| NIT           | <p><b>NIT related status</b></p> <p><i>vSS!ValidFrame</i> - always 0</p> <p><i>vSS!ContentError</i> - content error occurred while receiving</p> <p><i>vSS!SyntaxError</i> - syntax error occurred while receiving</p> <p><i>vSS!BViolation</i> - boundary violation while receiving</p> <p><i>vSS!TxConflict</i> - always 0</p> <p><b>received frame related status</b></p> <p><i>see static/dynamic slot</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 50.7.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR\_CASERCR) and Channel B Status Error Counter Register (FR\_CBSECR), incremented by one, if at least one of four slot status error bits, *vSS!SyntaxError*, *vSS!ContentError*, *vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap round after they have reached the maximum value.

### 50.7.18.2 Protocol Status Registers

The Protocol Status Register 2 (FR\_PSR2) provides slot status information about the Network Idle Time NIT and the Symbol Window. The Protocol Status Register 3 (FR\_PSR3) provides aggregated slot status information.

### 50.7.18.3 Slot Status Registers

The eight slot status registers, Slot Status Registers (FR\_SSR0–FR\_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status related and received frame / symbol related status information, as given in [Table 50-54](#), except of the *first valid* indicator for non-transmission slots.

### 50.7.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR\_SSCR0–FR\_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR\_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in the figure below.

**Figure 50-32. Slot Status Counting and FR\_SSCRn Update**

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR\_SSCRn register reflects, in cycle n, the status of the NIT of cycle n-2, and the status of all static slots and the symbol window of cycle n-1.

The increment condition for each slot status counter consists of two parts, the frame related condition part and the slot related condition part. The internal slot status counter FR\_SSCRn\_INT is incremented if at least one of the conditions is fulfilled:

1. frame related condition:

$$(FR\_SSCCRn[VFR] \mid FR\_SSCCRn[SYF] \mid FR\_SSCCRn[NUF] \mid FR\_SSCCRn[SUF]) // \text{count on frame condition}$$

= 1;

and

$$((\sim FR\_SSCCRn[VFR] \mid vSS!ValidFrame) \& // \text{valid frame restriction}$$

$$(\sim FR\_SSCCRn[SYF] \mid vRF!Header!SyFIndicator) \& // \text{sync frame indicator restriction}$$

$$(\sim FR\_SSCCRn[NUF] \mid \sim vRF!Header!NFIndicator) \& // \text{null frame indicator restriction}$$

$$(\sim FR\_SSCCRn[SUF] \mid vRF!Header!SuFIndicator)) // \text{startup frame indicator restriction}$$

= 1;

**Note**

The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus it is required to set the VFR always, whenever count on frame condition is used.

slot related condition:

*((FR\_SSCCRn[STATUSMASK[3]] & vSS!ContentError) | // increment on content error*

*(FR\_SSCCRn[STATUSMASK[2]] & vSS!SyntaxError) | // increment on syntax error*

*(FR\_SSCCRn[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation*

*(FR\_SSCCRn[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict*

*= 1;*

If the slot status counter is in single cycle mode, i.e. FR\_SSCCRn[MCY] = 0, the internal slot status counter FR\_SSCCRn\_INT is reset at each cycle start. If the slot status counter is in the multicycle mode, i.e. FR\_SSCCRn[MCY] = 1, the counter is not reset and incremented, until the maximum value is reached.

### 50.7.18.5 Message Buffer Slot Status Field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in [Table 50-54](#) for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update Sections in [Individual Message Buffer Configuration Data](#).

### 50.7.19 System Bus Access

This section provides a description of the system bus accesses failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in [System Bus Access Failure Types](#).

The behavior of the CC after the occurrence of a system bus access failure is described in [System Bus Access Failure Response](#).

### 50.7.19.1 System Bus Access Failure Types

This section describes the two types of system bus access failures.

#### 50.7.19.1.1 System Bus Illegal Address Access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions which are treated as a system bus illegal address access:

- The system bus subsystem detects an CC access to an illegal system memory address.
- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see [CHI LRAM Error Response after CC Read](#)).

If a system bus illegal address access is detected, the CC sets the ILSA\_EF flag in the CHI Error Flag Register (FR\_CHIERFR).

#### 50.7.19.1.2 System Bus Access Timeout

A system bus access timeout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see [Configure System Memory Access Time-Out Register \(FR\\_SYMATOR\)](#)).

If a system bus access timeout is detected, the CC sets the SBCF\_EF flag in the CHI Error Flag Register (FR\_CHIERFR).

### 50.7.19.2 System Bus Access Failure Response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR\_MCR).

#### 50.7.19.2.1 Continue after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR\_MCR) is 0, the CC will continue its operation after the occurrence of the system bus access failure, but will not generate any system bus accesses until the start of the next communication cycle. Since no

data are read from or written to the FlexRay memory area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated with the remaining header and frame data are replaced by all zeros. Depending on the point in time this can affect the PPI bit, the Header CRC, the Payload Length in case of a dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted and received, except for the key slot, where a sync or startup null-frame is transmitted, if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

#### **50.7.19.2.2 Freeze after System Bus Access Failure**

If the SBFF bit in the Module Configuration Register (FR\_MCR) is set to 1, the CC will go into the freeze mode immediately after the occurrence of one of the system bus access failures.

### **50.7.20 Interrupt Support**

The CC provides 108 individual interrupt sources and five combined interrupt sources.

#### **50.7.20.1 Individual Interrupt Sources**

Message buffer interrupts are discussed in this section.

##### **50.7.20.1.1 Message Buffer Interrupts**

The CC provides 64 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR\_MBCCSRn[MBIF] and an interrupt enable bit FR\_MBCCSRn[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

##### **50.7.20.1.2 FIFO Interrupts**

The CC provides 2 FIFO interrupt sources.

Each of the 2 FIFO provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR\_GIFER[FAFBIF], FR\_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR\_GIFER) if the corresponding Receive FIFO fill level exceeds the defined watermark.

### 50.7.20.1.3 Wakeup Interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR\_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR\_GIFER[WUPIE] is asserted.

### 50.7.20.1.4 Protocol Interrupts

The CC provides 25 interrupt sources for protocol related events. For details, see Protocol Interrupt Flag Register 0 (FR\_PIFR0) and Protocol Interrupt Flag Register 1 (FR\_PIFR1). Each interrupt source has its own interrupt enable bit.

### 50.7.20.1.5 CHI Interrupts

The CC provides 16 interrupt sources for CHI related error events. For details, see CHI Error Flag Register (FR\_CHIERFR). There is one common interrupt enable bit FR\_GIFER[CHIE] for all CHI error interrupt sources.

## 50.7.20.2 Combined Interrupt Sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

### 50.7.20.2.1 Receive Message Buffer Interrupt

The Receive Message Buffer Interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR\_GIFER[RBIE] is set.

### 50.7.20.2.2 Transmit Message Buffer Interrupt

The Transmit Message Buffer Interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR\_GIFER[TBIE] is asserted.

### 50.7.20.2.3 Protocol Interrupt

The Protocol Interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR\_GIFER[PRIE] is set..

### 50.7.20.2.4 CHI Interrupt

The CHI Interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR\_GIFER[CHIE] is set.

### 50.7.20.2.5 Module Interrupt

The Module Interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR\_GIFER[MIE] is set.

### 50.7.21 Lower Bit Rate Support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset*. The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR\_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings and related protocol parameter values are shown in the "FlexRay Channel Bit Rate Control" table below.

**Table 50-55. FlexRay Channel Bit Rate Control**

| FlexRay Channel<br>Bit Rate<br>[Mbit/s] | FR_MCR[BITRATE] | pdMicrotick [ns] | gdSampleClockPeriod [ns] | pSamplesPerMicrotick | cSamplesPerBit | cStrobeOffset |
|-----------------------------------------|-----------------|------------------|--------------------------|----------------------|----------------|---------------|
| 10.0                                    | 000             | 25.0             | 12.5                     | 2                    | 8              | 5             |
| 8.0                                     | 011             | 25.0             | 12.5                     | 2                    | 10             | 6             |
| 5.0                                     | 001             | 25.0             | 25.0                     | 1                    | 8              | 5             |
| 2.5                                     | 010             | 50.0             | 50.0                     | 1                    | 8              | 5             |

**Note**

The bit rate of 8 Mbit/s is not defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

**50.7.22 PE Data Memory (PE DRAM)**

The PE Data Memory (PE DRAM) is 128 word, 16-bit wide memory with byte access, which contains the program data of the PE internal CPU. The PE DRAM is divided into two banks, 8-bit each. The memory data [7:0] are assigned to BANK0, the memory data [15:8] are assigned to BANK1.

**Table 50-56. PE DRAM Layout**

| ADDR | BANK1   | BANK0   |
|------|---------|---------|
| 0x00 | byte1   | byte0   |
| 0x01 | byte3   | byte2   |
| ...  |         |         |
| 0x7F | byte255 | byte254 |

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via PE DRAM Access Register (FR\_PEDRAR) and PE DRAM Access Register (FR\_PEDRAR). This functionality is used to check the memory error detection.

### 50.7.22.1 PE DRAM Read Access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR\_PEDRAR:= 0x50E0;  
// INST=0x5; ADDR=070
2. wait until FR\_PEDRAR[DAD] == 1;  
// wait for end of PE DRAM access
3. val = FR\_PEDRDR[DATA];  
// read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25us).

### 50.7.22.2 PE DRAM Write Access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR\_PEDRDR:= DATA;  
// write value to be written into data register
2. FR\_PEDRAR:= 0x30E0;  
// INST=0x3; ADDR=0x70
3. wait until FR\_PEDRAR[DAD] == 1;  
// wait for end of PE DRAM access
4. val = FR\_PEDRDR[DATA];  
// read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may causes an response delay with a maximum of 1000 PE clock cycle (25us).

If the conditions given in [PE DRAM Write Access Limitations](#) are fulfilled, the data provided in PE DRAM Access Register (FR\_PEDRAR) are written into the PE DRAM, read back in the next clock cycle and stored into the PE DRAM Access Register (FR\_PEDRAR). Otherwise, data are not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR\_PEDRAR).

### 50.7.22.3 PE DRAM Write Access Limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not in *POC:default config* state, only PE DRAM address 0x70 is writable.

### 50.7.23 CHI Lookup-Table Memory (CHI LRAM)

The CHI Lookup-Table Memory (CHI LRAM) is an CHI internal memory which contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or 6 data field offsets are contained in one memory row. The CHI LRAM is divided into 6 memory BANKs.

**Table 50-57. CHI LRAM Layout**

| ADR  | BANK5       | BANK4       | BANK3      | BANK2       | BANK1      | BANK0       |
|------|-------------|-------------|------------|-------------|------------|-------------|
| 0x00 | FR_MBIDXR1  | FR_MBFIDR1  | FR_MBCCFR1 | FR_MBIDXR0  | FR_MBFIDR0 | FR_MBCCFR0  |
| 0x01 | FR_MBIDXR3  | FR_MBFIDR3  | FR_MBCCFR3 | FR_MBIDXR2  | FR_MBFIDR2 | FR_MBCCFR2  |
| ...  |             |             |            |             |            |             |
| 0x1F | FR_MBIDXR63 | FR_MBFIDR63 | MBCCF63    | FR_MBIDXR62 | MBFID62    | FR_MBCCFR62 |
| 0x20 | FR_MBDOR5   | FR_MBDOR4   | FR_MBDOR3  | FR_MBDOR2   | FR_MBDOR1  | FR_MBDOR0   |
| ...  |             |             |            |             |            |             |
| 0x2B | -           | -           | -          | -           | FR_MBDOR67 | FR_MBDOR66  |
| 0x2C | FR_LEETR5   | FR_LEETR4   | FR_LEETR3  | FR_LEETR2   | FR_LEETR1  | FR_LEETR0   |

### 50.7.23.1 CHI LRAM Read and Write Access

The CHI LRAM is accessed by the application via regular register read and write accesses.

### 50.7.24 Memory Content Fault Detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses an standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDDED) . The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

#### 50.7.24.1 Memory Error Types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as an special case. The FlexRay module detects and indicates the memory errors as shown in the "Detected Memory Error Types" table below. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row, and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error free bank has been read.

**Table 50-58. Detected Memory Error Types**

| Memory   | Priority    | Memory Data     | Indication          |
|----------|-------------|-----------------|---------------------|
| CHI LRAM | 0 (highest) | All Zero's      | Non-Corrected Error |
| PE DRAM  |             |                 | Non-Corrected Error |
| CHI LRAM |             | All One's       | Non-Corrected Error |
| PE DRAM  |             |                 |                     |
| CHI LRAM | 1 (lowest)  | One Bit Flipped | Non-Corrected Error |
| PE DRAM  |             |                 | Corrected Error     |

*Table continues on the next page...*

**Table 50-58. Detected Memory Error Types (continued)**

| Memory   | Priority | Memory Data                | Indication                                                                                                                                                     |
|----------|----------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHI LRAM |          | Two Bits Flipped           | Non-Corrected Error                                                                                                                                            |
| PE DRAM  |          |                            |                                                                                                                                                                |
| CHI LRAM |          | Three or more Bits Flipped | one out of {No error, Non-Corrected Error}, defined by coding given in <a href="#">CHI LRAM Checkbits</a> and <a href="#">CHI LRAM Syndrome</a>                |
| PE DRAM  |          |                            | one out of {No error, Corrected Error, Non-Corrected Error}, defined by coding given in <a href="#">PE DRAM Checkbits</a> and <a href="#">PE DRAM Syndrome</a> |

### 50.7.24.2 Memory Error Reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR\_MCR) is set.

For each of the two memories exists two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR\_EEIFER) is set.

- *If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.*
- *If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.*

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to above the Error indications (corrected / non corrected) along with the failing address is sent out from the module for external error logging and corrective actions by the Software.

### 50.7.24.2.1 PE DRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR\_EECCR) for PE DRAM memory errors is shown in Table 50-58. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

**Table 50-59. PE DRAM checkbits coding**

| CODE           | CODE |   |   |   | DATA |   |   |   |   |   |   |   |
|----------------|------|---|---|---|------|---|---|---|---|---|---|---|
|                | 3    | 2 | 1 | 0 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 4 <sup>1</sup> | X    | X | X | X | X    | X | X | X | X | X | X | X |
| 3 <sup>2</sup> | -    | - | - | - | X    | X | X | X | - | - | - | - |
| 2              | -    | - | - | - | X    | - | - | - | X | X | X | - |
| 1              | -    | - | - | - | -    | X | X | - | X | X | - | X |
| 0              | -    | - | - | - | -    | X | - | X | X | - | X | X |

1. The checkbit CODE[4] is set to 1 if and only if there is a even number of 1's in columns with X.
2. The checkbits CODE[3]... CODE[0] are set to 1 if and only if there is a odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFF F are valid code words and written into the memory.

### 50.7.24.2.2 PE DRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR\_EECCR) for PE DRAM memory errors is shown in the following table.

**Table 50-60. FR\_EECCR[CODE] PE DRAM Syndrome Coding**

| FR_EECCR[CODE] |       | Description                                                                                                                 |
|----------------|-------|-----------------------------------------------------------------------------------------------------------------------------|
| [4]            | [3:0] |                                                                                                                             |
| 0x1            | 0x0   | No Error (Never appears in error report registers)                                                                          |
| 0x0            | 0x0   | If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word)<br>If data!= 0: Corrected Error (Parity Bit 4) |
| 0x0            | 0x1   | Corrected Error (Parity Bit 0)                                                                                              |
| 0x0            | 0x2   | Corrected Error (Parity Bit 1)                                                                                              |
| 0x0            | 0x3   | Corrected Error (Data Bit 0)                                                                                                |
| 0x0            | 0x4   | Corrected Error (Parity Bit 2)                                                                                              |
| 0x0            | 0x5   | Corrected Error (Data Bit 1)                                                                                                |
| 0x0            | 0x6   | Corrected Error (Data Bit 2)                                                                                                |
| 0x0            | 0x7   | Corrected Error (Data Bit 3)                                                                                                |
| 0x0            | 0x8   | Corrected Error (Parity Bit 3)                                                                                              |
| 0x0            | 0x9   | Corrected Error (Data Bit 4)                                                                                                |

*Table continues on the next page...*

**Table 50-60. FR\_EECCR[CODE] PE DRAM Syndrome Coding (continued)**

| FR_EECCR[CODE] |         | Description                  |
|----------------|---------|------------------------------|
| [4]            | [3:0]   |                              |
| 0x0            | 0xA     | Corrected Error (Data Bit 5) |
| 0x0            | 0xB     | Corrected Error (Data Bit 6) |
| 0x0            | 0xC     | Corrected Error (Data Bit 7) |
| 0x0            | 0xD-0xF | Non-Corrected Error          |
| 0x1            | 0x1-0xF | Non-Corrected Error          |

### 50.7.24.2.3 CHI LRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR\_EECCR) for CHI LRAM memory errors is shown in the table below. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

**Table 50-61. CHI LRAM checkbits coding**

| CODE <sup>1</sup> | DATA |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------------|------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|                   | 15   | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 4                 | X    | X  | X  | X  | X  | -  | - | - | - | - | - | - | - | - | - | - |
| 3                 | -    | -  | -  | -  | -  | X  | X | X | X | X | X | X | - | - | - | - |
| 2                 | X    | X  | -  | -  | -  | X  | X | X | X | - | - | - | X | X | X | - |
| 1                 | -    | -  | X  | X  | -  | X  | X | - | - | X | X | - | X | X | - | X |
| 0                 | X    | -  | X  | -  | X  | X  | - | X | - | X | - | X | X | - | X | X |

1. The checkbit CODE[n] is set to 1 if and only if there is a odd number of 1's in all columns with X.

### 50.7.24.2.4 CHI LRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR\_EECCR) for CHI LRAM memory errors is shown in the next table.

**Table 50-62. FR\_EECCR[CODE] CHI LRAM Syndrome Coding**

| FR_EECCR[CODE] | Description                                        |
|----------------|----------------------------------------------------|
| 0x00           | No Error (Never appears in error report registers) |
| 0x01-0x1F      | Non Corrected Error                                |

### 50.7.24.3 Memory Error Response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR\_MCR) is set.

In case of the detection of a *corrected* memory error, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

#### 50.7.24.3.1 CHI LRAM Error Response after CC Read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access the error response of the module depends from LRAM location where the error occurred.

- *If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.*

If the affected message buffer is a tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is a rx message buffer, no frame will be received to this message buffer in the next slot.

- *If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx the first access to the system memory caused by payload read or write yields to the assertion of the FR\_CHIERFR[ILSA\_EF]. No memory access occurs w.r.t. payload access is performed for the complete frame.*

#### 50.7.24.3.2 CHI LRAM Error Response after Application Read

The application can read the content of the CHI LRAM via reading the FR\_MBCCFRn, FR\_MBFIDRn, FR\_MBIDXRn, FR\_MBDORn, and FR\_LEETRn registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read and continues its normal operation.

#### 50.7.24.3.3 PE DRAM Error Response after CC Read

If the CC detects an non-corrected memory error during internal read of program data which is contained in PE DRAM, this is considered as an fatal protocol error and the module enters the protocol freeze state immediately.

