 4, “Memory,”](#) for the absolute address assignments for all IIC registers. This section refers to registers and control bits only by their names. A

Freescall-provided equate or header file is used to translate these names into the appropriate absolute addresses.

### 12.3.1 IIC Address Register (IICxA)

Figure 12-3. IIC Address Register (IICxA)

Table 12-2. IICxA Field Descriptions

| Field          | Description                                                                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–1<br>AD[7:1] | <b>Slave Address.</b> The AD[7:1] field contains the slave address to be used by the IIC module. This field is used on the 7-bit address scheme and the lower seven bits of the 10-bit address scheme. |

### 12.3.2 IIC Frequency Divider Register (IICxF)

Figure 12-4. IIC Frequency Divider Register (IICxF)

**Table 12-3. IICxF Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–6<br>MULT | <p><b>IIC Multiplier Factor.</b> The MULT bits define the multiplier factor, mul. This factor, along with the SCL divider, generates the IIC baud rate. The multiplier factor mul as defined by the MULT bits is provided below.</p> <p>00 mul = 01<br/>01 mul = 02<br/>10 mul = 04<br/>11 Reserved</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 5–0<br>ICR  | <p><b>IIC Clock Rate.</b> The ICR bits are used to prescale the bus clock for bit rate selection. These bits and the MULT bits determine the IIC baud rate, the SDA hold time, the SCL Start hold time, and the SCL Stop hold time. <a href="#">Table 12-5</a> provides the SCL divider and hold values for corresponding values of the ICR.</p> <p>The SCL divider multiplied by multiplier factor mul generates IIC baud rate.</p> $\text{IIC baud rate} = \frac{\text{bus speed (Hz)}}{\text{mul} \times \text{SCLdivider}} \quad \text{Eqn. 12-1}$ <p>SDA hold time is the delay from the falling edge of SCL (IIC clock) to the changing of SDA (IIC data).</p> $\text{SDA hold time} = \text{bus period (s)} \times \text{mul} \times \text{SDA hold value} \quad \text{Eqn. 12-2}$ <p>SCL start hold time is the delay from the falling edge of SDA (IIC data) while SCL is high (Start condition) to the falling edge of SCL (IIC clock).</p> $\text{SCL Start hold time} = \text{bus period (s)} \times \text{mul} \times \text{SCL Start hold value} \quad \text{Eqn. 12-3}$ <p>SCL stop hold time is the delay from the rising edge of SCL (IIC clock) to the rising edge of SDA (IIC data) while SCL is high (Stop condition).</p> $\text{SCL Stop hold time} = \text{bus period (s)} \times \text{mul} \times \text{SCL Stop hold value} \quad \text{Eqn. 12-4}$ |

For example, if the bus speed is 8 MHz, the table below shows the possible hold time values with different ICR and MULT selections to achieve an IIC baud rate of 100kbps.

**Table 12-4. Hold Time Values for 8 MHz Bus Speed**

| MULT | ICR  | Hold Times (μs) |           |          |
|------|------|-----------------|-----------|----------|
|      |      | SDA             | SCL Start | SCL Stop |
| 0x2  | 0x00 | 3.500           | 3.000     | 5.500    |
| 0x1  | 0x07 | 2.500           | 4.000     | 5.250    |
| 0x1  | 0x0B | 2.250           | 4.000     | 5.250    |
| 0x0  | 0x14 | 2.125           | 4.250     | 5.125    |
| 0x0  | 0x18 | 1.125           | 4.750     | 5.125    |

Table 12-5. IIC Divider and Hold Values

| ICR (hex) | SCL Divider | SDA Hold Value | SCL Hold (Start) Value | SDA Hold (Stop) Value |
|-----------|-------------|----------------|------------------------|-----------------------|
| 00        | 20          | 7              | 6                      | 11                    |
| 01        | 22          | 7              | 7                      | 12                    |
| 02        | 24          | 8              | 8                      | 13                    |
| 03        | 26          | 8              | 9                      | 14                    |

| 5<br>BUSY  | <b>Bus Busy.</b> The BUSY bit indicates the status of the bus regardless of slave or master mode. The BUSY bit is set when a start signal is detected and cleared when a stop signal is detected.<br>0 Bus is idle<br>1 Bus is busy                                                                                                                                                                                            |
| 4<br>ARBL  | <b>Arbitration Lost.</b> This bit is set by hardware when the arbitration procedure is lost. The ARBL bit must be cleared by software by writing a 1 to it.<br>0 Standard bus operation<br>1 Loss of arbitration                                                                                                                                                                                                               |
| 2<br>SRW   | <b>Slave Read/Write.</b> When addressed as a slave, the SRW bit indicates the value of the R/W command bit of the calling address sent to the master.<br>0 Slave receive, master writing to slave<br>1 Slave transmit, master reading from slave                                                                                                                                                                               |
| 1<br>IICIF | <b>IIC Interrupt Flag.</b> The IICIF bit is set when an interrupt is pending. This bit must be cleared by software, by writing a 1 to it in the interrupt routine. One of the following events can set the IICIF bit: <ul style="list-style-type: none"> <li>One byte transfer completes</li> <li>Match of slave address to calling address</li> <li>Arbitration lost</li> </ul> 0 No interrupt pending<br>1 Interrupt pending |
| 0<br>RXAK  | <b>Receive Acknowledge.</b> When the RXAK bit is low, it indicates an acknowledge signal has been received after the completion of one byte of data transmission on the bus. If the RXAK bit is high it means that no acknowledge signal is detected.<br>0 Acknowledge received<br>1 No acknowledge received                                                                                                                   |

### 12.3.5 IIC Data I/O Register (IICxD)

Figure 12-7. IIC Data I/O Register (IICxD)

**Table 12-8. IICxD Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7–0<br>DATA | <b>Data</b> — In master transmit mode, when data is written to the IICxD, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates receiving of the next byte of data. |

**NOTE**

When transitioning out of master receive mode, the IIC mode should be switched before reading the IICxD register to prevent an inadvertent initiation of a master receive data transfer.

In slave mode, the same functions are available after an address match has occurred.

The TX bit in IICxC must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the IIC is configured for master transmit but a master receive is desired, reading the IICxD does not initiate the receive.

Reading the IICxD returns the last byte received while the IIC is configured in master receive or slave receive modes. The IICxD does not reflect every byte transmitted on the IIC bus, nor can software verify that a byte has been written to the IICxD correctly by reading it back.

In master transmit mode, the first byte of data written to IICxD following assertion of MST is used for the address transfer and should comprise of the calling address (in bit 7 to bit 1) concatenated with the required R/W bit (in position bit 0).

### 12.3.6 IIC Control Register 2 (IICxC2)

**Figure 12-8. IIC Control Register (IICxC2)**

**Table 12-9. IICxC2 Field Descriptions**

| Field           | Description                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>GCAEN      | <b>General Call Address Enable.</b> The GCAEN bit enables or disables general call address.<br>0 General call address is disabled<br>1 General call address is enabled        |
| 6<br>ADEXT      | <b>Address Extension.</b> The ADEXT bit controls the number of bits used for the slave address.<br>0 7-bit address scheme<br>1 10-bit address scheme                          |
| 2–0<br>AD[10:8] | <b>Slave Address.</b> The AD[10:8] field contains the upper three bits of the slave address in the 10-bit address scheme. This field is only valid when the ADEXT bit is set. |

## 12.4 Functional Description

This section provides a complete functional description of the IIC module.

### 12.4.1 IIC Protocol

The IIC bus system uses a serial data line (SDA) and a serial clock line (SCL) for data transfer. All devices connected to it must have open drain or open collector outputs. A logic AND function is exercised on both lines with external pullup resistors. The value of these resistors is system dependent.

Normally, a standard communication is composed of four parts:

- Start signal
- Slave address transmission
- Data transfer
- Stop signal

The stop signal should not be confused with the CPU stop instruction. The IIC bus system communication is described briefly in the following sections and illustrated in [Figure 12-9](#).

**Figure 12-9. IIC Bus Transmission Signals**

#### 12.4.1.1 Start Signal

When the bus is free, no master device is engaging the bus (SCL and SDA lines are at logical high), a master may initiate communication by sending a start signal. As shown in [Figure 12-9](#), a start signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

### 12.4.1.2 Slave Address Transmission

The first byte of data transferred immediately after the start signal is the slave address transmitted by the master. This is a seven-bit calling address followed by a  $R/\overline{W}$  bit. The  $R/\overline{W}$  bit tells the slave the desired direction of data transfer.

1 = Read transfer, the slave transmits data to the master.

0 = Write transfer, the master transmits data to the slave.

Only the slave with a calling address that matches the one transmitted by the master responds by sending back an acknowledge bit. This is done by pulling the SDA low at the ninth clock (see [Figure 12-9](#)).

No two slaves in the system may have the same address. If the IIC module is the master, it must not transmit an address equal to its own slave address. The IIC cannot be master and slave at the same time. However, if arbitration is lost during an address cycle, the IIC reverts to slave mode and operates correctly even if it is being addressed by another master.

### 12.4.1.3 Data Transfer

After successful slave addressing is achieved, the data transfer can proceed byte-by-byte in a direction specified by the  $R/\overline{W}$  bit sent by the calling master.

All transfers that come after an address cycle are referred to as data transfers, even if they carry sub-address information for the slave device

Each data byte is 8 bits long. Data may be changed only while SCL is low and must be held stable while SCL is high as shown in [Figure 12-9](#). There is one clock pulse on SCL for each data bit, the msb being transferred first. Each data byte is followed by a 9th (acknowledge) bit, which is signalled from the receiving device. An acknowledge is signalled by pulling the SDA low at the ninth clock. In summary, one complete data transfer needs nine clock pulses.

If the slave receiver does not acknowledge the master in the ninth bit time, the SDA line must be left high by the slave. The master interprets the failed acknowledge as an unsuccessful data transfer.

If the master receiver does not acknowledge the slave transmitter after a data byte transmission, the slave interprets this as an end of data transfer and releases the SDA line.

In either case, the data transfer is aborted and the master does one of two things:

- Relinquishes the bus by generating a stop signal.
- Commences a new calling by generating a repeated start signal.

### 12.4.1.4 Stop Signal

The master can terminate the communication by generating a stop signal to free the bus. However, the master may generate a start signal followed by a calling command without generating a stop signal first. This is called repeated start. A stop signal is defined as a low-to-high transition of SDA while SCL at logical 1 (see [Figure 12-9](#)).

The master can generate a stop even if the slave has generated an acknowledge at which point the slave must release the bus.

### 12.4.1.5 Repeated Start Signal

As shown in Figure 12-9, a repeated start signal is a start signal generated without first generating a stop signal to terminate the communication. This is used by the master to communicate with another slave or with the same slave in different mode (transmit/receive mode) without releasing the bus.

### 12.4.1.6 Arbitration Procedure

The IIC bus is a true multi-master bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, a clock synchronization procedure determines the bus clock, for which the low period is equal to the longest clock low period and the high is equal to the shortest one among the masters. The relative priority of the contending masters is determined by a data arbitration procedure, a bus master loses arbitration if it transmits logic 1 while another master transmits logic 0. The losing masters immediately switch over to slave receive mode and stop driving SDA output. In this case, the transition from master to slave mode does not generate a stop condition. Meanwhile, a status bit is set by hardware to indicate loss of arbitration.

### 12.4.1.7 Clock Synchronization

Because wire-AND logic is performed on the SCL line, a high-to-low transition on the SCL line affects all the devices connected on the bus. The devices start counting their low period and after a device's clock has gone low, it holds the SCL line low until the clock high state is reached. However, the change of low to high in this device clock may not change the state of the SCL line if another device clock is still within its low period. Therefore, synchronized clock SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see Figure 12-10). When all devices concerned have counted off their low period, the synchronized clock SCL line is released and pulled high. There is then no difference between the device clocks and the state of the SCL line and all the devices start counting their high periods. The first device to complete its high period pulls the SCL line low again.

Figure 12-10. IIC Clock Synchronization

### 12.4.1.8 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such a case, it halts the bus clock and forces the master clock into wait states until the slave releases the SCL line.

### 12.4.1.9 Clock Stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

## 12.4.2 10-bit Address

For 10-bit addressing, 0x11110 is used for the first 5 bits of the first address byte. Various combinations of read/write formats are possible within a transfer that includes 10-bit addressing.

### 12.4.2.1 Master-Transmitter Addresses a Slave-Receiver

The transfer direction is not changed (see [Table 12-10](#)). When a 10-bit address follows a start condition, each slave compares the first seven bits of the first byte of the slave address (11110XX) with its own address and tests whether the eighth bit ( $\overline{R/W}$  direction bit) is 0. More than one device can find a match and generate an acknowledge (A1). Then, each slave that finds a match compares the eight bits of the second byte of the slave address with its own address. Only one slave finds a match and generates an acknowledge (A2). The matching slave remains addressed by the master until it receives a stop condition (P) or a repeated start condition (Sr) followed by a different slave address.

|   |                                                |          |    |                                   |    |      |   |     |      |     |   |

|---|------------------------------------------------|----------|----|-----------------------------------|----|------|---|-----|------|-----|---|

**Table 12-10. Master-Transmitter Addresses Slave-Receiver with a 10-bit Address**

After the master-transmitter has sent the first byte of the 10-bit address, the slave-receiver sees an IIC interrupt. Software must ensure the contents of IICD are ignored and not treated as valid data for this interrupt.

### 12.4.2.2 Master-Receiver Addresses a Slave-Transmitter

The transfer direction is changed after the second  $\overline{R/W}$  bit (see [Table 12-11](#)). Up to and including acknowledge bit A2, the procedure is the same as that described for a master-transmitter addressing a slave-receiver. After the repeated start condition (Sr), a matching slave remembers that it was addressed before. This slave then checks whether the first seven bits of the first byte of the slave address following Sr are the same as they were after the start condition (S) and tests whether the eighth ( $\overline{R/W}$ ) bit is 1. If there is a match, the slave considers that it has been addressed as a transmitter and generates acknowledge A3. The slave-transmitter remains addressed until it receives a stop condition (P) or a repeated start condition (Sr) followed by a different slave address.

After a repeated start condition (Sr), all other slave devices also compare the first seven bits of the first byte of the slave address with their own addresses and test the eighth ( $R/\overline{W}$ ) bit. However, none of them are addressed because  $R/\overline{W} = 1$  (for 10-bit devices) or the 11110XX slave address (for 7-bit devices) does not match.

|   |                                                   |          |    |                                      |    |    |                                                   |          |    |      |   |     |      |   |   |
|---|---------------------------------------------------|----------|----|--------------------------------------|----|----|---------------------------------------------------|----------|----|------|---|-----|------|---|---|

|---|---------------------------------------------------|----------|----|--------------------------------------|----|----|---------------------------------------------------|----------|----|------|---|-----|------|---|---|

**Table 12-11. Master-Receiver Addresses a Slave-Transmitter with a 10-bit Address**

After the master-receiver has sent the first byte of the 10-bit address, the slave-transmitter sees an IIC interrupt. Software must ensure the contents of IICD are ignored and not treated as valid data for this interrupt.

### 12.4.3 General Call Address

General calls can be requested in 7-bit address or 10-bit address. If the GCAEN bit is set, the IIC matches the general call address as well as its own slave address. When the IIC responds to a general call, it acts as a slave-receiver and the IAAS bit is set after the address cycle. Software must read the IICD register after the first byte transfer to determine whether the address matches is its own slave address or a general call. If the value is 00, the match is a general call. If the GCAEN bit is clear, the IIC ignores any data supplied from a general call address by not issuing an acknowledgement.

## 12.5 Resets

The IIC is disabled after reset. The IIC cannot cause an MCU reset.

## 12.6 Interrupts

The IIC generates a single interrupt.

An interrupt from the IIC is generated when any of the events in [Table 12-12](#) occur, provided the IICIE bit is set. The interrupt is driven by bit IICIF (of the IIC status register) and masked with bit IICIE (of the IIC control register). The IICIF bit must be cleared by software by writing a 1 to it in the interrupt routine. You can determine the interrupt type by reading the status register.

**Table 12-12. Interrupt Summary**

| Interrupt Source                  | Status | Flag  | Local Enable |
|-----------------------------------|--------|-------|--------------|
| Complete 1-byte transfer          | TCF    | IICIF | IICIE        |
| Match of received calling address | IAAS   | IICIF | IICIE        |
| Arbitration Lost                  | ARBL   | IICIF | IICIE        |

### 12.6.1 Byte Transfer Interrupt

The TCF (transfer complete flag) bit is set at the falling edge of the ninth clock to indicate the completion of byte transfer.

## 12.6.2 Address Detect Interrupt

When the calling address matches the programmed slave address (IIC address register) or when the GCAEN bit is set and a general call is received, the IAAS bit in the status register is set. The CPU is interrupted, provided the IICIE is set. The CPU must check the SRW bit and set its Tx mode accordingly.

## 12.6.3 Arbitration Lost Interrupt

The IIC is a true multi-master bus that allows more than one master to be connected on it. If two or more masters try to control the bus at the same time, the relative priority of the contending masters is determined by a data arbitration procedure. The IIC module asserts this interrupt when it loses the data arbitration process and the ARBL bit in the status register is set.

Arbitration is lost in the following circumstances:

- SDA sampled as a low when the master drives a high during an address or data transmit cycle.
- SDA sampled as a low when the master drives a high during the acknowledge bit of a data receive cycle.
- A start cycle is attempted when the bus is busy.
- A repeated start cycle is requested in slave mode.
- A stop condition is detected when the master did not request it.

This bit must be cleared by software writing a 1 to it.

## 12.7 Initialization/Application Information

### Module Initialization (Slave)

1. Write: IICC2
  - to enable or disable general call
  - to select 10-bit or 7-bit addressing mode
2. Write: IICA
  - to set the slave address
3. Write: IICC1
  - to enable IIC and interrupts
4. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
5. Initialize RAM variables used to achieve the routine shown in [Figure 12-12](#)

### Module Initialization (Master)

1. Write: IICF
  - to set the IIC baud rate (example provided in this chapter)
2. Write: IICC1
  - to enable IIC and interrupts
3. Initialize RAM variables (IICEN = 1 and IICIE = 1) for transmit data
4. Initialize RAM variables used to achieve the routine shown in [Figure 12-12](#)
5. Write: IICC1
  - to enable TX

### Register Model

Figure 12-11. IIC Module Quick Start

NOTES:

1. If general call is enabled, a check must be done to determine whether the received address was a general call address (0x00). If the received address was a general call address, then the general call must be handled by user software.
2. When 10-bit addressing is used to address a slave, the slave sees an interrupt following the first byte of the extended address. User software must ensure that for this interrupt, the contents of IICD are ignored and not treated as a valid data transfer

Figure 12-12. Typical IIC Interrupt Routine

# Chapter 13

## Serial Communications Interface (S08SCIV4)

### 13.1 Introduction

Figure 13-1 shows the MC9S08LG32 series block diagram with the SCI highlighted.

#### 13.1.1 Module Instances

The MC9S08LG32 series MCUs contain two SCI modules: SCI1 and SCI2. The memory map, pins, interrupts, etc. for the two modules can be differentiated using the SCI1 and SCI2 nomenclature.

#### 13.1.2 Module Configuration

The SCI module pins, TX1, RX1, TX2, and RX2 can be repositioned under software control using TX1, RX1, TX2, and RX2 bits in PINPS4 and PINPS3 as shown in Table 13-1. TX1, RX1, TX2, and RX2 bits in PINPS4 and PINPS3 selects which general-purpose I/O ports are associated with IIC operation.

Table 13-1. SCI Position Options

| TX1/RX1/TX2/RX2 | Port Pin for TX1 | Port Pin for RX1 | Port Pin for TX2 | Port Pin for RX2 |
|-----------------|------------------|------------------|------------------|------------------|
| 0 (default)     | PTF0             | PTF1             | PTA3             | PTA4             |
| 1               | PTH5             | PTH4             | PTI1             | PTI0             |

#### 13.1.3 SCI Clock Gating

The bus clock to the SCI can be gated on and off using the SCI bit in SCGC1. This bit is cleared after any reset, which disables the bus clock to this module. To conserve power, the SCI bit can be cleared to disable the clock to this module when not in use. For more details, see Section 5.7, “Peripheral Clock Gating.”

Figure 13-1. MC9S08LG32 Series Block Diagram Highlighting SCI Block and Pins

### 13.1.4 Features

Features of SCI module include:

- Full-duplex, standard non-return-to-zero (NRZ) format
- Double-buffered transmitter and receiver with separate enables
- Programmable baud rates (13-bit modulo divider)
- Interrupt-driven or polled operation:
  - Transmit data register empty and transmission complete
  - Receive data register full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
- Hardware parity generation and checking
- Programmable 8-bit or 9-bit character length
- Receiver wakeup by idle-line or address-mark
- Optional 13-bit break character generation / 11-bit break character detection
- Selectable transmitter output polarity

### 13.1.5 Modes of Operation

See [Section 13.3, “Functional Description,”](#) for details concerning SCI operation in these modes:

- 8- and 9-bit data modes
- Stop mode operation
- Loop mode
- Single-wire mode

## 13.1.6 Block Diagram

Figure 13-2 shows the transmitter portion of the SCI.

Figure 13-2. SCI Transmitter Block Diagram

Figure 13-3 shows the receiver portion of the SCI.

Figure 13-3. SCI Receiver Block Diagram

# 13.2 Register Definition

The SCI has eight 8-bit registers to control baud rate, select SCI options, report SCI status, and for transmit/receive data.

Refer to the direct-page register summary in [Chapter 4, “Memory,”](#) or the absolute address assignments for all SCI registers. This section refers to registers and control bits only by their names. A Freescale-provided equate or header file is used to translate these names into the appropriate absolute addresses.

## 13.2.1 SCI Baud Rate Registers (SCIxBDH, SCIxBDL)

This pair of registers controls the prescale divisor for SCI baud rate generation. To update the 13-bit baud rate setting [SBR12:SBR0], first write to SCIxBDH to buffer the high half of the new value and then write to SCIxBDL. The working value in SCIxBDH does not change until SCIxBDL is written.

SCIxBDL is reset to a non-zero value, so after reset the baud rate generator remains disabled until the first time the receiver or transmitter is enabled (RE or TE bits in SCIxC2 are written to 1).

Figure 13-4. SCI Baud Rate Register (SCIxBDH)

Table 13-2. SCIxBDH Field Descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

When LOOPS is set, the transmitter output is internally connected to the receiver input.<br>0 Normal operation — RxD and TxD use separate pins.<br>1 Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input. (See <a href="#">RSRC</a> bit.) RxD pin is not used by SCI.                                                                                   |
| 6<br>SCISWAI | <b>SCI Stops in Wait Mode</b><br>0 SCI clocks continue to run in wait mode so the SCI can be the source of an interrupt that wakes up the CPU.<br>1 SCI clocks freeze while CPU is in wait mode.                                                                                                                                                                                                                                                                                                     |
| 5<br>RSRC    | <b>Receiver Source Select</b> — This bit has no meaning or effect unless the LOOPS bit is set to 1. When LOOPS is set, the receiver input is internally connected to the TxD pin and RSRC determines whether this connection is also connected to the transmitter output.<br>0 Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the SCI does not use the RxD pins.<br>1 Single-wire SCI mode where the TxD pin is connected to the transmitter output and receiver input. |
| 4<br>M       | <b>9-Bit or 8-Bit Mode Select</b><br>0 Normal — start + 8 data bits (lsb first) + stop.<br>1 Receiver and transmitter use 9-bit data characters<br>start + 8 data bits (lsb first) + 9th data bit + stop.                                                                                                                                                                                                                                                                                            |

**Table 13-4. SC1xC1 Field Descriptions (continued)**

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3<br>WAKE | <b>Receiver Wakeup Method Select</b> — Refer to <a href="#">Section 13.3.3.2, “Receiver Wakeup Operation,”</a> for more information.<br>0 Idle-line wakeup.<br>1 Address-mark wakeup.                                                                                                                                                                                                                                               |
| 2<br>ILT  | <b>Idle Line Type Select</b> — Setting this bit to 1 ensures that the stop bit and logic 1 bits at the end of a character do not count toward the 10 or 11 bit times of logic high level needed by the idle line detection logic. Refer to <a href="#">Section 13.3.3.2.1, “Idle-Line Wakeup,”</a> for more information.<br>0 Idle character bit count starts after start bit.<br>1 Idle character bit count starts after stop bit. |
| 1<br>PE   | <b>Parity Enable</b> — Enables hardware parity generation and checking. When parity is enabled, the most significant bit (msb) of the data character (eighth or ninth data bit) is treated as the parity bit.<br>0 No hardware parity generation or checking.<br>1 Parity enabled.                                                                                                                                                  |
| 0<br>PT   | <b>Parity Type</b> — Provided parity is enabled (PE = 1), this bit selects even or odd parity. Odd parity means the total number of 1s in the data character, including the parity bit, is odd. Even parity means the total number of 1s in the data character, including the parity bit, is even.<br>0 Even parity.<br>1 Odd parity.                                                                                               |

### 13.2.3 SCI Control Register 2 (SC1xC2)

This register can be read or written at any time.