#### 50.7.24.3.4 PE DRAM Error Response after Application Read in *POC:default config* state

If the CC detects a non-corrected memory error during an application triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered as a fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

#### 50.7.24.3.5 PE DRAM Error Response after Application Read out of *POC:default config*

If the CC detects a non-corrected memory error during an application triggered read from any PE DRAM address, and the protocol is not in the *POC:default config* state, this error is not considered as a fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

### 50.7.25 Memory Fault Injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR\_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR\_EERICR) are set.

The error injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR\_EERICR).

When the error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

#### 50.7.25.1 CHI LRAM Error Injection

The following sequence describes a memory error injection sequence for the CHI LRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke a distortion of the memory content. The content of the CHI LRAM is described in [Table 50-57](#).

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see [Memory Fault Injection out of POC:default config](#).

#### Injector Setup:

1. FR\_MCR[ECCE]:= 1;  
    // enable ECC functionality
2. FR\_EERICR[EIE]:=I\_MODE;  
    // configure error injection mode
3. FR\_EEIAR[MID]:= 1;  
    // select CHI LRAM for error injection
4. FR\_EEIAR[BANK]:= I\_BANK;  
    // select bank for error injection; I\_BANK = {0,1,2,3,4,5}
5. FR\_EEIAR[ADDR]:= I\_ADDR;  
    // select address for error injection; I\_ADDR <= 0x 2C
6. FR\_EEIDR[DATA]:= D\_DIST;  
    // define data distortion pattern
7. FR\_EEICR[CODE]:= C\_DIST;  
    // define checkbit distortion pattern
8. FR\_EERICR[EIE]:=1;  
    // enable error injection

#### Application Write Access:

If (I\_BANK==0) -> FR\_MBCCFR(2n) / FR\_MBDOR(6k) / FR\_LEETR0 := DATA;  
 If (I\_BANK==1) -> FR\_MBFIDR(2n) / FR\_MBDOR(6k+1) / FR\_LEETR1 := DATA;  
 If (I\_BANK==2) -> FR\_MBIDXR(2n) / FR\_MBDOR(6k+2) / FR\_LEETR2 := DATA;  
 If (I\_BANK==3) -> FR\_MBCCFR(2n+1) / FR\_MBDOR(6k+3) / FR\_LEETR3 := DATA;  
 If (I\_BANK==4) -> FR\_MBFIDR(2n+1) / FR\_MBDOR(6k+4) / FR\_LEETR4 := DATA;

If (I\_BANK==5) -> FR\_MBIDX(2n+1) / FR\_MBDOR(6k+5) / FR\_LEETR5 := DATA;

// write DATA to the defined injection bank and injection address (see [Table 50-57](#)).

### 50.7.25.2 PE DRAM Error Injection

The following sequence describes an memory error injection sequence for the PE DRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see [PE DRAM Error Injection out of POC:default config](#).

Injector Setup:

1. FR\_MCR[ECCE]:= 1;  
// enable ECC functionality
2. FR\_EERICR[EIE]:=I\_MODE;  
// configure error injection mode
3. FR\_EEIAR[MID]:= 0;  
// select PE DRAM for error injection
4. FR\_EEIAR[BANK]:= I\_BANK;  
// define bank for error injection; I\_BANK = {0,1}
5. FR\_EEIAR[ADDR]:= I\_ADDR;  
// define address for error injection; I\_ADDR <= 0x7F
6. FR\_EEIDR[DATA]:= D\_DIST;  
// define data distortion pattern
7. FR\_EEICR[CODE]:= C\_DIST;  
// define checkbit distortion pattern
8. FR\_EERICR[EIE]:=1;  
// enable error injection

Application Write Access (e.g. I\_ADDR=0x70):

1. FR\_PEDRAR:= 0x30E0;  
// INST=0x3; ADDR=0x70
2. wait until FR\_PEDRAR[DAD] == 1;  
// wait for end of PE DRAM access
3. val = FR\_PEDRDR[DATA];  
// get read back PE DRAM data

### Note

The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

## 50.8 Application Information

Module operation is discussed in this section.

### 50.8.1 Module Configuration

This section describes essential parts of the module configuration.

#### 50.8.1.1 Configure System Memory Access Time-Out Register (FR\_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in System Memory Access Time-Out Register (FR\_SYMATOR) and the CHI clock frequency  $f_{\text{CHI}}$  in MHz fulfill this equation<sup>1</sup>:

$$0 \leq \text{SYMATOR}[\text{TIMEOUT}] \leq \left\lfloor 0.45 \cdot f_{\text{CHI}} - 8 \right\rfloor$$

**Equation 48**

1. See [Controller Host Interface Clocking](#) for all constraints of minimum CHI clock frequency.

For a given SYMATOR[TIMEOUT] value,  $f_{CHI}$  can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given  $f_{CHI}$ .

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in the table below.

**Table 50-63. Maximum SYMATOR[TIMEOUT] examples**

| $f_{CHI}$     | SYMATOR[TIMEOUT] | $f_{CHI}$      | SYMATOR[TIMEOUT] |
|---------------|------------------|----------------|------------------|
| $\geq 18$ MHz | 0                | $\geq 100$ MHz | $\leq 37$        |
| $\geq 23$ MHz | $\leq 2$         | $\geq 120$ MHz | $\leq 46$        |
| $\geq 27$ MHz | $\leq 4$         | $\geq 140$ MHz | $\leq 55$        |
| $\geq 32$ MHz | $\leq 6$         | $\geq 160$ MHz | $\leq 64$        |
| $\geq 60$ MHz | $\leq 19$        | $\geq 180$ MHz | $\leq 73$        |
| $\geq 80$ MHz | $\leq 28$        | $\geq 200$ MHz | $\leq 82$        |

#### 50.8.1.1.1 System Bus Wait State Constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single channel configurations and if the sync frame table generation functionality is *not* used ( $FR\_SFTCCSR[SDVEN, SIDEN] = 0$ ) no timeout will be detected if less than  $2 \times SYMATOR[TIMEOUT] + 1$  wait states will be seen on the system bus for each system bus access.

For dual channel configurations, or if the sync frame table generation functionality is used, no timeout will be detected if less than  $SYMATOR[TIMEOUT] - 1$  wait states will be seen on the system bus for each system bus access.

#### 50.8.1.2 Configure Data Field Offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers ( $FR\_MBDORn$ ) and Receive FIFO Start Data Offset Register ( $FR\_RFSDOR$ ). The application has to configure the data field offset values for all message buffers which are used.

When the module is enabled, the initialization value of the  $FR\_MBDORn[MBDO]$  and  $FR\_RFSDOR[SDO]$  is 0. This value is considered to be illegal (see [System Bus Illegal Address Access](#)).

## 50.8.2 Initialization Sequence

This section describes the required steps to initialize the CC. The first subsection describes the steps required after a module reset, the second section describes the steps required after preceding shutdown of the CC.

### 50.8.2.1 Module Initialization

This section describes the module related initialization steps after a system reset.

1. Configure CC.
  - a. configure the control bits in the Module Configuration Register (FR\_MCR)
  - b. configure the system memory base address in System Memory Base Address Register (FR\_SYMBADR)
2. Enable the CC.
  - a. write 1 to the module enable bit MEN in the Module Configuration Register (FR\_MCR)

The CC now enters the Normal Mode. The application can commence with the protocol initialization described in [Protocol Initialization](#).

### 50.8.2.2 Protocol Initialization

This section describes the protocol related initialization steps.

1. Configure the Protocol Engine.
  - a. issue CONFIG command via Protocol Operation Control Register (FR\_POCR)
  - b. wait for *POC:config* in Protocol Status Register 0 (FR\_PSR0)
  - c. configure the FR\_PCR0,..., FR\_PCR30 registers to set all protocol parameters
2. Configure the Message Buffers and FIFOs.
  - a. set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR)

- b. define the message buffer data size in the Message Buffer Data Size Register (FR\_MBDSR)
- c. configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn), Message Buffer Cycle Counter Filter Registers (FR\_MBCCFRn), Message Buffer Frame ID Registers (FR\_MBFIDRn), Message Buffer Index Registers (FR\_MBIDXRn)
- d. configure the FIFOs
- e. issue CONFIG\_COMPLETE command via Protocol Operation Control Register (FR\_POCR)
- f. wait for *POC:ready* in Protocol Status Register 0 (FR\_PSR0)

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

### 50.8.2.3 CHI LRAM Initialization

The initialization of the CHI LRAM is performed by the CC when it leaves the Disabled Mode. The unitization runs for 45 CHI clock cycles. All fields in the FR\_MBCCSRn, FR\_MBCCFRn, FR\_MBFIDRn, FR\_MBDORn, and LEETRn registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

### 50.8.2.4 PE DRAM Initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8  $\mu$ s, and will delay the state transition from *POC:default config* into *POC:config*.

## 50.8.3 Memory Fault Injection out of POC:default config

This section provides information for application driven memory fault injection out of *POC:default config*. The CC provides means to inject memory faults from the application without any impacts to the internal protocol operation of the CC.

### 50.8.3.1 CHI LRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR\_LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in [CHI LRAM Error Injection](#).

### 50.8.3.2 PE DRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only one PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM location to inject memory errors into the PE DRAM. The injection sequence is described in [PE DRAM Error Injection](#).

## 50.8.4 Shut Down Sequence

This section describes a secure shut down sequence to stop the CC gracefully. The main targets of this sequence are

- *finish all ongoing reception and transmission*
- *do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication*

For a graceful shutdown the application shall perform the following tasks:

1. Disable all enabled message buffers.
  - a. repeatedly write 1 to FR\_MBCCSRn[EDT] until FR\_MBCCSRn[EDS] == 0.
2. Stop Protocol Engine.
  - a. issue HALT command via Protocol Operation Control Register (FR\_POCR)
  - b. wait for *POC:halt* in Protocol Status Register 0 (FR\_PSR0)

## 50.8.5 Number of Usable Message Buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR), a configured mini-slot length  $gdMinislot$ , and a configured nominal macrotick length  $gdMacrotick$ <sup>1</sup>.

Additional constraints for the minimum CHI clock frequency are given in [Controller Host Interface Clocking](#).

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of slot and must be finished before the start of the next slot.

The shortest FlexRay slot is a corrected empty dynamic slot. An corrected empty dynamic slot is a mini-slot and consists of  $gdMinislot$  corrected macroticks with a duration of  $gdMacrotick$ . The minimum duration of an corrected macrotick is  $gdMacrotick_{min} = 39 \mu T$ . This results in a minimum length of an correct slot

$$A_{slotmin} = 39 \cdot pdMicrotick \cdot gdMinislot$$

**Equation 49**

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers  $FR\_MBSSUTR[LAST\_MB\_UTIL] + 1$  and for a given CHI clock frequency  $f_{chi}$ , this results in a search duration of

$$A_{search} = \frac{1}{f_{chi}} \cdot (FR\_MBSSUTR[LAST\_MB\_UTIL] + 27)$$

**Equation 50**

The message buffer search must be finished within one slot which requires fulfillment of this equation::

$$A_{search} \leq A_{slotmin}$$

**Equation 51**

This results in the formula given below which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

1. See [Controller Host Interface Clocking](#) for all constraints of minimum CHI clock frequency.

$$f_{\text{chi}} \geq \frac{(\text{FR\_MBSSUTR}[\text{LAST\_MB\_UTIL}] + 27)}{39 \cdot \text{pdMicrotick} \cdot \text{gdMinislot}}$$

**Equation 52**

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST\_MB\_UTIL field in the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR) set to 63 is given in the following table.

**Table 50-64. Minimum fchi [MHz] examples (64 message buffers used)**

| <i>pdMicrotick</i><br>[ns] | <i>gdMinislot</i> |      |      |      |      |      |
|----------------------------|-------------------|------|------|------|------|------|
|                            | 2                 | 3    | 4    | 5    | 6    | 7    |
| 25.0                       | 46.7              | 31.2 | 23.4 | 18.7 | 15.6 | 13.4 |
| 50.0                       | 23.4              | 15.6 | 11.7 | 9.4  | 7.8  | 6.7  |

**Note**

If the minimum CHI frequency is not met the CHIERFR[MBS\_EF] flag is set. Refer to the CHI Error Flag Register (FR\_CHIERFR) for details.

## 50.8.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of the FR\_POCR Field Descriptions table, located in the Register Descriptions section, by writing the command to the POCCMD field of the Protocol Operation Control Register (FR\_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in the next table. If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC\_IF in the Protocol Interrupt Flag Register 1 (FR\_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by the table below. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

**Table 50-65. Protocol Control Command Priorities**

| Protocol Command | Priority    | Interrupted By                                                | Cleared and Terminated By                            |
|------------------|-------------|---------------------------------------------------------------|------------------------------------------------------|
| FREEZE           | (highest) 1 | none                                                          |                                                      |
| READY            | 2           |                                                               |                                                      |
| CONFIG_COMPLETE  | 3           |                                                               |                                                      |
| ALL_SLOTS        | 4           | FREEZE,<br>READY,<br>CONFIG_COMPLETE,<br>fatal protocol error | FREEZE, READY, CONFIG_COMPLETE, fatal protocol error |
| ALLOW_COLDSTART  | 5           |                                                               |                                                      |
| RUN              | 6           |                                                               | FREEZE, fatal protocol error                         |
| WAKEUP           | 7           |                                                               | FREEZE, fatal protocol error                         |
| DEFAULT_CONFIG   | 8           |                                                               | FREEZE, fatal protocol error                         |
| CONFIG           | 9           |                                                               |                                                      |
| HALT             | (lowest) 10 |                                                               | FREEZE, READY, CONFIG_COMPLETE, fatal protocol error |

## 50.8.7 Message Buffer Search On Simple Message Buffer Configuration

This section describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

### 50.8.7.1 Simple Message Buffer Configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot  $S$ . The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number  $t$  and has following configuration

**Table 50-66. Transmit Buffer Configuration**

| Register      | Field | Value | Description     |
|---------------|-------|-------|-----------------|
| FR_MBCCSR $t$ | MTD   | 1     | transmit buffer |

*Table continues on the next page...*

**Table 50-66. Transmit Buffer Configuration (continued)**

| Register   | Field  | Value  | Description                               |
|------------|--------|--------|-------------------------------------------|
| FR_MBCCFRt | MTM    | 0      | event transition mode                     |
|            | CHA    | 1      | assigned to channel A                     |
|            | CHB    | 0      | not assigned to channel B                 |
|            | CCFE   | 1      | cycle counter filter enabled              |
|            | CCFMSK | 000011 | cycle set = $\{4n\} = \{0,4,8,12,\dots\}$ |
|            | CCFVAL | 000000 |                                           |
| FR_MBFIDRt | FID    | S      | assigned to slot S                        |

The availability of data in the transmit buffer is indicated by the commit bit FR\_MBCCSRt[CMT] and the lock bit FR\_MBCCSRt[LCKS].

The receive message buffer has the message buffer number r and has following configuration

**Table 50-67. Receive Buffer Configuration**

| Register   | Field  | Value  | Description                              |
|------------|--------|--------|------------------------------------------|
| FR_MBCCSRr | MTD    | 0      | receive buffer                           |
| FR_MBCCFRr | MTM    | -      | n/a                                      |
|            | CHA    | 1      | assigned to channel A                    |
|            | CHB    | 0      | not assigned to channel B                |
|            | CCFE   | 1      | cycle counter filter enabled             |
|            | CCFMSK | 000001 | cycle set = $\{2n\} = \{0,2,4,6,\dots\}$ |
|            | CCFVAL | 000000 |                                          |
| FR_MBFIDRr | FID    | S      | subscribed slot                          |

Furthermore the assumption is that both message buffers are enabled (FR\_MBCCSRt[EDS] = 1 and FR\_MBCCSRr[EDS] = 1)

### Note

The cycle set  $\{4n+2\} = \{2,6,10,\dots\}$  is assigned to the receive buffer only.

The cycle set  $\{4n\} = \{0,4,8,12,\dots\}$  is assigned to both buffers.

## 50.8.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *S* in the *static* segment.

The configuration of a transmit buffer for a static slot  $S$  assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot  $S$ . In any case, the result of the message buffer search will be the transmit message buffer  $t$ . The receive message buffer  $r$  will not be found, no reception is possible.

### 50.8.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot  $S$  in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

#### 50.8.7.3.1 Transmit Data Not Available

If transmit data are *not available*, i.e. the transmit buffer is not committed  $FR\_MBCCSRt[CMT]=0$  and/or locked  $FR\_MBCCSRt[LCKS]=1$ ,

1. for the cycles in the set  $\{4n\}$ , which is assigned to both buffers, the receive buffer will be found and the node can receive data, and
2. for the cycles in the set  $\{4n+2\}$ , which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in the following figure.

### Figure 50-36. Transmit Data Not Available

### 50.8.7.3.2 Transmit Data Available

If transmit data are *available*, i.e. the transmit buffer is committed FR\_MBCCSR $t$ [CMT]=1 and not locked FR\_MBCCSR $t$ [LCKS]=0,

1. for the cycles in the set  $\{4n\}$ , which is assigned to both buffers, the transmit buffer will be found and the node transmits data.
2. for the cycles in the set  $\{4n+2\}$ , which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in the following figure.

**Figure 50-37. Transmit Data Available**

# Chapter 51

## SENT Receiver (SRX)

### 51.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled "SENT - Single Edge Nibble Transmission for Automotive Applications" and released on January 27, 2010 (<http://www.sae.org>), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

#### 51.1.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See the device configuration details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
  - Programmable option per channel to support reading of messages via DMA or Interrupt
  - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
  - A FIFO for storing the received Fast Messages from all channels that are to be read out via DMA. FIFO depth is device-specific. See the device configuration section for details.
  - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
  - Separate buffers for storing Fast and Slow Serial Messages
  - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to  $\pm 25\%$  and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel
  - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel
- Supports all bit rates by having per channel configurable Rx clock periods from 3  $\mu\text{s}$  to 90  $\mu\text{s}$
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings

- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See [Clocks and resets](#) for more details on the clocks.

## 51.1.2 Modes of operation

Modes of operation.

### 51.1.2.1 Debug mode

In debug mode, message reception will be halted (without waiting for the current message being received to be completed) and all existing status and messages will be retained. DBG\_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL\_LEN\_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

### 51.1.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL\_LEN\_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

**Modes where both system bus clock and protocol clock are gated:** In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

**Modes where frequency of system bus clock is changed:** For reduced power consumption the system bus clock can be reduced but not below a minimum value (See [System bus clock requirements](#)) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See [High frequency receiver clock \(protocol clock\) requirements](#)) for accurate receive operations.

### Note

Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

### NOTE

If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.