**Figure 13-7. SCI Control Register 2 (SC1xC2)**

**Table 13-5. SC1xC2 Field Descriptions**

| Field     | Description                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>TIE  | <b>Transmit Interrupt Enable (for TDRE)</b><br>0 Hardware interrupts from TDRE disabled (use polling).<br>1 Hardware interrupt requested when TDRE flag is 1.        |
| 6<br>TCIE | <b>Transmission Complete Interrupt Enable (for TC)</b><br>0 Hardware interrupts from TC disabled (use polling).<br>1 Hardware interrupt requested when TC flag is 1. |
| 5<br>RIE  | <b>Receiver Interrupt Enable (for RDRF)</b><br>0 Hardware interrupts from RDRF disabled (use polling).<br>1 Hardware interrupt requested when RDRF flag is 1.        |
| 4<br>ILIE | <b>Idle Line Interrupt Enable (for IDLE)</b><br>0 Hardware interrupts from IDLE disabled (use polling).<br>1 Hardware interrupt requested when IDLE flag is 1.       |

**Table 13-5. SCIxC2 Field Descriptions (continued)**

| Field    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3<br>TE  | <b>Transmitter Enable</b><br>0 Transmitter off.<br>1 Transmitter on.<br>TE must be 1 in order to use the SCI transmitter. When TE is set, the SCI forces the TxD pin to act as an output for the SCI system.<br>When the SCI is configured for single-wire operation (LOOPS = RSRC = 1), TXDIR controls the direction of traffic on the single SCI communication line (TxD pin).<br>TE can also queue an idle character by clearing TE then setting TE while a transmission is in progress. Refer to <a href="#">Section 13.3.2.1, “Send Break and Queued Idle,”</a> for more details.<br>When TE is written to 0, the transmitter keeps control of the port TxD pin until any data, queued idle, or queued break character finishes transmitting before allowing the pin to revert to a general-purpose I/O pin. |
| 2<br>RE  | <b>Receiver Enable</b> — When the SCI receiver is off, the RxD pin reverts to being a general-purpose port I/O pin. If LOOPS is set, the RxD pin reverts to being a general-purpose I/O pin even if RE is set.<br>0 Receiver off.<br>1 Receiver on.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 1<br>RWU | <b>Receiver Wakeup Control</b> — This bit can be written to 1 to place the SCI receiver in a standby state where it waits for automatic hardware detection of a selected wakeup condition. The wakeup condition is an idle line between messages (WAKE = 0, idle-line wakeup), or a logic 1 in the most significant data bit in a character (WAKE = 1, address-mark wakeup). Application software sets RWU and (normally) a selected hardware condition automatically clears RWU. Refer to <a href="#">Section 13.3.3.2, “Receiver Wakeup Operation,”</a> for more details.<br>0 Normal SCI receiver operation.<br>1 SCI receiver in standby waiting for wakeup condition.                                                                                                                                        |
| 0<br>SBK | <b>Send Break</b> — Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 10 or 11 (13 or 14 if BRK13 = 1) bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the information currently being transmitted, a second break character may be queued before software clears SBK. Refer to <a href="#">Section 13.3.2.1, “Send Break and Queued Idle,”</a> for more details.<br>0 Normal transmitter operation.<br>1 Queue break character(s) to be sent.                                                                                                                                                                                                                          |

### 13.2.4 SCI Status Register 1 (SCIS1)

This register has eight read-only status flags. Writes have no effect. Special software sequences (which do not involve writing to this register) are used to clear these status flags.

**Figure 13-8. SCI Status Register 1 (SCIS1)**

Table 13-6. SCiXS1 Field Descriptions

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>TDRE | <b>Transmit Data Register Empty Flag</b> — TDRE is set out of reset and when a transmit data value transfers from the transmit data buffer to the transmit shifter, leaving room for a new character in the buffer. To clear TDRE, read SCiXS1 with TDRE set and then write to the SCI data register (SCiXD).<br>0 Transmit data register (buffer) full.<br>1 Transmit data register (buffer) empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6<br>TC   | <b>Transmission Complete Flag</b> — TC is set out of reset and when TDRE is set and no data, preamble, or break character is being transmitted.<br>0 Transmitter active (sending data, a preamble, or a break).<br>1 Transmitter idle (transmission activity complete).<br>TC is cleared automatically by reading SCiXS1 with TC set and then doing one of the following: <ul style="list-style-type: none"> <li>Write to the SCI data register (SCiXD) to transmit new data</li> <li>Queue a preamble by changing TE from 0 to 1</li> <li>Queue a break character by writing 1 to SBK in SCiXC2</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 5<br>RDRF | <b>Receive Data Register Full Flag</b> — RDRF becomes set when a character transfers from the receive shifter into the receive data register (SCiXD). To clear RDRF, read SCiXS1 with RDRF set and then read the SCI data register (SCiXD).<br>0 Receive data register empty.<br>1 Receive data register full.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4<br>IDLE | <b>Idle Line Flag</b> — IDLE is set when the SCI receive line becomes idle for a full character time after a period of activity. When ILT is cleared, the receiver starts counting idle bit times after the start bit. So if the receive character is all 1s, these bit times and the stop bit time count toward the full character time of logic high (10 or 11 bit times depending on the M control bit) needed for the receiver to detect an idle line. When ILT is set, the receiver doesn't start counting idle bit times until after the stop bit. The stop bit and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.<br>To clear IDLE, read SCiXS1 with IDLE set and then read the SCI data register (SCiXD). After IDLE has been cleared, it cannot become set again until after a new character has been received and RDRF has been set. IDLE is set only once even if the receive line remains idle for an extended period.<br>0 No idle line detected.<br>1 Idle line was detected. |
| 3<br>OR   | <b>Receiver Overrun Flag</b> — OR is set when a new serial character is ready to be transferred to the receive data register (buffer), but the previously received character has not been read from SCiXD yet. In this case, the new character (and all associated error information) is lost because there is no room to move it into SCiXD. To clear OR, read SCiXS1 with OR set and then read the SCI data register (SCiXD).<br>0 No overrun.<br>1 Receive overrun (new SCI data lost).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 2<br>NF   | <b>Noise Flag</b> — The advanced sampling technique used in the receiver takes seven samples during the start bit and three samples in each data bit and the stop bit. If any of these samples disagrees with the rest of the samples within any bit time in the frame, the flag NF is set at the same time as RDRF is set for the character. To clear NF, read SCiXS1 and then read the SCI data register (SCiXD).<br>0 No noise detected.<br>1 Noise detected in the received character in SCiXD.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Table 13-6. SCIS1 Field Descriptions (continued)

| Field   | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1<br>FE | <b>Framing Error Flag</b> — FE is set at the same time as RDRF when the receiver detects a logic 0 where the stop bit was expected. This suggests the receiver was not properly aligned to a character frame. To clear FE, read SCIS1 with FE set and then read the SCI data register (SCID).<br>0 No framing error detected. This does not guarantee the framing is correct.<br>1 Framing error. |
| 0<br>PF | <b>Parity Error Flag</b> — PF is set at the same time as RDRF when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, read SCIS1 and then read the SCI data register (SCID).<br>0 No parity error.<br>1 Parity error.                                                                                            |

### 13.2.5 SCI Status Register 2 (SCIS2)

This register has one read-only status flag.

Figure 13-9. SCI Status Register 2 (SCIS2)

Table 13-7. SCIS2 Field Descriptions

| Field                   | Description                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>LBKDIF             | <b>LIN Break Detect Interrupt Flag</b> — LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.<br>0 No LIN break character has been detected.<br>1 LIN break character has been detected.                                                                      |
| 6<br>RXEDGIF            | <b>RxD Pin Active Edge Interrupt Flag</b> — RXEDGIF is set when an active edge (falling if RXINV = 0, rising if RXINV=1) on the RxD pin occurs. RXEDGIF is cleared by writing a 1 to it.<br>0 No active edge on the receive pin has occurred.<br>1 An active edge on the receive pin has occurred.                                                   |
| 4<br>RXINV <sup>1</sup> | <b>Receive Data Inversion</b> — Setting this bit reverses the polarity of the received data input.<br>0 Receive data not inverted<br>1 Receive data inverted                                                                                                                                                                                         |
| 3<br>RWUID              | <b>Receive Wake Up Idle Detect</b> — RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit.<br>0 During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character.<br>1 During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. |
| 2<br>BRK13              | <b>Break Character Generation Length</b> — BRK13 is used to select a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit.<br>0 Break character is transmitted with length of 10 bit times (11 if M = 1)<br>1 Break character is transmitted with length of 13 bit times (14 if M = 1)   |

**Table 13-7. SCIxS2 Field Descriptions (continued)**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1<br>LBKDE | <b>LIN Break Detection Enable</b> — LBKDE selects a longer break character detection length. While LBKDE is set, framing error (FE) and receive data register full (RDRF) flags are prevented from setting.<br>0 Break character is detected at length of 10 bit times (11 if M = 1).<br>1 Break character is detected at length of 11 bit times (12 if M = 1).                                                    |
| 0<br>RAF   | <b>Receiver Active Flag</b> — RAF is set when the SCI receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line. This status flag can be used to check whether an SCI character is being received before instructing the MCU to go to stop mode.<br>0 SCI receiver idle waiting for a start bit.<br>1 SCI receiver active (RxD input not idle). |

<sup>1</sup> Setting RXINV inverts the RxD input for all cases: data bits, start and stop bits, break, and idle.

When using an internal oscillator in a LIN system, it is necessary to raise the break detection threshold one bit time. Under the worst case timing conditions allowed in LIN, it is possible that a 0x00 data character can appear to be 10.26 bit times long at a slave running 14% faster than the master. This would trigger normal break detection circuitry designed to detect a 10-bit break symbol. When the LBKDE bit is set, framing errors are inhibited and the break detection threshold changes from 10 bits to 11 bits, preventing false detection of a 0x00 data character as a LIN break symbol.

### 13.2.6 SCI Control Register 3 (SClxC3)

**Figure 13-10. SCI Control Register 3 (SClxC3)**

**Table 13-8. SClxC3 Field Descriptions**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>R8    | <b>Ninth Data Bit for Receiver</b> — When the SCI is configured for 9-bit data (M = 1), R8 can be thought of as a ninth receive data bit to the left of the msb of the buffered data in the SClxD register. When reading 9-bit data, read R8 before reading SClxD because reading SClxD completes automatic flag clearing sequences that could allow R8 and SClxD to be overwritten with new data.                                                                                                                                                                                    |
| 6<br>T8    | <b>Ninth Data Bit for Transmitter</b> — When the SCI is configured for 9-bit data (M = 1), T8 may be thought of as a ninth transmit data bit to the left of the msb of the data in the SClxD register. When writing 9-bit data, the entire 9-bit value is transferred to the SCI shift register after SClxD is written so T8 should be written (if it needs to change from its previous value) before SClxD is written. If T8 does not need to change in the new value (such as when it is used to generate mark or space parity), it need not be written each time SClxD is written. |
| 5<br>TXDIR | <b>TxD Pin Direction in Single-Wire Mode</b> — When the SCI is configured for single-wire half-duplex operation (LOOPS = RSRC = 1), this bit determines the direction of data at the TxD pin.<br>0 TxD pin is an input in single-wire mode.<br>1 TxD pin is an output in single-wire mode.                                                                                                                                                                                                                                                                                            |

**Table 13-8. SCIxC3 Field Descriptions (continued)**

| Field                   | Description                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4<br>TXINV <sup>1</sup> | <b>Transmit Data Inversion</b> — Setting this bit reverses the polarity of the transmitted data output.<br>0 Transmit data not inverted<br>1 Transmit data inverted                                                        |

<sup>1</sup> Setting TXINV inverts the TxD output for all cases: data bits, start and stop bits, break, and idle.

### 13.2.7 SCI Data Register (SClxD)

This register is actually two separate registers. Reads return the contents of the read-only receive data buffer and writes go to the write-only transmit data buffer. Reads and writes of this register are also involved in the automatic flag clearing mechanisms for the SCI status flags.

|       |    |    |    |    |    |    |    |    |

| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Figure 13-11. SCI Data Register (SClxD)**

## 13.3 Functional Description

The SCI allows full-duplex, asynchronous, NRZ serial communication among the MCU and remote devices, including other MCUs. The SCI comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. During normal operation, the MCU monitors the status of the SCI, writes the data to be transmitted, and processes received data. The following describes each of the blocks of the SCI.

### 13.3.1 Baud Rate Generation

As shown in [Figure 13-12](#), the clock source for the SCI baud rate generator is the bus-rate clock.

**Figure 13-12. SCI Baud Rate Generation**

SCI communications require the transmitter and receiver (which typically derive baud rates from independent clock sources) to use the same baud rate. Allowed tolerance on this baud frequency depends on the details of how the receiver synchronizes to the leading edge of the start bit and how bit sampling is performed.

The MCU resynchronizes to bit boundaries on every high-to-low transition. In the worst case, there are no such transitions in the full 10- or 11-bit time character frame so any mismatch in baud rate is accumulated for the whole character time. For a Freescale Semiconductor SCI system whose bus frequency is driven by a crystal, the allowed baud rate mismatch is about  $\pm 4.5$  percent for 8-bit data format and about  $\pm 4$  percent for 9-bit data format. Although baud rate modulo divider settings do not always produce baud rates that exactly match standard rates, it is normally possible to get within a few percent, which is acceptable for reliable communications.

### 13.3.2 Transmitter Functional Description

This section describes the overall block diagram for the SCI transmitter, as well as specialized functions for sending break and idle characters. The transmitter block diagram is shown in [Figure 13-2](#).

The transmitter output (TxD) idle state defaults to logic high (TXINV is cleared following reset). The transmitter output is inverted by setting TXINV. The transmitter is enabled by setting the TE bit in SCIxC2. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the SCI data register (SCIxD).

The central element of the SCI transmitter is the transmit shift register that is 10 or 11 bits long depending on the setting in the M control bit. For the remainder of this section, assume M is cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new SCI character, the value waiting in the transmit data register is transferred to the shift register (synchronized with the baud rate clock) and the transmit data register empty (TDRE) status flag is set to indicate another character may be written to the transmit data buffer at SCIxD.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the TxD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TxD high, waiting for more characters to transmit.

Writing 0 to TE does not immediately release the pin to be a general-purpose I/O pin. Any transmit activity in progress must first be completed. This includes data characters in progress, queued idle characters, and queued break characters.

### 13.3.2.1 Send Break and Queued Idle

The SBK control bit in SCIxC2 sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0 (10 bit times including the start and stop bits). A longer break of 13 bit times can be enabled by setting BRK13. Normally, a program would wait for TDRE to become set to indicate the last character of a message has moved to the transmit shifter, then write 1 and then write 0 to the SBK bit. This action queues a break character to be sent as soon as the shifter is available. If SBK remains 1 when the queued break moves into the shifter (synchronized to the baud rate clock), an additional break character is queued. If the receiving device is another Freescale Semiconductor SCI, the break characters are received as 0s in all eight data bits and a framing error (FE = 1) occurs.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for TDRE to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the TE bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while TE is cleared, the SCI transmitter never actually releases control of the TxD pin. If there is a possibility of the shifter finishing while TE is cleared, set the general-purpose I/O controls so the pin shared with TxD is an output driving a logic 1. This ensures that the TxD line looks like a normal idle line even if the SCI loses control of the port pin between writing 0 and then 1 to TE.

The length of the break character is affected by the BRK13 and M bits as shown below.

**Table 13-9. Break Character Length**

| BRK13 | M | Break Character Length |
|-------|---|------------------------|
| 0     | 0 | 10 bit times           |
| 0     | 1 | 11 bit times           |
| 1     | 0 | 13 bit times           |
| 1     | 1 | 14 bit times           |

### 13.3.3 Receiver Functional Description

In this section, the receiver block diagram ([Figure 13-3](#)) is used as a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, two variations of the receiver wakeup function are explained.

The receiver input is inverted by setting RXINV. The receiver is enabled by setting the RE bit in SCIxC2. Character frames consist of a start bit of logic 0, eight (or nine) data bits (lsb first), and a stop bit of logic 1. For information about 9-bit data mode, refer to [Section 13.3.5.1, “8-Bit and 9-Bit Data Modes.”](#) For the remainder of this discussion, assume the SCI is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (RDRF) status flag is set. If RDRF was already set indicating the receive data register (buffer) was already full, the

overflow (OR) status flag is set and the new data is lost. Because the SCI receiver is double-buffered, the program has one full character time after RDRF is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full ( $RDRF = 1$ ), it gets the data from the receive data register by reading SCIxD. The RDRF flag is cleared automatically by a two-step sequence which is normally satisfied in the course of the user's program that handles receive data. Refer to [Section 13.3.4, "Interrupts and Status Flags,"](#) for more details about flag clearing.

### 13.3.3.1 Data Sampling Technique

The SCI receiver uses a  $16\times$  baud rate clock for sampling. The receiver starts by taking logic level samples at 16 times the baud rate to search for a falling edge on the RxD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The  $16\times$  baud rate clock divides the bit time into 16 segments labeled RT1 through RT16. When a falling edge is located, three more samples are taken at RT3, RT5, and RT7 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a receive character.

The receiver then samples each bit time, including the start and stop bits, at RT8, RT9, and RT10 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. In the case of the start bit, the bit is assumed to be 0 if at least two of the samples at RT3, RT5, and RT7 are 0 even if one or all of the samples taken at RT8, RT9, and RT10 are 1s. If any sample in any bit time (including the start and stop bits) in a character frame fails to agree with the logic level for that bit, the noise flag (NF) is set when the received character is transferred to the receive data buffer.

The falling edge detection logic continuously looks for falling edges. If an edge is detected, the sample clock is resynchronized to bit times. This improves the reliability of the receiver in the presence of noise or mismatched baud rates. It does not improve worst case analysis because some characters do not have any extra falling edges anywhere in the character frame.

In the case of a framing error, provided the received character was not a break character, the sampling logic that searches for a falling edge is filled with three logic 1 samples so that a new start bit can be detected almost immediately.

In the case of a framing error, the receiver is inhibited from receiving any new characters until the framing error flag is cleared. The receive shift register continues to function, but a complete character cannot transfer to the receive data buffer if FE remains set.

### 13.3.3.2 Receiver Wakeup Operation

Receiver wakeup is a hardware mechanism that allows an SCI receiver to ignore the characters in a message intended for a different SCI receiver. In such a system, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up (RWU) control bit in SCIxC2. When RWU bit is set, the status flags associated with the receiver (with the exception of the idle bit, IDLE, when RWUID bit is set) are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At

the end of a message, or at the beginning of the next message, all receivers automatically force RWU to 0 so all receivers wakeup in time to look at the first character(s) of the next message.

### 13.3.3.2.1 Idle-Line Wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, RWU is cleared automatically when the receiver detects a full character time of the idle-line level. The M control bit selects 8-bit or 9-bit data mode that determines how many bit times of idle are needed to constitute a full character time (10 or 11 bit times because of the start and stop bits).

When RWU is one and RWUID is zero, the idle condition that wakes up the receiver does not set the IDLE flag. The receiver wakes up and waits for the first data character of the next message that sets the RDRF flag and generates an interrupt if enabled. When RWUID is one, any idle condition sets the IDLE flag and generates an interrupt if enabled, regardless of whether RWU is zero or one.

The idle-line type (ILT) control bit selects one of two ways to detect an idle line. When ILT is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When ILT is set, the idle bit counter does not start until after a stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

### 13.3.3.2.2 Address-Mark Wakeup

When wake is set, the receiver is configured for address-mark wakeup. In this mode, RWU is cleared automatically when the receiver detects a logic 1 in the most significant bit of a received character (eighth bit when M is cleared and ninth bit when M is set).

Address-mark wakeup allows messages to contain idle characters, but requires the msb be reserved for use in address frames. The logic 1 msb of an address frame clears the RWU bit before the stop bit is received and sets the RDRF flag. In this case, the character with the msb set is received even though the receiver was sleeping during most of this character time.

## 13.3.4 Interrupts and Status Flags

The SCI system has three separate interrupt vectors to reduce the amount of software needed to isolate the cause of the interrupt. One interrupt vector is associated with the transmitter for TDRE and TC events. Another interrupt vector is associated with the receiver for RDRF, IDLE, RXEDGIF, and LBKDIF events. A third vector is used for OR, NF, FE, and PF error conditions. Each of these ten interrupt sources can be separately masked by local interrupt enable masks. The flags can be polled by software when the local masks are cleared to disable generation of hardware interrupt requests.

The SCI transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty (TDRE) indicates when there is room in the transmit data buffer to write another transmit character to SCIxD. If the transmit interrupt enable (TIE) bit is set, a hardware interrupt is requested when TDRE is set. Transmit complete (TC) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TxD at the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (TCIE) bit is set, a hardware interrupt is requested when TC is set. Instead of hardware

interrupts, software polling may be used to monitor the TDRE and TC status flags if the corresponding TIE or TCIE local interrupt masks are cleared.

When a program detects that the receive data register is full ( $RDRF = 1$ ), it gets the data from the receive data register by reading SCiXD. The RDRF flag is cleared by reading SCiXS1 while RDRF is set and then reading SCiXD.

When polling is used, this sequence is naturally satisfied in the normal course of the user program. If hardware interrupts are used, SCiXS1 must be read in the interrupt service routine (ISR). Normally, this is done in the ISR anyway to check for receive errors, so the sequence is automatically satisfied.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RxD line remains idle for an extended period of time. IDLE is cleared by reading SCiXS1 while IDLE is set and then reading SCiXD. After IDLE has been cleared, it cannot become set again until the receiver has received at least one new character and has set RDRF.

If the associated error was detected in the received character that caused RDRF to be set, the error flags — noise flag (NF), framing error (FE), and parity error flag (PF) — are set at the same time as RDRF. These flags are not set in overrun cases.

If RDRF was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (OR) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

At any time, an active edge on the RxD serial data input pin causes the RXEDGIF flag to set. The RXEDGIF flag is cleared by writing a 1 to it. This function does depend on the receiver being enabled ( $RE = 1$ ).

### 13.3.5 Additional SCI Functions

The following sections describe additional SCI functions.

#### 13.3.5.1 8-Bit and 9-Bit Data Modes

The SCI system (transmitter and receiver) can be configured to operate in 9-bit data mode by setting the M control bit in SCiXC1. In 9-bit mode, there is a ninth data bit to the left of the msb of the SCI data register. For the transmit data buffer, this bit is stored in T8 in SCiXC3. For the receiver, the ninth bit is held in R8 in SCiXC3.

For coherent writes to the transmit data buffer, write to the T8 bit before writing to SCiXD.

If the bit value to be transmitted as the ninth bit of a new character is the same as for the previous character, it is not necessary to write to T8 again. When data is transferred from the transmit data buffer to the transmit shifter, the value in T8 is copied at the same time data is transferred from SCiXD to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. In custom protocols, the ninth bit can also serve as a software-controlled marker.

### 13.3.5.2 Stop Mode Operation

During all stop modes, clocks to the SCI module are halted.

In stop2 mode, all SCI register data is lost and must be re-initialized upon recovery from this mode. No SCI module registers are affected in stop3 mode.

The receive input active edge detect circuit remains active in stop3 mode, but not in stop2. An active edge on the receive input brings the CPU out of stop3 mode if the interrupt is not masked (RXEDGIE = 1).

Because the clocks are halted, the SCI module resumes operation upon exit from stop (only in stop3 mode). Software should ensure stop mode is not entered while there is a character being transmitted out of or received into the SCI module.

### 13.3.5.3 Loop Mode

When LOOPS is set, the RSRC bit in the same register chooses between loop mode (RSRC = 0) or single-wire mode (RSRC = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RxD pin is not used by the SCI, so it reverts to a general-purpose port I/O pin.