### NOTE

The message read registers [Channel 'n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn\_FMSG\_DATA), Channel 'n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn\_FMSG\_CRC), Channel 'n' Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn\_FMSG\_TS), Channel 'n' Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn\_SMSG\_BIT3), Channel 'n' Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn\_SMSG\_BIT2), Channel 'n' Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn\_SMSG\_TS), DMA Fast Message Data Read Register (DMA\_FMSG\_DATA), DMA Fast Message CRC Read Register (DMA\_FMSG\_CRC), DMA Fast Message Time Stamp Read Register (DMA\_FMSG\_TS), DMA Slow Serial Message Bit3 Read Register (DMA\_SMSG\_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA\_SMSG\_BIT2) and

DMA Slow Serial Message Time Stamp Read Register (DMA\_SMSG\_TS)] will appear to lose their contents in the following conditions:

- The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros
- Auto clear functionality is enabled (GBL\_CTRL[FAST\_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable "Auto Clear" (GBL\_CTRL[FAST\_CLR] = 0), to allow messages to be read in debug or stop mode.

## 51.1.3 Block diagram

**Figure 51-1. SENT Receiver block diagram**

### 51.1.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. [Figure 51-1](#) shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages. A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the DMA FIFOs (for channels which are selected to be connected to the DMA) or in corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the FIFOs or buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

#### 51.1.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message FIFOs or buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the DMA FIFO or message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the FIFOs or buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see [Functional description](#).

## 51.2 External signal description

This section lists all inputs to the SENT Receiver block.

### 51.2.1 SENT\_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT Receiver channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

**Note**

The value of CH is device-specific. See the device configuration details.

## 51.3 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT Receiver block.

The following table gives an overview on all SENT Receiver registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

**NOTE**

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the device configuration section for details.

**NOTE**

The value of the CH is device-specific. See the device configuration section for details.

### SRX memory map

| Address offset (hex) | Register name                                            | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|----------------------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Global Control Register (SRX_GBL_CTRL)                   | 32              | R/W    | 0001_0010h  | <a href="#">51.3.1/1889</a> |
| 4                    | Channel Enable Register (SRX_CHNL_EN)                    | 32              | R/W    | 0000_0000h  | <a href="#">51.3.2/1891</a> |
| 8                    | Global Status Register (SRX_GBL_STATUS)                  | 32              | w1c    | 0000_0000h  | <a href="#">51.3.3/1892</a> |
| C                    | Fast Message Ready Status Register (SRX_FMSG_RDY)        | 32              | R/W    | 0000_0000h  | <a href="#">51.3.4/1893</a> |
| 10                   | Slow Serial Message Ready Status Register (SRX_SMSG_RDY) | 32              | R/W    | 0000_0000h  | <a href="#">51.3.5/1894</a> |
| 18                   | Data Control Register 1 (SRX_DATA_CTRL1)                 | 32              | R/W    | 1100_0000h  | <a href="#">51.3.6/1895</a> |

## 51.3.1 Global Control Register (SRX\_GBL\_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT\_EN bit must be programmed after all other modules settings and control bits have been written to.

Address: 0h base + 0h offset = 0h

**SRX\_GBL\_CTRL field descriptions (continued)**

| Field         | Description                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31<br>SENT_EN | SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0.<br><br>0 Entire module is disabled<br>1 Module is enabled |

**51.3.2 Channel Enable Register (SRX\_CHNL\_EN)**

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

**NOTE**

Reads of bits beyond those for the supported number of channels should be ignored, and these bits must be written to 0.

Address: 0h base + 4h offset = 4h

**51.3.4 Fast Message Ready Status Register (SRX\_FMSG\_RDY)**

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#) ), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#) ) and the channel is enabled, the message ready status bit in this register will be asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST\_CLR bit in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) .

**NOTE**

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

**SRX\_FMSG\_RDY field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). |
|       | <b>NOTE:</b> These bits are either "write 1 to clear" (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL).                                                                                                                                                                   |
|       | The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section <a href="#">Global Control Register (SRX_GBL_CTRL)</a> for details on FAST_CLR bit.                                                                                                                           |
|       | <b>NOTE:</b> When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported.                                     |
|       | <b>NOTE:</b> When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.                                                                                                                                                                                                           |
|       | 0 No Fast Message is available to be read out via Interrupt                                                                                                                                                                                                                                                                          |
|       | 1 Fast Message is available to be read out via Interrupt                                                                                                                                                                                                                                                                             |

### 51.3.5 Slow Serial Message Ready Status Register (SRX\_SMSG\_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#) and [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#) and [Slow Serial Message Ready Interrupt Enable Register \(SRX\\_SRDY\\_IE\)](#)) and the channel is enabled, the message ready status bit in this register will be asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST\_CLR bit in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#).

#### NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

| 30–31<br>S_RDY   | <p>Slow Serial Message Data Ready Status bits for channels 1 to 0 . Each bit indicates that a Slow Serial Message is ready to be read by CPU from that specific channel. This bit is asserted only when DMA is NOT enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Serial Message Read Registers would automatically clear this bit (Fast Clearing Mechanism).</p> <p><b>NOTE:</b> These bits are either "write 1 to clear" (w1c) or self-clearing depending on the value of the FAST_CLR bit in the Global Control Register (GBL_CTRL).</p> <p>The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section <a href="#">Global Control Register (SRX_GBL_CTRL)</a> for details on FAST_CLR bit.</p> <p><b>NOTE:</b> When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 Fast Message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported.</p> <p><b>NOTE:</b> When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.</p> <p>0 No Slow Serial Message is available to be read out via Interrupt<br/>1 Slow Serial Message is available to be read out via Interrupt</p> |

**51.3.6 Data Control Register 1 (SRX\_DATA\_CTRL1)**

The Data Control Register 1 (DATA\_CTRL1) is described below.

**NOTE**

Reset value changes depending on the number of channels that are enabled on the device.

Address: 0h base + 18h offset = 18h

### 51.3.11 DMA Fast Message Data Read Register (SRX\_DMA\_FMSG\_DATA)

DMA Source Size must be set to 32 bits when reading this register (DMA\_FMSG\_DATA) via DMA. When FIFO is enabled, the DMA must read the complete message using this register only. Three read accesses must be made to read complete message.

Address: 0h base + 40h offset = 40h

### 51.3.12 DMA Fast Message CRC Read Register (SRX\_DMA\_FMSG\_CRC)

DMA Source Size must be set to 32 bits when reading this register (DMA\_FMSG\_CRC) via DMA. When FIFO is enabled, fast messages are read out from FIFO through the DMA Fast Message Data Read register only. Reading this register will generate an access error.

Address: 0h base + 44h offset = 44h

### 51.3.13 DMA Fast Message Time Stamp Read Register (SRX\_DMA\_FMSG\_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) register. DMA Source Size must be set to 32 bits when reading this register (DMA\_FMSG\_TS) via DMA. When FIFO is enabled, fast messages are read out from FIFO through the DMA Fast Message Data Read register only. Reading this register will generate an access error.

Address: 0h base + 48h offset = 48h

### 51.3.14 DMA Slow Serial Message Bit3 Read Register (SRX\_DMA\_SMSG\_BIT3)

The above register (DMA\_SMSG\_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Table 51-2](#), [Table 51-3](#) and [Table 51-4](#). [Table 51-2](#) and [Table 51-3](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Table 51-4](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

**NOTE**

If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID and DATA) will be redundant and read zeros. The short serial message will be located in DMA\_SMSG\_BIT2 register fields. If TYPE bit is '1', then the message in register is Enhanced Serial Message and using CFG bit, software can decode the ID and DATA fields.

Address: 0h base + 50h offset = 50h

| 0–31<br>TS | Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received. |

**51.3.17 Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX\_CHn\_CLK\_CTRL)****NOTE**

The value of the CH is device-specific. See the device configuration section for details.

The SENT Receiver module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock. See [Adjustment for variation in sensor \(Tx\) clock](#) for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#).

| 18–31<br>PRSC  | Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (Trx_clk) is not divisible by the high frequency receiver clock (protocol clock) period (Thf_clk), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value.<br><br>0 Prescaler is bypassed. Should not be used.<br><br>Non-Zero Value Enables Prescaler<br><br>The required value is computed by software as follows:<br><br>$\text{Prescaler\_value} = \text{floor}\left(\frac{T_{\text{rx\_clk}}}{T_{\text{hf\_clk}}}\right)$ <p style="text-align: center;"><b>Equation 54</b></p><br>(both clock periods taken in μs).<br><br>Please see <a href="#">High frequency receiver clock (protocol clock) requirements</a> before setting this value.<br><br>e.g. if the required receiver clock tick period is 43 μs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 μs) then,<br><br>Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register. |

**51.3.18 Channel 'n' Status Register (n=0 to (CH-1))  
(SRX\_CHn\_STATUS)**

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#) bit for the corresponding channel.

**NOTE**

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 64h offset + (16d × i), where i=0d to 1d

**SRX\_CHn\_STATUS field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected).<br><br>0 No interrupt<br>1 Interrupt Status condition has occurred                                                                                                                                                                                                                             |
| 5<br>CAL_20_25     | Calibration Variation 20 - 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between $\pm 20\%$ to $\pm 25\%$ from 56 ticks.<br><br>0 No Interrupt<br>1 Interrupt Status condition has occurred                                                                                                                                                                                                                              |
| 6<br>MSG_OFLW      | Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause state machine to halt stopping reception of new messages.<br><br>0 No Interrupt<br>1 Interrupt Status condition has occurred                                                                                                                                                                                                                                              |
| 7<br>MSG_OFLW      | Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written.<br><br>0 No Interrupt<br>1 Interrupt Status condition has occurred |
| 8<br>Reserved      | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                  |
| 9<br>PP_DIAG_ERR   | This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than $\pm 1.5625\%$ between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                          |
| 10<br>CAL_LEN_ERR  | This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks $\pm 25\%$ . This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                                                                                                                                                                  |
| 11<br>CAL_DIAG_ERR | Successive Calibration pulses differ by $\pm 1.56\%$ . SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (See <a href="#">High frequency receiver clock (protocol clock) requirements</a> ). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                           |
| 12<br>NIB_VAL_ERR  | Any nibble data value $< 0$ or $> 15$ . This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                                                                                                                                                                                                       |
| 13<br>MSG_CRC_ERR  | Checksum error in Slow Serial Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.                                                                                                                                                                                                                                                                                                    |

**51.3.19 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX\_CHn\_CONFIG)**

This register (CHn\_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#).

**NOTE**

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 68h offset + (16d × i), where i=0d to 1d

### SRX\_CHn\_CONFIG field descriptions

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0-3<br>BUS_IDLE_CNT | Bus Idle Count. This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows:<br><br>0000 Disabled.<br>0001 127*2 Receiver Clock Tick Counts<br>0010 127*4 Receiver Clock Tick Counts<br>0100 127*8 Receiver Clock Tick Counts<br>1000 127*16 Receiver Clock Tick Counts                           |
| 4<br>IE_CAL_RESYNC  | Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled |
| 5<br>IE_CAL_20_25   | Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                         |
| 6<br>IE_SMSG_OFLW   | Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                              |
| 7<br>IE_FMSG_OFLW   | Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                           |
| 8<br>FCRC_CHK_OFF   | Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message<br><br>0 Check is enabled<br>1 Check is disabled/off                                                                                                                                                                                                                                |
| 9<br>IE_PP_DIAG_ERR | Ratio of calibration pulse length to message length varies by more than $\pm 1.5625\%$ between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                       |

**SRX\_CHn\_CONFIG field descriptions (continued)**

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10<br>IE_CAL_LEN_ERR   | Calibration pulse is wider than 56 ticks $\pm 25\%$ . This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 11<br>IE_CAL_DIAG_ERR  | Successive Calibration pulses differ by more than $\pm 1.56\%$ . SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                                                                                                         |
| 12<br>IE_NIB_VAL_ERR   | Any nibble data value $<0$ or $>15$ . This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 13<br>IE_SMSG_CRC_ERR  | Checksum error in Slow Serial Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 14<br>IE_FMSG_CRC_ERR  | Checksum error in Fast Message. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 15<br>IE_NUM_EDGES_ERR | Not the expected number of negative edges between calibration pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 16<br>DCHNG_INT        | Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, or FIFO, and neither Fast Message Ready Interrupt nor DMA request will be generated.<br><br>0 All Fast Messages will be received even if data nibbles are same<br>1 Only Fast Messages with differing values of data nibbles will be received |
| 17<br>CAL_RNG          | Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse<br><br>0 20% variation is acceptable<br>1 25% variation is acceptable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 18<br>PP_CHKSEL        | Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses.<br><br>0 Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run<br>1 Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.                                                                                                                                                                                                                                                                                                                                                                                                            |

**SRX\_CHn\_CONFIG field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19<br>FCRC_TYPE    | Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages<br><br>0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles)<br>1 Legacy implementation (no additional 0 data nibble is XORed)                                                                                                                                                                                                                                                                                                                                   |
| 20<br>FCRC_SC_EN   | Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages.<br><br>0 Status and Communication Nibble not included in CRC calculation<br>1 Status and Communication Nibble is included in CRC calculation                                                                                                                                                                                                                                                                                                                    |
| 21<br>SCRC_TYPE    | Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages.<br><br>0 Recommended implementation (additional 0 data nibble XORed with the rest of the nibbles)<br>1 Legacy implementation (no additional 0 data nibble XORed)                                                                                                                                                                                                                                                                                                                       |
| 22<br>PAUSE_EN     | Pause Pulse Enable. Enables the channel receiver to detect a pause pulse.<br><br>0 Detection of Pause Pulse is disabled<br>1 Detection of Pause Pulse enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 23<br>SUCC_CAL_CHK | Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1.<br><br>0 Option 2 i.e. Low Latency Option as per SAE Specification<br>1 Option 1 i.e. Preferred but High Latency Option as per SAE Specification                                                                                                                                                                                                                                                                                                                      |
| 24–31<br>FIL_CNT   | Input Filter Sample Count. This indicates twice the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'.<br><br>0 No filtering. Input from device's pad is only synchronized<br>1 Non-Zero Filtering is enabled |

**51.3.20 Channel 'n' Fast Message Data Read Register (n=0 to (CH-1)) (SRX\_CHn\_FMSG\_DATA)**

Address offset: 0x0160 + 0x18 x n

This is register CHn\_FMSG\_DATA. The contents of this register are same as [DMA Fast Message Data Read Register \(SRX\\_DMA\\_FMSG\\_DATA\)](#) .

**NOTE**

The value of the CH is device-specific. See the device configuration section for details.

Address:  $0h \text{ base} + 160h \text{ offset} + (24d \times i)$ , where  $i=0d$  to  $1d$

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>TS | Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received. |

## 51.4 Functional description

This section describes the function of the SRX.

### 51.4.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) to generate the time stamping clock
- Rx Prescaler Value in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CH<sub>n</sub>\\_CLK\\_CTRL\)](#) to generate the channel's receiver clock
- Compensation enable in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CH<sub>n</sub>\\_CLK\\_CTRL\)](#)
- Channel Configuration settings in the [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CH<sub>n</sub>\\_CONFIG\)](#)
- Number of Data Nibbles in Channel in the [Data Control Register 1 \(SRX\\_DATA\\_CTRL1\)](#)
- Control bits that control whether messages received in channel are to read by interrupt or DMA in [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#), [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#), [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#) and [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#)

### 51.4.2 DMA read logic

The SENT Receiver module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in [Time stamp logic](#).

### 51.4.2.1 DMA request for Fast Message reading via FIFO

A single DMA request is generated for all Fast Messages received on any channel. There is a DMA read FIFO to store the incoming messages from all the channels and allow them to be read via DMA. The DMA operation will happen as follows:

- DMA request will be asserted when number of messages stored in FIFO crosses the configured watermark level (in Global Control Register (GBL\_CTRL)).
- DMA request will be de-asserted when number of messages stored goes below watermark level. It is assumed that DMA Controller's TCD would be set to transfer bytes equal to the messages indicated by watermark level so as to empty the FIFO.
- It is assumed that when responding to a DMA request, the DMA controller will read at a rate faster than the rate at which messages are getting received and stored in FIFO.
- The complete received message can be read by three consecutive read accesses to DMA Fast Message Data Read Register. The message will be read out in following sequence:
  - Fast Message data as described by DMA Fast Message Data Read Register (DMA\_FMSG\_DATA)
  - CRC for the Fast Message as described by DMA Fast Message CRC Read Register (DMA\_FMSG\_CRC)
  - Time stamp value for the Fast Message as described by DMA Fast Message Time Stamp Read Register (DMA\_FMSG\_TS)
- The channel number is prefixed in each valid message (no error) to allow software to identify messages pertaining to a channel
- [Table 51-1](#) shows the format in which the messages will be stored in any memory-mapped message buffer and when being read out from FIFO.
- Since multiple messages can be received at the same time, there is a [Fixed round robin sequencing logic](#), which will scan all active channels configured for DMA and store their message into the FIFO one by one. Channel configured for DMA but do not have ready messages will be automatically skipped till their turn comes again in the round robin sequence.
- Messages received can be stored in a different order to which they are actually received. The time stamp will indicate the order of reception of messages in a particular channel. However, the time stamp cannot be used to determine the order across channels.

This figure below shows the data for the three 32-bit accesses to be made by DMA to get one complete message with time stamp.

**Table 51-1. Format of storing of Fast Messages in FIFO**

|                   |                          |              |              |              |              |              |              |

## Functional description

**Figure 51-2. Fast Message DMA Read Logic using FIFO**

### 51.4.2.1.1 Fixed round robin sequencing logic

Figure 51-2 shows a scenario where 8 channels (0-7) with all channels are enabled for DMA reading except channel 2. DMA request will be asserted when FIFO has received packets more than watermark level set. Figure 51-2 shows channels 6 and 4 have not received the complete message. The following points describe the complete round robin sequencing scheme.

- The round robin sequencing logic which stores the messages in the FIFO by looping through each channels' Fast Message register and checking for the availability of the message.
- As shown in Figure 51-2, the arbitration logic will check for messages in sequence 0 -> 1 -> 3 -> 5 -> 7 and back to channel 0 and keep looping. Channel 2 is skipped as it's not enabled to be read via DMA) and channel 4 and 6 are skipped as message is not received completely at the instance the sequencing logic checked their buffers. This sequence continues in this fashion.
- The sequence in which messages are stored in FIFO is not deterministic and depends on the sequence they are detected after the noise filtering by the input filter of the channel.
- The DMA controller responds to the DMA request by reading from the DMA Fast Message Read register. When a DMA read happens, a message is read from the FIFO and split into three 32-bit values and provided to DMA in the order as described in previous section. The three 32-bit values together form one complete Fast Message.
- Once all three 32-bit access are completed, the next data from the FIFO is popped.

Figure 51-2 also shows how the received data (light gray colored boxes) from a channel is stored in FIFO along with the time stamp and channel number appended (both white colored).