### 13.3.5.4 Single-Wire Operation

When LOOPS is set, the RSRC bit in the same register chooses between loop mode (RSRC = 0) or single-wire mode (RSRC = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TxD pin. The RxD pin is not used and reverts to a general-purpose port I/O pin.

In single-wire mode, the TXDIR bit in SCIxC3 controls the direction of serial data on the TxD pin. When TXDIR is cleared, the TxD pin is an input to the SCI receiver and the transmitter is temporarily disconnected from the TxD pin so an external device can send serial data to the receiver. When TXDIR is set, the TxD pin is an output driven by the transmitter. In single-wire mode, the internal loop back connection from the transmitter to the receiver causes the receiver to receive characters that are sent out by the transmitter.

# Chapter 14

## Serial Peripheral Interface (S08SPIV4)

### 14.1 Introduction

The serial peripheral interface (SPI) module provides for full-duplex, synchronous, serial communication between the MCU and peripheral devices. These peripheral devices can include other microcontrollers, analog-to-digital converters, shift registers, sensors, memories, etc.

The SPI runs at a baud rate up to the bus clock divided by two in master mode and up to the bus clock divided by 4 in slave mode. Software can poll the status flags, or SPI operation can be interrupt driven. The SPI also supports a data length of 8 or 16 bits and includes a hardware match feature for the receive data buffer.

Figure 14-1 shows the MC9S08LG32 series block diagram with the SPI block and pins highlighted.

#### 14.1.1 Module Configuration

The SPI module pins, MISO, MOSI, SPCK, and  $\overline{SS}$  can be repositioned under software control using MISO, MOSI, SCK, and SS bits in PINPS3 register as shown in Table 14-1. MISO, MOSI, SCK, and SS bits in PINPS3 register selects which general-purpose I/O ports are associated with SPI operation.

Table 14-1. SPI Position Options

| MISO/MOSI/SPCK/SS | Port Pin for MISO | Port Pin for MOSI | Port Pin for SPCK | Port Pin for $\overline{SS}$ |
|-------------------|-------------------|-------------------|-------------------|------------------------------|
| 0 (default)       | PTF4              | PTF5              | PTF2              | PTF3                         |
| 1                 | PTI2              | PTI3              | PTI4              | PTI5                         |

#### 14.1.2 SPI Clock Gating

The bus clock to the SPI can be gated on and off using the SPI bit in SCGC2. These bits are cleared after any reset, which disables the bus clock to this module. To conserve power, these bits can be cleared to disable the clock to this module when not in use. For more details, see Section 5.7, “Peripheral Clock Gating.”

Figure 14-1. MC9S08LG32 series Block Diagram Highlighting SPI Block and Pins

### 14.1.3 Features

Features of the SPI module include:

- Master or slave mode operation
- Full-duplex or single-wire bidirectional option
- Programmable transmit bit rate
- Double-buffered transmit and receive
- Serial clock phase and polarity options
- Slave select output
- Selectable MSB-first or LSB-first shifting

### 14.1.4 Block Diagrams

This section includes block diagrams showing SPI system connections, the internal organization of the SPI module, and the SPI clock dividers that control the master mode bit rate.

#### 14.1.4.1 SPI System Block Diagram

Figure 14-2 shows the SPI modules of two MCUs connected in a master-slave arrangement. The master device initiates all SPI data transfers. During a transfer, the master shifts data out (on the MOSI pin) to the slave while simultaneously shifting data in (on the MISO pin) from the slave. The transfer effectively exchanges the data that was in the SPI shift registers of the two SPI systems. The SPSCCK signal is a clock output from the master and an input to the slave. The slave device must be selected by a low level on the slave select input ( $\overline{SS}$  pin). In this system, the master device has configured its  $\overline{SS}$  pin as an optional slave select output.

Figure 14-2. SPI System Connections

The most common uses of the SPI system include connecting simple shift registers for adding input or output ports or connecting small peripheral devices such as serial A/D or D/A converters. Although [Figure 14-2](#) shows a system where data is exchanged between two MCUs, many practical systems involve simpler connections where data is unidirectionally transferred from the master MCU to a slave or from a slave to the master MCU.

#### 14.1.4.2 SPI Module Block Diagram

[Figure 14-3](#) is a block diagram of the SPI module. The central element of the SPI is the SPI shift register. Data is written to the double-buffered transmitter (write to SPIxD) and gets transferred to the SPI shift register at the start of a data transfer. After shifting in a byte of data, the data is transferred into the double-buffered receiver where it can be read (read from SPIxD). Pin multiplexing logic controls connections between MCU pins and the SPI module.

When the SPI is configured as a master, the clock output is routed to the SPSCCK pin, the shifter output is routed to MOSI, and the shifter input is routed from the MISO pin.

When the SPI is configured as a slave, the SPSCCK pin is routed to the clock input of the SPI, the shifter output is routed to MISO, and the shifter input is routed from the MOSI pin.

In the external SPI system, simply connect all SPSCCK pins to each other, all MISO pins together, and all MOSI pins together. Peripheral devices often use slightly different names for these pins.

As shown in [Figure 14-4](#), the clock source for the SPI baud rate generator is the bus clock. The three prescale bits (SPPR2:SPPR1:SPPR0) choose a prescale divisor of 1, 2, 3, 4, 5, 6, 7, or 8. The three rate select bits (SPR3:SPR2:SPR1:SPR0) divide the output of the prescaler stage by 2, 4, 8, 16, 32, 64, 128, 256, or 512 to get the internal SPI master mode bit-rate clock.

Figure 14-4. SPI Baud Rate Generation

## 14.2 External Signal Description

The SPI optionally shares four port pins. The function of these pins depends on the settings of SPI control bits. When the SPI is disabled ( $SPE = 0$ ), these four pins revert to being general-purpose port I/O pins that are not controlled by the SPI.

### 14.2.1 SPCK — SPI Serial Clock

When the SPI is enabled as a slave, this pin is the serial clock input. When the SPI is enabled as a master, this pin is the serial clock output.

### 14.2.2 MOSI — Master Data Out, Slave Data In

When the SPI is enabled as a master and SPI pin control zero ( $SPC0$ ) is 0 (not bidirectional mode), this pin is the serial data output. When the SPI is enabled as a slave and  $SPC0 = 0$ , this pin is the serial data input. If  $SPC0 = 1$  to select single-wire bidirectional mode, and master mode is selected, this pin becomes the bidirectional data I/O pin (MOMI). Also, the bidirectional mode output enable bit determines whether the pin acts as an input ( $BIDIROE = 0$ ) or an output ( $BIDIROE = 1$ ). If  $SPC0 = 1$  and slave mode is selected, this pin is not used by the SPI and reverts to being a general-purpose port I/O pin.

### 14.2.3 MISO — Master Data In, Slave Data Out

When the SPI is enabled as a master and SPI pin control zero ( $SPC0$ ) is 0 (not bidirectional mode), this pin is the serial data input. When the SPI is enabled as a slave and  $SPC0 = 0$ , this pin is the serial data output. If  $SPC0 = 1$  to select single-wire bidirectional mode, and slave mode is selected, this pin becomes the bidirectional data I/O pin (SISO) and the bidirectional mode output enable bit determines whether the pin acts as an input ( $BIDIROE = 0$ ) or an output ( $BIDIROE = 1$ ). If  $SPC0 = 1$  and master mode is selected, this pin is not used by the SPI and reverts to being a general-purpose port I/O pin.

### 14.2.4 $\overline{SS}$ — Slave Select

When the SPI is enabled as a slave, this pin is the low-true slave select input. When the SPI is enabled as a master and mode fault enable is off ( $MODFEN = 0$ ), this pin is not used by the SPI and reverts to being a general-purpose port I/O pin. When the SPI is enabled as a master and  $MODFEN = 1$ , the slave select output enable bit determines whether this pin acts as the mode fault input ( $SSOE = 0$ ) or as the slave select output ( $SSOE = 1$ ).

## 14.3 Modes of Operation

### 14.3.1 SPI in Stop Modes

The SPI is disabled in all stop modes, regardless of the settings before executing the STOP instruction. During stop2 mode, the SPI module will be fully powered down. Upon wake-up from stop2 mode, the SPI module will be in the reset state. During stop3 mode, clocks to the SPI module are halted. No registers are affected. If stop3 is exited with a reset, the SPI will be put into its reset state. If stop3 is exited with an interrupt, the SPI continues from the state it was in when stop3 was entered.

## 14.4 Register Definition

The SPI has five 8-bit registers to select SPI options, control baud rate, report SPI status, and for transmit/receive data.

Refer to the direct-page register summary in [Chapter 4, “Memory,”](#) for the absolute address assignments for all SPI registers. This section refers to registers and control bits only by their names, and a Freescale-provided equate or header file is used to translate these names into the appropriate absolute addresses.

### 14.4.1 SPI Control Register 1 (SPIxC1)

This read/write register includes the SPI enable control, interrupt enables, and configuration options.

|       |   |   |   |   |   |   |   |   |
|-------|---|---|---|---|---|---|---|---|
|       | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     |   |   |   |   |   |   |   |   |
| W     |   |   |   |   |   |   |   |   |
| Reset | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |

Figure 14-5. SPI Control Register 1 (SPIxC1)

Table 14-2. SPIxC1 Field Descriptions

| Field      | Description                                                                                                                                                                                                                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>SPIE  | <b>SPI Interrupt Enable (for SPRF and MODF)</b> — This is the interrupt enable for SPI receive buffer full (SPRF) and mode fault (MODF) events.<br>0 Interrupts from SPRF and MODF inhibited (use polling)<br>1 When SPRF or MODF is 1, request a hardware interrupt                    |
| 6<br>SPE   | <b>SPI System Enable</b> — Disabling the SPI halts any transfer that is in progress, clears data buffers, and initializes internal state machines. SPRF is cleared and SPTEF is set to indicate the SPI transmit data buffer is empty.<br>0 SPI system inactive<br>1 SPI system enabled |
| 5<br>SPTIE | <b>SPI Transmit Interrupt Enable</b> — This is the interrupt enable bit for SPI transmit buffer empty (SPTEF).<br>0 Interrupts from SPTEF inhibited (use polling)<br>1 When SPTEF is 1, hardware interrupt requested                                                                    |

**Table 14-2. SPIxC1 Field Descriptions (continued)**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4<br>MSTR  | <b>Master/Slave Mode Select</b><br>0 SPI module configured as a slave SPI device<br>1 SPI module configured as a master SPI device                                                                                                                                                                                                                                                                      |
| 3<br>CPOL  | <b>Clock Polarity</b> — This bit effectively places an inverter in series with the clock signal from a master SPI or to a slave SPI device. Refer to <a href="#">Section 14.5.3, “SPI Clock Formats,”</a> for more details.<br>0 Active-high SPI clock (idles low)<br>1 Active-low SPI clock (idles high)                                                                                               |
| 2<br>CPHA  | <b>Clock Phase</b> — This bit selects one of two clock formats for different kinds of synchronous serial peripheral devices. Refer to <a href="#">Section 14.5.3, “SPI Clock Formats,”</a> for more details.<br>0 First edge on SPSCCK occurs at the middle of the first cycle of an 8-cycle data transfer<br>1 First edge on SPSCCK occurs at the start of the first cycle of an 8-cycle data transfer |
| 1<br>SSOE  | <b>Slave Select Output Enable</b> — This bit is used in combination with the mode fault enable (MODFEN) bit in SPCR2 and the master/slave (MSTR) control bit to determine the function of the $\overline{SS}$ pin as shown in <a href="#">Table 14-3</a> .                                                                                                                                              |
| 0<br>LSBFE | <b>LSB First (Shifter Direction)</b><br>0 SPI serial data transfers start with most significant bit<br>1 SPI serial data transfers start with least significant bit                                                                                                                                                                                                                                     |

**Table 14-3.  $\overline{SS}$  Pin Function**

| MODFEN | SSOE | Master Mode                          | Slave Mode         |
|--------|------|--------------------------------------|--------------------|
| 0      | 0    | General-purpose I/O (not SPI)        | Slave select input |
| 0      | 1    | General-purpose I/O (not SPI)        | Slave select input |
| 1      | 0    | $\overline{SS}$ input for mode fault | Slave select input |
| 1      | 1    | Automatic $\overline{SS}$ output     | Slave select input |

**NOTE**

Ensure that the SPI should not be disabled (SPE=0) at the same time as a bit change to the CPHA bit. These changes should be performed as separate operations or unexpected behavior may occur.

### 14.4.2 SPI Control Register 2 (SPIxC2)

This read/write register is used to control optional features of the SPI system. Bits 7, 6, 5, and 2 are not implemented and always read 0.

|       |   |   |   |        |         |   |         |      |
|-------|---|---|---|--------|---------|---|---------|------|
|       | 7 | 6 | 5 | 4      | 3       | 2 | 1       | 0    |
| R     | 0 | 0 | 0 | MODFEN | BIDIROE | 0 | SPISWAI | SPC0 |
| W     |   |   |   |        |         |   |         |      |
| Reset | 0 | 0 | 0 | 0      | 0       | 0 | 0       | 0    |

= Unimplemented or Reserved

**Figure 14-6. SPI Control Register 2 (SPIxC2)**

**Table 14-4. SPIxCS2 Register Field Descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4<br>MODFEN  | <b>Master Mode-Fault Function Enable</b> — When the SPI is configured for slave mode, this bit has no meaning or effect. (The $\overline{SS}$ pin is the slave select input.) In master mode, this bit determines how the $\overline{SS}$ pin is used (refer to <a href="#">Table 14-3</a> for more details).<br>0 Mode fault function disabled, master $\overline{SS}$ pin reverts to general-purpose I/O not controlled by SPI<br>1 Mode fault function enabled, master $\overline{SS}$ pin acts as the mode fault input or the slave select output |
| 3<br>BIDIROE | <b>Bidirectional Mode Output Enable</b> — When bidirectional mode is enabled by SPI pin control 0 (SPC0) = 1, BIDIROE determines whether the SPI data output driver is enabled to the single bidirectional SPI I/O pin. Depending on whether the SPI is configured as a master or a slave, it uses either the MOSI (MOMI) or MISO (SISO) pin, respectively, as the single SPI data I/O pin. When SPC0 = 0, BIDIROE has no meaning or effect.<br>0 Output driver disabled so SPI data I/O pin acts as an input<br>1 SPI I/O pin enabled as an output   |
| 1<br>SPISWAI | <b>SPI Stop in Wait Mode</b><br>0 SPI clocks continue to operate in wait mode<br>1 SPI clocks stop when the MCU enters wait mode                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0<br>SPC0    | <b>SPI Pin Control 0</b> — The SPC0 bit chooses single-wire bidirectional mode. If MSTR = 0 (slave mode), the SPI uses the MISO (SISO) pin for bidirectional SPI data transfers. If MSTR = 1 (master mode), the SPI uses the MOSI (MOMI) pin for bidirectional SPI data transfers. When SPC0 = 1, BIDIROE is used to enable or disable the output driver for the single bidirectional SPI I/O pin.<br>0 SPI uses separate pins for data input and data output<br>1 SPI configured for single-wire bidirectional operation                             |

### 14.4.3 SPI Baud Rate Register (SPIxBR)

This register is used to set the prescaler and bit rate divisor for an SPI master. This register may be read or written at any time.

**Figure 14-7. SPI Baud Rate Register (SPIxBR)**

**Table 14-5. SPIxBR Register Field Descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:4<br>SPPR[2:0] | <b>SPI Baud Rate Prescale Divisor</b> — This 3-bit field selects one of eight divisors for the SPI baud rate prescaler as shown in <a href="#">Table 14-6</a> . The input to this prescaler is the bus rate clock (BUSCLK). The output of this prescaler drives the input of the SPI baud rate divider (see <a href="#">Figure 14-4</a> ). |
| 2:0<br>SPR[3:0]  | <b>SPI Baud Rate Divisor</b> — This 4-bit field selects one of eight divisors for the SPI baud rate divider as shown in <a href="#">Table 14-7</a> . The input to this divider comes from the SPI baud rate prescaler (see <a href="#">Figure 14-4</a> ). The output of this divider is the SPI bit rate clock for master mode.            |

**Table 14-6. SPI Baud Rate Prescaler Divisor**

| SPPR2:SPPR1:SPPR0 | Prescaler Divisor |
|-------------------|-------------------|
| 0:0:0             | 1                 |
| 0:0:1             | 2                 |
| 0:1:0             | 3                 |
| 0:1:1             | 4                 |
| 1:0:0             | 5                 |
| 1:0:1             | 6                 |
| 1:1:0             | 7                 |
| 1:1:1             | 8                 |

**Table 14-7. SPI Baud Rate Divisor**

| SPR3:SPR2:SPR1:SPR0    | Rate Divisor |
|------------------------|--------------|
| 0:0:0:0                | 2            |
| 0:0:0:1                | 4            |
| 0:0:1:0                | 8            |
| 0:0:1:1                | 16           |
| 0:1:0:0                | 32           |
| 0:1:0:1                | 64           |
| 0:1:1:0                | 128          |
| 0:1:1:1                | 256          |

| All other combinations | reserved     |

### 14.4.4 SPI Status Register (SPIS)

This register has three read-only status bits. Bits 6, 3, 2, 1, and 0 are not implemented and always read 0. Writes have no meaning or effect.

|       | 7    | 6 | 5     | 4    | 3 | 2 | 1 | 0 |
|-------|------|---|-------|------|---|---|---|---|
| R     | SPRF | 0 | SPTEF | MODF | 0 | 0 | 0 | 0 |
| W     |      |   |       |      |   |   |   |   |
| Reset | 0    | 0 | 1     | 0    | 0 | 0 | 0 | 0 |

 = Unimplemented or Reserved

**Figure 14-8. SPI Status Register (SPIS)**

**Table 14-8. SPIxS Register Field Descriptions**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 7<br>SPRF  | <b>SPI Read Buffer Full Flag</b> — SPRF is set at the completion of an SPI transfer to indicate that received data may be read from the SPI data register (SPIxD). SPRF is cleared by reading SPRF while it is set, then reading the SPI data register.<br>0 No data available in the receive data buffer<br>1 Data available in the receive data buffer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5<br>SPTEF | <b>SPI Transmit Buffer Empty Flag</b> — This bit is set when there is room in the transmit data buffer. It is cleared by reading SPIxS with SPTEF set, followed by writing a data value to the transmit buffer at SPIxD. SPIxS must be read with SPTEF = 1 before writing data to SPIxD or the SPIxD write will be ignored. SPTEF generates an SPTEF CPU interrupt request if the SPTIE bit in the SPIxC1 is also set. SPTEF is automatically set when a data byte transfers from the transmit buffer into the transmit shift register. For an idle SPI (no data in the transmit buffer or the shift register and no transfer in progress), data written to SPIxD is transferred to the shifter almost immediately so SPTEF is set within two bus cycles allowing a second 8-bit data value to be queued into the transmit buffer. After completion of the transfer of the value in the shift register, the queued value from the transmit buffer will automatically move to the shifter and SPTEF will be set to indicate there is room for new data in the transmit buffer. If no new data is waiting in the transmit buffer, SPTEF simply remains set and no data moves from the buffer to the shifter.<br>0 SPI transmit buffer not empty<br>1 SPI transmit buffer empty |
| 4<br>MODF  | <b>Master Mode Fault Flag</b> — MODF is set if the SPI is configured as a master and the slave select input goes low, indicating some other SPI device is also configured as a master. The $\overline{SS}$ pin acts as a mode fault error input only when MSTR = 1, MODFEN = 1, and SSOE = 0; otherwise, MODF will never be set. MODF is cleared by reading MODF while it is 1, then writing to SPI control register 1 (SPIxC1).<br>0 No mode fault error<br>1 Mode fault error detected                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 14.4.5 SPI Data Register (SPIxD)

|       |       |   |   |   |   |   |   |       |

| W     |       |   |   |   |   |   |   |       |
| Reset | 0     | 0 | 0 | 0 | 0 | 0 | 0 | 0     |

**Figure 14-9. SPI Data Register (SPIxD)**

Reads of this register return the data read from the receive data buffer. Writes to this register write data to the transmit data buffer. When the SPI is configured as a master, writing data to the transmit data buffer initiates an SPI transfer.

Data should not be written to the transmit data buffer unless the SPI transmit buffer empty flag (SPTEF) is set, indicating there is room in the transmit buffer to queue a new transmit byte.

Data may be read from SPIxD any time after SPRF is set and before another transfer is finished. Failure to read the data out of the receive data buffer before a new transfer ends causes a receive overrun condition and the data from the new transfer is lost.

## 14.5 Functional Description

The SPI system is enabled by setting the SPI enable (SPE) bit in SPI Control Register 1. While the SPE bit is set, the four associated SPI port pins are dedicated to the SPI function as:

- Slave select ( $\overline{SS}$ )
- Serial clock (SPSCK)
- Master out/slave in (MOSI)
- Master in/slave out (MISO)

An SPI transfer is initiated in the master SPI device by reading the SPI status register (SPIxS) when SPTEF = 1 and then writing data to the transmit data buffer (write to SPIxD). When a transfer is complete, received data is moved into the receive data buffer. The SPIxD register acts as the SPI receive data buffer for reads and as the SPI transmit data buffer for writes.

The clock phase control bit (CPHA) and a clock polarity control bit (CPOL) in the SPI Control Register 1 (SPIxC1) select one of four possible clock formats to be used by the SPI system. The CPOL bit simply selects a non-inverted or inverted clock. The CPHA bit is used to accommodate two fundamentally different protocols by sampling data on odd numbered SPSCK edges or on even numbered SPSCK edges.

The SPI can be configured to operate as a master or as a slave. When the MSTR bit in SPI control register 1 is set, master mode is selected, when the MSTR bit is clear, slave mode is selected.

### 14.5.1 Master Mode

The SPI operates in master mode when the MSTR bit is set. Only a master SPI module can initiate transmissions. A transmission begins by reading the SPIxS register while SPTEF = 1 and writing to the master SPI data registers. If the shift register is empty, the byte immediately transfers to the shift register. The data begins shifting out on the MOSI pin under the control of the serial clock.

- SPSCK

The SPR3, SPR2, SPR1, and SPR0 baud rate selection bits in conjunction with the SPPR2, SPPR1, and SPPR0 baud rate preselection bits in the SPI Baud Rate register control the baud rate generator and determine the speed of the transmission. The SPSCK pin is the SPI clock output. Through the SPSCK pin, the baud rate generator of the master controls the shift register of the slave peripheral.

- MOSI, MISO pin

In master mode, the function of the serial data output pin (MOSI) and the serial data input pin (MISO) is determined by the SPC0 and BIDIROE control bits.

- $\overline{SS}$  pin

If MODFEN and SSOE bit are set, the  $\overline{SS}$  pin is configured as slave select output. The  $\overline{SS}$  output becomes low during each transmission and is high when the SPI is in idle state.

If MODFEN is set and SSOE is cleared, the  $\overline{SS}$  pin is configured as input for detecting mode fault error. If the  $\overline{SS}$  input becomes low this indicates a mode fault error where another master tries to drive the MOSI and SPSCK lines. In this case, the SPI immediately switches to slave mode, by clearing the MSTR bit and also disables the slave output buffer MISO (or SISO in bidirectional mode). So the result is that all outputs

are disabled and SPSCCK, MOSI and MISO are inputs. If a transmission is in progress when the mode fault occurs, the transmission is aborted and the SPI is forced into idle state.

This mode fault error also sets the mode fault (MODF) flag in the SPI Status Register (SPIxS). If the SPI interrupt enable bit (SPIE) is set when the MODF flag gets set, then an SPI interrupt sequence is also requested.

When a write to the SPI Data Register in the master occurs, there is a half SPSCCK-cycle delay. After the delay, SPSCCK is started within the master. The rest of the transfer operation differs slightly, depending on the clock format specified by the SPI clock phase bit, CPHA, in SPI Control Register 1 (see [Section 14.5.3](#), “SPI Clock Formats”).

#### NOTE

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0, BIDIROE with SPC0 set, SPPR2-SPPR0 and SPR3-SPR0 in master mode will abort a transmission in progress and force the SPI into idle state. The remote slave cannot detect this, therefore the master has to ensure that the remote slave is set back to idle state.

### 14.5.2 Slave Mode

The SPI operates in slave mode when the MSTR bit in SPI Control Register1 is clear.