### 51.4.2.2 DMA request for Fast Message reading when FIFO is disabled

In this mode no FIFO will be used as it is disabled via the FIFO Enable bit in the Global Control Register (GBL\_CTRL). Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA Controller must read all 3 DMA Read Registers to obtain the complete message, unlike the case when FIFO is enabled and message is read out from the DMA Fast Message Data Read register only. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
  - [DMA Fast Message Data Read Register \(SRX\\_DMA\\_FMSG\\_DATA\)](#)
  - [DMA Fast Message CRC Read Register \(SRX\\_DMA\\_FMSG\\_CRC\)](#)
  - [DMA Fast Message Time Stamp Read Register \(SRX\\_DMA\\_FMSG\\_TS\)](#)
- A fixed round robin sequencing runs, as shown in [Figure 51-3](#), and this logic checks for messages in sequence 0→1→3→5→7 and back to channel 0 and so on. Channel 2 is skipped as it is not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

**Figure 51-3. Fast Message DMA read logic (when FIFO is disabled)**

### 51.4.2.3 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers

- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
  - [DMA Slow Serial Message Bit3 Read Register \(SRX\\_DMA\\_SMSG\\_BIT3\)](#)
  - [DMA Slow Serial Message Bit2 Read Register \(SRX\\_DMA\\_SMSG\\_BIT2\)](#)
  - [DMA Slow Serial Message Time Stamp Read Register \(SRX\\_DMA\\_SMSG\\_TS\)](#)
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see [DMA request for Fast Message reading when FIFO is disabled](#))

[Figure 51-4](#) shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

**Note:** The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in

**Figure 51-4. Slow Serial Message DMA read logic**

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

**Table 51-2. Enhanced Serial Message with 8-bit ID field**

| CH NUM<br>[3:0]   |  | P |           |  |  |  |    | 0 | C                 | ID [7:4] |  | 0 | ID [3:0] | 0 |
|                   |  |   | CRC [5:0] |  |  |  |    |   | Data Field [11:0] |          |  |   |          |   |
| TIME STAMP [31:0] |  |   |           |  |  |  |    |   |                   |          |  |   |          |   |

**Table 51-3. Enhanced Serial Message with 4-bit ID field**

|                   |   |    |  |           |  |    |  |                   |   |          |   |                       |   |
|-------------------|---|----|--|-----------|--|----|--|-------------------|---|----------|---|-----------------------|---|
| 31                | 1 | 16 |  |           |  | 15 |  | 1                 |   | 0        |   |                       |   |
| CH NUM<br>[3:0]   | P |    |  |           |  |    |  | 0                 | C | ID [3:0] | 0 | Data Field<br>[15:12] | 0 |
|                   |   |    |  | CRC [5:0] |  |    |  | Data Field [11:0] |   |          |   |                       |   |
| TIME STAMP [31:0] |   |    |  |           |  |    |  |                   |   |          |   |                       |   |

Table 51-2 and Table 51-3 shows the enhanced serial messages. Bit C (shown in figure) or CFG (as shown in DMA Slow Serial Message Bit3 Read Register (DMA\_SMSG\_BIT3) description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in DMA Slow Serial Message Bit3 Read Register (DMA\_SMSG\_BIT3) description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Table 51-4 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

**Table 51-4. Short serial message**

|                   |   |           |          |                  |
|-------------------|---|-----------|----------|------------------|
| 31                | 0 | 16        | 15       | 0                |
| CH NUM<br>[3:0]   | P |           |          |                  |
|                   |   | CRC [3:0] | ID [3:0] | Data Field [7:0] |
| TIME STAMP [31:0] |   |           |          |                  |

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

### 51.4.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

### 51.4.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

#### When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

#### When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable

- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

## 51.4.4 Overflow behavior

This section describes the overflow behavior.

### 51.4.4.1 Fast messages buffers/FIFO

Overflow in Fast Message buffers or FIFO can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full. When FIFO is used, overflow is indicated when the FIFO gets full and another fast message is to be stored.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

#### NOTE

In the case of a fast message overflow and continuous reading of register `SRX_CHn_FMSG_DATA`, `SRX_CHn_FMSG_CRC`, and `SRX_CHn_FMSG_TS` without clearing the `SRX_FMSG_RDY[F_RDYn]` bit there is a possibility that one message will be lost. Additionally, if the pause pulse feature is enabled the module asserts up to two `NUM_EDGES_ERR` in the status register (`SRX_CHn_STATUS`). In this case up to two frames can be lost. Note that some debuggers perform a continuous read of memory which can cause this issue to occur.

In order to avoid this software should ensure that fast message overflow does not occur. If interrupts are used to read the SENT messages the interrupt for data reception should be enabled for every channel  $n$  ( $\text{SRX\_FRDY\_IE}[\text{FRDY\_IE}n]=1$ ) and the interrupt priority should be such that the software is able to read the message before the next message arrives. When using Direct Memory Accesses (eDMA) to access the messages the DMA request from the SENT module should be serviced before the next message arrives. The minimum duration between the reception of two consecutive messages in one channel is 92 times the utick length (time).

Else ensure that the  $\text{SRX\_CH}n\_\text{FMSG\_DATA}$ ,  $\text{SRX\_CH}n\_\text{FMSG\_CRC}$ , and  $\text{SRX\_CH}n\_\text{FMSG\_TS}$  registers are not read continuously either in the software code or as a result of a debugger being connected. They should be read once per message and the  $\text{FMSG\_RDY}[\text{F\_RDY}n]$  bit should be cleared after the reads.

#### 51.4.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

#### 51.4.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or  $\text{Rx\_CLK}$ ) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register ([Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CHn\\_CLK\\_CTRL\)](#)). Software can use this value to determine the variation in Tx Clock.

### Note

A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

#### 51.4.5.1 Adjustment for nibble length variation

Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

#### 51.4.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency

receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register **Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX\_CHn\_CONFIG)**. When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (**Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX\_CHn\_CONFIG)**). A timing diagram of the input filter when FIL\_CNT is 4, is shown in the following figure.

**Figure 51-5. Input programmable filter timing diagram**

### 51.4.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%
- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended.
- Any nibble data values measured as < 0 or > 15

- Successive calibration pulses differ by  $> +1.5625\%$  ( $1/64$ ) or  $< -1.5625\%$ . The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register ([Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#)). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM\_EDGES\_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

#### 51.4.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL\_LEN\_ERR status bit on failure.

#### 51.4.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by  $> +1.5625\%$  ( $1/64$ ) or  $< -1.5625\%$ . The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is  $T_{HF\_CLK}$  and channel tick period is  $T_{TX\_CLK}$  then the check will be of  $1.5625\% \pm \{100 \times (4 \times T_{HF\_CLK}) / (42 \times T_{TX\_CLK})\}$ . So it won't allow variance in clock of a channel by  $1.5625\% - \{100 \times (4 \times T_{HF\_CLK}) / (42 \times T_{TX\_CLK})\}$ . This check will assert the CAL\_DIAG\_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL\_RESYNC bit will be asserted on every third successive error detected by this check.

### 51.4.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM\_EDGES\_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL\_DIAG\_ERR and CAL\_LEN\_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

### 51.4.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB\_VAL\_ERR status bit on failure. This error can be flagged along with NUM\_EDGES\_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

### 51.4.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new recommended CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn\_CONFIG\_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG\_CRC\_ERR or SMSG\_CRC\_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG\_CRC\_ERR can be flagged along with the NUM\_EDGES\_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

### 51.4.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP\_DIAG\_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel 'n' Configuration Register - CHn\_CONFIG[PAUSE\_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM\_EDGES error can get asserted spuriously (Channel 'n' Status Register - CHn\_STATUS(NUM\_EDGES\_ERR) = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM\_EDGES\_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM\_EDGES\_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. Table 1 contains information due to erratum behavior and Table 2 below contains clarification of normal NUM\_EDGES\_ERR behavior.

**Table 51-5. Behavior of NUM\_EDGES\_ERR**

| First Error Detected | Other error bits asserted    | Cause for extra error bits getting asserted                                                                                                                                                                                                                                                                                                                                     | Action                           |
|----------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| NIB_VAL_ERR          | NUM_EDGES_ERR asserted twice | Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between. | Ignore both NUM_EDGES_ERR error  |
| FMSG_CRC_ERR         | NUM_EDGES_ERR asserted twice | Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between. | Ignore both NUM_EDGES_ERR errors |
| CAL_LEN_ERR          | NUM_EDGES_ERR asserted once  | Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and                                                                                                                                                                                                                                 | Ignore NUM_EDGES_ERR error       |

**Table 51-5. Behavior of NUM\_EDGES\_ERR**

|  |  |                                                                                      |  |
|--|--|--------------------------------------------------------------------------------------|--|
|  |  | start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted. |  |
|--|--|--------------------------------------------------------------------------------------|--|

**Table 51-6. Expected behavior, clarification of NUM\_EDGES\_ERR cases**

| First Error Detected                              | Other error bits asserted                | Cause for extra error bits getting asserted                                                                                                                                                                                                                                                                                                            | Action                             |
|---------------------------------------------------|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
| NUM_EDGES_ERR (when edges are less than expected) | NIB_VAL_ERR is asserted                  | When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles when actually there is a pause pulse present. This generates NIB_VAL_ERR.                                                                                                                  | Ignore the NIB_VAL_ERR             |
| NUM_EDGES_ERR (when edges are more than expected) | NIB_VAL_ERR and PP_DIAG_ERR are asserted | When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted. | Ignore NIB_VAL_ERR and PP_DIAG_ERR |

## 51.4.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in [Global Control Register \(SRX\\_GBL\\_CTRL\)](#)) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1  $\mu$ s. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value is 59 to generate a time stamp clock of 1  $\mu$ s resolution.

### Note

The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

#### 51.4.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

#### 51.4.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_CONFIG\)](#)). Status bit (bus\_idle in [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#)) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.

## 51.5 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

### 51.5.1 Clocking strategy

The following figure shows the clock domain in which each module is functioning.

Figure 51-6. SENT Receiver module clock domains

## 51.5.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3  $\mu$ s receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4  $\mu$ s (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as  $154 \times 2.4 = 369.6$   $\mu$ s. Now since messages are arriving in parallel, 369.6  $\mu$ s is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that ' $N_{\text{CHNL}}$ ' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be  $369.6/N_{\text{CHNL}}$   $\mu$ s or  $\sim 370/N_{\text{CHNL}}$   $\mu$ s. Since the CPU or the DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as ' $T_{\text{RD}}$ ' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

$$3 \times T_{\text{RD}} + T_{\text{ISR}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

where  $T_{\text{ISR}}$  is the overhead in initiating an ISR and  $T_{\text{WAKUP}}$  is the time to wakeup from low power mode

For DMA,

$$3 \times T_{\text{RD}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

Replacing  $T_{\text{RD}} = N_{\text{RD}} \times T_{\text{SYS\_CLK}}$  and  $T_{\text{ISR}} = N_{\text{ISR}} \times T_{\text{SYS\_CLK}}$ , where  $N_{\text{RD}}$  is the number of System Bus Clock cycles in one 32-bit read access,  $N_{\text{ISR}}$  is the number of System Bus Clock Cycles in initiating an interrupt service routine and  $T_{\text{SYS\_CLK}}$  is the period of the same clock, we get

For CPU,

$$(3 \times N_{\text{RD}} + N_{\text{ISR}}) \times T_{\text{SYS\_CLK}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

(all units is  $\mu$ s)

For DMA,

$$3 \times N_{RD} \times T_{SYS\_CLK} + T_{WAKUP} < 370 / N_{CHNL}$$

(all units is  $\mu s$ )

### 51.5.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula: Guard Band >  $2.5 * T_{HF\_CLK}$

where  $T_{HF\_CLK}$  is the High Frequency Receiver Clock or Protocol Clock in ns and Guard Band is guard band in ns as specified in SAE specification, at particular transmitter uTick.

#### **Note**

$T_{HF\_CLK}$  in the above equation should be chosen based on the fastest sensor clock (with minimum guard band as specified in SAE spec) among all channels in the device.

# Chapter 52

## LINFlexD

### 52.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, and 2.1. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

#### 52.1.1 Glossary and acronyms

Table 52-1. Glossary and acronyms

| Term | Description                                 |
|------|---------------------------------------------|
| LIN  | Local interconnect network                  |
| UART | Universal asynchronous transmitter receiver |
| ID   | LIN identifier field                        |
| DMA  | Direct memory access                        |

*Table continues on the next page...*

**Table 52-1. Glossary and acronyms (continued)**

| Term | Description                 |
|------|-----------------------------|
| TCD  | Transfer control descriptor |
| IPS  | Peripheral Bus Interface    |
| IRQ  | Interrupt request           |
| FSM  | Finite state machine        |
| WS   | Wait state                  |
| SW   | Software                    |
| CPU  | Central processing unit     |
| SoC  | System on a chip            |

## 52.1.2 References

Figure 52-1. Block diagram

Notes:

1: The value of n depends on the no\_of\_filters. Refer to the chip configuration details to see the number of filters used in this device.

## 52.2 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features that are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode:Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

### 52.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection

- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation

### 52.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers - see [Baud rate generation](#)
- Separate clock for baud rate calculation
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management

## 52.3 Functional description

### 52.3.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task. All other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

52.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 52-2. Frames

Figure 52-3. Structure of LIN frame

52.3.1.2 Data field

Each byte is transmitted as shown in [Figure 52-4](#). The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

Figure 52-4. Structure of byte field

### 52.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in [Figure 52-5](#). The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

Figure 52-5. Break field

### 52.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

Figure 52-6. Sync byte field

### 52.3.1.5 Identifier

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 52-7. Identifier field

$$P0 = ID0 \text{ XOR } ID1 \text{ XOR } ID2 \text{ XOR } ID4$$

$$P1 = \text{NOT} (ID1 \text{ XOR } ID3 \text{ XOR } ID4 \text{ XOR } ID5)$$

### 52.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum and is used for communication with LIN 2.0 slaves.

## 52.3.2 LINFlexD features

### 52.3.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization**, **Normal** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

#### Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINCRL. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller software must:

1. Set up the baud rate registers
2. Reset UART bit
3. Select the mode (master or slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

#### Normal mode (NM)

Once software has completed initialization of the LINFlexD controller, it can enter the Normal mode by clearing the INIT bit.

#### Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINC1R1. In this mode the LINFlexD clock is stopped. LINFlexD can be awakened from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150  $\mu$ s on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to [Wakeup management](#).

**Figure 52-8. Operating modes**

### 52.3.2.2 Test mode

#### Loop Back mode

This mode is entered by setting the LBKM bit in LINC1R1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is an internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

**Figure 52-9. LINFlexD in Loop Back Mode**

### 52.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

#### Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

#### Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDRL and BDRM. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling).

It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been

transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

### **Data reception**

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINSR (refer to Error handling).

It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

### **Data Discard**

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

## **52.3.2.4 Slave mode**

This mode is selected when the MME bit of the LINCR1 register is cleared.

### **Data transmission**

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL[5:0] bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit, and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7].

The use of a filter saves software the processing time required to read the ID value in the BDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

### **Data reception**

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software then you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

### **52.3.2.5 Errors**

### 52.3.2.5.1 Header error

A header error is an error during the header reception. The error types are:

1. Sync Del error (SDEF)
2. Sync field error (SFEF)
3. Identifier Parity error (IDPEF)

#### Sync Del error (SDEF)

The delimiter should be 1 for at least one bit time; otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if *HEIE* bit of *LINEIER* is set.

#### Sync field error (SFEF)

The SFEF error condition is monitored differently depending on whether autosynchronization (LASE) is ON or OFF.

#### **Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):**

When Autosynchronization is enabled, the SFEF flag indicates:

- The deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators or
- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

#### Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator).

This check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as *D*.

If SFEF field is asserted it means that:

$$D > 14.0625\%$$

If there is no error, it means that:

$$D < 14.84375\%$$

If  $14.0625\% < D < 14.84375\%$ , then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the *LIN\_CLK*.

### Overflow during Sync Field Measurement

This check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

#### **Case 2: Autosynchronization OFF (LASE bit of LINCR1 = '0')**

In this case the Sync character is received as a normal character. If the received character is 0x55 then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync\_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

### **Identifier Parity error(IDPEF)**

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

$$P0 = ID0 \text{ XOR } ID1 \text{ XOR } ID2 \text{ XOR } ID4$$

$$P1 = \text{NOT} (ID1 \text{ XOR } ID3 \text{ XOR } ID4 \text{ XOR } ID5)$$

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

#### **52.3.2.5.2 Bit error**

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN\_CPU cycles. Bit error is not checked during break field transmission.

$$1\text{-bit time at } 20 \text{ Kbit/s} = 50 \mu\text{s}$$

$$6 \text{ LIN\_CLK cycles at } 80 \text{ MHz} = 75 \text{ ns}$$

$$\text{Thus, } (1\text{-bit time}) - (6 \text{ LIN\_CLK cycles}) = 49.925 \mu\text{s}$$

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

### Note

If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

#### 52.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if FEIE bit is set in LINEIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

#### 52.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINEIER.

#### 52.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of slave, if buffer is not released (RMB is not reset) before reception of next Identifier and if RBLM is set, then the ID along with the data is discarded.

### 52.3.2.5.6 Timeout error

Figure 52-10. Incomplete response (for example, missing checksum)

Figure 52-11. No response

#### Response timeout mechanism

- Master mode
  - OC2 is loaded with  $\text{Nominal\_time\_out} + \text{LINFlexD\_LINTCSR}[\text{CNT}]$  at the end of the stop bit of the Identifier field (where  $\text{nominal\_time\_out} = 1.4 \times ((\text{DFL} + 2) \times 10 \text{ bit time})$ .  
This loading takes place at the end of id field (and not at the beginning of data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).
- Slave mode

- **Case 1:** The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, OC2 can be loaded with  $\text{Nominal\_time\_out} + \text{LINFlexD\_LINTCSR}[\text{CNT}]$  at the end of the stop bit of the Identifier field (where  $\text{nominal\_time\_out} = 1.4 \times ((\text{DFL} + 2) \times 10 \text{ bit time})$ )
- **Case 2:** The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the implementation is the following:
  - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) +  $\text{LINFlexD\_LINTCSR}[\text{CNT}]$ .
  - At the end of the first\_data\_byte it is reloaded again according to DFL
  - Before reloading, LINFlexD checks the count\_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

### NOTE

The value of nominal\_time\_out ( $1.4 \times ((\text{DFL} + 2) \times 10 \text{ bit time})$ ) shown is as per the reset value of  $\text{LINTOCR}[\text{RTO}]$  and  $\text{LINCR1}[\text{CFD}]$ . It changes with change in value of  $\text{LINTOCR}[\text{RTO}]$  and  $\text{LINCR1}[\text{CFD}]$ . Here, 1.4 corresponds to  $(\text{LINTOCR}[\text{RTO}])/10$  and 2 corresponds to  $(2 - \text{LINCR1}[\text{CFD}])$

### Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length),
  - an error occurs on the bus and LINFlexD flags it in  $\text{LINESR}$  register (typically a bit error).

Therefore there is no meaning of header timeout in master mode, so it is disabled.

- Slave mode
  - $\text{header\_nominal} = 13 + 2 + 10 + 10 = 35 \text{ Tbit}$
  - $\text{header\_max} = 1.4 \times \text{Header\_nominal} = 49 \text{ Tbit}$

- taking into account a possible 14% clock deviation, header\_max seen by LINFlexD is  $49 \times 1.14 = 56$  Tbit
- If the counter starts after 11 Tbit (break duration), the HTO value is  $56 - 11 = 45$  Tbit.

The reset value of HTO is 45, and this register can only be programmed in slave mode. Counter restarts after break duration and OC1 gets loaded with the value of HTO.

As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be reset and the output compare value can be updated in the LINTOCR register by software.

### Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

#### 52.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8<sup>th</sup>, 9<sup>th</sup> and 10<sup>th</sup> samples. If any one of these three samples has a value different from the other two, this error is flagged.

This error is flagged when there is noise detected in the start bit (see [LIN Error Status Register \(LINFlexD\\_LINESR\)](#)).

#### 52.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic `no_of_filters`) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

### **Identifier list mode**

If the  $n^{\text{th}}$  bit of IFMR is cleared, then filter number  $2n$  and  $2n+1$  is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals `no_of_filters`, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR $2n$  or IFCR $2n+1$  (if the corresponding FACT bit is set).

### **Identifier mask mode**

If the number of filters required is more than `no_of_filters`, then filters should be configured in Mask mode. If the  $n^{\text{th}}$  bit of IFMR is set, then filter number  $2n$  is the filter and  $2n+1$  acts as a mask for it. The FACT bit for filter  $2n+1$  has no effect in this case. In this mode, if the  $x^{\text{th}}$  bit of the mask is set, then the  $x^{\text{th}}$  bit of the received identifier must match the  $x^{\text{th}}$  bit of filter.

If there is a match of identifier with the  $m^{\text{th}}$  filter in any mode, then  $m+1$  is loaded in the IFMI register by hardware. No match condition is denoted by  $\text{IFMI} = 0$ .

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition ( $\text{IFMI} = 0$ ) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note

If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In mask mode if two filters match with the identifier then the filter having the lower number prevails.

52.3.2.7 Start detection and break delimiter detection in receiver

There is a 10-bit-shift register sample register in the receiver that shifts signal data to the next least significant bit on each incoming sample.

**Table 52-2. Start Detection and Delimiter Detection in receiver**

| 9   | 8   | 7   | 6    | 5    | 4    | 3    | 2    | 1    | 0    | Sample_reg       |
|-----|-----|-----|------|------|------|------|------|------|------|------------------|
| —   | —   | —   | —    | —    | —    | —    | —    | —    | RT1  | counter = 0      |
| —   | —   | —   | —    | —    | —    | —    | —    | RT1  | RT2  | counter = 1      |
| —   | —   | —   | —    | —    | —    | —    | RT1  | RT2  | RT3  | counter = 2      |
| —   | —   | —   | —    | —    | —    | RT1  | RT2  | RT3  | RT4  | counter = 3      |
| —   | —   | —   | —    | —    | RT1  | RT2  | RT3  | RT4  | RT5  | counter = 4      |
| —   | —   | —   | —    | RT1  | RT2  | RT3  | RT4  | RT5  | RT6  | counter = 5      |

| RT5 | RT6 | RT7 | RT8  | RT9  | RT10 | RT11 | RT12 | RT13 | RT14 | counter = 13     |
| RT6 | RT7 | RT8 | RT9  | RT10 | RT11 | RT12 | RT13 | RT14 | RT15 | counter = 14     |
| RT7 | RT8 | RT9 | RT10 | RT11 | RT12 | RT13 | RT14 | RT15 | RT16 | counter = 15     |
| 1   | 1   | 1   | 0    | x    | 0    | x    | 0    | x    | 0    | start detect     |
| 1   | 1   | 1   | 0    | x    | 0    | x    | 0    | x    | 1    |                  |
| 1   | 1   | 1   | 0    | x    | 0    | x    | 1    | x    | 0    |                  |
| 1   | 1   | 1   | 0    | x    | 1    | x    | 0    | x    | 0    |                  |
| 0   | 0   | 0   | 1    | x    | 1    | x    | 1    | x    | 1    | delimiter detect |
| 0   | 0   | 0   | 1    | x    | 1    | x    | 1    | x    | 0    |                  |
| 0   | 0   | 0   | 1    | x    | 1    | x    | 0    | x    | 1    |                  |
| 0   | 0   | 0   | 1    | x    | 0    | x    | 1    | x    | 1    |                  |

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero.

Similarly for delimiter detection, qualification samples are 0001 and at least two of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

### 52.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to [Table 52-2](#) for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '0', then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to '0' then Noise flag is set.

#### 52.3.2.7.2 Break delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to [Table 52-2](#) for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '1', then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero.

Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

### 52.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate Register and the LIN Fraction baud rate register. The Baud Rate Registers can be programmed only during Initialization mode.

Baud rate is calculated with the following formula for both receiver and transmitter.

$$T_x = R_x = \text{LIN\_CLK} / (16 \times \text{LDIV})$$

Where LIN\_CLK is the frequency of the baud clock.

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBR.

### 52.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When auto synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN\_CLK.

### 52.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250  $\mu$ s to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150  $\mu$ s) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready,

starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1 On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated if WUPIE is set. LINFlexD is now in normal mode and ready to receive frames.
2. AUTOWU = 0 On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE bit is set). It is then up to the software to clear the SLEEP bit.

**Figure 52-14. Wakeup sequence**

### 52.3.3 Timer

There is an 8-bit counter which has different behavior in different modes as described below:

- **In Output Compare Mode (LINTCSR[MODE]= 1):**

This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has reset the stuck FSM state.

- **In LIN Mode:**

The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

### 52.3.4 UART mode

Main features in the UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames, 13-bit frames, 16-bit frames, 17-bit frames
- Even/Odd/0/1 Parity

#### 52.3.4.1 8-bit data frames

The eighth bit can be a data or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

Figure 52-15. UART mode 8-bit data frame

#### 52.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

Figure 52-16. UART mode 9-bit data frame

### 52.3.4.3 16-bit data frames

The sixteenth bit can be a data or a parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

Figure 52-17. UART mode 16-bit data frame

### 52.3.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

Figure 52-18. UART mode 17-bit data frame

### 52.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

Figure 52-19. UART mode 13-bit data frame

### 52.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in the following figure:

|     |      |
|-----|------|
| Tx0 | BDR0 |
| Tx1 | BDR1 |
| Tx2 | BDR2 |
| Tx3 | BDR3 |
| Rx0 | BDR4 |
| Rx1 | BDR5 |
| Rx2 | BDR6 |
| Rx3 | BDR7 |

Figure 52-20. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and upper eight bits in BDR1. The same applies for reception.

### 52.3.4.7 UART transmitter

#### UART transmitter

In order to start transmission in the UART mode, UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the TxEn bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

### NOTE

If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

**Table 52-3. BDRL access in UART mode**

| IPS operation      | Register | Mode (UARTCR[TFBM]) | Word length (UARTCR[WL]) | IPS operation result |
|--------------------|----------|---------------------|--------------------------|----------------------|
| Write Byte0        | BDRL     | FIFO                | Byte                     | OK                   |
| Write Byte1-2-3    | BDRL     | FIFO                | Byte                     | IPS transfer error   |
| Write Half-word0-1 | BDRL     | FIFO                | Byte                     | IPS transfer error   |
| Write Word         | BDRL     | FIFO                | Byte                     | IPS transfer error   |
| Write Byte0-1-2-3  | BDRL     | FIFO                | Half-word                | IPS transfer error   |
| Write Half-word0   | BDRL     | FIFO                | Half-word                | OK                   |
| Write Half-word1   | BDRL     | FIFO                | Half-word                | IPS transfer error   |
| Write Word         | BDRL     | FIFO                | Half-word                | IPS transfer error   |
| Read Byte0-1-2-3   | BDRL     | FIFO                | Byte/Half-word           | IPS transfer error   |
| Read Half-word0-1  | BDRL     | FIFO                | Byte/Half-word           | IPS transfer error   |
| Read Word          | BDRL     | FIFO                | Byte/Half-word           | IPS transfer error   |
| Write Byte0-1-2-3  | BDRL     | BUFFER              | Byte/Half-word           | OK                   |
| Write Half-word0-1 | BDRL     | BUFFER              | Byte/Half-word           | OK                   |
| Write Word         | BDRL     | BUFFER              | Byte/Half-word           | OK                   |
| Read Byte0-1-2-3   | BDRL     | BUFFER              | Byte/Half-word           | OK                   |
| Read Half-word0-1  | BDRL     | BUFFER              | Byte/Half-word           | OK                   |
| Read Word          | BDRL     | BUFFER              | Byte/Half-word           | OK                   |

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

## 52.3.4.8 UART receiver

### UART receiver

The reception of a data byte is started as soon as the user exits initialization mode, sets the RxEn bit, and detects start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-half-words (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. RxEn bit needs to be set only to start the reception. The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

**Table 52-4. BDRM access in UART mode**

| IPS operation      | Register | Mode (UARTCR[RFBM]) | Word length (UARTCR:WL) | IPS operation result |
|--------------------|----------|---------------------|-------------------------|----------------------|
| Read Byte4         | BDRM     | FIFO                | Byte                    | OK                   |
| Read Byte5-6-7     | BDRM     | FIFO                | Byte                    | IPS transfer error   |
| Read Half-word2-3  | BDRM     | FIFO                | Byte                    | IPS transfer error   |
| Read Word          | BDRM     | FIFO                | Byte                    | IPS transfer error   |
| Read Byte4-5-6-7   | BDRM     | FIFO                | Half-word               | IPS transfer error   |
| Read Half-word2    | BDRM     | FIFO                | Half-word               | OK                   |
| Read Half-word3    | BDRM     | FIFO                | Half-word               | IPS transfer error   |
| Read Word          | BDRM     | FIFO                | Half-word               | IPS transfer error   |
| Write Byte4-5-6-7  | BDRM     | FIFO                | Byte/Half-word          | IPS transfer error   |
| Write Half-word2-3 | BDRM     | FIFO                | Byte/Half-word          | IPS transfer error   |
| Write Word         | BDRM     | FIFO                | Byte/Half-word          | IPS transfer error   |
| Read Byte4-5-6-7   | BDRM     | BUFFER              | Byte/Half-word          | OK                   |
| Read Half-word2-3  | BDRM     | BUFFER              | Byte/Half-word          | OK                   |
| Read Word          | BDRM     | BUFFER              | Byte/Half-word          | OK                   |
| Write Byte4-5-6-7  | BDRM     | BUFFER              | Byte/Half-word          | IPS transfer error   |
| Write Half-word2-3 | BDRM     | BUFFER              | Byte/Half-word          | IPS transfer error   |
| Write Word         | BDRM     | BUFFER              | Byte/Half-word          | IPS transfer error   |

### Note

Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and data bits of the registers BDRL/BDRM.

### Note

- If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number of bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to Idle state.
- If a STOP request arrives in the middle of one reception, it is only acknowledged after all the programmed number of data bytes have received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout. When the state machine moves to Idle state, then only a stop request is served.
- If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if FEIE bit in LINIER is set. As there is only one register bit for framing error, this interrupt will be helpful in identifying which byte has framing error.
- If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is depending on RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.
- When WLS bit = 1, BDRM access depends on WL bit setting.

- When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.
- When IPG\_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG\_STOP\_ACK is generated and IP enters STOP mode.

## 52.3.5 DMA interface

### 52.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

### 52.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in [Table 52-5](#) and [Table 52-6](#).

**Table 52-5. LINFlexD control/status fields description**

| Register | Field | Level | Description                                                                      |
|----------|-------|-------|----------------------------------------------------------------------------------|
| LINCR2   | DDRQ  | High  | Data discard request in reception mode                                           |
|          | DTRQ  | High  | Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM |
|          | HTRQ  | High  | Header transmission request (master mode)                                        |

*Table continues on the next page...*

**Table 52-5. LINFlexD control/status fields description (continued)**

| Register                          | Field     | Level   | Description                                                                                                                                                                                                                                               |
|-----------------------------------|-----------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BIDR                              | DFL [5:0] | —       | Data field length: <ul style="list-style-type: none"> <li>• 1 to 8 bytes: normal frames</li> <li>• 1 to 64 bytes: extended frames</li> </ul>                                                                                                              |
|                                   | DIR       | —       | Direction of the data field: <ul style="list-style-type: none"> <li>• 0 =&gt; reception</li> <li>• 1 =&gt; transmission</li> </ul>                                                                                                                        |
|                                   | CCS       | —       | Checksum type: <ul style="list-style-type: none"> <li>• 0 enhanced</li> <li>• 1 classic</li> </ul>                                                                                                                                                        |
|                                   | ID[5:0]   | —       | Identifier.                                                                                                                                                                                                                                               |
| LINSR                             | RMB       | —       | Buffer data ready to be read via CPU/DMA. <ul style="list-style-type: none"> <li>• 0 buffer data is free</li> <li>• 1 buffer data is ready</li> </ul>                                                                                                     |
|                                   | DBFF      | High    | Data buffer full (8 bytes received) and DFL > 7. Used for the extended frames.                                                                                                                                                                            |
|                                   | DBEF      | High    | Data buffer empty (8 bytes have been transmitted) and DFL > 7. Used for the extended frames.                                                                                                                                                              |
|                                   | DRF       | High    | Data reception completed                                                                                                                                                                                                                                  |
|                                   | DTF       | High    | Data transmission completed                                                                                                                                                                                                                               |
|                                   | HRF       | High    | Header received. Used in slave mode in case of Tx filter match.                                                                                                                                                                                           |
| IFMI                              | IFMIx     | != zero | Filter match index (slave mode).                                                                                                                                                                                                                          |
| UARTCR                            | FBM       | —       | FIFO/Buffer mode <ul style="list-style-type: none"> <li>• 0 Buffer mode</li> <li>• 1 FIFO mode (mandatory in DMA mode)</li> </ul>                                                                                                                         |
| UARTSR                            | RFE       | —       | Rx FIFO empty <ul style="list-style-type: none"> <li>• 0 Rx FIFO not empty</li> <li>• 1 Rx FIFO empty</li> </ul>                                                                                                                                          |
|                                   | TFF       | —       | Tx FIFO full <ul style="list-style-type: none"> <li>• 0 Tx FIFO not full</li> <li>• 1 Tx FIFO full</li> </ul>                                                                                                                                             |
| DMATXE[2**TX_CH_NUM] <sup>1</sup> |           | High    | DMA Tx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.<br><br>In LIN slave mode: # DMA TX channel = IFMI[3:0] - 1.<br><br>DMATXE[x] = 0b => TX channel x disabled<br>DMATXE[x] = 1b => TX channel x enabled |
| DMARXE[2**RX_CH_NUM] <sup>1</sup> |           | High    | DMA Rx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.                                                                                                                                                      |

**Table 52-5. LINFlexD control/status fields description**

| Register | Field | Level | Description                                                                                                                               |
|----------|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------|

1. \*\* stands for exponentiation.

1. \*\* stands for exponentiation

**Table 52-6. LINFlexD DMA control fields description**

| Field   | Mode                           | Value                     | Level | Description                                                    |
|---------|--------------------------------|---------------------------|-------|----------------------------------------------------------------|
| DMA_TEN | LIN master Tx<br>or<br>UART Tx | DMATXE[0]                 | High  | Logical AND between the 2 DMA enable bits (LINFlexD and eDMA). |
| DMA_TEN | LIN slave Tx                   | DMATXE[x]<br>x = IFMI — 1 | High  |                                                                |
| DMA_REN | LIN master Rx<br>or<br>UART Rx | DMARXE[0]                 | High  |                                                                |
| DMA_REN | LIN slave Rx                   | DMARXE[x]<br>x = IFMI — 1 | High  |                                                                |

Control/status fields of the TCD descriptors referred to in this document are described in [Table 52-7](#).

**Table 52-7. TCD control fields description**

| TCD Field    | Level | Description                                                                                                  |
|--------------|-------|--------------------------------------------------------------------------------------------------------------|
| CITER[14:0]  | —     | Current "major" iteration count                                                                              |
| BITER[14:0]  | —     | Beginning "major" iteration count                                                                            |
| NBYTES[31:0] | —     | Inner "minor" byte transfer count. Number of bytes to be transferred in each service request of the channel. |
| SADDR[31:0]  | —     | Source address                                                                                               |
| SOFF[15:0]   | —     | Source address signed offset applied to the current source address as each source read is completed.         |
| SSIZE[2:0]   | —     | Source data transfer size<br>000 => 8-bit<br>001 => 16-bit<br>010 => 32-bit<br>011 => 64-bit                 |
| SLAST[31:0]  | —     | Last source address adjustment                                                                               |
| DADDR[31:0]  | —     | Destination address                                                                                          |

*Table continues on the next page...*

**Table 52-7. TCD control fields description (continued)**

| TCD Field       | Level | Description                                                                                                                                                  |
|-----------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DOFF[15:0]      | —     | Destination address signed offset applied to the current destination address as each destination write is completed.                                         |
| DSIZE[2:0]      | —     | Destination data transfer size<br>000 => 8-bit<br>001 => 16-bit<br>010 => 32-bit<br>011 => 64-bit                                                            |
| DLAST_SGA[31:0] | —     | Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)                                   |
| INT_MAJ         | High  | Enable an interrupt when major iteration count completes                                                                                                     |
| START           | High  | The channel is explicitly started via a software initiated service request.                                                                                  |
| DONE            | High  | Channel done (the DMA has completed the outer major loop).                                                                                                   |
| D_REQ           | High  | Disable request. If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero. |

### 52.3.5.3 Master node –TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

**Figure 52-21. Master node –TX memory map**

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

The following table provides the register settings of the LINC2 and BIDR for each class of LIN frame.

**Table 52-8. Master node – Tx mode – Register setting**

| LIN frame       | LINC2                            | BIDR                                                                 |
|-----------------|----------------------------------|----------------------------------------------------------------------|
| Master to Slave | DDRQ = 1<br>DTRQ = 0<br>HTRQ = 0 | DFL = payload size<br>ID = address<br>CCS = checksum<br>DIR = 1 (TX) |
| Slave to Master | DDRQ = 0<br>DTRQ = 0<br>HTRQ = 0 | DFL = payload size<br>ID = address<br>CCS = checksum<br>DIR = 0 (RX) |

*Table continues on the next page...*

**Table 52-8. Master node – Tx mode – Register setting (continued)**

| LIN frame      | LINCR2                           | BIDR                                                                 |
|----------------|----------------------------------|----------------------------------------------------------------------|
| Slave to Slave | DDRQ = 1<br>DTRQ = 0<br>HTRQ = 0 | DFL = payload size<br>ID = address<br>CCS = checksum<br>DIR = 0 (RX) |

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in [Table 52-9](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

**Table 52-9. TCD setting – Master node – Tx mode**

| TCD Field       | Value                 | Description                                                                                               |
|-----------------|-----------------------|-----------------------------------------------------------------------------------------------------------|
| CITER[14:0]     | 1                     | Single iteration for the "major" loop                                                                     |
| BITER[14:0]     | 1                     | Single iteration for the "major" loop                                                                     |

**Figure 52-22. Master node – DMA Tx FSM (concept scheme)**

#### 52.3.5.4 Master node - RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

**Figure 52-23. Master node – RX memory map**

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in the following figure. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in the next table. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

**Table 52-10. TCD setting – Master node – Rx mode**

| TCD Field    | Value         | Description                                                                                      |

**Figure 52-24. Master node – DMA Rx FSM (concept scheme)**

### 52.3.5.5 Slave node – TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

**Figure 52-25. Slave node – TX memory map**

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in [Table 52-11](#).