- SPSCCK

In slave mode, SPSCCK is the SPI clock input from the master.

- MISO, MOSI pin

In slave mode, the function of the serial data output pin (MISO) and serial data input pin (MOSI) is determined by the SPC0 bit and BIDIROE bit in SPI Control Register 2.

- $\overline{SS}$  pin

The  $\overline{SS}$  pin is the slave select input. Before a data transmission occurs, the  $\overline{SS}$  pin of the slave SPI must be low.  $\overline{SS}$  must remain low until the transmission is complete. If  $\overline{SS}$  goes high, the SPI is forced into idle state.

The  $\overline{SS}$  input also controls the serial data output pin, if  $\overline{SS}$  is high (not selected), the serial data output pin is high impedance, and, if  $\overline{SS}$  is low the first bit in the SPI Data Register is driven out of the serial data output pin. Also, if the slave is not selected ( $\overline{SS}$  is high), then the SPSCCK input is ignored and no internal shifting of the SPI shift register takes place.

Although the SPI is capable of duplex operation, some SPI peripherals are capable of only receiving SPI data in a slave mode. For these simpler devices, there is no serial data out pin.

#### NOTE

When peripherals with duplex capability are used, take care not to simultaneously enable two receivers whose serial outputs drive the same system slave's serial data output line.

As long as no more than one slave device drives the system slave's serial data output line, it is possible for several slaves to receive the same transmission from a master, although the master would not receive return information from all of the receiving slaves.

If the CPHA bit in SPI Control Register 1 is clear, odd numbered edges on the SPSCCK input cause the data at the serial data input pin to be latched. Even numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

If the CPHA bit is set, even numbered edges on the SPSCCK input cause the data at the serial data input pin to be latched. Odd numbered edges cause the value previously latched from the serial data input pin to shift into the LSB or MSB of the SPI shift register, depending on the LSBFE bit.

When CPHA is set, the first edge is used to get the first data bit onto the serial data output pin. When CPHA is clear and the  $\overline{SS}$  input is low (slave selected), the first bit of the SPI data is driven out of the serial data output pin. After the eighth shift, the transfer is considered complete and the received data is transferred into the SPI data registers. To indicate transfer is complete, the SPRF flag in the SPI Status Register is set.

### NOTE

A change of the bits CPOL, CPHA, SSOE, LSBFE, MODFEN, SPC0 and BIDIROE with SPC0 set in slave mode will corrupt a transmission in progress and has to be avoided.

## 14.5.3 SPI Clock Formats

To accommodate a wide variety of synchronous serial peripherals from different manufacturers, the SPI system has a clock polarity (CPOL) bit and a clock phase (CPHA) control bit to select one of four clock formats for data transfers. CPOL selectively inserts an inverter in series with the clock. CPHA chooses between two different clock phase relationships between the clock and data.

Figure 14-10 shows the clock formats when CPHA = 1. At the top of the figure, the eight bit times are shown for reference with bit 1 starting at the first SPSCCK edge and bit 8 ending one-half SPSCCK cycle after the sixteenth SPSCCK edge. The MSB first and LSB first lines show the order of SPI data bits depending on the setting in LSBFE. Both variations of SPSCCK polarity are shown, but only one of these waveforms applies for a specific transfer, depending on the value in CPOL. The SAMPLE IN waveform applies to the MOSI input of a slave or the MISO input of a master. The MOSI waveform applies to the MOSI output pin from a master and the MISO waveform applies to the MISO output from a slave. The  $\overline{SS}$  OUT waveform applies to the slave select output from a master (provided MODFEN and SSOE = 1). The master  $\overline{SS}$  output goes to active low one-half SPSCCK cycle before the start of the transfer and goes back high at the end of the eighth bit time of the transfer. The  $\overline{SS}$  IN waveform applies to the slave select input of a slave.

**Figure 14-10. SPI Clock Formats (CPHA = 1)**

When CPHA = 1, the slave begins to drive its MISO output when  $\overline{SS}$  goes to active low, but the data is not defined until the first SPSCCK edge. The first SPSCCK edge shifts the first bit of data from the shifter onto the MOSI output of the master and the MISO output of the slave. The next SPSCCK edge causes both the master and the slave to sample the data bit values on their MISO and MOSI inputs, respectively. At the third SPSCCK edge, the SPI shifter shifts one bit position which shifts in the bit value that was just sampled, and shifts the second data bit value out the other end of the shifter to the MOSI and MISO outputs of the master and slave, respectively. When CHPA = 1, the slave's  $\overline{SS}$  input is not required to go to its inactive high level between transfers.

Figure 14-11 shows the clock formats when CPHA = 0. At the top of the figure, the eight bit times are shown for reference with bit 1 starting as the slave is selected ( $\overline{SS}$  IN goes low), and bit 8 ends at the last SPSCCK edge. The MSB first and LSB first lines show the order of SPI data bits depending on the setting in LSBFE. Both variations of SPSCCK polarity are shown, but only one of these waveforms applies for a specific transfer, depending on the value in CPOL. The SAMPLE IN waveform applies to the MOSI input of a slave or the MISO input of a master. The MOSI waveform applies to the MOSI output pin from a master and the MISO waveform applies to the MISO output from a slave. The  $\overline{SS}$  OUT waveform applies to the slave select output from a master (provided MODFEN and SSOE = 1). The master  $\overline{SS}$  output goes to active low at the start of the first bit time of the transfer and goes back high one-half SPSCCK cycle after

the end of the eighth bit time of the transfer. The  $\overline{SS}$  IN waveform applies to the slave select input of a slave.

Figure 14-11. SPI Clock Formats (CPHA = 0)

When CPHA = 0, the slave begins to drive its MISO output with the first data bit value (MSB or LSB depending on LSBFE) when  $\overline{SS}$  goes to active low. The first SPSCK edge causes both the master and the slave to sample the data bit values on their MISO and MOSI inputs, respectively. At the second SPSCK edge, the SPI shifter shifts one bit position which shifts in the bit value that was just sampled and shifts the second data bit value out the other end of the shifter to the MOSI and MISO outputs of the master and slave, respectively. When CPHA = 0, the slave's  $\overline{SS}$  input must go to its inactive high level between transfers.

## 14.5.4 Special Features

### 14.5.4.1 $\overline{SS}$ Output

The  $\overline{SS}$  output feature automatically drives the  $\overline{SS}$  pin low during transmission to select external devices and drives it high during idle to deselect external devices. When  $\overline{SS}$  output is selected, the  $\overline{SS}$  output pin is connected to the  $\overline{SS}$  input pin of the external device.

The  $\overline{SS}$  output is available only in master mode during normal SPI operation by asserting the SSOE and MODFEN bits as shown in Table 14-3.

The mode fault feature is disabled while  $\overline{SS}$  output is enabled.

#### NOTE

Care must be taken when using the  $\overline{SS}$  output feature in a multi-master system since the mode fault feature is not available for detecting system errors between masters.

### 14.5.4.2 Bidirectional Mode (MOMI or SISO)

The bidirectional mode is selected when the SPC0 bit is set in SPI Control Register 2 (see Table 14-9). In this mode, the SPI uses only one serial data pin for the interface with external device(s). The MSTR bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the master mode, and the MISO pin becomes serial data I/O (SISO) pin for the slave mode. The MISO pin in master mode and MOSI pin in slave mode are not used by the SPI.

**Table 14-9. Normal Mode and Bidirectional Mode**

| When SPE = 1                          | Master Mode MSTR = 1 | Slave Mode MSTR = 0 |
|---------------------------------------|----------------------|---------------------|
| <b>Normal Mode</b><br>SPC0 = 0        |                      |                     |
| <b>Bidirectional Mode</b><br>SPC0 = 1 |                      |                     |

The direction of each serial I/O pin depends on the BIDIROE bit. If the pin is configured as an output, serial data from the shift register is driven out on the pin. The same pin is also the serial input to the shift register.

The SPSCCK is output for the master mode and input for the slave mode.

The  $\overline{SS}$  is the input or output for the master mode, and it is always the input for the slave mode.

The bidirectional mode does not affect SPSCCK and  $\overline{SS}$  functions.

**NOTE**

In bidirectional master mode, with mode fault enabled, both data pins MISO and MOSI can be occupied by the SPI, though MOSI is normally used for transmissions in bidirectional mode and MISO is not used by the SPI. If a mode fault occurs, the SPI is automatically switched to slave mode, in this case MISO becomes occupied by the SPI and MOSI is not used. This has to be considered, if the MISO pin is used for another purpose.

**14.5.5 SPI Interrupts**

There are three flag bits, two interrupt mask bits, and one interrupt vector associated with the SPI system. The SPI interrupt enable mask (SPIE) enables interrupts from the SPI receiver full flag (SPRF) and mode fault flag (MODF). The SPI transmit interrupt enable mask (SPTIE) enables interrupts from the SPI transmit buffer empty flag (SPTEF). When one of the flag bits is set, and the associated interrupt mask bit is set, a hardware interrupt request is sent to the CPU. If the interrupt mask bits are cleared, software can poll the associated flag bits instead of using interrupts. The SPI interrupt service routine (ISR) should check the flag bits to determine what event caused the interrupt. The service routine should also clear the flag bit(s) before returning from the ISR (usually near the beginning of the ISR).

**14.5.6 Mode Fault Detection**

A mode fault occurs and the mode fault flag (MODF) becomes set when a master SPI device detects an error on the  $\overline{SS}$  pin (provided the  $\overline{SS}$  pin is configured as the mode fault input signal). The  $\overline{SS}$  pin is configured to be the mode fault input signal when  $MSTR = 1$ , mode fault enable is set ( $MODFEN = 1$ ), and slave select output enable is clear ( $SSOE = 0$ ).

The mode fault detection feature can be used in a system where more than one SPI device might become a master at the same time. The error is detected when a master's  $\overline{SS}$  pin is low, indicating that some other SPI device is trying to address this master as if it were a slave. This could indicate a harmful output driver conflict, so the mode fault logic is designed to disable all SPI output drivers when such an error is detected.

When a mode fault is detected, MODF is set and MSTR is cleared to change the SPI configuration back to slave mode. The output drivers on the SPSCK, MOSI, and MISO (if not bidirectional mode) are disabled.

MODF is cleared by reading it while it is set, then writing to the SPI control register 1 (SPIxC1). User software should verify the error condition has been corrected before changing the SPI back to master mode.

## Chapter 15

# Real-Time Counter (S08RTCV1)

### 15.1 Introduction

The Real-Time Counter (RTC) module consists of one 8-bit counter, one 8-bit comparator, several binary-based and decimal-based prescaler dividers, three clock sources, and one programmable periodic interrupt. This module can be used for time-of-day, calendar, or any task scheduling functions. It can also serve as a cyclic wake up from low-power modes without the need of external components.

#### NOTE

For details on low-power mode operation, refer to [Table 3-2](#) in [Chapter 3](#), “[Modes of Operation](#).”

#### 15.1.1 RTC Clock Gating

The bus clock to the RTC can be gated on and off using the RTC bit in SCGC1. This bit is cleared after any reset, which disables the bus clock to this module. To conserve power, this bit can be cleared to disable the clock to this module when not in use. For more details, see [Section 5.7](#), “[Peripheral Clock Gating](#).”

Figure 15-1. MC9S08LG32 Series Block Diagram Highlighting RTC Block and Pins

## 15.1.2 Features

Features of the RTC module include:

- 8-bit up-counter
  - 8-bit modulo match limit
  - Software controllable periodic interrupt on match
- Three software selectable clock sources for input to prescaler with selectable binary-based and decimal-based divider values
  - 1 kHz internal low-power oscillator (LPO)
  - External clock (OSCOU)
  - 32 kHz internal clock (IRCLK)

## 15.1.3 Modes of Operation

This section defines the operation in stop, wait and background debug modes.

### 15.1.3.1 Wait Mode

The RTC continues to run in wait mode if enabled before executing the appropriate instruction. Therefore, the RTC can bring the MCU out of wait mode if the real-time interrupt is enabled. For lowest possible current consumption, the RTC should be stopped by software if not needed as an interrupt source during wait mode.

### 15.1.3.2 Stop Modes

The RTC continues to run in stop2 or stop3 mode if the RTC is enabled before executing the STOP instruction. Therefore, the RTC can bring the MCU out of stop modes with no external components, if the real-time interrupt is enabled.

The LPO clock can be used in stop2 and stop3 modes. OSCOU and IRCLK clocks are only available in stop3 mode.

Power consumption is lower when all clock sources are disabled, but in that case, the real-time interrupt cannot wakeup the MCU from stop modes.

### 15.1.3.3 Active Background Mode

The RTC suspends all counting during active background mode until the microcontroller returns to normal user operating mode. Counting resumes from the suspended value as long as the RTCMOD register is not written and the RTCPS and RTCLKS bits are not altered.

### 15.1.4 Block Diagram

The block diagram for the RTC module is shown in [Figure 15-2](#).

Figure 15-2. Real-Time Counter (RTC) Block Diagram

## 15.2 External Signal Description

The RTC does not include any off-chip signals.

## 15.3 Register Definition

The RTC includes a status and control register, an 8-bit counter register, and an 8-bit modulo register.

Refer to the direct-page register summary in the memory section of this document for the absolute address assignments for all RTC registers. This section refers to registers and control bits only by their names and relative address offsets.

[Table 15-1](#) is a summary of RTC registers.

Table 15-1. RTC Register Summary

| Name   |   | 7      | 6      | 5 | 4    | 3     | 2 | 1 | 0 |
|--------|---|--------|--------|---|------|-------|---|---|---|
| RTCSC  | R | RTIF   | RTCLKS |   | RTIE | RTGPS |   |   |   |
|        | W |        |        |   |      |       |   |   |   |
| RTCCNT | R | RTCCNT |        |   |      |       |   |   |   |
|        | W |        |        |   |      |       |   |   |   |
| RTCMOD | R | RTCMOD |        |   |      |       |   |   |   |
|        | W |        |        |   |      |       |   |   |   |

### 15.3.1 RTC Status and Control Register (RTCSC)

RTCSC contains the real-time interrupt status flag (RTIF), the clock select bits (RTCLKS), the real-time interrupt enable bit (RTIE), and the prescaler select bits (RTCPS).

Figure 15-3. RTC Status and Control Register (RTCSC)

Table 15-2. RTCSC Field Descriptions

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>RTIF     | Real-Time Interrupt Flag This status bit indicates the RTC counter register reached the value in the RTC modulo register. Writing a logic 0 has no effect. Writing a logic 1 clears the bit and the real-time interrupt request. Reset clears RTIF.<br>0 RTC counter has not reached the value in the RTC modulo register.<br>1 RTC counter has reached the value in the RTC modulo register.                                                                                                                                            |
| 6–5<br>RTCLKS | Real-Time Clock Source Select. These two read/write bits select the clock source input to the RTC prescaler. Changing the clock source clears the prescaler and RTCCNT counters. When selecting a clock source, ensure that the clock source is properly enabled (if applicable) to ensure correct operation of the RTC. Reset clears RTCLKS.<br>00 Real-time clock source is the 1 kHz low power oscillator (LPO)<br>01 Real-time clock source is the external clock (OSCOU)<br>1x Real-time clock source is the internal clock (IRCLK) |
| 4<br>RTIE     | Real-Time Interrupt Enable. This read/write bit enables real-time interrupts. If RTIE is set, then an interrupt is generated when RTIF is set. Reset clears RTIE.<br>0 Real-time interrupt requests are disabled. Use software polling.<br>1 Real-time interrupt requests are enabled.                                                                                                                                                                                                                                                   |
| 3–0<br>RTCPS  | Real-Time Clock Prescaler Select. These four read/write bits select binary-based or decimal-based divide-by values for the clock source. See <a href="#">Table 15-3</a> . Changing the prescaler value clears the prescaler and RTCCNT counters. Reset clears RTCPS.                                                                                                                                                                                                                                                                     |

### 15.3.2 RTC Counter Register (RTCCNT)

RTCCNT is the read-only value of the current RTC count of the 8-bit counter.

Figure 15-4. RTC Counter Register (RTCCNT)

Table 15-4. RTCCNT Field Descriptions

| Field         | Description                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>RTCCNT | RTC Count. These eight read-only bits contain the current value of the 8-bit counter. Writes have no effect to this register. Reset, writing to RTCMOD, or writing different values to RTCLKS and RTCPS clear the count to 0x00. |

### 15.3.3 RTC Modulo Register (RTCMOD)

Figure 15-5. RTC Modulo Register (RTCMOD)

Table 15-5. RTCMOD Field Descriptions

| Field         | Description                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>RTCMOD | RTC Modulo. These eight read/write bits contain the modulo value used to reset the count to 0x00 upon a compare match and set the RTIF status bit. A value of 0x00 sets the RTIF bit on each rising edge of the prescaler output. Writing to RTCMOD resets the prescaler and the RTCCNT counters to 0x00. Reset sets the modulo to 0x00. |

## 15.4 Functional Description

The RTC is composed of a main 8-bit up-counter with an 8-bit modulo register, a clock source selector, and a prescaler block with binary-based and decimal-based selectable values. The module also contains software selectable interrupt logic.

After any MCU reset, the counter is stopped and reset to 0x00, the modulus register is set to 0x00, and the prescaler is off. The 1 kHz internal oscillator clock is selected as the default clock source. To start the prescaler, write any value other than zero to the prescaler select bits (RTCPS).

Three clock sources are software selectable: the low power oscillator clock (LPO), the external clock (OSCOU), and the internal clock (IRCLK). The RTC clock select bits (RTCLKS) select the desired clock source. If a different value is written to RTCLKS, the prescaler and RTCCNT counters are reset to 0x00.

RTCPS and the RTCLKS[0] bit select the desired divide-by value. If a different value is written to RTCPS, the prescaler and RTCCNT counters are reset to 0x00. Table 15-6 shows different prescaler period values.

**Table 15-6. Prescaler Period**

| RTCPS | 1 kHz Internal Clock<br>(RTCLKS = 00) | 1 MHz External Clock<br>(RTCLKS = 01) | 32 kHz Internal Clock<br>(RTCLKS = 10) | 32 kHz Internal Clock<br>(RTCLKS = 11) |
|-------|---------------------------------------|---------------------------------------|----------------------------------------|----------------------------------------|
| 0000  | Off                                   | Off                                   | Off                                    | Off                                    |
| 0001  | 8 ms                                  | 1.024 ms                              | 250 $\mu$ s                            | 32 ms                                  |

| 1001  | 2 ms                                  | 2 ms                                  | 62.5 $\mu$ s                           | 62.5 ms                                |
| 1010  | 4 ms                                  | 5 ms                                  | 125 $\mu$ s                            | 156.25 ms                              |
| 1011  | 10 ms                                 | 10 ms                                 | 312.5 $\mu$ s                          | 312.5 ms                               |
| 1100  | 16 ms                                 | 20 ms                                 | 0.5 ms                                 | 0.625 s                                |
| 1101  | 0.1 s                                 | 50 ms                                 | 3.125 ms                               | 1.5625 s                               |
| 1110  | 0.5 s                                 | 0.1 s                                 | 15.625 ms                              | 3.125 s                                |
| 1111  | 1 s                                   | 0.2 s                                 | 31.25 ms                               | 6.25 s                                 |

The RTC modulo register (RTCMOD) allows the compare value to be set to any value from 0x00 to 0xFF. When the counter is active, the counter increments at the selected rate until the count matches the modulo value. When these values match, the counter resets to 0x00 and continues counting. The real-time interrupt flag (RTIF) is set when a match occurs. The flag sets on the transition from the modulo value to 0x00. Writing to RTCMOD resets the prescaler and the RTCCNT counters to 0x00.

The RTC allows for an interrupt to be generated when RTIF is set. To enable the real-time interrupt, set the real-time interrupt enable bit (RTIE) in RTCSC. RTIF is cleared by writing a 1 to RTIF.

### 15.4.1 RTC Operation Example

This section shows an example of the RTC operation as the counter reaches a matching value from the modulo register.

**Figure 15-6. RTC Counter Overflow Example**

In the example of [Figure 15-6](#), the selected clock source is the 1 kHz internal oscillator clock source. The prescaler (RTCPs) is set to 0xA or divide-by-4. The modulo value in the RTCMOD register is set to 0x55. When the counter, RTCCNT, reaches the modulo value of 0x55, the counter overflows to 0x00 and continues counting. The real-time interrupt flag, RTIF, sets when the counter value changes from 0x55 to 0x00. A real-time interrupt is generated when RTIF is set, if RTIE is set.

## 15.5 Initialization/Application Information

This section provides example code to give some basic direction to a user on how to initialize and configure the RTC module. The example software is implemented in C language.

The example below shows how to implement time of day with the RTC using the 1 kHz clock source to achieve the lowest possible power consumption. Because the 1 kHz clock source is not as accurate as a crystal, software can be added for any adjustments. For accuracy without adjustments at the expense of additional power consumption, the external clock (OSCOU) or the internal clock (IRCLK) can be selected with appropriate prescaler and modulo values.

```
/* Initialize the elapsed time counters */
Seconds = 0;
Minutes = 0;
Hours = 0;
Days=0;

/* Configure RTC to interrupt every 1 second from 1 kHz clock source */
RTCMOD.byte = 0x00;
RTCSC.byte = 0x1F;

/*****
Function Name : RTC_ISR
Notes : Interrupt service routine for RTC module.
*****/
```

```
#pragma TRAP_PROC
void RTC_ISR(void)
{
    /* Clear the interrupt flag */
    RTCSC.byte = RTCSC.byte | 0x80;
    /* RTC interrupts every 1 Second */
    Seconds++;
    /* 60 seconds in a minute */
    if (Seconds > 59){
        Minutes++;
        Seconds = 0;
    }
    /* 60 minutes in an hour */
    if (Minutes > 59){
        Hours++;
        Minutes = 0;
    }
    /* 24 hours in a day */
    if (Hours > 23){
        Days ++;
        Hours = 0;
    }
}
```

# Chapter 16

## Timer/Pulse-Width Modulator (S08TPMV3)

### 16.1 Introduction

The TPM is a one-to-eight-channel timer system which supports traditional input capture, output compare, or edge-aligned PWM on each channel. A control bit allows the TPM to be configured such that all channels may be used for center-aligned PWM functions. Timing functions are based on a 16-bit counter with prescaler and modulo features to control frequency and range (period between overflows) of the time reference. This timing system is ideally suited for a wide range of control applications, and the center-aligned PWM capability extends the field of application to motor control in small appliances.

Figure 16-1 shows the MC9S08LG32 series block diagram with the TPM blocks and pins highlighted.

#### 16.1.1 TPM External Clock

The TPM modules on the MC9S08LG32 series use the TPMCLK pin.

#### 16.1.2 Module Instances

The MC9S08LG32 series MCUs contain two TPM modules: TPM1 and TPM2. The memory map, pins, interrupts, etc. for the two modules can be differentiated using the TPM1 and TPM2 nomenclature.

#### 16.1.3 Module Configuration

The TPM module pins, TPMxCHn can be repositioned under software control using TPM2CH5, TPM2CH4, TPM2CH3, TPM2CH2, TPM2CH1, TPM2CH0, TPM1CH1, and TPM1CH0 bits in PINPS2 register as shown in Table 16-1. TPM2CH5, TPM2CH4, TPM2CH3, TPM2CH2, TPM2CH1, TPM2CH0, TPM1CH1, and TPM1CH0 bits in PINPS2 register selects which general-purpose I/O ports are associated with TPM operation.

**Table 16-1. TPM Position Options**

| TPMxCHn     | Port Pin for TPM2CH5 | Port Pin for TPM2CH4 | Port Pin for TPM2CH3 | Port Pin for TPM2CH2 |
|-------------|----------------------|----------------------|----------------------|----------------------|
| 0 (default) | PTF3                 | PTF4                 | PTF5                 | PTF0                 |
| 1           | PTH6                 | PTH7                 | PTI2                 | PTI3                 |

## 16.1.4 TPM Clock Gating

The bus clock to the TPMs can be gated on and off using the TPM2 bit and TPM1 bit in SCGC1. These bits are cleared after any reset, which disables the bus clock to this module. To conserve power, these bits can be cleared to disable the clock to this module when not in use. For more details, see [Section 5.7](#), “Peripheral Clock Gating.”

Figure 16-1. MC9S08LG32 Series Block Diagram Highlighting TPMx Blocks and Pins

## 16.1.5 Features

The TPM includes these distinctive features:

- One to eight channels:
  - Each channel is input capture, output compare, or edge-aligned PWM
  - Rising-edge, falling-edge, or any-edge input capture trigger
  - Set, clear, or toggle output compare action
  - Selectable polarity on PWM outputs
- Module is configured for buffered, center-aligned pulse-width-modulation (CPWM) on all channels
- Timer clock source selectable as bus clock, fixed frequency clock, or an external clock
  - Prescale taps for divide-by 1, 2, 4, 8, 16, 32, 64, or 128 used for any clock input selection
  - Fixed frequency clock is an additional clock input to allow the selection of an on chip clock source other than bus clock
  - Selecting external clock connects TPM clock to a chip level input pin therefore allowing to synchronize the TPM counter with an off chip clock source
- 16-bit free-running or modulus count with up/down selection
- One interrupt per channel and one interrupt for TPM counter overflow

## 16.1.6 Modes of Operation

In general, TPM channels are independently configured to operate in input capture, output compare, or edge-aligned PWM modes. A control bit allows the whole TPM (all channels) to switch to center-aligned PWM mode. When center-aligned PWM mode is selected, input capture, output compare, and edge-aligned PWM functions are not available on any channels of this TPM module.

When the MCU is in active BDM background or BDM foreground mode, the TPM temporarily suspends all counting until the MCU returns to normal user operating mode. During stop mode, all TPM input clocks are stopped, so the TPM is effectively disabled until clocks resume. During wait mode, the TPM continues to operate normally. If the TPM does not need to produce a real time reference or provide the interrupt sources needed to wake the MCU from wait mode, the power can then be saved by disabling TPM functions before entering wait mode.

- Input capture mode
 

When a selected edge event occurs on the associated MCU pin, the current value of the 16-bit timer counter is captured into the channel value register and an interrupt flag bit is set. Rising edges, falling edges, any edge, or no edge (disable channel) are selected as the active edge that triggers the input capture.
- Output compare mode
 

When the value in the timer counter register matches the channel value register, an interrupt flag bit is set, and a selected output action is forced on the associated MCU pin. The output compare action is selected to force the pin to zero, force the pin to one, toggle the pin, or ignore the pin (used for software timing functions).
- Edge-aligned PWM mode

The value of a 16-bit modulo register plus 1 sets the period of the PWM output signal. The channel value register sets the duty cycle of the PWM output signal. You can also choose the polarity of the PWM output signal. Interrupts are available at the end of the period and at the duty-cycle transition point. This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period that is same for all channels within a TPM.

- Center-aligned PWM mode

Twice the value of a 16-bit modulo register sets the period of the PWM output, and the channel-value register sets the half-duty-cycle duration. The timer counter counts up until it reaches the modulo value and then counts down until it reaches zero. As the count matches the channel value register while counting down, the PWM output becomes active. When the count matches the channel value register while counting up, the PWM output becomes inactive. This type of PWM signal is called center-aligned because the centers of the active duty cycle periods for all channels are aligned with a count value of zero. This type of PWM is required for types of motors used in small appliances.

This is a high-level description only. Detailed descriptions of operating modes are in later sections.

### 16.1.7 Block Diagram

The TPM uses one input/output (I/O) pin per channel, TPMxCHn (timer channel n) where n is the channel number (1–8). The TPM shares its I/O pins with general purpose I/O port pins (refer to I/O pin descriptions in full-chip specification for the specific chip implementation).

Figure 16-2 shows the TPM structure. The central component of the TPM is the 16-bit counter that can operate as a free-running counter or a modulo up/down counter. The TPM counter (when operating in normal up-counting mode) provides the timing reference for the input capture, output compare, and edge-aligned PWM functions. The timer counter modulo registers, TPMxMODH:TPMxMODL, control the modulo value of the counter (the values 0x0000 or 0xFFFF effectively make the counter free running). Software can read the counter value at any time without affecting the counting sequence. Any write to either half of the TPMxCNT counter resets the counter, regardless of the data value written.

**Figure 16-2. TPM Block Diagram**

The TPM channels are programmable independently as input capture, output compare, or edge-aligned PWM channels. Alternately, the TPM can be configured to produce CPWM outputs on all channels. When the TPM is configured for CPWMs (the counter operates as an up/down counter) input capture, output compare, and EPWM functions are not practical.

## 16.2 Signal Description

Table 16-2 shows the user-accessible signals for the TPM. The number of channels are varied from one to eight. When an external clock is included, it can be shared with the same pin as any TPM channel; however, it could be connected to a separate input pin. Refer to the I/O pin descriptions in full-chip specification for the specific chip implementation.

**Table 16-2. Signal Properties**

| Name                 | Function                                                         |
|----------------------|------------------------------------------------------------------|
| EXTCLK <sup>1</sup>  | External clock source that is selected to drive the TPM counter. |
| TPMxCHn <sup>2</sup> | I/O pin associated with TPM channel n.                           |

<sup>1</sup> The external clock pin can be shared with any channel pin. However, depending upon full-chip implementation, this signal could be connected to a separate external pin.

<sup>2</sup> n = channel number (1–8)

### 16.2.1 Detailed Signal Descriptions

#### 16.2.1.1 EXTCLK — External Clock Source

The external clock signal can share the same pin as a channel pin, however the channel pin can not be used for channel I/O function when external clock is selected. If this pin is used as an external clock (CLKSB:CLKSA = 1:1), the channel can still be configured to output compare mode therefore allowing its use as a timer (ELSnB:ELSnA = 0:0).

For proper TPM operation, the external clock frequency must not exceed one-fourth of the bus clock frequency.

#### 16.2.1.2 TPMxCHn — TPM Channel n I/O Pins

The TPM channel does not control the I/O pin when ELSnB:ELSnA or CLKSB:CLKSA are cleared so it normally reverts to general purpose I/O control. When CPWMS is set and ELSnB:ELSnA are not cleared, all TPM channels are configured for center-aligned PWM and the TPMxCHn pins are all controlled by TPM. When CPWMS is cleared, the MSnB:MSnA control bits determine whether the channel is configured for input capture, output compare, or edge-aligned PWM.

When a channel is configured for input capture (CPWMS = 0, MSnB:MSnA = 0:0, and ELSnB:ELSnA ≠ 0:0), the TPMxCHn pin is forced to act as an edge-sensitive input to the TPM. ELSnB:ELSnA control bits determine what polarity edge or edges trigger input capture events. The channel input signal is synchronized on the bus clock. This implies the minimum pulse width—that can

be reliably detected—on an input capture pin is four bus clock periods (with ideal clock pulses as near as two bus clocks can be detected).

When a channel is configured for output compare (CPWMS = 0, MSnB:MSnA = 0:1, and ELSnB:ELSnA  $\neq$  0:0), the TPMxCHn pin is an output controlled by the TPM. The ELSnB:ELSnA bits determine whether the TPMxCHn pin is toggled, cleared, or set each time the 16-bit channel value register matches the TPM counter.

When the output compare toggle mode is initially selected, the previous value on the pin is driven out until the next output compare event, the pin is then toggled.

When a channel is configured for edge-aligned PWM (CPWMS = 0, MSnB = 1, and ELSnB:ELSnA  $\neq$  0:0), the TPMxCHn pin is an output controlled by the TPM, and ELSnB:ELSnA bits control the polarity of the PWM output signal. When ELSnB is set and ELSnA is cleared, the TPMxCHn pin is forced high at the start of each new period (TPMxCNT=0x0000), and it is forced low when the channel value register matches the TPM counter. When ELSnA is set, the TPMxCHn pin is forced low at the start of each new period (TPMxCNT=0x0000), and it is forced high when the channel value register matches the TPM counter.

TPMxMODH:TPMxMODL = 0x0008  
TPMxCnVH:TPMxCnVL = 0x0005

**Figure 16-3. High-true pulse of an edge-aligned PWM**

TPMxMODH:TPMxMODL = 0x0008  
TPMxCnVH:TPMxCnVL = 0x0005

**Figure 16-4. Low-true pulse of an edge-aligned PWM**

When the TPM is configured for center-aligned PWM (CPWMS = 1 and ELSnB:ELSnA  $\neq$  0:0), the TPMxCHn pins are outputs controlled by the TPM, and ELSnB:ELSnA bits control the polarity of the PWM output signal. If ELSnB is set and ELSnA is cleared, the corresponding TPMxCHn pin is cleared when the TPM counter is counting up, and the channel value register matches the TPM counter; and it is

set when the TPM counter is counting down, and the channel value register matches the TPM counter. If ELSnA is set, the corresponding TPMxCHn pin is set when the TPM counter is counting up and the channel value register matches the TPM counter; and it is cleared when the TPM counter is counting down and the channel value register matches the TPM counter.

TPMxMODH:TPMxMODL = 0x0008  
 TPMxCnVH:TPMxCnVL = 0x0005

## 16.3 Register Definition

### 16.3.1 TPM Status and Control Register (TPMxSC)

TPMxSC contains the overflow status flag and control bits used to configure the interrupt enable, TPM configuration, clock source, and prescale factor. These controls relate to all channels within this timer module.

|       |     |      |       |       |       |     |     |     |
|-------|-----|------|-------|-------|-------|-----|-----|-----|
|       | 7   | 6    | 5     | 4     | 3     | 2   | 1   | 0   |
| R     | TOF | TOIE | CPWMS | CLKSB | CLKSA | PS2 | PS1 | PS0 |
| W     | 0   |      |       |       |       |     |     |     |
| Reset | 0   | 0    | 0     | 0     | 0     | 0   | 0   | 0   |

**Figure 16-7. TPM Status and Control Register (TPMxSC)**

**Table 16-3. TPMxSC Field Descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>TOF         | Timer overflow flag. This read/write flag is set when the TPM counter resets to 0x0000 after reaching the modulo value programmed in the TPM counter modulo registers. Clear TOF by reading the TPM status and control register when TOF is set and then writing a logic 0 to TOF. If another TPM overflow occurs before the clearing sequence is completed, the sequence is reset so TOF remains set after the clear sequence was completed for the earlier TOF. This is done so a TOF interrupt request cannot be lost during the clearing sequence for a previous TOF. Reset clears TOF. Writing a logic 1 to TOF has no effect.<br>0 TPM counter has not reached modulo value or overflow.<br>1 TPM counter has overflowed. |
| 6<br>TOIE        | Timer overflow interrupt enable. This read/write bit enables TPM overflow interrupts. If TOIE is set, an interrupt is generated when TOF equals one. Reset clears TOIE.<br>0 TOF interrupts inhibited (use for software polling).<br>1 TOF interrupts enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 5<br>CPWMS       | Center-aligned PWM select. This read/write bit selects CPWM operating mode. By default, the TPM operates in up-counting mode for input capture, output compare, and edge-aligned PWM functions. Setting CPWMS reconfigures the TPM to operate in up/down counting mode for CPWM functions. Reset clears CPWMS.<br>0 All channels operate as input capture, output compare, or edge-aligned PWM mode as selected by the MSnB:MSnA control bits in each channel's status and control register.<br>1 All channels operate in center-aligned PWM mode.                                                                                                                                                                              |
| 4–3<br>CLKS[B:A] | Clock source selection bits. As shown in <a href="#">Table 16-4</a> , this 2-bit field is used to disable the TPM counter or select one of three clock sources to TPM counter and counter prescaler.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2–0<br>PS[2:0]   | Prescale factor select. This 3-bit field selects one of eight division factors for the TPM clock as shown in <a href="#">Table 16-5</a> . This prescaler is located after any clock synchronization or clock selection so it affects the clock selected to drive the TPM counter. The new prescale factor affects the selected clock on the next bus clock cycle after the new value is updated into the register bits.                                                                                                                                                                                                                                                                                                         |

### 16.3.2 TPM-Counter Registers (TPMxCNTH:TPMxCNTL)

The two read-only TPM counter registers contain the high and low bytes of the value in the TPM counter. Reading either byte (TPMxCNTH or TPMxCNTL) latches the contents of both bytes into a buffer where they remain latched until the other half is read. This allows coherent 16-bit reads in big-endian or little-endian order that makes this more friendly to various compiler implementations. The coherency mechanism is automatically restarted by an MCU reset or any write to the timer status/control register (TPMxSC).

Reset clears the TPM counter registers. Writing any value to TPMxCNTH or TPMxCNTL also clears the TPM counter (TPMxCNTH:TPMxCNTL) and resets the coherency mechanism, regardless of the data involved in the write.

Figure 16-8. TPM Counter Register High (TPMxCNTH)

Figure 16-9. TPM Counter Register Low (TPMxCNTL)

When BDM is active, the timer counter is frozen (this is the value you read). The coherency mechanism is frozen so the buffer latches remain in the state they were in when the BDM became active, even if one or both counter halves are read while BDM is active. This assures that if you were in the middle of reading a 16-bit register when BDM became active, it reads the appropriate value from the other half of the 16-bit value after returning to normal execution.

In BDM mode, writing any value to TPMxSC, TPMxCNTH, or TPMxCNTL registers resets the read coherency mechanism of the TPMxCNTH:TPMxCNTL registers, regardless of the data involved in the write.

### 16.3.3 TPM Counter Modulo Registers (TPMxMODH:TPMxMODL)

The read/write TPM modulo registers contain the modulo value for the TPM counter. After the TPM counter reaches the modulo value, the TPM counter resumes counting from 0x0000 at the next clock, and the overflow flag (TOF) becomes set. Writing to TPMxMODH or TPMxMODL inhibits the TOF bit and overflow interrupts until the other byte is written. Reset sets the TPM counter modulo registers to 0x0000 that results in a free running timer counter (modulo disabled).

Writes to any of the registers TPMxMODH and TPMxMODL actually writes to buffer registers and the registers are updated with the value of their write buffer according to the value of CLKSB:CLKSA bits:

- If CLKSB and CLKSA are cleared, the registers are updated when the second byte is written
- If CLKSB and CLKSA are not cleared, the registers are updated after both bytes were written, and the TPM counter changes from (TPMxMODH:TPMxMODL – 1) to (TPMxMODH:TPMxMODL). If the TPM counter is a free-running counter, the update is made when the TPM counter changes from 0xFFFFE to 0xFFFF

The latching mechanism is manually reset by writing to the TPMxSC address (whether BDM is active or not).

When BDM is active, the coherency mechanism is frozen (unless reset by writing to TPMxSC register) so the buffer latches remain in the state they were in when the BDM became active, even if one or both halves of the modulo register are written while BDM is active. Any write to the modulo registers bypasses the buffer latches and directly writes to the modulo register while BDM is active.

Figure 16-10. TPM Counter Modulo Register High (TPMxMODH)

Figure 16-11. TPM Counter Modulo Register Low (TPMxMODL)

Reset the TPM counter before writing to the TPM modulo registers to avoid confusion about when the first counter overflow occurs.

### 16.3.4 TPM Channel n Status and Control Register (TPMxCnSC)

TPMxCnSC contains the channel-interrupt-status flag and control bits that configure the interrupt enable, channel configuration, and pin function.

**Figure 16-12. TPM Channel n Status and Control Register (TPMxCnSC)**

**Table 16-6. TPMxCnSC Field Descriptions**

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>CHnF             | Channel n flag. When channel n is an input capture channel, this read/write bit is set when an active edge occurs on the channel n input. When channel n is an output compare or edge-aligned/center-aligned PWM channel, CHnF is set when the value in the TPM counter registers matches the value in the TPM channel n value registers. When channel n is an edge-aligned/center-aligned PWM channel and the duty cycle is set to 0% or 100%, CHnF is not set even when the value in the TPM counter registers matches the value in the TPM channel n value registers.<br><br>A corresponding interrupt is requested when this bit is set and channel n interrupt is enabled (CHnIE = 1). Clear CHnF by reading TPMxCnSC while this bit is set and then writing a logic 0 to it. If another interrupt request occurs before the clearing sequence is completed CHnF remains set. This is done so a CHnF interrupt request is not lost due to clearing a previous CHnF.<br><br>Reset clears this bit. Writing a logic 1 to CHnF has no effect.<br>0 No input capture or output compare event occurred on channel n.<br>1 Input capture or output compare event on channel n. |
| 6<br>CHnIE            | Channel n interrupt enable. This read/write bit enables interrupts from channel n. Reset clears this bit.<br>0 Channel n interrupt requests disabled (use for software polling).<br>1 Channel n interrupt requests enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 5<br>MSnB             | Mode select B for TPM channel n. When CPWMS is cleared, setting the MSnB bit configures TPM channel n for edge-aligned PWM mode. Refer to the summary of channel mode and setup controls in <a href="#">Table 16-7</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4<br>MSnA             | Mode select A for TPM channel n. When CPWMS and MSnB are cleared, the MSnA bit configures TPM channel n for input capture mode or output compare mode. Refer to <a href="#">Table 16-7</a> for a summary of channel mode and setup controls.<br><b>Note:</b> If the associated port pin is not stable for at least two bus clock cycles before changing to input capture mode, it is possible to get an unexpected indication of an edge trigger.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3–2<br>ELSnB<br>ELSnA | Edge/level select bits. Depending upon the operating mode for the timer channel as set by CPWMS:MSnB:MSnA and shown in <a href="#">Table 16-7</a> , these bits select the polarity of the input edge that triggers an input capture event, select the level that is driven in response to an output compare match, or select the polarity of the PWM output.<br><br>If ELSnB and ELSnA bits are cleared, the channel pin is not controlled by TPM. This configuration can be used by software compare only, because it does not require the use of a pin for the channel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 16-7. Mode, Edge, and Level Selection**

| CPWMS | MSnB:MSnA | ELSnB:ELSnA | Mode                                                                                            | Configuration                                                                    |
|-------|-----------|-------------|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|

|       |           | X1          |                                                                                                 | Low-true pulses (set output on channel match when TPM counter is counting up)    |

### 16.3.5 TPM Channel Value Registers (TPMxCnVH:TPMxCnVL)

These read/write registers contain the captured TPM counter value of the input capture function or the output compare value for the output compare or PWM functions. The channel registers are cleared by reset.

**Figure 16-13. TPM Channel Value Register High (TPMxCnVH)**

**Figure 16-14. TPM Channel Value Register Low (TPMxCnVL)**

In input capture mode, reading either byte (TPMxCnVH or TPMxCnVL) latches the contents of both bytes into a buffer where they remain latched until the other half is read. This latching mechanism also resets (becomes unlatched) when the TPMxCnSC register is written (whether BDM mode is active or not). Any write to the channel registers is ignored during the input capture mode.

When BDM is active, the coherency mechanism is frozen (unless reset by writing to TPMxCnSC register) so the buffer latches remain in the state they were in when the BDM became active, even if one or both halves of the channel register are read while BDM is active. This assures that if you were in the middle of reading a 16-bit register when BDM became active, it reads the appropriate value from the other half of the 16-bit value after returning to normal execution. The value read from the TPMxCnVH and TPMxCnVL registers in BDM mode is the value of these registers and not the value of their read buffer.

In output compare or PWM modes, writing to either byte (TPMxCnVH or TPMxCnVL) latches the value into a buffer. After both bytes were written, they are transferred as a coherent 16-bit value into the timer-channel registers according to the value of CLKSB:CLKSA bits and the selected mode:

- If CLKSB and CLKSA are cleared, the registers are updated when the second byte is written.
- If CLKSB and CLKSA are not cleared and in output compare mode, the registers are updated after the second byte is written and on the next change of the TPM counter (end of the prescaler counting).
- If CLKSB and CLKSA are not cleared and in EPWM or CPWM modes, the registers are updated after both bytes were written, and the TPM counter changes from (TPMxMODH:TPMxMODL – 1) to (TPMxMODH:TPMxMODL). If the TPM counter is a free-running counter, the update is made when the TPM counter changes from 0xFFFFE to 0xFFFF.

The latching mechanism is manually reset by writing to the TPMxCnSC register (whether BDM mode is active or not). This latching mechanism allows coherent 16-bit writes in either big-endian or little-endian order that is friendly to various compiler implementations.

When BDM is active, the coherency mechanism is frozen so the buffer latches remain in the state they were in when the BDM became active even if one or both halves of the channel register are written while BDM is active. Any write to the channel registers bypasses the buffer latches and directly write to the channel register while BDM is active. The values written to the channel register while BDM is active are used for PWM and output compare operation after normal execution resumes. Writes to the channel registers while BDM is active do not interfere with partial completion of a coherency sequence. After the coherency mechanism is fully exercised, the channel registers are updated using the buffered values (while BDM was not active).

## 16.4 Functional Description

All TPM functions are associated with a central 16-bit counter that allows flexible selection of the clock and prescale factor. There is also a 16-bit modulo register associated with this counter.

The CPWMS control bit chooses between center-aligned PWM operation for all channels in the TPM (CPWMS=1) or general purpose timing functions (CPWMS=0) where each channel can independently be configured to operate in input capture, output compare, or edge-aligned PWM mode. The CPWMS control bit is located in the TPM status and control register because it affects all channels within the TPM and influences the way the main counter operates. (In CPWM mode, the counter changes to an up/down mode rather than the up-counting mode used for general purpose timer functions.)

The following sections describe TPM counter and each of the timer operating modes (input capture, output compare, edge-aligned PWM, and center-aligned PWM). Because details of pin operation and interrupt

activity depend upon the operating mode, these topics are covered in the associated mode explanation sections.

## 16.4.1 Counter

All timer functions are based on the main 16-bit counter (TPMxCNTH:TPMxCNTL). This section discusses selection of the clock, end-of-count overflow, up-counting vs. up/down counting, and manual counter reset.

### 16.4.1.1 Counter Clock Source

The 2-bit field, CLKS<sub>B</sub>:CLKS<sub>A</sub>, in the timer status and control register (TPMxSC) disables the TPM counter or selects one of three clock sources to TPM counter (Table 16-4). After any MCU reset, CLKS<sub>B</sub> and CLKS<sub>A</sub> are cleared so no clock is selected and the TPM counter is disabled (TPM is in a very low power state). You can read or write these control bits at any time. Disabling the TPM counter by writing 00 to CLKS<sub>B</sub>:CLKS<sub>A</sub> bits, does not affect the values in the TPM counter or other registers.

The fixed frequency clock is an alternative clock source for the TPM counter that allows the selection of a clock other than the bus clock or external clock. This clock input is defined by chip integration. You can refer chip specific documentation for further information. Due to TPM hardware implementation limitations, the frequency of the fixed frequency clock must not exceed the bus clock frequency. The fixed frequency clock has no limitations for low frequency operation.

The external clock passes through a synchronizer clocked by the bus clock to assure that counter transitions are properly aligned to bus clock transitions. Therefore, in order to meet Nyquist criteria considering also jitter, the frequency of the external clock source must not exceed 1/4 of the bus clock frequency.

When the external clock source is shared with a TPM channel pin, this pin must not be used in input capture mode. However, this channel can be used in output compare mode with ELSn<sub>B</sub>:ELS<sub>nA</sub> = 0:0 for software timing functions. In this case, the channel output is disabled, but the channel match events continue to set the appropriate flag.

### 16.4.1.2 Counter Overflow and Modulo Reset

An interrupt flag and enable are associated with the 16-bit main counter. The flag (TOF) is a software-accessible indication that the timer counter has overflowed. The enable signal selects between software polling (TOIE = 0) where no interrupt is generated, or interrupt-driven operation (TOIE = 1) where the interrupt is generated whenever the TOF is set.

The conditions causing TOF to become set depend on whether the TPM is configured for center-aligned PWM (CPWMS = 1). If CPWMS is cleared and there is no modulus limit, the 16-bit timer counter counts from 0x0000 through 0xFFFF and overflows to 0x0000 on the next counting clock. TOF is set at the transition from 0xFFFF to 0x0000. When a modulus limit is set, TOF is set at the transition from the value set in the modulus register to 0x0000. When the TPM is in center-aligned PWM mode (CPWMS = 1), the TOF flag is set as the counter changes direction at the end of the count value set in the modulus register (at the transition from the value set in the modulus register to the next lower count value). This corresponds to the end of a PWM period (the 0x0000 count value corresponds to the center of a period).

### 16.4.1.3 Counting Modes

The main timer counter has two counting modes. When center-aligned PWM is selected (CPWMS = 1), the counter operates in up/down counting mode. Otherwise, the counter operates as a simple up counter. As an up counter, the timer counter counts from 0x0000 through its terminal count and continues with 0x0000. The terminal count is 0xFFFF or a modulus value in TPMxMODH:TPMxMODL.