**Table 52-11. Slave node – Tx mode – Register setting**

| LIN frame                            | LINCR2                           | IFER                                                     | IFMR                                                                                                     | IFCR                                                                 |
|--------------------------------------|----------------------------------|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Slave to Master<br>or Slave to Slave | DDRQ = 0<br>DTRQ = 0<br>HTRQ = 0 | To enable an ID filter (Tx mode) for each DMA TX channel | <ul style="list-style-type: none"> <li>• Identifier list mode</li> <li>• Identifier mask mode</li> </ul> | DFL = payload size<br>ID = address<br>CCS = checksum<br>DIR = 1 (TX) |

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state if  $DMATXE[x] = 0$  where  $x = IFMI - 1$ . The TCD setting (word transfer) is given in [Table 52-12](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

**Table 52-12. TCD setting – Slave node – Tx mode**

Figure 52-26. Slave node – DMA Tx FSM (concept scheme)

### 52.3.5.6 Slave node – RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

**Figure 52-27. Slave node – RX memory map**

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, IFCR registers is given in [Table 52-13](#).

**Table 52-13. Slave node – Rx mode – Register setting**

| LIN frame                            | LINCR2                           | IFER                                                           | IFMR                                                                                                     | IFCR                                                                 |
|--------------------------------------|----------------------------------|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| Master to Slave<br>or Slave to Slave | DDRQ = 0<br>DTRQ = 0<br>HTRQ = 0 | To enable an ID filter (Rx<br>mode) for each DMA RX<br>channel | <ul style="list-style-type: none"> <li>• Identifier list mode</li> <li>• Identifier mask mode</li> </ul> | DFL = payload size<br>ID = address<br>CCS = checksum<br>DIR = 0 (RX) |

The concept FSM to control the DMA Rx interface is given in the following figure. DMA Rx FSM moves to Idle state if  $DMARXE[x] = 0$  where  $x = IFMI - 1$ . The TCD setting (word transfer) is given in [Table 52-14](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

**Table 52-14. TCD setting – Slave node – Rx mode**

| TCD Field       | Value           | Description                                                                                      |

**Figure 52-28. Slave node – DMA Rx FSM (concept scheme)**

### 52.3.5.7 UART – TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Figure 52-29](#).

**Figure 52-29. UART – TX memory map**

The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8 bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

The concept FSM to control the DMA Tx interface is given in [Figure 52-30](#). DMA Tx FSM will move to Idle state if `DMATXE[0] = 0`. The TCD setting (typical case) is given in [Table 52-15](#). All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 52-15. TCD setting – UART – Tx mode

| TCD Field       | Value       |              | Description                              |
|-----------------|-------------|--------------|------------------------------------------|
|                 | 8 bits data | 16 bits data |                                          |

| START           | 0           |              | No SW request                            |

Figure 52-30. UART – DMA Tx FSM (concept scheme)

### 52.3.5.8 UART – RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Table 52-16](#).

**Figure 52-31. UART – RX memory map**

The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format

This will sufficient because just one byte allows a reaction time of about 3.8  $\mu$ s (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

The concept FSM to control the DMA Rx interface is given in [Figure 52-32](#). DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/ halfword as soon an entry is available in the Rx FIFO. A new software reset bit is

required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

**Table 52-16. TCD setting – UART – Rx mode**

| TCD Field       | Value       |              | Description                              |
|-----------------|-------------|--------------|------------------------------------------|
|                 | 8 bits data | 16 bits data |                                          |
| CITER[14:0]     | M           |              | Multiple iterations for the "major" loop |
| BITER[14:0]     | M           |              | Multiple iterations for the "major" loop |
| NBYTES[31:0]    | 1           | 2            | Minor loop transfer = 1 or 2 bytes       |
| SADDR[31:0]     | -           |              | BDRM address                             |
| SOFF[15:0]      | 0           |              | No increment (FIFO)                      |
| SSIZE[2:0]      | 0           | 1            | Byte/Half-word transfer                  |
| SLAST[31:0]     | 0           |              |                                          |
| DADDR[31:0]     | -           |              | RAM address                              |
| DOFF[15:0]      | 1           | 2            | Byte/Half-word increment                 |
| DSIZE[2:0]      | 0           | 1            | Byte/Half-word transfer                  |
| DLAST_SGA[31:0] | -M          | -M × 2       | No scatter/gather processing             |
| INT_MAJ         | 0/1         |              | Interrupt disabled/enabled               |
| D_REQ           | 1           |              | Only on the last TCD of the chain.       |
| START           | 0           |              | No SW request                            |

**Figure 52-32. UART – DMA Rx FSM (concept scheme)**

### 52.3.5.9 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index)
- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses

- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG\_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG\_STOP\_ACK is generated and IP enters STOP mode.

## 52.4 Memory map and register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

### NOTE

In Master mode, the registers IFCR0-IFCR15 are not present and the corresponding absolute address of the below register changes as shown in the following table.

**Table 52-17. Offsets of the register from offsets 8C to 9C**

| Register name    | Master/slave mode | Master only mode |
|------------------|-------------------|------------------|
| LINFlexD_GCR     | 0x8C              | 0x4C             |
| LINFlexD_UARTPTO | 0x90              | 0x50             |
| LINFlexD_UARTCTO | 0x94              | 0x54             |
| LINFlexD_DMATXE  | 0x98              | 0x58             |
| LINFlexD_DMARXE  | 0x9C              | 0x5C             |

### NOTE

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in transfer error.

### NOTE

Any access to A0 location will not generate a transfer error.

## 52.4.1 LIN Control Register 1 (LINFlexD\_LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

**NOTE**

When accessing the LINCR1 register, each reserved bit should be written to its original reset value.

Address: 0h base + 0h offset = 0h

|       |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

## LINFlexD\_LINESR field descriptions (continued)

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19<br>CEF         | Checksum Error flag<br>This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set.<br>Reset by hardware in Initialization mode.                                                                                                                                   |
| 20<br>SFEF        | Sync Field Error flag<br>This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software.<br>Reset by hardware in Initialization mode.<br>If generic slave = 0, then this bit will always read a 0, and cannot be programmed.                                                                                                                                      |
| 21<br>SDEF        | Sync Delimiter Error flag<br>This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software.<br>Reset by hardware in Initialization mode.<br><b>NOTE:</b> If generic slave = 0, then this bit will always read a 0, and cannot be programmed.                                                                                         |
| 22<br>IDPEF       | ID Parity Error flag<br>This bit is set by hardware when there is an error in the ID parity. It should be cleared by software.<br><b>NOTE:</b> Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set.<br>If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1, this bit is reset by hardware in Initialization mode. |
| 23<br>FEF         | Framing Error flag<br>This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software.<br>Reset by hardware in initialization mode.                                                                                                                                                                                                                            |
| 24<br>BOF         | Buffer overrun flag<br>This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software.<br>Reset by hardware in initialization mode.                                                                                                                                                                                                                  |
| 25–30<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                       |
| 31<br>NF          | Noise flag<br>This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.                                                                                                                                                                                                                                       |

## 52.4.5 UART Mode Control Register (LINFlexD\_UARTCR)

**NOTE**

When accessing the UARTCR register, reserved bits should always be written to zero.

**NOTE**

- The LINFlexD module in UART mode does not support communication with Special Word Length (UARTCR[WLS] = 1) in buffer mode.
- The LINFlexD module in UART mode supports communication with Special Word Length (UARTCR[WLS] = 1) in FIFO mode only with UARTCR[WL1, WL0] = 1,1.

Address: 0h base + 10h offset = 10h

## LINFlexD\_UARTSR field descriptions (continued)

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18–21<br>PE | <p>Parity Error flag</p> <p>These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs.</p> <p>This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set.</p> <p><b>NOTE:</b> Parity is checked only after complete frame is received. Following are the conditions when WL bits = 01 or 11 (either PE0 or PE2 is only set).</p> <ul style="list-style-type: none"> <li>• When PE0 is set, it indicates Parity error in either first or second byte received</li> <li>• When PE2 is set, it indicates Parity error in either third or fourth byte received</li> </ul> <p>0 No parity error<br/>1 Parity error in the corresponding received byte</p>       |
| 22<br>RMB   | <p>Release Message Buffer</p> <p>This bit should be cleared by software.</p> <p>This bit will reflect the same value as in LINSR, when in Initialization mode and the UART bit is set.</p> <p>0 Buffer data is free<br/>1 Buffer data ready to be read by software</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 23<br>FEF   | <p>Framing Error flag</p> <p>This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set.</p> <p>This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 24<br>BOF   | <p>FIFO/Buffer overrun flag</p> <p>This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the new value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set.</p> <p>This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.</p> |
| 25<br>RDI   | <p>Receiver Data Input signal</p> <p>This bit reflects the current status of the RX pin.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 26<br>WUF   | <p>Wakeup flag</p> <p>This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set.</p> <p>This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 27<br>RFNE  | <p>Receive FIFO Not Empty</p> <p>RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 28<br>TO    | <p>Timeout</p> <p>This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode.</p>                                                                                                                                                                                                                                                                                                                                                   |

|              | An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 29<br>DRFRFE | <p>Data Reception Completed Flag /Rx FIFO Empty Flag</p> <p>DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set.</p> <p>DRF bit is set when the configured number of valid stop bits are received for the last frame (number of frames is configurable by RDFL bits).</p> <p>DRF is set irrespective of framing error in case framing error is in the last STOP bit configured, parity error or overrun error. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set.</p> <p>Register bit can be read/cleared by software. Writing 1 clears contents.</p> <p>RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.</p> |
| 30<br>DTFTFF | <p>Data Transmission Completed Flag/ TX FIFO Full Flag</p> <p>DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set.</p> <p>Register bit can be read/cleared by software. Writing 1 clears contents.</p> <p>TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.</p>                                                                                                                                                                                                                                                                                                                             |
| 31<br>NF     | <p>Noise flag</p> <p>This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**52.4.7 LIN Time-Out Control Status Register (LINFlexD\_LINTCSR)**

This register contains control and status bits for timeout feature.

**NOTE**

When the MODE bit is 0, any activity on the transmit or receive pins will cause an unwanted change in the value of the 8-bit field Output Compare Value 2 (OC2) of the LIN Output Compare register (LINOCR). The LINFlexD module is enabled in LIN mode and the value of the MODE bit of the LIN Timeout Control Status register (LINTCSR) is changed from '1' to '0', then the old value of the Output Compare Value 1 (OC1) and Output Compare Value 2 (OC2) of the LIN Output Compare register (LINOCR) is retained. As a consequence, if the module is reconfigured from UART to LIN mode, or LINTCSR MODE bit is changed from '1' to '0', an incorrect

timeout exception is generated when a LIN communication starts. To avoid this, set mode bit to '1', then reconfigure the LINFlexD in LIN mode and then reset the MODE bit. Before switching LINTCSR[MODE] from 1 to 0 in between frames, load LINOCR with 0xFFFF.

Address: 0h base + 18h offset = 18h

| 24<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                         |
| 25–31<br>HTO     | Header timeout value<br>This register contains the header timeout duration (in bit time). This register can be written only for Slave mode.<br>If Master mode is enabled then these bits will always reflect 28 (1.4 x 10 bits of sync + 1.4 x 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break. |

## 52.4.10 LIN Fractional Baud Rate Register (LINFlexD\_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

### NOTE

When LASE bit is set, this register should be read only after AUTOSYNC\_COMP bit in LINSR register is set to obtain the correct value.

## 52.4.12 LIN Checksum Field Register (LINFlexD\_LINCFR)

## NOTE

There is a delay between 4 to 6 clock cycles of PBRIDGE<sub>Ex</sub>\_CLK for the internal checksum's value (which is clocked with LIN\_CLK/16 \* LDIV) to reflect on LINCFR.

This register consists of checksum bits.

| CFD | CCD | LINCHKSUM Read/write | Checksum sent       |
|-----|-----|----------------------|---------------------|
| 1   | 1   | read/write           | None                |
| 1   | 0   | read-only            | None                |
| 0   | 1   | read/write           | Programmed checksum |
| 0   | 0   | read-only            | Calculated checksum |

Address: 0h base + 2Ch offset = 2Ch

|       |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| 0–23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                             |
| 24–31<br>CF      | Checksum bits<br>When the CCD bit is reset these bits are read-only and are calculated by hardware. When the CCD bit is set, these bits can be written by software. |

### 52.4.13 LIN Control Register 2 (LINFlexD\_LINCR2)

This register includes control status bits related to buffer operations.

#### NOTE

When accessing the LINCR2 register, each reserved bit should be written to its original reset value.

Address: 0h base + 30h offset = 30h

|       |      |      |      |      |      |      |      |      |    |    |    |    |    |    |    |    |

## LINFlexD\_LINCR2 field descriptions (continued)

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <p>Register bit can be read in any mode, written only in initialization mode.</p> <p>If generic slave = 0, then this bit will always read a 1 else 0, and cannot be programmed.</p> <p>0 Parity Error does not reset LIN state machine<br/>1 Parity Error resets LIN state machine</p>                                                                                                                                                                                                                                                                              |
| 19<br>WURQ        | <p>Wakeup Generate Request</p> <p>Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit.</p> <p>Bit Error is not checked when transmitting the wakeup request.</p> <p>Register bit can be read/set by software</p>                                                                                                          |
| 20<br>DDRQ        | <p>Data Discard request</p> <p>Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.</p> <p>Register bit can be read/set by software</p>                                                                                                                                                                                                         |
| 21<br>DTRQ        | <p>Data Transmission Request</p> <p>Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception).</p> <p>Cleared by hardware when the request has been completed, or on abort request or error condition.</p> <p>In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.</p> <p>Register bit can be read/set by software</p> |
| 22<br>ABRQ        | <p>Abort Request</p> <p>Set by software to abort the current transmission.</p> <p>Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.</p> <p>Register bit can be read/set by software</p> <p>Register bit can be read/set by software</p>                                                                                                                                                                       |
| 23<br>HTRQ        | <p>Header Transmission Request</p> <p>Set by software to request the transmission of the LIN Header.</p> <p>Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode.</p> <p><b>NOTE:</b> In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.</p>                                                                                                     |
| 24–31<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 52.4.14 Buffer Identifier Register (LINFlexD\_BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

### NOTE

All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0h base + 34h offset = 34h

## 52.4.20 Identifier Filter Control Register (LINFlexD\_IFCRn)

This register is read-only in normal mode and can be programmed only in Initialization mode.

Even-numbered instances (IFCR0, IFCR2, IFCR4, ...) of this register act as filters in both Identifier list and Identifier mask modes.

Odd-numbered instances (IFCR1, IFCR3, IFCR5, ...) of this register act:

- As filters in Identifier list mode
- As a mask for the preceding-numbered register in identifier mask mode

Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 4Ch offset + (4d × i), where i=0d to 15d

## 52.4.21 Global Control Register (LINFlexD\_GCR)

This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

The address offset depends on the no\_of\_filters. Refer to the chip configuration details for the number of filters used in this device.

Table 52-18. Register fields reset by SR

| Register | Comment                                              |
|----------|------------------------------------------------------|
| LINSR    | All fields except RXbusy and AUTOSYNC_COMP are reset |
| LINESR   | All fields are reset                                 |
| LINTCSR  | Only CNT[0:7] is reset                               |
| UARTSR   | All fields except RFE & TFF are reset                |
| UARTCR   | Only TFC & RFC are reset                             |
| UARTCTO  | All fields are reset                                 |

| 31<br>SR         | Soft reset<br>SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware).<br>Register bit can be written only by software in initialization mode. Bit is always read 0 by software.<br><a href="#">Table 52-18</a> describes the register fields reset by SR.           |

## 52.4.22 UART Preset Timeout Register (LINFlexD\_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received. This register can be written by software any time.

The address offset depends on no\_of\_filters. Refer to the chip configuration details to see the number of filters used in the device.

Address: 0h base + 90h offset = 90h

**LINFlexD\_UARTPTO field descriptions**

| Field            | Description                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                               |
| 20–31<br>PTO     | Preset Timeout<br>PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer also to register UARTCTO. |

## 52.4.23 UART Current Timeout Register (LINFlexD\_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see [UART Preset Timeout Register \(LINFlexD\\_UARTPTO\)](#)) to monitor the number of bits received by UART. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN\_CLK / (16 \* LDIV) synchronized to PBRIDGE<sub>x</sub>\_CLK
- Is automatically enabled when UARTCR[RXEN] = 1

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO

## Memory map and register description

- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

The address offset depends on no\_of\_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 94h offset = 94h

## LINFlexD\_DMATXE field descriptions (continued)

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <b>NOTE:</b> The number of reserved bits varies, and is equal to $32 - 2^{TX\_CH\_NUM}$ . These lies from 0 to $(31 - 2^{TX\_CH\_NUM})$ . Refer to the chip configuration details for the value of TX_CH_NUM used in this device.                                                                                                                                                                                                                                                                                         |
| 16–31<br>DTE | DMA Tx channel Y enable<br><br><b>NOTE:</b> The actual size of the register DMATXE depends on the value of the static parameter TX_CH_NUM. The size is $[2^{TX\_CH\_NUM} - 1 : 0]$ . The position of these bits are $(32 - 2^{TX\_CH\_NUM})$ to 31. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state.<br><br><b>NOTE:</b> Refer to the chip configuration details for the value of TX_CH_NUM used in this device.<br><br>0 DMA Tx channel Y disabled<br>1 DMA Tx channel Y enabled |

## 52.4.25 DMA Rx Enable Register (LINFlexD\_DMARXE)

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no\_of\_filters. Refer to device configuration chapter to see the number of filters used in the device.

Address: 0h base + 9Ch offset = 9Ch

When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state.<br><br><b>NOTE:</b> Refer to the chip configuration details for the value of RX_CH_NUM used in this device.<br><br>0 DMA Rx channel Y disabled<br>1 DMA Rx channel Y enabled |

## 52.5 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

### 52.5.1 Master node

LINFlexD acts as Master when the MME bit is set.

#### 52.5.1.1 Transmitter

Transmitter Master Node - Transmitter configuration.

Figure 52-33. Master node – Transmitter configuration

#### 52.5.1.2 Receiver

Receiver Master Mode - RX Configuration

Figure 52-34. Master node – Receiver configuration

### 52.5.1.3 Transmitter, Bit Error

Figure 52-35. Master node – Transmitter, Bit Error configuration

Figure 52-36. Master node – Transmitter, Checksum Error configuration

### 52.5.1.4 Receiver, Checksum Error

Checksum Error for Receiver.

Figure 52-37. Master node – Receiver, Checksum Error configuration

## 52.5.2 Slave node

Slave node (transmitter).

### 52.5.2.1 Transmitter (no identifier filters)

Figure 52-38. Slave node – Transmitter (no identifier filters) configuration

### 52.5.2.2 Receiver (no identifier filters)

Figure 52-39. Slave node – Receiver (no identifier filters) configuration

Figure 52-40. Slave node – Receiver (no identifier filters) configuration

### 52.5.2.3 No filters, Transmitter, Bit error

The following figure shows Slave node - No filters, Transmitter, Bit error configuration.