When center-aligned PWM operation is specified, the counter counts up from 0x0000 through its terminal count and then down to 0x0000 where it changes back to up counting. The terminal count value and 0x0000 are normal length counts (one timer clock period long). In this mode, the timer overflow flag (TOF) is set at the end of the terminal-count period (as the count changes to the next lower count value).

### 16.4.1.4 Manual Counter Reset

The main timer counter can be manually reset at any time by writing any value to TPMxCNTH or TPMxCNTL. Resetting the counter in this manner also resets the coherency mechanism in case only half of the counter was read before resetting the count.

## 16.4.2 Channel Mode Selection

If CPWMS is cleared, MSnB and MSnA bits determine the basic mode of operation for the corresponding channel. Choices include input capture, output compare, and edge-aligned PWM.

### 16.4.2.1 Input Capture Mode

With the input capture function, the TPM can capture the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the TPM latches the contents of the TPM counter into the channel-value registers (TPMxCnVH:TPMxCnVL). Rising edges, falling edges, or any edge is chosen as the active edge that triggers an input capture.

In input capture mode, the TPMxCnVH and TPMxCnVL registers are read only.

When either half of the 16-bit capture register is read, the other half is latched into a buffer to support coherent 16-bit accesses in big-endian or little-endian order. The coherency sequence can be manually reset by writing to TPMxCnSC.

An input capture event sets a flag bit (CHnF) that optionally generates a CPU interrupt request.

While in BDM, the input capture function works as configured. When an external event occurs, the TPM latches the contents of the TPM counter (frozen because of the BDM mode) into the channel value registers and sets the flag bit.

### 16.4.2.2 Output Compare Mode

With the output compare function, the TPM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter reaches the value in TPMxCnVH:TPMxCnVL registers of an output compare channel, the TPM can set, clear, or toggle the channel pin.

Writes to any of TPMxCnVH and TPMxCnVL registers actually write to buffer registers. In output compare mode, the TPMxCnVH:TPMxCnVL registers are updated with the value of their write buffer only after both bytes were written and according to the value of CLKSB:CLKSA bits:

- If CLKSB and CLKSA are cleared, the registers are updated when the second byte is written
- If CLKSB and CLKSA are not cleared, the registers are updated at the next change of the TPM counter (end of the prescaler counting) after the second byte is written.

The coherency sequence can be manually reset by writing to the channel status/control register (TPMxCnSC).

An output compare event sets a flag bit (CHnF) that optionally generates a CPU interrupt request.

## 16.4.2.3 Edge-Aligned PWM Mode

This type of PWM output uses the normal up-counting mode of the timer counter (CPWMS=0) and can be used when other channels in the same TPM are configured for input capture or output compare functions. The period of this PWM signal is determined by the value of the modulus register (TPMxMODH:TPMxMODL) plus 1. The duty cycle is determined by the value of the timer channel register (TPMxCnVH:TPMxCnVL). The polarity of this PWM signal is determined by ELSnA bit. 0% and 100% duty cycle cases are possible.

The time between the modulus overflow and the channel match value (TPMxCnVH:TPMxCnVL) is the pulse width or duty cycle (Figure 16-15). If ELSnA is cleared, the counter overflow forces the PWM signal high, and the channel match forces the PWM signal low. If ELSnA is set, the counter overflow forces the PWM signal low, and the channel match forces the PWM signal high.

**Figure 16-15. EPWM period and pulse width (ELSnA=0)**

When the channel value register is set to 0x0000, the duty cycle is 0%. A 100% duty cycle is achieved by setting the timer-channel register (TPMxCnVH:TPMxCnVL) to a value greater than the modulus setting. This implies that the modulus setting must be less than 0xFFFF in order to get 100% duty cycle.

The timer channel registers are buffered to ensure coherent 16-bit updates and to avoid unexpected PWM pulse widths. Writes to any of the registers TPMxCnVH and TPMxCnVL actually write to buffer registers. In edge-aligned PWM mode, the TPMxCnVH:TPMxCnVL registers are updated with the value of their write buffer according to the value of CLKSB:CLKSA bits:

- If CLKSB and CLKSA are cleared, the registers are updated when the second byte is written
- If CLKSB and CLKSA are not cleared, the registers are updated after both bytes were written, and the TPM counter changes from (TPMxMODH:TPMxMODL – 1) to

(TPMxMODH:TPMxMODL). If the TPM counter is a free-running counter, the update is made when the TPM counter changes from 0xFFFFE to 0xFFFF.

#### 16.4.2.4 Center-Aligned PWM Mode

This type of PWM output uses the up/down counting mode of the timer counter (CPWMS=1). The channel match value in TPMxCnVH:TPMxCnVL determines the pulse width (duty cycle) of the PWM signal while the period is determined by the value in TPMxMODH:TPMxMODL. TPMxMODH:TPMxMODL must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results. ELSnA determines the polarity of the CPWM signal.

pulse width =  $2 \times (\text{TPMxCnVH:TPMxCnVL})$

period =  $2 \times (\text{TPMxMODH:TPMxMODL})$ ; TPMxMODH:TPMxMODL = 0x0001–0x7FFF

If TPMxCnVH:TPMxCnVL is zero or negative (bit 15 set), the duty cycle is 0%. If TPMxCnVH:TPMxCnVL is a positive value (bit 15 clear) and is greater than the non-zero modulus setting, the duty cycle is 100% because the channel match never occurs. This implies the usable range of periods set by the modulus register is 0x0001 through 0x7FFE (0x7FFF if you do not need to generate 100% duty cycle). This is not a significant limitation. The resulting period is much longer than required for normal applications.

All zeros in TPMxMODH:TPMxMODL is a special case that must not be used with center-aligned PWM mode. When CPWMS is cleared, this case corresponds to the counter running free from 0x0000 through 0xFFFF. When CPWMS is set, the counter needs a valid match to the modulus register somewhere other than at 0x0000 in order to change directions from up-counting to down-counting.

The channel match value in the TPM channel registers (times two) determines the pulse width (duty cycle) of the CPWM signal (Figure 16-16). If ELSnA is cleared, a channel match occurring while counting up clears the CPWM output signal and a channel match occurring while counting down sets the output. The counter counts up until it reaches the modulo setting in TPMxMODH:TPMxMODL, then counts down until it reaches zero. This sets the period equal to two times TPMxMODH:TPMxMODL.

Figure 16-16. CPWM period and pulse width (ELSnA=0)

Center-aligned PWM outputs typically produce less noise than edge-aligned PWMs because fewer I/O pin transitions are lined up at the same system clock edge. This type of PWM is also required for some types of motor drives.

Input capture, output compare, and edge-aligned PWM functions do not make sense when the counter is operating in up/down counting mode so this implies that all active channels within a TPM must be used in CPWM mode when CPWMS is set.

The timer channel registers are buffered to ensure coherent 16-bit updates and to avoid unexpected PWM pulse widths. Writes to any of the registers TPMxCnVH and TPMxCnVL actually write to buffer registers. In center-aligned PWM mode, the TPMxCnVH:TPMxCnVL registers are updated with the value of their write buffer according to the value of CLKSB:CLKSA bits:

- If CLKSB and CLKSA are cleared, the registers are updated when the second byte is written
- If CLKSB and CLKSA are not cleared, the registers are updated after both bytes were written, and the TPM counter changes from (TPMxMODH:TPMxMODL – 1) to (TPMxMODH:TPMxMODL). If the TPM counter is a free-running counter, the update is made when the TPM counter changes from 0xFFFFE to 0xFFFF.

When TPMxCNTH:TPMxCNTL equals TPMxMODH:TPMxMODL, the TPM can optionally generate a TOF interrupt (at the end of this count).

## 16.5 Reset Overview

### 16.5.1 General

The TPM is reset whenever any MCU reset occurs.

### 16.5.2 Description of Reset Operation

Reset clears TPMxSC that disables TPM counter clock and overflow interrupt (TOIE=0). CPWMS, MSnB, MSnA, ELSnB, and ELSnA are all cleared. This configures all TPM channels for input capture operation and the associated pins are not controlled by TPM.

## 16.6 Interrupts

### 16.6.1 General

The TPM generates an optional interrupt for the main counter overflow and an interrupt for each channel. The meaning of channel interrupts depends on each channel's mode of operation. If the channel is configured for input capture, the interrupt flag is set each time the selected input capture edge is recognized. If the channel is configured for output compare or PWM modes, the interrupt flag is set each time the main timer counter matches the value in the 16-bit channel value register.

All TPM interrupts are listed in [Table 16-8](#).

**Table 16-8. Interrupt Summary**

| Interrupt | Local Enable | Source           | Description                                                                                      |
|-----------|--------------|------------------|--------------------------------------------------------------------------------------------------|
| TOF       | TOIE         | Counter overflow | Set each time the TPM counter reaches its terminal count (at transition to its next count value) |
| CHnF      | CHnIE        | Channel event    | An input capture event or channel match took place on channel n                                  |

The TPM module provides high-true interrupt signals.

## 16.6.2 Description of Interrupt Operation

For each interrupt source in the TPM, a flag bit is set upon recognition of the interrupt condition such as timer overflow, channel input capture, or output compare events. This flag is read (polled) by software to determine that the action has occurred, or an associated enable bit (TOIE or CHnIE) can be set to enable the interrupt generation. While the interrupt enable bit is set, the interrupt is generated whenever the associated interrupt flag is set. Software must perform a sequence of steps to clear the interrupt flag before returning from the interrupt-service routine.

TPM interrupt flags are cleared by a two-step process including a read of the flag bit while it is set followed by a write of zero to the bit. If a new event is detected between these two steps, the sequence is reset and the interrupt flag remains set after the second step to avoid the possibility of missing the new event.

### 16.6.2.1 Timer Overflow Interrupt (TOF) Description

The meaning and details of operation for TOF interrupts varies slightly depending upon the mode of operation of the TPM system (general purpose timing functions versus center-aligned PWM operation). The flag is cleared by the two step sequence described above.

#### 16.6.2.1.1 Normal Case

When CPWMS is cleared, TOF is set when the timer counter changes from the terminal count (the value in the modulo register) to 0x0000. If the TPM counter is a free-running counter, the update is made when the TPM counter changes from 0xFFFF to 0x0000.

#### 16.6.2.1.2 Center-Aligned PWM Case

When CPWMS is set, TOF is set when the timer counter changes direction from up-counting to down-counting at the end of the terminal count (the value in the modulo register).

### 16.6.2.2 Channel Event Interrupt Description

The meaning of channel interrupts depends on the channel's current mode (input capture, output compare, edge-aligned PWM, or center-aligned PWM).

### 16.6.2.2.1 Input Capture Events

When a channel is configured as an input capture channel, the ELSnB:ELSnA bits select if channel pin is not controlled by TPM, rising edges, falling edges, or any edge as the edge that triggers an input capture event. When the selected edge is detected, the interrupt flag is set. The flag is cleared by the two-step sequence described in [Section 16.6.2, “Description of Interrupt Operation.”](#)

### 16.6.2.2.2 Output Compare Events

When a channel is configured as an output compare channel, the interrupt flag is set each time the main timer counter matches the 16-bit value in the channel value register. The flag is cleared by the two-step sequence described in [Section 16.6.2, “Description of Interrupt Operation.”](#)

### 16.6.2.2.3 PWM End-of-Duty-Cycle Events

When the channel is configured for edge-aligned PWM, the channel flag is set when the timer counter matches the channel value register that marks the end of the active duty cycle period. When the channel is configured for center-aligned PWM, the timer count matches the channel value register twice during each PWM cycle. In this CPWM case, the channel flag is set at the start and at the end of the active duty cycle period when the timer counter matches the channel value register. The flag is cleared by the two-step sequence described in [Section 16.6.2, “Description of Interrupt Operation.”](#)

## Chapter 17

# Modulo Timer (S08MTIMV1)

### 17.1 Introduction

The MTIM is a simple 8-bit timer with four software-selectable clock sources and a programmable interrupt.

The central component of the MTIM is the 8-bit counter that can operate as a free-running counter or a modulo counter. A timer overflow interrupt can be enabled to generate periodic interrupts for time-based software loops.

[Figure 17-1](#) shows the MC9S08LG32 series block diagram highlighting the MTIM block and pin.

#### 17.1.1 MTIM Clock Gating

The bus clock to the MTIM can be gated on and off using the MTIM bit in SCGC1. This bit is cleared after any reset, which disables the bus clock to this module. To conserve power, the MTIM bit can be cleared to disable the clock to this module when not in use. See [Section 5.7, “Peripheral Clock Gating,”](#) for details.

**Figure 17-1. MC9S08LG32 Series Block Diagram Highlighting MTIM Block and Pins**

## 17.1.2 Features

Timer system features include:

- 8-bit up-counter
  - Free-running or 8-bit modulo limit
  - Software controllable interrupt on overflow
  - Counter reset bit (TRST)
  - Counter stop bit (TSTP)
- Four software selectable clock sources for input to prescaler:
  - System bus clock — rising edge
  - Fixed frequency clock (XCLK) — rising edge
  - External clock source on the TPMCLK pin — rising edge
  - External clock source on the TPMCLK pin — falling edge
- Nine selectable clock prescale values:
  - Clock source divide by 1, 2, 4, 8, 16, 32, 64, 128, or 256

## 17.1.3 Modes of Operation

This section defines the MTIM's operation in stop, wait and background debug modes.

### 17.1.3.1 MTIM in Wait Mode

The MTIM continues to run in wait mode if enabled before executing the WAIT instruction. Therefore, the MTIM can be used to bring the MCU out of wait mode if the timer overflow interrupt is enabled. For lowest possible current consumption, the MTIM should be stopped by software if not needed as an interrupt source during wait mode.

### 17.1.3.2 MTIM in Stop Modes

The MTIM is disabled in all stop modes, regardless of the settings before executing the STOP instruction. Therefore, the MTIM cannot be used as a wake up source from stop modes.

Waking from stop2 modes, the MTIM will be put into its reset state. If stop3 is exited with a reset, the MTIM will be put into its reset state. If stop3 is exited with an interrupt, the MTIM continues from the state it was in when stop3 was entered. If the counter was active upon entering stop3, the count will resume from the current value.

### 17.1.3.3 MTIM in Active Background Mode

The MTIM suspends all counting until the microcontroller returns to normal user operating mode. Counting resumes from the suspended value as long as an MTIM reset did not occur (TRST written to a 1 or MTIMMOD written).

### 17.1.4 Block Diagram

The block diagram for the modulo timer module is shown [Figure 17-2](#).

Figure 17-2. Modulo Timer (MTIM) Block Diagram

## 17.2 External Signal Description

The MTIM includes one external signal, TPMCLK, used to input an external clock when selected as the MTIM clock source. The signal properties of TPMCLK are shown in [Table 17-1](#).

Table 17-1. External Signal Description

| Signal | Function                              | I/O |
|--------|---------------------------------------|-----|
| TPMCLK | External clock source input into MTIM | I   |

The TPMCLK input must be synchronized by the bus clock. Also, variations in duty cycle and clock jitter must be accommodated. Therefore, the TPMCLK signal must be limited to one-fourth of the bus frequency.

The TPMCLK pin can be muxed with a general-purpose port pin. See the [Chapter 2, “Pins and Connections,”](#) chapter for the pin location and priority of this function.

# 17.3 Memory Map and Register Definition

## 17.3.1 Memory Map (Register Summary)

Figure 17-3. MTIM Register Summary

| Name    |   | 7     | 6    | 5    | 4    | 3  | 2 | 1 | 0 |
|---------|---|-------|------|------|------|----|---|---|---|
| MTIMSC  | R | TOF   | TOIE | 0    | TSTP | 0  | 0 | 0 | 0 |
|         | W |       |      | TRST |      |    |   |   |   |
| MTIMCLK | R | 0     | 0    | CLKS |      | PS |   |   |   |
|         | W |       |      |      |      |    |   |   |   |
| MTIMCNT | R | COUNT |      |      |      |    |   |   |   |
|         | W |       |      |      |      |    |   |   |   |
| MTIMMOD | R | MOD   |      |      |      |    |   |   |   |
|         | W |       |      |      |      |    |   |   |   |

## 17.3.2 Register Descriptions

Each MTIM includes four registers:

- An 8-bit status and control register
- An 8-bit clock configuration register
- An 8-bit counter register
- An 8-bit modulo register

Refer to the direct-page register summary in the [Chapter 4, “Memory,”](#) for the absolute address assignments for all MTIM registers. This section refers to registers and control bits only by their names and relative address offsets.

### 17.3.2.1 MTIM Status and Control Register (MTIMSC)

MTIMSC contains the overflow status flag and control bits which are used to configure the interrupt enable, reset the counter, and stop the counter.

Figure 17-4. MTIM Status and Control Register (MTIMSC)

Table 17-2. MTIMSC Field Descriptions

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>TOF  | <b>MTIM Overflow Flag</b> — This read-only bit is set when the MTIM counter register overflows to \$00 after reaching the value in the MTIM modulo register. Clear TOF by reading the MTIMSC register while TOF is set, then writing a 0 to TOF. TOF is also cleared when TRST is written to a 1 or when any value is written to the MTIMMOD register.<br>0 MTIM counter has not reached the overflow value in the MTIM modulo register.<br>1 MTIM counter has reached the overflow value in the MTIM modulo register. |
| 6<br>TOIE | <b>MTIM Overflow Interrupt Enable</b> — This read/write bit enables MTIM overflow interrupts. If TOIE is set, then an interrupt is generated when TOF = 1. Reset clears TOIE. Do not set TOIE if TOF = 1. Clear TOF first, then set TOIE.<br>0 TOF interrupts are disabled. Use software polling.<br>1 TOF interrupts are enabled.                                                                                                                                                                                     |
| 5<br>TRST | <b>MTIM Counter Reset</b> — When a 1 is written to this write-only bit, the MTIM counter register resets to \$00 and TOF is cleared. Reading this bit always returns 0.<br>0 No effect. MTIM counter remains at current state.<br>1 MTIM counter is reset to \$00.                                                                                                                                                                                                                                                     |
| 4<br>TSTP | <b>MTIM Counter Stop</b> — When set, this read/write bit stops the MTIM counter at its current value. Counting resumes from the current value when TSTP is cleared. Reset sets TSTP to prevent the MTIM from counting.<br>0 MTIM counter is active.<br>1 MTIM counter is stopped.                                                                                                                                                                                                                                      |

### 17.3.2.2 MTIM Clock Configuration Register (MTIMCLK)

MTIMCLK contains the clock select bits (CLKS) and the prescaler select bits (PS).

Figure 17-5. MTIM Clock Configuration Register (MTIMCLK)

**Table 17-3. MTIMCLK Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Table 17-5. MTIMMOD Field Descriptions

| Field      | Description                                                                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0<br>MOD | <b>MTIM Modulo</b> — These eight read/write bits contain the modulo value used to reset the count and set TOF. A value of \$00 puts the MTIM in free-running mode. Writing to MTIMMOD resets the COUNT to \$00 and clears TOF. Reset sets the modulo to \$00. |

## 17.4 Functional Description

The MTIM is composed of a main 8-bit up-counter with an 8-bit modulo register, a clock source selector, and a prescaler block with nine selectable values. The module also contains software selectable interrupt logic.

The MTIM counter (MTIMCNT) has three modes of operation: stopped, free-running, and modulo. Out of reset, the counter is stopped. If the counter is started without writing a new value to the modulo register, then the counter will be in free-running mode. The counter is in modulo mode when a value other than \$00 is in the modulo register while the counter is running.

After any MCU reset, the counter is stopped and reset to \$00, and the modulus is set to \$00. The bus clock is selected as the default clock source and the prescale value is divide by 1. To start the MTIM in free-running mode, simply write to the MTIM status and control register (MTIMSC) and clear the MTIM stop bit (TSTP).

Four clock sources are software selectable: the internal bus clock, the fixed frequency clock (XCLK), and an external clock on the TPMCLK pin, selectable as incrementing on either rising or falling edges. The MTIM clock select bits (CLKS1:CLKS0) in MTIMSC are used to select the desired clock source. If the counter is active (TSTP = 0) when a new clock source is selected, the counter will continue counting from the previous value using the new clock source.

Nine prescale values are software selectable: clock source divided by 1, 2, 4, 8, 16, 32, 64, 128, or 256. The prescaler select bits (PS[3:0]) in MTIMSC select the desired prescale value. If the counter is active (TSTP = 0) when a new prescaler value is selected, the counter will continue counting from the previous value using the new prescaler value.

The MTIM modulo register (MTIMMOD) allows the overflow compare value to be set to any value from \$01 to \$FF. Reset clears the modulo value to \$00, which results in a free running counter.

When the counter is active (TSTP = 0), the counter increments at the selected rate until the count matches the modulo value. When these values match, the counter overflows to \$00 and continues counting. The MTIM overflow flag (TOF) is set whenever the counter overflows. The flag sets on the transition from the modulo value to \$00. Writing to MTIMMOD while the counter is active resets the counter to \$00 and clears TOF.

Clearing TOF is a two-step process. The first step is to read the MTIMSC register while TOF is set. The second step is to write a 0 to TOF. If another overflow occurs between the first and second steps, the clearing process is reset and TOF will remain set after the second step is performed. This will prevent the second occurrence from being missed. TOF is also cleared when a 1 is written to TRST or when any value is written to the MTIMMOD register.

The MTIM allows for an optional interrupt to be generated whenever TOF is set. To enable the MTIM overflow interrupt, set the MTIM overflow interrupt enable bit (TOIE) in MTIMSC. TOIE should never be written to a 1 while TOF = 1. Instead, TOF should be cleared first, then the TOIE can be set to 1.

### 17.4.1 MTIM Operation Example

This section shows an example of the MTIM operation as the counter reaches a matching value from the modulo register.

**Figure 17-8. MTIM counter overflow example**

In the example of [Figure 17-8](#), the selected clock source could be any of the four possible choices. The prescaler is set to PS = %0010 or divide-by-4. The modulo value in the MTIMMOD register is set to \$AA. When the counter, MTIMCNT, reaches the modulo value of \$AA, the counter overflows to \$00 and continues counting. The timer overflow flag, TOF, sets when the counter value changes from \$AA to \$00. An MTIM overflow interrupt is generated when TOF is set, if TOIE = 1.

## Chapter 18

# Development Support

### 18.1 Introduction

Development support systems in the HCS08 include the background debug controller (BDC) and the on-chip debug module (DBG). The BDC provides a single-wire debug interface to the target MCU that provides a convenient interface for programming the on-chip flash and other nonvolatile memories. The BDC is also the primary debug interface for development and allows non-intrusive access to memory data and traditional debug features such as CPU register modify, breakpoints, and single instruction trace commands.

In the HCS08 Family, address and data bus signals are not available on external pins. Debug is done through commands fed into the target MCU through the single-wire background debug interface. The debug module provides a means to selectively trigger and capture bus information so an external development system can reconstruct what happened inside the MCU on a cycle-by-cycle basis without having external access to the address and data signals.

#### 18.1.1 Forcing Active Background

The method for forcing active background mode depends on the specific HCS08 derivative. For the MC9S08LG32 series, you can force active background after a power-on reset by holding the BKGD pin low as the device exits the reset condition. You can also force active background by driving BKGD low immediately after a serial background command that writes a one to the BDFR bit in the SBDFR register. Other causes of reset, including an external pin reset or an internally generated error reset ignore the state of the BKGD pin and reset into normal user mode. If no debug pod is connected to the BKGD pin, the MCU will always reset into normal operating mode.

#### 18.1.2 Module Configuration

The alternate BDC clock source is the ICSLCLK. To select this clock source, clear the CLKSW bit in the BDCSCR register. For details on ICSLCLK, see [Section 11.4, “Functional Description.”](#)

### 18.1.3 Features

Features of the BDC module include:

- Single pin for mode selection and background communications
- BDC registers are not located in the memory map
- SYNC command to determine target communications rate
- Non-intrusive commands for memory access
- Active background mode commands for CPU register access
- GO and TRACE1 commands
- BACKGROUND command can wake CPU from stop or wait modes
- One hardware address breakpoint built into BDC
- Oscillator runs in stop mode, if BDC enabled
- COP watchdog disabled while in active background mode

## 18.2 Background Debug Controller (BDC)

All MCUs in the HCS08 Family contain a single-wire background debug interface that supports in-circuit programming of on-chip nonvolatile memory and sophisticated non-intrusive debug capabilities. Unlike debug interfaces on earlier 8-bit MCUs, this system does not interfere with normal application resources. It does not use any user memory or locations in the memory map and does not share any on-chip peripherals.