**Figure 52-41. Slave node – No filters, Transmitter, Bit error configuration**

#### 52.5.2.4 No filters, Receiver, Checksum Error

The following figure shows Slave node - No filters, Receiver, Checksum error configuration.

**Figure 52-42. Slave node – No filters, Receiver, Checksum error configuration**

#### 52.5.2.5 At least one TX filter, BF is reset, ID matches filter

This configuration can be used in case slave never receives data, for example, sensor.

**Figure 52-43. Slave node – one TX filter configuration**

#### 52.5.2.6 At least one RX filter, BF reset, ID matches filter

The following figure shows Slave node - one RX filter configuration.

**Figure 52-44. Slave node – one RX filter configuration**

### 52.5.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

The following figure shows RX only, TX only, RX and TX filters configuration.

**Figure 52-45. RX only, TX only, RX & TX filters configuration**

### 52.5.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

**Figure 52-46. TX filter, BF is set configuration – ID has matched**

Figure 52-47. TX filter, BF is set configuration – ID not matched

### 52.5.2.9 RX filter, BF is set

The following figures show RX filter configurations.

Figure 52-48. RX filter, BF is set configuration – ID matched

Figure 52-49. RX filter, BF is set configuration – ID not matched (ID is Rx)

Figure 52-50. RX filter, BF is set configuration – (ID is Tx)

### 52.5.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

Figure 52-51. TX filter, RX filter, BF set configuration – (ID matched)

Figure 52-52. TX filter, RX filter, BF set configuration – (ID matched + 1)

Figure 52-53. TX filter, RX filter, BF set configuration – (ID not matched, RX/TX Interrupt)

## 52.5.3 Extended frames

The following figure shows Extended frames (RX Interrupt).

Figure 52-54. Extended frames (TX Interrupt)

Figure 52-55. Extended frames (RX Interrupt)

### 52.5.4 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

Figure 52-56. Response timeout

Figure 52-57. Frame timeout

Figure 52-58. Header timeout

## 52.5.5 UART mode

The following figure shows UART mode configuration.

Figure 52-59. UART mode configuration

## 52.5.6 Interrupts

Interrupt section.

**Table 52-19. Interrupts**

| Interrupt Event         | Event flag                                              | Enable control bit | Interrupt vector                                  |
|-------------------------|---------------------------------------------------------|--------------------|---------------------------------------------------|
| Stuck at zero           | SZF                                                     | SZIE               | Error                                             |
| Output compare          | OCF                                                     | OCIE               | Error                                             |
| Bit error               | BEF                                                     | BEIE               | Error                                             |
| Checksum error          | CEF                                                     | CEIE               | Error                                             |
| Header error            | SFEF orSDEF orIDPEF                                     | HEIE               | Error                                             |
| Frame error             | FEF                                                     | FEIE               | Error                                             |
| Buffer Overrun error    | BOF                                                     | BOIE               | Error                                             |
| UART Timeout error      | TO                                                      | TOIE               | Error                                             |
| Lin state               | Sync Del, Sync Field,Identifier field or Checksum Field | LSIE               | Rx                                                |
| Wakeup                  | WUF                                                     | WUIE               | Rx                                                |
| Data buffer full        | DBFF                                                    | DBFIE              | Rx                                                |
| Data buffer empty       | DBEF                                                    | DBEIE              | Tx                                                |
| Data Reception Complete | DRF                                                     | DRIE               | Rx                                                |
| Data transmitted        | DTF                                                     | DTIE               | Tx                                                |
| Header received         | HRF                                                     | HRIE               | Rx                                                |
| Header received         | HRF                                                     | HRIE               | Tx (if there is a filter match for Tx identifier) |

The following figure shows an Interrupt Flow Diagram.

Figure 52-60. Interrupt diagram

## 52.5.7 LINFlexD Clock Tolerance

### 1. Faster receiver tolerance:

In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct noise and framing error free reception bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

Figure 52-61. Faster receiver

## 2. Slower receiver tolerance:

In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct noise and framing error free reception bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

Figure 52-62. Slower receiver

# Chapter 53

## 10/100-Mbps Ethernet MAC (ENET)

### 53.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

### 53.2 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

## 53.2.1 Features

### 53.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q

- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors

### 53.2.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers

- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

### **53.2.1.3 IEEE 1588 features**

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

## 53.2.2 Block diagram

Figure 53-1. Ethernet MAC-NET core block diagram

## 53.3 External signal description

### NOTE

The MII column pertains only to devices that support MII.

| MII     | RMII | Description                                                                                                                                         | I/O |
|---------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII_COL | —    | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.          | I   |
| MII_CRS | —    | Carrier sense. When asserted, indicates transmit or receive medium is not idle.<br><br>In RMII mode, this signal is present on the RMII_CRS_DV pin. | I   |

Table continues on the next page...

## External signal description

| MII          | RMII          | Description                                                                                                                                                                                                                                                                                                       | I/O |
|--------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
| MII_MDC      | RMII_MDC      | Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.                                                                                                                                                                                                                        | O   |
| MII_MDIO     | RMII_MDIO     | Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.                                                                                                                                                          | I/O |
| MII_RXCLK    | —             | In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER.                                                                                                                                                                                                                                            | I   |
| MII_RXDV     | RMII_CRS_DV   | Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. | I   |
| MII_RXD[3:0] | RMII_RXD[1:0] | Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.                                                                                                                                                                                                   | I   |
| MII_RXER     | RMII_RXER     | When asserted with RXDV, indicates the PHY detects an error in the current frame.                                                                                                                                                                                                                                 | I   |
| MII_TXCLK    | —             | Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.                                                                                                                                                                                                                                      | I   |
| MII_TXD[3:0] | RMII_TXD[1:0] | Serial output Ethernet data. Only valid during TXEN assertion.                                                                                                                                                                                                                                                    | O   |
| MII_TXEN     | RMII_TXEN     | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame.                                                                                                                | O   |
| MII_TXER     | —             | When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.                                                                                                                                                                                                    | O   |

| —                     | RMII_REF_CLK          | In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | I   |
| 1588_TMR <sub>n</sub> | 1588_TMR <sub>n</sub> | <p>Capture/Compare block input/output event bus.</p> <p>When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR<sub>n</sub> register for inspection by software.</p> <p>When configured for compare, the corresponding signal 1588_TMR<sub>n</sub> is asserted for one cycle when the timer reaches the compare value programmed in ENET_TCCR<sub>n</sub>.</p> <p>An interrupt can be triggered if ENET_TCSR<sub>n</sub>[TIE] is set.</p> <p>A DMA request can be triggered if ENET_TCSR<sub>n</sub>[TDRE] is set.</p> | I/O |
| ENET_1588_CLKIN       | ENET_1588_CLKIN       | Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | I   |

## 53.4 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

**Table 53-1. Register map summary**

| Offset Address  | Section               | Description                                            |
|-----------------|-----------------------|--------------------------------------------------------|
| 0x0000 – 0x01FF | Configuration         | Core control and status registers                      |
| 0x0200 – 0x03FF | Statistics counters   | MIB and Remote Network Monitoring (RFC 2819) registers |
| 0x0400 – 0x0430 | 1588 control          | 1588 adjustable timer (TSM) and 1588 frame control     |
| 0x0600 – 0x07FC | Capture/Compare block | Registers for the Capture/Compare block                |

## ENET memory map

| Address offset (hex) | Register name                                              | Width (in bits) | Access | Reset value | Section/ page                |
|----------------------|------------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 4                    | Interrupt Event Register (ENET_EIR)                        | 32              | w1c    | 0000_0000h  | <a href="#">53.4.1/2052</a>  |
| 8                    | Interrupt Mask Register (ENET_EIMR)                        | 32              | R/W    | 0000_0000h  | <a href="#">53.4.2/2055</a>  |
| 10                   | Receive Descriptor Active Register (ENET_RDAR)             | 32              | R/W    | 0000_0000h  | <a href="#">53.4.3/2058</a>  |
| 14                   | Transmit Descriptor Active Register (ENET_TDAR)            | 32              | R/W    | 0000_0000h  | <a href="#">53.4.4/2058</a>  |
| 24                   | Ethernet Control Register (ENET_ECR)                       | 32              | R/W    | F000_0000h  | <a href="#">53.4.5/2059</a>  |
| 40                   | MII Management Frame Register (ENET_MMFR)                  | 32              | R/W    | 0000_0000h  | <a href="#">53.4.6/2061</a>  |
| 44                   | MII Speed Control Register (ENET_MSCR)                     | 32              | R/W    | 0000_0000h  | <a href="#">53.4.7/2062</a>  |
| 64                   | MIB Control Register (ENET_MIBC)                           | 32              | R/W    | C000_0000h  | <a href="#">53.4.8/2064</a>  |
| 84                   | Receive Control Register (ENET_RCR)                        | 32              | R/W    | 05EE_0001h  | <a href="#">53.4.9/2065</a>  |
| C4                   | Transmit Control Register (ENET_TCR)                       | 32              | R/W    | 0000_0000h  | <a href="#">53.4.10/2068</a> |
| E4                   | Physical Address Lower Register (ENET_PALR)                | 32              | R/W    | 0000_0000h  | <a href="#">53.4.11/2070</a> |
| E8                   | Physical Address Upper Register (ENET_PAUR)                | 32              | R/W    | 0000_8808h  | <a href="#">53.4.12/2070</a> |
| EC                   | Opcode/Pause Duration Register (ENET_OPD)                  | 32              | R/W    | 0001_0000h  | <a href="#">53.4.13/2071</a> |
| 118                  | Descriptor Individual Upper Address Register (ENET_IAUR)   | 32              | R/W    | 0000_0000h  | <a href="#">53.4.14/2071</a> |
| 11C                  | Descriptor Individual Lower Address Register (ENET_IALR)   | 32              | R/W    | 0000_0000h  | <a href="#">53.4.15/2072</a> |
| 120                  | Descriptor Group Upper Address Register (ENET_GAUR)        | 32              | R/W    | 0000_0000h  | <a href="#">53.4.16/2072</a> |
| 124                  | Descriptor Group Lower Address Register (ENET_GALR)        | 32              | R/W    | 0000_0000h  | <a href="#">53.4.17/2073</a> |
| 144                  | Transmit FIFO Watermark Register (ENET_TFWR)               | 32              | R/W    | 0000_0000h  | <a href="#">53.4.18/2073</a> |
| 180                  | Receive Descriptor Ring Start Register (ENET_RDSCR)        | 32              | R/W    | 0000_0000h  | <a href="#">53.4.19/2074</a> |
| 184                  | Transmit Buffer Descriptor Ring Start Register (ENET_TDSR) | 32              | R/W    | 0000_0000h  | <a href="#">53.4.20/2075</a> |
| 188                  | Maximum Receive Buffer Size Register (ENET_MRBR)           | 32              | R/W    | 0000_0000h  | <a href="#">53.4.21/2076</a> |
| 190                  | Receive FIFO Section Full Threshold (ENET_RSFL)            | 32              | R/W    | 0000_0000h  | <a href="#">53.4.22/2077</a> |
| 194                  | Receive FIFO Section Empty Threshold (ENET_RSEM)           | 32              | R/W    | 0000_0000h  | <a href="#">53.4.23/2077</a> |
| 198                  | Receive FIFO Almost Empty Threshold (ENET_RAEM)            | 32              | R/W    | 0000_0004h  | <a href="#">53.4.24/2078</a> |
| 19C                  | Receive FIFO Almost Full Threshold (ENET_RAFL)             | 32              | R/W    | 0000_0004h  | <a href="#">53.4.25/2078</a> |

**53.4.1 Interrupt Event Register (ENET\_EIR)**

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

**NOTE**

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET\_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 0h base + 4h offset = 4h

**ENET\_EIR field descriptions**

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                   |
| 1<br>BABR     | Babbling Receive Error<br>Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.                                                                                                                                                                                                                                                                                                                                      |
| 2<br>BABT     | Babbling Transmit Error<br>Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.                                                                                                                                                                                                        |
| 3<br>GRA      | Graceful Stop Complete<br>This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop.<br><b>NOTE:</b> The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again. |
| 4<br>TXF      | Transmit Frame Interrupt<br>Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                         |
| 5<br>TXB      | Transmit Buffer Interrupt<br>Indicates a transmit buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                                                                     |
| 6<br>RXF      | Receive Frame Interrupt<br>Indicates a frame has been received and the last corresponding buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                             |

*Table continues on the next page...*

**ENET\_EIR field descriptions (continued)**

| Field             | Description                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>RXB          | Receive Buffer Interrupt<br><br>Indicates a receive buffer descriptor is not the last in the frame has been updated.                                                                                                                                                                                       |
| 8<br>MII          | MII Interrupt.<br><br>Indicates that the MII has completed the data transfer requested.                                                                                                                                                                                                                    |
| 9<br>EBERR        | Ethernet Bus Error<br><br>Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation. |
| 10<br>LC          | Late Collision<br><br>Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.                                                                                                          |
| 11<br>RL          | Collision Retry Limit<br><br>Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.                                         |
| 12<br>UN          | Transmit FIFO Underrun<br><br>Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.                                                                                                 |
| 13<br>PLR         | Payload Receive Error<br><br>Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.                                                                                                                                    |
| 14<br>WAKEUP      | Node Wakeup Request Indication<br><br>Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.                                                                                                                                                        |
| 15<br>TS_AVAIL    | Transmit Timestamp Available<br><br>Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.                                                                                                                                                                 |
| 16<br>TS_TIMER    | Timestamp Timer<br><br>The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].                                  |

## 53.4.2 Interrupt Mask Register (ENET\_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 0h base + 8h offset = 8h

53.4.3 Receive Descriptor Active Register (ENET\_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 0h base + 10h offset = 10h

53.4.4 Transmit Descriptor Active Register (ENET\_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 0h base + 14h offset = 14h

**53.4.5 Ethernet Control Register (ENET\_ECR)**

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 0h base + 24h offset = 24h

**53.4.6 MII Management Frame Register (ENET\_MMFR)**

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

**53.4.7 MII Speed Control Register (ENET\_MSCR)**

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII\_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII\_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII\_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII\_SPEED as a function of IPS bus clock frequency.

**Table 53-2. Programming Examples for MSCR**

| Internal module clock frequency | MSCR [MII_SPEED] | MDC frequency |
|---------------------------------|------------------|---------------|
| 25 MHz                          | 0x4              | 2.50 MHz      |
| 33 MHz                          | 0x6              | 2.36 MHz      |
| 40 MHz                          | 0x7              | 2.50 MHz      |
| 50 MHz                          | 0x9              | 2.50 MHz      |

*Table continues on the next page...*

A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of:<br><br>$1/((\text{MII\_SPEED} + 1) \times 2)$ of the internal module clock frequency           |
| 31<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                    |

53.4.8 MIB Control Register (ENET\_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB\_DIS field resets to 1.

Address: 0h base + 64h offset = 64h

| <b>Field</b>    | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p>0 TxBD[TC] controls whether the frame has a CRC from the application.</p> <p>1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 23<br>ADDINS    | <p>Set MAC Address On Transmit</p> <p>0 The source MAC address is not modified by the MAC.</p> <p>1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 24–26<br>ADDSEL | <p>Source MAC Address Select On Transmit</p> <p>If ADDINS is set, indicates the MAC address that overwrites the source MAC address.</p> <p>000 Node MAC address programmed on PADDR1/2 registers.</p> <p>100 Reserved.</p> <p>101 Reserved.</p> <p>110 Reserved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                |
| 27<br>RFC_PAUSE | <p>Receive Frame Control Pause</p> <p>This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.</p>                                                                                                                                                                                                                                                                                                                                                                                                            |
| 28<br>TFC_PAUSE | <p>Transmit Frame Control Pause</p> <p>Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.</p> <p>0 No PAUSE frame transmitted.</p> <p>1 The MAC stops transmission of data frames after the current transmission is complete.</p>                                                                                                                   |
| 29<br>FDEN      | <p>Full-Duplex Enable</p> <p>If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 30<br>Reserved  | <p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 31<br>GTS       | <p>Graceful Transmit Stop</p> <p>When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.</p> |

53.4.11 Physical Address Lower Register (ENET\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 0h base + E4h offset = E4h

ENET\_PALR field descriptions

| Field          | Description                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>PADDR1 | Pause Address<br><br>Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames. |

53.4.12 Physical Address Upper Register (ENET\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 0h base + E8h offset = E8h

ENET\_PAUR field descriptions

| Field          | Description                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>PADDR2 | Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames. |
| 16–31<br>TYPE  | Type Field In PAUSE Frames<br><br>These fields have a constant value of 0x8808.                                                              |

### 53.4.13 Opcode/Pause Duration Register (ENET\_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 0h base + ECh offset = ECh

### 53.4.14 Descriptor Individual Upper Address Register (ENET\_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

**ENET\_IAUR field descriptions**

| Field          | Description                                                                                                                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>IADDR1 | Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32. |

53.4.15 Descriptor Individual Lower Address Register (ENET\_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 0h base + 11Ch offset = 11Ch

ENET\_IALR field descriptions

| Field          | Description                                                                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>IADDR2 | Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0. |

53.4.16 Descriptor Group Upper Address Register (ENET\_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 0h base + 120h offset = 120h

ENET\_GAUR field descriptions

| Field          | Description                                                                                                                                                                                                                       |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>GADDR1 | Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32. |

### 53.4.17 Descriptor Group Lower Address Register (ENET\_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 0h base + 124h offset = 124h

#### ENET\_GALR field descriptions

| 0–31<br>GADDR2 | Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0. |

### 53.4.18 Transmit FIFO Watermark Register (ENET\_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR\_FWD is set to '0', the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR\_FWD to '1'. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

## Memory map/register definition

Address: 0h base + 144h offset = 144h

## 53.4.19 Receive Descriptor Ring Start Register (ENET\_RDSR)

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, it is recommended to be 128-bit aligned, that is, evenly divisible by 16.

### NOTE

This register must be initialized prior to operation

Address: 0h base + 180h offset = 180h

|       |             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**53.4.21 Maximum Receive Buffer Size Register (ENET\_MRBR)**

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- R\_BUF\_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX\_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 16. To ensure this, the lower four bits are set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

**NOTE**

This register must be initialized before operation.

Address: 0h base + 188h offset = 188h

| 24–31<br>TX_ALMOST_FULL | Value Of The Transmit FIFO Almost Full Threshold<br><br>Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).<br><br>When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See <a href="#">Transmit FIFO</a> for more information.<br><br><b>NOTE:</b> A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN. |

## 53.4.29 Transmit Inter-Packet Gap (ENET\_TIPG)

Address: 0h base + 1ACh offset = 1ACh

| 18–31<br>TRUNC_FL | Frame Truncation Length<br><br>Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].<br><br><b>NOTE:</b> Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit. |

**53.4.31 Transmit Accelerator Function Configuration (ENET\_TACC)**

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

#### ENET\_IEEE\_R\_OCTETS\_OK field descriptions

| Field         | Description                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>COUNT | Number of octets for frames received without error<br><br><b>NOTE:</b> Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR). |

### 53.4.87 Adjustable Timer Control Register (ENET\_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

Address: 0h base + 400h offset = 400h

|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>PERIOD | Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10 <sup>9</sup> ) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.<br><br><b>NOTE:</b> The value of PERIOD has the following constraint:<br>$2^{32} - \text{ENET\_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET\_ATINC}[\text{INC}] \geq \text{PERIOD} > 0.$ |

**ENET\_TCCR<sub>n</sub> field descriptions**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>TCC | <p>Timer Capture Compare</p> <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p> |

**53.5 Functional description**

This section provides a complete functional description of the MAC-NET core.