BDC commands are divided into two groups:

- Active background mode commands require that the target MCU is in active background mode (the user program is not running). Active background mode commands allow the CPU registers to be read or written, and allow the user to trace one user instruction at a time, or GO to the user program from active background mode.
- Non-intrusive commands can be executed at any time even while the user's program is running. Non-intrusive commands allow a user to read or write MCU memory locations or access status and control registers within the background debug controller.

Typically, a relatively simple interface pod is used to translate commands from a host computer into commands for the custom serial interface to the single-wire background debug system. Depending on the development tool vendor, this interface pod may use a standard RS-232 serial port, a parallel printer port, or some other type of communications such as a universal serial bus (USB) to communicate between the host PC and the pod. The pod typically connects to the target system with ground, the BKGD pin,  $\overline{\text{RESET}}$ , and sometimes  $V_{DD}$ . An open-drain connection to reset allows the host to force a target system reset, which is useful to regain control of a lost target system or to control startup of a target system before the on-chip nonvolatile memory has been programmed. Sometimes  $V_{DD}$  can be used to allow the pod to use power from the target system to avoid the need for a separate power supply. However, if the pod is powered separately, it can be connected to a running target system without forcing a target system reset or otherwise disturbing the running application program.

Figure 18-1. BDM Tool Connector

## 18.2.1 BKGD Pin Description

BKGD is the single-wire background debug interface pin. The primary function of this pin is for bidirectional serial communication of active background mode commands and data. During reset, this pin is used to select between starting in active background mode or starting the user's application program. This pin is also used to request a timed sync response pulse to allow a host development tool to determine the correct clock frequency for background debug serial communications.

BDC serial communications use a custom serial protocol first introduced on the M68HC12 Family of microcontrollers. This protocol assumes the host knows the communication clock rate that is determined by the target BDC clock rate. All communication is initiated and controlled by the host that drives a high-to-low edge to signal the beginning of each bit time. Commands and data are sent most significant bit first (MSB first). For a detailed description of the communications protocol, refer to [Section 18.2.2, "Communication Details."](#)

If a host is attempting to communicate with a target MCU that has an unknown BDC clock rate, a SYNC command may be sent to the target MCU to request a timed sync response signal from which the host can determine the correct communication speed.

BKGD is a pseudo-open-drain pin and there is an on-chip pullup so no external pullup resistor is required. Unlike typical open-drain pins, the external RC time constant on this pin, which is influenced by external capacitance, plays almost no role in signal rise time. The custom protocol provides for brief, actively driven speedup pulses to force rapid rise times on this pin without risking harmful drive level conflicts. Refer to [Section 18.2.2, "Communication Details,"](#) for more detail.

When no debugger pod is connected to the 6-pin BDM interface connector, the internal pullup on BKGD chooses normal operating mode. When a debug pod is connected to BKGD it is possible to force the MCU into active background mode after reset. The specific conditions for forcing active background depend upon the HCS08 derivative (refer to the introduction to this Development Support section). It is not necessary to reset the target MCU to communicate with it through the background debug interface.

## 18.2.2 Communication Details

The BDC serial interface requires the external controller to generate a falling edge on the BKGD pin to indicate the start of each bit time. The external controller provides this falling edge whether data is transmitted or received.

BKGD is a pseudo-open-drain pin that can be driven either by an external controller or by the MCU. Data is transferred MSB first at 16 BDC clock cycles per bit (nominal speed). The interface times out if 512 BDC clock cycles occur between falling edges from the host. Any BDC command that was in progress

when this timeout occurs is aborted without affecting the memory or operating mode of the target MCU system.

The custom serial protocol requires the debug pod to know the target BDC communication clock speed.

The clock switch (CLKSW) control bit in the BDC status and control register allows the user to select the BDC clock source. The BDC clock source can either be the bus or the alternate BDC clock source.

The BKGD pin can receive a high or low level or transmit a high or low level. The following diagrams show timing for each of these cases. Interface timing is synchronous to clocks in the target BDC, but asynchronous to the external host. The internal BDC clock signal is shown for reference in counting cycles.

Figure 18-2 shows an external host transmitting a logic 1 or 0 to the BKGD pin of a target HCS08 MCU. The host is asynchronous to the target so there is a 0-to-1 cycle delay from the host-generated falling edge to where the target perceives the beginning of the bit time. Ten target BDC clock cycles later, the target senses the bit level on the BKGD pin. Typically, the host actively drives the pseudo-open-drain BKGD pin during host-to-target transmissions to speed up rising edges. Because the target does not drive the BKGD pin during the host-to-target transmission period, there is no need to treat the line as an open-drain signal during this period.

Figure 18-2. BDC Host-to-Target Serial Bit Timing

Figure 18-3 shows the host receiving a logic 1 from the target HCS08 MCU. Because the host is asynchronous to the target MCU, there is a 0-to-1 cycle delay from the host-generated falling edge on BKGD to the perceived start of the bit time in the target MCU. The host holds the BKGD pin low long enough for the target to recognize it (at least two target BDC cycles). The host must release the low drive before the target MCU drives a brief active-high speedup pulse seven cycles after the perceived start of the bit time. The host should sample the bit level about 10 cycles after it started the bit time.

**Figure 18-3. BDC Target-to-Host Serial Bit Timing (Logic 1)**

Figure 18-4 shows the host receiving a logic 0 from the target HCS08 MCU. Because the host is asynchronous to the target MCU, there is a 0-to-1 cycle delay from the host-generated falling edge on BKGD to the start of the bit time as perceived by the target MCU. The host initiates the bit time but the target HCS08 finishes it. Because the target wants the host to receive a logic 0, it drives the BKGD pin low for 13 BDC clock cycles, then briefly drives it high to speed up the rising edge. The host samples the bit level about 10 cycles after starting the bit time.

Figure 18-4. BDM Target-to-Host Serial Bit Timing (Logic 0)

### 18.2.3 BDC Commands

BDC commands are sent serially from a host computer to the BKGD pin of the target HCS08 MCU. All commands and data are sent MSB-first using a custom BDC communications protocol. Active background mode commands require that the target MCU is currently in the active background mode while non-intrusive commands may be issued at any time whether the target MCU is in active background mode or running a user application program.

Table 18-1 shows all HCS08 BDC commands, a shorthand description of their coding structure, and the meaning of each command.

#### Coding Structure Nomenclature

This nomenclature is used in Table 18-1 to describe the coding structure of the BDC commands.

|      |                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------|
|      | Commands begin with an 8-bit hexadecimal command code in the host-to-target direction (most significant bit first) |
| /    | = separates parts of the command                                                                                   |
| d    | = delay 16 target BDC clock cycles                                                                                 |
| AAAA | = a 16-bit address in the host-to-target direction                                                                 |
| RD   | = 8 bits of read data in the target-to-host direction                                                              |
| WD   | = 8 bits of write data in the host-to-target direction                                                             |
| RD16 | = 16 bits of read data in the target-to-host direction                                                             |
| WD16 | = 16 bits of write data in the host-to-target direction                                                            |
| SS   | = the contents of BDCSCR in the target-to-host direction (STATUS)                                                  |
| CC   | = 8 bits of write data for BDCSCR in the host-to-target direction (CONTROL)                                        |
| RBKP | = 16 bits of read data in the target-to-host direction (from BDCBKPT breakpoint register)                          |
| WBKP | = 16 bits of write data in the host-to-target direction (for BDCBKPT breakpoint register)                          |

Table 18-1. BDC Command Summary

| Command Mnemonic | Active BDM/ Non-intrusive | Coding Structure | Description                                                                              |
|------------------|---------------------------|------------------|------------------------------------------------------------------------------------------|
| SYNC             | Non-intrusive             | n/a <sup>1</sup> | Request a timed reference pulse to determine target BDC communication speed              |
| ACK_ENABLE       | Non-intrusive             | D5/d             | Enable acknowledge protocol. Refer to Freescale document order no. HCS08RMv1/D.          |
| ACK_DISABLE      | Non-intrusive             | D6/d             | Disable acknowledge protocol. Refer to Freescale document order no. HCS08RMv1/D.         |
| BACKGROUND       | Non-intrusive             | 90/d             | Enter active background mode if enabled (ignore if ENBDM bit equals 0)                   |
| READ_STATUS      | Non-intrusive             | E4/SS            | Read BDC status from BDCSCR                                                              |
| WRITE_CONTROL    | Non-intrusive             | C4/CC            | Write BDC controls in BDCSCR                                                             |
| READ_BYTE        | Non-intrusive             | E0/AAAA/d/RD     | Read a byte from target memory                                                           |
| READ_BYTE_WS     | Non-intrusive             | E1/AAAA/d/SS/RD  | Read a byte and report status                                                            |
| READ_LAST        | Non-intrusive             | E8/SS/RD         | Re-read byte from address just read and report status                                    |
| WRITE_BYTE       | Non-intrusive             | C0/AAAA/WD/d     | Write a byte to target memory                                                            |
| WRITE_BYTE_WS    | Non-intrusive             | C1/AAAA/WD/d/SS  | Write a byte and report status                                                           |
| READ_BKPT        | Non-intrusive             | E2/RBKP          | Read BDCBKPT breakpoint register                                                         |
| WRITE_BKPT       | Non-intrusive             | C2/WBKP          | Write BDCBKPT breakpoint register                                                        |
| GO               | Active BDM                | 08/d             | Go to execute the user application program starting at the address currently in the PC   |
| TRACE1           | Active BDM                | 10/d             | Trace 1 user instruction at the address in the PC, then return to active background mode |
| TAGGO            | Active BDM                | 18/d             | Same as GO but enable external tagging (HCS08 devices have no external tagging pin)      |
| READ_A           | Active BDM                | 68/d/RD          | Read accumulator (A)                                                                     |
| READ_CCR         | Active BDM                | 69/d/RD          | Read condition code register (CCR)                                                       |
| READ_PC          | Active BDM                | 6B/d/RD16        | Read program counter (PC)                                                                |
| READ_HX          | Active BDM                | 6C/d/RD16        | Read H and X register pair (H:X)                                                         |
| READ_SP          | Active BDM                | 6F/d/RD16        | Read stack pointer (SP)                                                                  |
| READ_NEXT        | Active BDM                | 70/d/RD          | Increment H:X by one then read memory byte located at H:X                                |
| READ_NEXT_WS     | Active BDM                | 71/d/SS/RD       | Increment H:X by one then read memory byte located at H:X. Report status and data.       |
| WRITE_A          | Active BDM                | 48/WD/d          | Write accumulator (A)                                                                    |
| WRITE_CCR        | Active BDM                | 49/WD/d          | Write condition code register (CCR)                                                      |
| WRITE_PC         | Active BDM                | 4B/WD16/d        | Write program counter (PC)                                                               |
| WRITE_HX         | Active BDM                | 4C/WD16/d        | Write H and X register pair (H:X)                                                        |
| WRITE_SP         | Active BDM                | 4F/WD16/d        | Write stack pointer (SP)                                                                 |
| WRITE_NEXT       | Active BDM                | 50/WD/d          | Increment H:X by one, then write memory byte located at H:X                              |
| WRITE_NEXT_WS    | Active BDM                | 51/WD/d/SS       | Increment H:X by one, then write memory byte located at H:X. Also report status.         |

<sup>1</sup> The SYNC command is a special operation that does not have a command code.

The SYNC command is unlike other BDC commands because the host does not necessarily know the correct communications speed to use for BDC communications until after it has analyzed the response to the SYNC command.

To issue a SYNC command, the host:

- Drives the BKGD pin low for at least 128 cycles of the slowest possible BDC clock (The slowest clock is normally the reference oscillator/64 or the self-clocked rate/64.)
- Drives BKGD high for a brief speedup pulse to get a fast rise time (This speedup pulse is typically one cycle of the fastest clock in the system.)
- Removes all drive to the BKGD pin so it reverts to high impedance
- Monitors the BKGD pin for the sync response pulse

The target, upon detecting the SYNC request from the host (which is a much longer low time than would ever occur during normal BDC communications):

- Waits for BKGD to return to a logic high
- Delays 16 cycles to allow the host to stop driving the high speedup pulse
- Drives BKGD low for 128 BDC clock cycles
- Drives a 1-cycle high speedup pulse to force a fast rise time on BKGD
- Removes all drive to the BKGD pin so it reverts to high impedance

The host measures the low time of this 128-cycle sync response pulse and determines the correct speed for subsequent BDC communications. Typically, the host can determine the correct communication speed within a few percent of the actual target speed and the communication protocol can easily tolerate speed errors of several percent.

## 18.2.4 BDC Hardware Breakpoint

The BDC includes one relatively simple hardware breakpoint that compares the CPU address bus to a 16-bit match value in the BDCBKPT register. This breakpoint can generate a forced breakpoint or a tagged breakpoint. A forced breakpoint causes the CPU to enter active background mode at the first instruction boundary following any access to the breakpoint address. The tagged breakpoint causes the instruction opcode at the breakpoint address to be tagged so that the CPU will enter active background mode rather than executing that instruction if and when it reaches the end of the instruction queue. This implies that tagged breakpoints can only be placed at the address of an instruction opcode while forced breakpoints can be set at any address.

The breakpoint enable (BKPTEN) control bit in the BDC status and control register (BDCSCR) is used to enable the breakpoint logic (BKPTEN = 1). When BKPTEN = 0, its default value after reset, the breakpoint logic is disabled and no BDC breakpoints are requested regardless of the values in other BDC breakpoint registers and control bits. The force/tag select (FTS) control bit in BDCSCR is used to select forced (FTS = 1) or tagged (FTS = 0) type breakpoints.

## 18.3 Register Definition

This section contains the descriptions of the BDC registers and control bits.

This section refers to registers and control bits only by their names. A Freescale-provided equate or header file is used to translate these names into the appropriate absolute addresses.

### 18.3.1 BDC Registers and Control Bits

The BDC has two registers:

- The BDC status and control register (BDCSCR) is an 8-bit register containing control and status bits for the background debug controller.
- The BDC breakpoint match register (BDCBKPT) holds a 16-bit breakpoint match address.

These registers are accessed with dedicated serial BDC commands and are not located in the memory space of the target MCU (so they do not have addresses and cannot be accessed by user programs).

Some of the bits in the BDCSCR have write limitations; otherwise, these registers may be read or written at any time. For example, the ENBDM control bit may not be written while the MCU is in active background mode. (This prevents the ambiguous condition of the control bit forbidding active background mode while the MCU is already in active background mode.) Also, the four status bits (BDMACT, WS, WSF, and DVF) are read-only status indicators and can never be written by the WRITE\_CONTROL serial BDC command. The clock switch (CLKSW) control bit may be read or written at any time.

### 18.3.1.1 BDC Status and Control Register (BDCSCR)

This register can be read or written by serial BDC commands (READ\_STATUS and WRITE\_CONTROL) but is not accessible to user programs because it is not located in the normal memory map of the MCU.

|                      | 7     | 6      | 5      | 4   | 3     | 2  | 1   | 0   |
|----------------------|-------|--------|--------|-----|-------|----|-----|-----|

**Table 18-2. BDCSCR Register Field Descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>ENBDM  | <b>Enable BDM (Permit Active Background Mode)</b> — Typically, this bit is written to 1 by the debug host shortly after the beginning of a debug session or whenever the debug host resets the target and remains 1 until a normal reset clears it.<br>0 BDM cannot be made active (non-intrusive commands still allowed)<br>1 BDM can be made active to allow active background mode commands                                                                                                                                                                                                                                                |
| 6<br>BDMACT | <b>Background Mode Active Status</b> — This is a read-only status bit.<br>0 BDM not active (user application program running)<br>1 BDM active and waiting for serial commands                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 5<br>BKPTEN | <b>BDC Breakpoint Enable</b> — If this bit is clear, the BDC breakpoint is disabled and the FTS (force tag select) control bit and BDCBKPT match register are ignored.<br>0 BDC breakpoint disabled<br>1 BDC breakpoint enabled                                                                                                                                                                                                                                                                                                                                                                                                               |
| 4<br>FTS    | <b>Force/Tag Select</b> — When FTS = 1, a breakpoint is requested whenever the CPU address bus matches the BDCBKPT match register. When FTS = 0, a match between the CPU address bus and the BDCBKPT register causes the fetched opcode to be tagged. If this tagged opcode ever reaches the end of the instruction queue, the CPU enters active background mode rather than executing the tagged opcode.<br>0 Tag opcode at breakpoint address and enter active background mode if CPU attempts to execute that instruction<br>1 Breakpoint match forces active background mode at next instruction boundary (address need not be an opcode) |
| 3<br>CLKSW  | <b>Select Source for BDC Communications Clock</b> — CLKSW defaults to 0, which selects the alternate BDC clock source.<br>0 Alternate BDC clock source<br>1 MCU bus clock                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 18-2. BDCSCR Register Field Descriptions (continued)**

| Field    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2<br>WS  | <p><b>Wait or Stop Status</b> — When the target CPU is in wait or stop mode, most BDC commands cannot function. However, the BACKGROUND command can be used to force the target CPU out of wait or stop and into active background mode where all BDC commands work. Whenever the host forces the target MCU into active background mode, the host should issue a READ_STATUS command to check that BDMACT = 1 before attempting other BDC commands.</p> <p>0 Target CPU is running user application code or in active background mode (was not in wait or stop mode when background became active)</p> <p>1 Target CPU is in wait or stop mode, or a BACKGROUND command was used to change from wait or stop to active background mode</p> |
| 1<br>WSF | <p><b>Wait or Stop Failure Status</b> — This status bit is set if a memory access command failed due to the target CPU executing a wait or stop instruction at or about the same time. The usual recovery strategy is to issue a BACKGROUND command to get out of wait or stop mode into active background mode, repeat the command that failed, then return to the user program. (Typically, the host would restore CPU registers and stack values and re-execute the wait or stop instruction.)</p> <p>0 Memory access did not conflict with a wait or stop instruction</p> <p>1 Memory access command failed because the CPU entered wait or stop mode</p>                                                                               |
| 0<br>DVF | <p><b>Data Valid Failure Status</b> — This status bit is not used in the MC9S08LG32 series because it does not have any slow access memory.</p> <p>0 Memory access did not conflict with a slow memory access</p> <p>1 Memory access command failed because CPU was not finished with a slow memory access</p>                                                                                                                                                                                                                                                                                                                                                                                                                              |

### 18.3.1.2 BDC Breakpoint Match Register (BDCBKPT)

This 16-bit register holds the address for the hardware breakpoint in the BDC. The BKPTEN and FTS control bits in BDCSCR are used to enable and configure the breakpoint logic. Dedicated serial BDC commands (READ\_BKPT and WRITE\_BKPT) are used to read and write the BDCBKPT register but is not accessible to user programs because it is not located in the normal memory map of the MCU. Breakpoints are normally set while the target MCU is in active background mode before running the user application program. For additional information about setup and use of the hardware breakpoint logic in the BDC, refer to [Section 18.2.4, “BDC Hardware Breakpoint.”](#)

### 18.3.2 System Background Debug Force Reset Register (SBDFR)

This register contains a single write-only control bit. A serial background mode command such as WRITE\_BYTE must be used to write to SBDFR. Attempts to write this register from a user program are ignored. Reads always return 0x00.

<sup>1</sup> BDFR is writable only through serial background mode debug commands, not from user programs.

Figure 18-6. System Background Debug Force Reset Register (SBDFR)

Table 18-3. SBDFR Register Field Description

| Field     | Description                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>BDFR | <b>Background Debug Force Reset</b> — A serial active background mode command such as WRITE_BYTE allows an external debug host to force a target system reset. Writing 1 to this bit forces an MCU reset. This bit cannot be written from a user program. |

## Chapter 19

# Debug Module (DBG) (64K)

### 19.1 Introduction

The DBG module implements an on-chip ICE (in-circuit emulation) system and allows non-intrusive debug of application software by providing an on-chip trace buffer with flexible triggering capability. The trigger also can provide extended breakpoint capacity. The on-chip ICE system is optimized for the HCS08 8-bit architecture and supports 64K bytes or 128K bytes of memory space.

#### 19.1.1 Features

The on-chip ICE system includes these distinctive features:

- Three comparators (A, B, and C) with ability to match addresses in 64K space
  - Dual mode, Comparators A and B used to compare addresses
  - Full mode, Comparator A compares address and Comparator B compares data
  - Can be used as triggers and/or breakpoints
  - Comparator C can be used as a normal hardware breakpoint
  - Loop1 capture mode, Comparator C is used to track most recent COF event captured into FIFO
- Tag and Force type breakpoints
- Nine trigger modes
  - A
  - A Or B
  - A Then B
  - A And B, where B is data (Full mode)
  - A And Not B, where B is data (Full mode)
  - Event Only B, store data
  - A Then Event Only B, store data
  - Inside Range,  $A \leq \text{Address} \leq B$
  - Outside Range,  $\text{Address} < A$  or  $\text{Address} > B$
- FIFO for storing change of flow information and event only data
  - Source address of conditional branches taken
  - Destination address of indirect JMP and JSR instruction
  - Destination address of interrupts, RTI, RTC, and RTS instruction
  - Data associated with Event B trigger modes

- Ability to End-trace until reset and Begin-trace from reset

## 19.1.2 Modes of Operation

The on-chip ICE system can be enabled in all MCU functional modes. The DBG module is disabled if the MCU is secure. The DBG module comparators are disabled when executing a Background Debug Mode (BDM) command.

## 19.1.3 Block Diagram

Figure 19-1 shows the structure of the DBG module.

1. In 64K versions of this module there are only 16 address lines [15:0], there are no core\_cpu\_aob\_14\_t2, core\_cpu\_aob\_15\_t2, core\_ppage\_t2[2:0], and ppage\_sel signals.

**Figure 19-1. DBG Block Diagram**

## 19.2 Signal Description

The DBG module contains no external signals.

## 19.3 Memory Map and Registers

This section provides a detailed description of all DBG registers accessible to the end user.

### 19.3.1 Module Memory Map

Table 19-1 shows the registers contained in the DBG module.

**Table 19-1. Module Memory Map**

| Address       | Use                                            | Access     |
|---------------|------------------------------------------------|------------|
| Base + \$0000 | Debug Comparator A High Register (DBGCAH)      | Read/write |
| Base + \$0001 | Debug Comparator A Low Register (DBGCAL)       | Read/write |
| Base + \$0002 | Debug Comparator B High Register (DBGCBH)      | Read/write |
| Base + \$0003 | Debug Comparator B Low Register (DBGCBL)       | Read/write |
| Base + \$0004 | Debug Comparator C High Register (DBGCCH)      | Read/write |
| Base + \$0005 | Debug Comparator C Low Register (DBGCCL)       | Read/write |
| Base + \$0006 | Debug FIFO High Register (DBGFH)               | Read only  |
| Base + \$0007 | Debug FIFO Low Register (DBGFL)                | Read only  |
| Base + \$0008 | Debug Comparator A Extension Register (DBGCAH) | Read/write |
| Base + \$0009 | Debug Comparator B Extension Register (DBGCBH) | Read/write |
| Base + \$000A | Debug Comparator C Extension Register (DBGCCX) | Read/write |
| Base + \$000B | reserved                                       | Read only  |
| Base + \$000C | Debug Control Register (DBGC)                  | Read/write |
| Base + \$000D | Debug Trigger Register (DBGT)                  | Read/write |
| Base + \$000E | Debug Status Register (DBGS)                   | Read only  |
| Base + \$000F | Debug FIFO Count Register (DBGCNT)             | Read only  |

Table 19-2 shows the register bit summary for the registers contained in the DBG module.

**Table 19-2. Register Bit Summary (Sheet 1 of 2)**

|                | 7      | 6      | 5      | 4      | 3      | 2      | 1     | 0     |

## 19.3.2 Register Descriptions

This section consists of the DBG register descriptions in address order.

### NOTE

For all registers below, consider: U = Unchanged, bit maintain its value after reset.

### 19.3.2.1 Debug Comparator A High Register (DBGCAH)

Module Base + 0x0000

|                            | 7      | 6      | 5      | 4      | 3      | 2      | 1     | 0     |
|----------------------------|--------|--------|--------|--------|--------|--------|-------|-------|
| R                          | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9 | Bit 8 |
| W                          |        |        |        |        |        |        |       |       |
| POR or non-end-run         | 1      | 1      | 1      | 1      | 1      | 1      | 1     | 1     |
| Reset end-run <sup>1</sup> | U      | U      | U      | U      | U      | U      | U     | U     |

**Figure 19-2. Debug Comparator A High Register (DBGCAH)**

<sup>1</sup> In the case of an end-trace to reset where DBGGEN=1 and BEGIN=0, the bits in this register do not change after reset.

**Table 19-3. DBGCAH Field Descriptions**

| Field     | Description                                                                                                                                                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 19.3.2.6 Debug Comparator C Low Register (DBGCCCL)

Module Base + 0x0005

|                            | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|----------------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| R                          | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
| W                          |       |       |       |       |       |       |       |       |
| POR or non-end-run         | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |
| Reset end-run <sup>1</sup> | U     | U     | U     | U     | U     | U     | U     | U     |

**Figure 19-7. Debug Comparator C Low Register (DBGCCCL)**

<sup>1</sup> In the case of an end-trace to reset where DBGEN=1 and BEGIN=0, the bits in this register do not change after reset.

**Table 19-8. DBGCCCL Field Descriptions**

| Field    | Description                                                                                                                                                                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bits 7–0 | <b>Comparator C Low Compare Bits</b> — The Comparator C Low compare bits control whether Comparator C will compare the address bus bits [7:0] to a logic 1 or logic 0.<br>0 Compare corresponding address bit to a logic 0<br>1 Compare corresponding address bit to a logic 1 |

### 19.3.2.7 Debug FIFO High Register (DBGFHH)

Module Base + 0x0006

|                            | 7      | 6      | 5      | 4      | 3      | 2      | 1     | 0     |
|----------------------------|--------|--------|--------|--------|--------|--------|-------|-------|
| R                          | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9 | Bit 8 |
| W                          |        |        |        |        |        |        |       |       |
| POR or non-end-run         | 0      | 0      | 0      | 0      | 0      | 0      | 0     | 0     |
| Reset end-run <sup>1</sup> | U      | U      | U      | U      | U      | U      | U     | U     |

 = Unimplemented or Reserved

**Figure 19-8. Debug FIFO High Register (DBGFHH)**

<sup>1</sup> In the case of an end-trace to reset where DBGEN=1 and BEGIN=0, the bits in this register do not change after reset.

**Table 19-9. DBGFHH Field Descriptions**

| Field     | Description                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bits 15–8 | <b>FIFO High Data Bits</b> — The FIFO High data bits provide access to bits [15:8] of data in the FIFO. This register is not used in event only modes and will read a \$00 for valid FIFO words. |

### 19.3.2.8 Debug FIFO Low Register (DBGFL)

Module Base + 0x0007

|                            | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|----------------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| R                          | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |
| W                          |       |       |       |       |       |       |       |       |
| POR or non-end-run         | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |
| Reset end-run <sup>1</sup> | U     | U     | U     | U     | U     | U     | U     | U     |
|                            |       |       |       |       |       |       |       |       |

 = Unimplemented or Reserved

**Figure 19-9. Debug FIFO Low Register (DBGFL)**

<sup>1</sup> In the case of an end-trace to reset where DBGGEN=1 and BEGIN=0, the bits in this register do not change after reset.

**Table 19-10. DBGFL Field Descriptions**

| Field    | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bits 7–0 | <b>FIFO Low Data Bits</b> — The FIFO Low data bits contain the least significant byte of data in the FIFO. When reading FIFO words, read DBGFX and DBGFH before reading DBGFL because reading DBGFL causes the FIFO pointers to advance to the next FIFO location. In event-only modes, there is no useful information in DBGFX and DBGFH so it is not necessary to read them before reading DBGFL. |

### 19.3.2.9 Debug Comparator A Extension Register (DBGCAx)

Module Base + 0x0008

|                            | 7     | 6   | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------------------|-------|-----|---|---|---|---|---|---|
| R                          | RWAEN | RWA | 0 | 0 | 0 | 0 | 0 | 0 |
| W                          |       |     |   |   |   |   |   |   |
| POR or non-end-run         | 0     | 0   | 0 | 0 | 0 | 0 | 0 | 0 |
| Reset end-run <sup>1</sup> | U     | U   | U | 0 | 0 | 0 | 0 | U |
|                            |       |     |   |   |   |   |   |   |

 = Unimplemented or Reserved

**Figure 19-10. Debug Comparator A Extension Register (DBGCAx)**

<sup>1</sup> In the case of an end-trace to reset where DBGGEN=1 and BEGIN=0, the bits in this register do not change after reset.

Table 19-11. DBGCAx Field Descriptions

| Field      | Description                                                                                                                                                                                                                       |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Table 19-18. DBGS Field Descriptions**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3–0<br>CNT | <b>FIFO Valid Count Bits</b> — The CNT bits indicate the amount of valid data stored in the FIFO. <a href="#">Table 19-16</a> shows the correlation between the CNT bits and the amount of valid data in FIFO. The CNT will stop after a count to eight even if more data is being stored in the FIFO. The CNT bits are cleared when the DBG module is armed, and the count is incremented each time a new word is captured into the FIFO. The host development system is responsible for checking the value in CNT[3:0] and reading the correct number of words from the FIFO because the count does not decrement as data is read out of the FIFO at the end of a trace run. |

**Table 19-19. CNT Bits**

| CNT Value | Meaning       |
|-----------|---------------|
| 0000      | No data valid |
| 0001      | 1 word valid  |
| 0010      | 2 words valid |
| 0011      | 3 words valid |
| 0100      | 4 words valid |
| 0101      | 5 words valid |
| 0110      | 6 words valid |
| 0111      | 7 words valid |
| 1000      | 8 words valid |

## 19.4 Functional Description

This section provides a complete functional description of the on-chip ICE system. The DBG module is enabled by setting the DBGGEN bit in the DBGCR register. Enabling the module allows the arming, triggering and storing of data in the FIFO. The DBG module is made up of three main blocks, the Comparators, Trigger Break Control logic and the FIFO.

### 19.4.1 Comparator

The DBG module contains three comparators, A, B, and C. Comparator A compares the core address bus with the address stored in the DBGCAH and DBGCAL registers. Comparator B compares the core address bus with the address stored in the DBGCBH and DBGCBL registers except in full mode, where it compares the data buses to the data stored in the DBGCBL register. Comparator C compares the core address bus with the address stored in the DBGCCCH and DBGCCCL registers. Matches on Comparators A, B, and C are signaled to the Trigger Break Control (TBC) block.

#### 19.4.1.1 RWA and RWAEN in Full Modes

In full modes ("A And B" and "A And Not B") RWAEN and RWA are used to select read or write comparisons for both comparators A and B. To select write comparisons and the write data bus in Full Modes set RWAEN=1 and RWA=0, otherwise read comparisons and the read data bus will be selected. The RWBEN and RWB bits are not used and will be ignored in Full Modes.

#### 19.4.1.2 Comparator C in LOOP1 Capture Mode

Normally comparator C is used as a third hardware breakpoint and is not involved in the trigger logic for the on-chip ICE system. In this mode, it compares the core address bus with the address stored in the DBGCCCH and DBGCCCL registers. However, in LOOP1 capture mode, comparator C is managed by logic in the DBG module to track the address of the most recent change-of-flow event that was captured into the FIFO buffer. In LOOP1 capture mode, comparator C is not available for use as a normal hardware breakpoint.

When the ARM and DBGGEN bits are set to one in LOOP1 capture mode, comparator C value registers are cleared to prevent the previous contents of these registers from interfering with the LOOP1 capture mode operation. When a COF event is detected, the address of the event is compared to the contents of the DBGCCCH and DBGCCCL registers to determine whether it is the same as the previous COF entry in the capture FIFO. If the values match, the capture is inhibited to prevent the FIFO from filling up with duplicate entries. If the values do not match, the COF event is captured into the FIFO and the DBGCCCH and DBGCCCL registers are updated to reflect the address of the captured COF event.

### 19.4.2 Breakpoints

A breakpoint request to the CPU at the end of a trace run can be created if the BRKEN bit in the DBGCR register is set. The value of the BEGIN bit in DBGTR register determines when the breakpoint request to the CPU will occur. If the BEGIN bit is set, begin-trigger is selected and the breakpoint request will not occur until the FIFO is filled with 8 words. If the BEGIN bit is cleared, end-trigger is selected and the breakpoint request will occur immediately at the trigger cycle.

When traditional hardware breakpoints from comparators A or B are desired, set BEGIN=0 to select an end-trace run and set the trigger mode to either 0x0 (A-only) or 0x1 (A OR B) mode.

There are two types of breakpoint requests supported by the DBG module, tag-type and force-type. Tagged breakpoints are associated with opcode addresses and allow breaking just before a specific instruction executes. Force breakpoints are not associated with opcode addresses and allow breaking at the next instruction boundary. The TAG bit in the DBGC register determines whether CPU breakpoint requests will be a tag-type or force-type breakpoints. When TAG=0, a force-type breakpoint is requested and it will take effect at the next instruction boundary after the request. When TAG=1, a tag-type breakpoint is registered into the instruction queue and the CPU will break if/when this tag reaches the head of the instruction queue and the tagged instruction is about to be executed.

### 19.4.2.1 Hardware Breakpoints

Comparators A, B, and C can be used as three traditional hardware breakpoints whether the on-chip ICE real-time capture function is required or not. To use any breakpoint or trace run capture functions set DBGEN=1. BRKEN and TAG affect all three comparators. When BRKEN=0, no CPU breakpoints are enabled. When BRKEN=1, CPU breakpoints are enabled and the TAG bit determines whether the breakpoints will be tag-type or force-type breakpoints. To use comparators A and B as hardware breakpoints, set DBGT=0x81 for tag-type breakpoints and 0x01 for force-type breakpoints. This sets up an end-type trace with trigger mode “A OR B”.

Comparator C is not involved in the trigger logic for the on-chip ICE system.

### 19.4.3 Trigger Selection

The TRGSEL bit in the DBGT register is used to determine the triggering condition of the on-chip ICE system. TRGSEL applies to both trigger A and B except in the event only trigger modes. By setting the TRGSEL bit, the comparators will qualify a match with the output of opcode tracking logic. The opcode tracking logic is internal to each comparator and determines whether the CPU executed the opcode at the compare address. With the TRGSEL bit cleared a comparator match is all that is necessary for a trigger condition to be met.

#### NOTE

If the TRGSEL is set, the address stored in the comparator match address registers must be an opcode address for the trigger to occur.

### 19.4.4 Trigger Break Control (TBC)

The TBC is the main controller for the DBG module. Its function is to decide whether data should be stored in the FIFO based on the trigger mode and the match signals from the comparator. The TBC also determines whether a request to break the CPU should occur.

The TAG bit in DBGC controls whether CPU breakpoints are treated as tag-type or force-type breakpoints. The TRGSEL bit in DBGT controls whether a comparator A or B match is further qualified by opcode tracking logic. Each comparator has a separate circuit to track opcodes because the comparators could

correspond to separate instructions that could be propagating through the instruction queue at the same time.

In end-type trace runs (BEGIN=0), when the comparator registers match, including the optional R/W match, this signal goes to the CPU break logic where BRKEN determines whether a CPU break is requested and the TAG control bit determines whether the CPU break will be a tag-type or force-type breakpoint. When TRGSEL is set, the R/W qualified comparator match signal also passes through the opcode tracking logic. If/when it propagates through this logic, it will cause a trigger to the ICE logic to begin or end capturing information into the FIFO. In the case of an end-type (BEGIN=0) trace run, the qualified comparator signal stops the FIFO from capturing any more information.

If a CPU breakpoint is also enabled, you would want TAG and TRGSEL to agree so that the CPU break occurs at the same place in the application program as the FIFO stopped capturing information. If TRGSEL was 0 and TAG was 1 in an end-type trace run, the FIFO would stop capturing as soon as the comparator address matched, but the CPU would continue running until a TAG signal could propagate through the CPU's instruction queue which could take a long time in the case where changes of flow caused the instruction queue to be flushed. If TRGSEL was one and TAG was zero in an end-type trace run, the CPU would break before the comparator match signal could propagate through the opcode tracking logic to end the trace run.

In begin-type trace runs (BEGIN=1), the start of FIFO capturing is triggered by the qualified comparator signals, and the CPU breakpoint (if enabled by BRKEN=1) is triggered when the FIFO becomes full. Since this FIFO full condition does not correspond to the execution of a tagged instruction, it would not make sense to use TAG=1 for a begin-type trace run.

#### 19.4.4.1 Begin- and End-Trigger

The definition of begin- and end-trigger as used in the DBG module are as follows:

- Begin-trigger: Storage in FIFO occurs after the trigger and continues until 8 locations are filled.
- End-trigger: Storage in FIFO occurs until the trigger with the least recent data falling out of the FIFO if more than 8 words are collected.

#### 19.4.4.2 Arming the DBG Module

Arming occurs by enabling the DBG module by setting the DBGEN bit and by setting the ARM bit in the DBGCR register. The ARM bit in the DBGCR register and the ARMF bit in the DBGS register are cleared when the trigger condition is met in end-trigger mode or when the FIFO is filled in begin-trigger mode. In the case of an end-trace where DBGEN=1 and BEGIN=0, ARM and ARMF are cleared by any reset to end the trace run that was in progress. The ARMF bit is also cleared if ARM is written to zero or when the DBGEN bit is low. The TBC logic determines whether a trigger condition has been met based on the trigger mode and the trigger selection.

#### 19.4.4.3 Trigger Modes

The on-chip ICE system supports nine trigger modes. The trigger modes are encoded as shown in [Table 19-16](#). The trigger mode is used as a qualifier for either starting or ending the storing of data in the FIFO. When the match condition is met, the appropriate flag AF or BF is set in DBGS register. Arming

the DBG module clears the AF, BF, and CF flags in the DBGS register. In all trigger modes except for the event only modes change of flow addresses are stored in the FIFO. In the event only modes only the value on the data bus at the trigger event B comparator match address will be stored.

#### **19.4.4.3.1 A Only**

In the A Only trigger mode, if the match condition for A is met, the AF flag in the DBGS register is set.

#### **19.4.4.3.2 A Or B**

In the A Or B trigger mode, if the match condition for A or B is met, the corresponding flag(s) in the DBGS register are set.

#### **19.4.4.3.3 A Then B**

In the A Then B trigger mode, the match condition for A must be met before the match condition for B is compared. When the match condition for A or B is met, the corresponding flag in the DBGS register is set.

#### **19.4.4.3.4 Event Only B**

In the Event Only B trigger mode, if the match condition for B is met, the BF flag in the DBGS register is set. The Event Only B trigger mode is considered a begin-trigger type and the BEGIN bit in the DBGT register is ignored.

#### **19.4.4.3.5 A Then Event Only B**

In the A Then Event Only B trigger mode, the match condition for A must be met before the match condition for B is compared. When the match condition for A or B is met, the corresponding flag in the DBGS register is set. The A Then Event Only B trigger mode is considered a begin-trigger type and the BEGIN bit in the DBGT register is ignored.

#### **19.4.4.3.6 A And B (Full Mode)**

In the A And B trigger mode, Comparator A compares to the address bus and Comparator B compares to the data bus. In the A and B trigger mode, if the match condition for A and B happen on the same bus cycle, both the AF and BF flags in the DBGS register are set. If a match condition on only A or only B happens, no flags are set.

For Breakpoint tagging operation with an end-trigger type trace, only matches from Comparator A will be used to determine if the Breakpoint conditions are met and Comparator B matches will be ignored.

#### **19.4.4.3.7 A And Not B (Full Mode)**

In the A And Not B trigger mode, comparator A compares to the address bus and comparator B compares to the data bus. In the A And Not B trigger mode, if the match condition for A and Not B happen on the same bus cycle, both the AF and BF flags in the DBGS register are set. If a match condition on only A or only Not B occur no flags are set.

For Breakpoint tagging operation with an end-trigger type trace, only matches from Comparator A will be used to determine if the Breakpoint conditions are met and Comparator B matches will be ignored.

#### 19.4.4.3.8 Inside Range, $A \leq \text{address} \leq B$

In the Inside Range trigger mode, if the match condition for A and B happen on the same bus cycle, both the AF and BF flags in the DBGS register are set. If a match condition on only A or only B occur no flags are set.

#### 19.4.4.3.9 Outside Range, $\text{address} < A$ or $\text{address} > B$

In the Outside Range trigger mode, if the match condition for A or B is met, the corresponding flag in the DBGS register is set.

The four control bits BEGIN and TRGSEL in DBGT, and BRKEN and TAG in DBGCR, determine the basic type of debug run as shown in Table 1.21. Some of the 16 possible combinations are not used (refer to the notes at the end of the table).

**Table 19-20. Basic Types of Debug Runs**

| BEGIN | TRGSEL | BRKEN | TAG              | Type of Debug Run                                                                  |
|-------|--------|-------|------------------|------------------------------------------------------------------------------------|
| 0     | 0      | 0     | x <sup>(1)</sup> | Fill FIFO until trigger address (No CPU breakpoint - keep running)                 |
| 0     | 0      | 1     | 0                | Fill FIFO until trigger address, then force CPU breakpoint                         |
| 0     | 0      | 1     | 1                | Do not use <sup>(2)</sup>                                                          |
| 0     | 1      | 0     | x <sup>(1)</sup> | Fill FIFO until trigger opcode about to execute (No CPU breakpoint - keep running) |
| 0     | 1      | 1     | 0                | Do not use <sup>(3)</sup>                                                          |
| 0     | 1      | 1     | 1                | Fill FIFO until trigger opcode about to execute (trigger causes CPU breakpoint)    |
| 1     | 0      | 0     | x <sup>(1)</sup> | Start FIFO at trigger address (No CPU breakpoint - keep running)                   |
| 1     | 0      | 1     | 0                | Start FIFO at trigger address, force CPU breakpoint when FIFO full                 |
| 1     | 0      | 1     | 1                | Do not use <sup>(4)</sup>                                                          |
| 1     | 1      | 0     | x <sup>(1)</sup> | Start FIFO at trigger opcode (No CPU breakpoint - keep running)                    |
| 1     | 1      | 1     | 0                | Start FIFO at trigger opcode, force CPU breakpoint when FIFO full                  |
| 1     | 1      | 1     | 1                | Do not use <sup>(4)</sup>                                                          |

<sup>1</sup> When BRKEN = 0, TAG is do not care (x in the table).

<sup>2</sup> In end trace configurations (BEGIN = 0) where a CPU breakpoint is enabled (BRKEN = 1), TRGSEL should agree with TAG. In this case, where TRGSEL = 0 to select no opcode tracking qualification and TAG = 1 to specify a tag-type CPU breakpoint, the CPU breakpoint would not take effect until sometime after the FIFO stopped storing values. Depending on program loops or interrupts, the delay could be very long.

<sup>3</sup> In end trace configurations (BEGIN = 0) where a CPU breakpoint is enabled (BRKEN = 1), TRGSEL should agree with TAG. In this case, where TRGSEL = 1 to select opcode tracking qualification and TAG = 0 to specify a force-type CPU breakpoint, the CPU breakpoint would erroneously take effect before the FIFO stopped storing values and the debug run would not complete normally.

<sup>4</sup> In begin trace configurations (BEGIN = 1) where a CPU breakpoint is enabled (BRKEN = 1), TAG should not be set to 1. In begin trace debug runs, the CPU breakpoint corresponds to the FIFO full condition which does not correspond to a taggable instruction fetch.

## 19.4.5 FIFO

The FIFO is an eight word deep FIFO. In all trigger modes except for event only, the data stored in the FIFO will be change of flow addresses. In the event only trigger modes only the data bus value corresponding to the event is stored. In event only trigger modes, the high byte of the valid data from the FIFO will always read a 0x00.

### 19.4.5.1 Storing Data in FIFO

In all trigger modes except for the event only modes, the address stored in the FIFO will be determined by the change of flow indicators from the core. The signal `core_cof[1]` indicates the current core address is the destination address of an indirect JSR or JMP instruction, or a RTS or RTI instruction or interrupt vector and the destination address should be stored. The signal `core_cof[0]` indicates that a conditional branch was taken and that the source address of the conditional branch should be stored.

### 19.4.5.2 Storing with Begin-Trigger

Storing with Begin-Trigger can be used in all trigger modes. Once the DBG module is enabled and armed in the begin-trigger mode, data is not stored in the FIFO until the trigger condition is met. Once the trigger condition is met the DBG module will remain armed until 8 words are stored in the FIFO. If the `core_cof[1]` signal becomes asserted, the current address is stored in the FIFO. If the `core_cof[0]` signal becomes asserted, the address registered during the previous last cycle is decremented by two and stored in the FIFO.

### 19.4.5.3 Storing with End-Trigger

Storing with End-Trigger cannot be used in event-only trigger modes. Once the DBG module is enabled and armed in the end-trigger mode, data is stored in the FIFO until the trigger condition is met. If the `core_cof[1]` signal becomes asserted, the current address is stored in the FIFO. If the `core_cof[0]` signal becomes asserted, the address registered during the previous last cycle is decremented by two and stored in the FIFO. When the trigger condition is met, the ARM and ARMF will be cleared and no more data will be stored. In non-event only end-trigger modes, if the trigger is at a change of flow address the trigger event will be stored in the FIFO.

### 19.4.5.4 Reading Data from FIFO

The data stored in the FIFO can be read using BDM commands provided the DBG module is enabled and not armed (DBGEN=1 and ARM=0). The FIFO data is read out first-in-first-out. By reading the CNT bits in the DBG CNT register at the end of a trace run, the number of valid words can be determined. The FIFO data is read by optionally reading the DBG FH register followed by the DBG FL register. Each time the DBG FL register is read the FIFO is shifted to allow reading of the next word however the count does not decrement. In event-only trigger modes where the FIFO will contain only the data bus values stored, to read the FIFO only DBG FL needs to be accessed.

The FIFO is normally only read while ARM and ARMF=0, however reading the FIFO while the DBG module is armed will return the data value in the oldest location of the FIFO and the TBC will not allow

the FIFO to shift. This action could cause a valid entry to be lost because the unexpected read blocked the FIFO advance.

If the DBG module is not armed and the DBGFL register is read, the TBC will store the current opcode address. Through periodic reads of the DBGFL and DBGFL registers while the DBG module is not armed, host software can provide a histogram of program execution. This is called profile mode.

### 19.4.6 Interrupt Priority

When TRGSEL is set and the DBG module is armed to trigger on begin- or end-trigger types, a trigger is not detected in the condition where a pending interrupt occurs at the same time that a target address reaches the top of the instruction pipe. In these conditions, the pending interrupt has higher priority and code execution switches to the interrupt service routine.

When TRGSEL is clear and the DBG module is armed to trigger on end-trigger types, the trigger event is detected on a program fetch of the target address, even when an interrupt becomes pending on the same cycle. In these conditions, the pending interrupt has higher priority, the exception is processed by the core and the interrupt vector is fetched. Code execution is halted before the first instruction of the interrupt service routine is executed. In this scenario, the DBG module will have cleared ARM without having recorded the change-of-flow that occurred as part of the interrupt exception. Note that the stack will hold the return addresses and can be used to reconstruct execution flow in this scenario.

When TRGSEL is clear and the DBG module is armed to trigger on begin-trigger types, the trigger event is detected on a program fetch of the target address, even when an interrupt becomes pending on the same cycle. In this scenario, the FIFO captures the change of flow event. Because the system is configured for begin-trigger, the DBG remains armed and does not break until the FIFO has been filled by subsequent change of flow events.

## 19.5 Resets

The DBG module cannot cause an MCU reset.

There are two different ways this module will respond to reset depending upon the conditions before the reset event. If the DBG module was setup for an end trace run with DBGGEN=1 and BEGIN=0, ARM, ARMF, and BRKEN are cleared but the reset function on most DBG control and status bits is overridden so a host development system can read out the results of the trace run after the MCU has been reset. In all other cases including POR, the DBG module controls are initialized to start a begin trace run starting from when the reset vector is fetched. The conditions for the default begin trace run are:

- DBGCAH=0xFF, DBGCAL=0xFE so comparator A is set to match when the 16-bit CPU address 0xFFFFE appears during the reset vector fetch
- DBGCR=0xC0 to enable and arm the DBG module
- DBGT=0x40 to select a force-type trigger, a BEGIN trigger, and A-only trigger mode

## 19.6 Interrupts

The DBG contains no interrupt source.