### 53.5.1 Ethernet MAC frame formats

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

**Figure 53-2. MAC frame format overview**

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

Figure 53-3. VLAN-tagged MAC frame format overview

Table 53-3. MAC frame definition

| Term                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame length                   | Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.                                                                                                                                                                                                                                                                                                                                                           |
| Payload length                 | The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. <ul style="list-style-type: none"><li>• If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</li><li>• If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</li></ul> |
| Destination and source address | 48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in <a href="#">MAC address check</a> .                                                                                                                                                                                                                                                                                                                                           |

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

53.5.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

**Table 53-4. Pause Frame Format (Values in Hex)**

|                |    |    |    |    |    |      |     |                               |    |    |    |          |    |
|----------------|----|----|----|----|----|------|-----|-------------------------------|----|----|----|----------|----|
| 1              | 2  | 3  | 4  | 5  | 6  | 7    | 8   | 9                             | 10 | 11 | 12 | 13       | 14 |
| 55             | 55 | 55 | 55 | 55 | 55 | 55   | D5  | 01                            | 80 | C2 | 00 | 00       | 01 |
| Preamble       |    |    |    |    |    |      | SFD | Multicast Destination Address |    |    |    |          |    |
| 15             | 16 | 17 | 18 | 19 | 20 | 21   | 22  | 23                            | 24 | 25 | 26 | 27 –68   |    |
| 00             | 00 | 00 | 00 | 00 | 00 | 88   | 08  | 00                            | 01 | hi | lo | 00       |    |
| Source Address |    |    |    |    |    | Type |     | Opcode                        |    | P1 | P2 | pad (42) |    |
| 69             | 70 | 71 | 72 |    |    |      |     |                               |    |    |    |          |    |
| 26             | 6B | AE | 0A |    |    |      |     |                               |    |    |    |          |    |
| CRC-32         |    |    |    |    |    |      |     |                               |    |    |    |          |    |

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

### 53.5.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

## 53.5.2 IP and higher layers frame format

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

### 53.5.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

**Table 53-5. Ethernet type value examples**

| Type   | Description                                                              |
|--------|--------------------------------------------------------------------------|
| 0x8100 | VLAN-tagged frame. The actual type is found 4 octets later in the frame. |
| 0x0800 | IPv4                                                                     |
| 0x0806 | ARP                                                                      |
| 0x86DD | IPv6                                                                     |

### 53.5.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

**Table 53-6. IPv4 header format**

|                     |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|-----|----|----|----|----------|----|----|----|----|----|----|----|-----------------|----|----|----|-----------------|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27  | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15              | 14 | 13 | 12 | 11              | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Version             |    |    |    | IHL |    |    |    | TOS      |    |    |    |    |    |    |    | Length          |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Fragment ID         |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    | Flags           |    |    |    | Fragment offset |    |   |   |   |   |   |   |   |   |   |   |
| TTL                 |    |    |    |     |    |    |    | Protocol |    |    |    |    |    |    |    | Header checksum |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Source address      |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |
| Options             |    |    |    |     |    |    |    |          |    |    |    |    |    |    |    |                 |    |    |    |                 |    |   |   |   |   |   |   |   |   |   |   |

**Table 53-7. IPv4 header fields**

| Field name                          | Description                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Version                             | 4-bit IP version information. 0x4 for IPv4 frames.                                                                                                           |
| IHL                                 | 4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5. |
| TOS                                 | Type of service/DiffServ field.                                                                                                                              |
| Length                              | Total length of the datagram in bytes, including all octets of header and payload.                                                                           |
| Fragment ID, flags, fragment offset | Fields used for IP fragmentation.                                                                                                                            |
| TTL                                 | Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.                                                         |
| Protocol                            | Identifier of protocol that follows in the datagram.                                                                                                         |
| Header checksum                     | Checksum of IP header. For computational purposes, this field's value is zero.                                                                               |
| Source address                      | Source IP address.                                                                                                                                           |
| Destination address                 | Destination IP address.                                                                                                                                      |

### 53.5.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

**Figure 53-4. IPv6 header format**

**Table 53-8. IPv6 header fields**

| Field name          | Description                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| Version             | 4-bit IP version information. 0x6 for all IPv6 frames.                                                                    |
| Traffic class       | 8-bit field defining the traffic class.                                                                                   |
| Flow label          | 20-bit flow label identifying frames of the same flow.                                                                    |
| Payload length      | 16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.                         |
| Next header         | Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header. |
| Hop limit           | Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.   |
| Source address      | 128-bit IPv6 source address.                                                                                              |
| Destination address | 128-bit IPv6 destination address.                                                                                         |

### 53.5.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

**Table 53-9. ICMP header format**

|                   |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------------|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Type              |    |    |    |    |    |    |    | Code |    |    |    |    |    |    |    | Checksum |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| ICMP message data |    |    |    |    |    |    |    |      |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 53-10. IP header fields**

| Field name | Description                                                      |
|------------|------------------------------------------------------------------|
| Type       | 8-bit type information                                           |
| Code       | 8-bit code that is related to the message type                   |
| Checksum   | 16-bit one's complement checksum over the complete ICMP datagram |

### 53.5.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

**Table 53-11. UDP header format**

|             |    |    |    |    |    |    |    |    |    |    |    |                  |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|----|----|----|----|----|----|------------------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19               | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source port |    |    |    |    |    |    |    |    |    |    |    | Destination port |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Length      |    |    |    |    |    |    |    |    |    |    |    | Checksum         |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 53-12. UDP header fields**

| Field name       | Description                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------|
| Source port      | Source application port                                                                                          |
| Destination port | Destination application port                                                                                     |
| Length           | Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8) |
| Checksum         | Checksum over the complete datagram and some IP header information                                               |

### 53.5.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

**Table 53-13. TCP header format**

|                        |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
|------------------------|----|----|----|----------|----|----|----|----|----|----|----|-------|----|----|----|------------------|----|----|----|--------|----|---|---|---|---|---|---|---|---|---|---|--|--|--|--|
| 31                     | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19    | 18 | 17 | 16 | 15               | 14 | 13 | 12 | 11     | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |  |  |  |
| Source port            |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    | Destination port |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| Sequence number        |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| Acknowledgement number |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| Offset                 |    |    |    | Reserved |    |    |    |    |    |    |    | Flags |    |    |    |                  |    |    |    | Window |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| Checksum               |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    | Urgent pointer   |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |
| Options                |    |    |    |          |    |    |    |    |    |    |    |       |    |    |    |                  |    |    |    |        |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |

**Table 53-14. TCP header fields**

| Field name       | Description                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------|
| Source port      | Source application port                                                                                         |
| Destination port | Destination application port                                                                                    |
| Sequence number  | Transmit sequence number                                                                                        |
| Ack. number      | Receive sequence number                                                                                         |
| Offset           | Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5 |

*Table continues on the next page...*

**Table 53-14. TCP header fields (continued)**

| Field name | Description                                                                         |
|------------|-------------------------------------------------------------------------------------|
| Flags      | URG, ACK, PSH, RST, SYN, FIN flags                                                  |
| Window     | TCP receive window size information                                                 |
| Checksum   | Checksum over the complete datagram (TCP header and data) and IP header information |
| Options    | Additional 32-bit words for protocol options                                        |

### 53.5.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

#### 53.5.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

##### 53.5.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

[Table 53-15](#) shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

**Table 53-15. UDP/IP multicast domains**

| Name                | IP Address  | MAC Address mapping |
|---------------------|-------------|---------------------|
| DefaultPTPdomain    | 224.0.1.129 | 01-00-5E-00-01-81   |
| AlternatePTPdomain1 | 224.0.1.130 | 01-00-5E-00-01-82   |
| AlternatePTPdomain2 | 224.0.1.131 | 01-00-5E-00-01-83   |
| AlternatePTPdomain3 | 224.0.1.132 | 01-00-5E-00-01-84   |

**Table 53-16. UDP port numbers**

| Message type | UDP port | Note                                                        |
|--------------|----------|-------------------------------------------------------------|
| Event        | 319      | Used for SYNC and DELAY_REQUEST messages                    |
| General      | 320      | All other messages (for example, follow-up, delay-response) |

### 53.5.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

**Table 53-17. PTPv2 multicast domains**

| Name                | MAC address       |
|---------------------|-------------------|
| Normal messages     | 01-1B-19-00-00-00 |
| Peer delay messages | 01-80-C2-00-00-0E |

### 53.5.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

#### 53.5.3.2.1 PTPv1 header

**Table 53-18. Common PTPv1 message header**

| Offset | Octets | Bits                          |   |   |   |   |   |   |   |
|--------|--------|-------------------------------|---|---|---|---|---|---|---|
|        |        | 7                             | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0      | 2      | versionPTP = 0x0001           |   |   |   |   |   |   |   |
| 2      | 2      | versionNetwork                |   |   |   |   |   |   |   |
| 4      | 16     | subdomain                     |   |   |   |   |   |   |   |
| 20     | 1      | messageType                   |   |   |   |   |   |   |   |
| 21     | 1      | sourceCommunicationTechnology |   |   |   |   |   |   |   |
| 22     | 6      | sourceUuid                    |   |   |   |   |   |   |   |
| 28     | 2      | sourcePortId                  |   |   |   |   |   |   |   |
| 30     | 2      | sequenceId                    |   |   |   |   |   |   |   |

*Table continues on the next page...*

**Table 53-18. Common PTPv1 message header (continued)**

| Offset | Octets | Bits     |   |   |   |   |   |   |   |
|--------|--------|----------|---|---|---|---|---|---|---|
|        |        | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 32     | 1      | control  |   |   |   |   |   |   |   |
| 33     | 1      | 0x00     |   |   |   |   |   |   |   |
| 34     | 2      | flags    |   |   |   |   |   |   |   |
| 36     | 4      | reserved |   |   |   |   |   |   |   |

The type of message is encoded in the messageType and control fields as shown in [Table 53-19](#) :

**Table 53-19. PTPv1 message type identification**

| messageType | control | Message Name | Message         |
|-------------|---------|--------------|-----------------|
| 0x01        | 0x0     | SYNC         | Event message   |
| 0x01        | 0x1     | DELAY_REQ    | Event message   |
| 0x02        | 0x2     | FOLLOW_UP    | General message |
| 0x02        | 0x3     | DELAY_RESP   | General message |
| 0x02        | 0x4     | MANAGEMENT   | General message |
| other       | other   | —            | Reserved        |

The field sequenceId is used to non-ambiguously identify a message.

### 53.5.3.2.2 PTPv2 header

**Table 53-20. Common PTPv2 message header**

| Offset | Octets | Bits                   |   |   |   |                  |   |   |   |
|--------|--------|------------------------|---|---|---|------------------|---|---|---|
|        |        | 7                      | 6 | 5 | 4 | 3                | 2 | 1 | 0 |
| 0      | 1      | transportSpecific      |   |   |   | messageId        |   |   |   |
| 1      | 1      | reserved               |   |   |   | versionPTP = 0x2 |   |   |   |
| 2      | 2      | messageLength          |   |   |   |                  |   |   |   |
| 4      | 1      | domainNumber           |   |   |   |                  |   |   |   |
| 5      | 1      | reserved               |   |   |   |                  |   |   |   |
| 6      | 2      | flags                  |   |   |   |                  |   |   |   |
| 8      | 8      | correctionField        |   |   |   |                  |   |   |   |
| 16     | 4      | reserved               |   |   |   |                  |   |   |   |
| 20     | 10     | sourcePortIdentity     |   |   |   |                  |   |   |   |
| 30     | 2      | sequenceId             |   |   |   |                  |   |   |   |
| 32     | 1      | control                |   |   |   |                  |   |   |   |
| 33     | 1      | logMeanMessageInterval |   |   |   |                  |   |   |   |

The type of message is encoded in the field `messageId` as follows:

**Table 53-21. PTPv2 message type identification**

| messageId | Message name         | Message         |
|-----------|----------------------|-----------------|
| 0x0       | SYNC                 | Event message   |
| 0x1       | DELAY_REQ            | Event message   |
| 0x2       | PATH_DELAY_REQ       | Event message   |
| 0x3       | PATH_DELAY_RESP      | Event message   |
| 0x4–0x7   | —                    | Reserved        |
| 0x8       | FOLLOW_UP            | General message |
| 0x9       | DELAY_RESP           | General message |
| 0xa       | PATH_DELAY_FOLLOW_UP | General message |
| 0xb       | ANNOUNCE             | General message |
| 0xc       | SIGNALING            | General message |
| 0xd       | MANAGEMENT           | General message |

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the `TWO_STEP` bit in the first octet of the flags field as shown below. Reserved bits are cleared.

**Table 53-22. PTPv2 message flags field definitions**

| Bit | Name             | Description                                                                         |
|-----|------------------|-------------------------------------------------------------------------------------|
| 0   | ALTERNATE_MASTER | See IEEE 1588 Clause 17.4                                                           |
| 1   | TWO_STEP         | 1 Two-step clock<br>0 One-step clock                                                |

| 3   | —                | Reserved                                                                            |
| 4   | —                | Reserved                                                                            |
| 5   | Profile specific |                                                                                     |
| 6   | Profile specific |                                                                                     |
| 7   | —                | Reserved                                                                            |

### 53.5.4 MAC receive

- Check frame framing
- Remove frame preamble and frame SFD field

- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

**Figure 53-5. MAC receive flow**

#### 53.5.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

### 53.5.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

### 53.5.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

#### 53.5.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ( $RCR[PROM] = 1$ ) no address checking is performed and all unicast frames are accepted.

#### 53.5.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in  $ENETn\_GAUR/GALR$  (group address hash match) or  $ENETn\_IAUR/IALR$  (individual address hash match).

### Functional description

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET $n$ \_GAUR (msb = 1) or ENET $n$ \_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $$\text{FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

If Promiscuous mode is enabled (ENET $n$ \_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET $n$ \_GAUR/GALR and ENET $n$ \_IAUR/IALR settings.

### 53.5.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC\_REJ is cleared or ENET $n$ \_RCR[PROM] is set. If PROM is cleared when ENET $n$ \_RCR[BC\_REJ] is set, all broadcast frames are rejected.

**Table 53-23. Broadcast address reject programming**

| PROM | BC_REJ | Broadcast frames |
|------|--------|------------------|
| 0    | 0      | Accepted         |
| 0    | 1      | Rejected         |
| 1    | 0      | Accepted         |
| 1    | 1      | Accepted         |

#### 53.5.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxB<sub>D</sub>[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[**PROM**] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC\_REJ is set
- A unicast is received that does not match either:
  - Node address (PALR[PADDR1] and PAUR[PADDR2])
  - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

#### 53.5.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

#### 53.5.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX\_FL bytes, the BABR interrupt is generated and the RxB<sub>D</sub>[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET<sub>n</sub>\_FTRL[TRUNC\_FL]. If the frame is truncated, RxB<sub>D</sub>[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxB<sub>D</sub>[CR]).

### 53.5.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

### 53.5.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET $n$ \_RCR[FCE] is cleared and are forwarded to the client interface when ENET $n$ \_RCR[PAUFWD] is set.

### 53.5.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET $n$ \_RCR[CRCFWD] is cleared and ENET $n$ \_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $$\text{FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the  $x^{31}$  term as right-most bit of the first octet. The CRC bits are thus received in the following order:  $x^{31}, x^{30}, \dots, x^1, x^0$ .

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

### 53.5.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENETn_RCR[PADEN]`.

#### Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

### 53.5.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if `ENETn_TCR[TFC_PAUSE]` is set with `ENETn_OPD[PAUSE_DUR]` set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if `TFC_PAUSE` is set with `PAUSE_DUR` cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

**Figure 53-6. Frame transmit overview**

### 53.5.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC ( $\text{TxBD}[\text{TC}] = 1$ ), the user application is responsible for providing frames with a minimum length of 64 octets.

### 53.5.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields ( $\text{ENET}_n\text{TCR}[\text{ADDINS}] = 1$ )
- Transparently forwarded to the Ethernet line ( $\text{ENET}_n\text{TCR}[\text{ADDINS}] = 0$ )

### 53.5.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the  $x^{31}$  term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order:  $x^{31}$ ,  $x^{30}$ , ...,  $x^1$ ,  $x^0$ .

### 53.5.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in `ENETn_TIPG`) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

### 53.5.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

**Figure 53-7. Packet re-transmit overview**

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the  $n^{\text{th}}$  re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$ ; where  $n$  is the number of retransmissions and  $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by  $N = 10$  as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET $n$ \_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

**warning**

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

### 53.5.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

#### 53.5.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

Optionally and independent of  $\text{ENETn\_RCR[FCE]}$ , pause frames are forwarded to the client interface if  $\text{PAUFWD}$  is set.

### 53.5.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets  $\text{ENETn\_TCR[TFC\_PAUSE]}$ . A single pause frame is generated when the current frame transfer is completed and  $\text{TFC\_PAUSE}$  is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in  $\text{ENETn\_OPD[PAUSE\_DUR]}$ .

**Figure 53-8. Pause frame generation overview**

#### Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO,

the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

### 53.5.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

#### 53.5.7.1 Sleep mode

To put the MAC in Sleep mode, set `ENETn_ECR[SLEEP]`. At the same time `ENETn_ECR[MAGICEN]` should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the `ENETn_ECR` register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

#### 53.5.7.2 Magic packet detection

The core is designed to detect magic packets with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in `PADDR1/2`

When a magic packet is detected, `EIR[WAKEUP]` is set and none of the statistic registers are incremented.

### 53.5.7.3 Wakeup

When a magic packet is detected, indicated by  $ENETn\_EIR[WAKEUP]$ ,  $ENETn\_ECR[SLEEP]$  should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks  $ENETn\_ECR[MAGICEN]$ , disabling magic packet detection.

## 53.5.8 IP accelerator functions

### 53.5.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

**Table 53-24. IPv4 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15             | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    | Protocol |    |    |    |    |    |    |    | TCP/UDP length |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

**Table 53-25. IPv6 pseudo-header for checksum calculation**

|                     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
|---------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-------------|---|---|---|---|---|---|---|
| 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7           | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Source address      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| Destination address |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| TCP/UDP length      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |             |   |   |   |   |   |   |   |
| Zero                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | Next header |   |   |   |   |   |   |   |

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 53.5.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 53.5.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET $n$ \_TACC and ENET $n$ \_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 53-26](#).

**Table 53-26. 64-bit interface data structure with SHIFT16 enabled**

|         |         |         |         |        |        |           |           |
|---------|---------|---------|---------|--------|--------|-----------|-----------|
| 63 56   | 55 48   | 47 40   | 39 32   | 31 24  | 23 16  | 15 8      | 7 0       |
| Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 | Any value | Any value |
| Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 | Byte 7    | Byte 6    |
| ...     |         |         |         |        |        |           |           |

### 53.5.8.3.1 Receive processing

When `ENETn_RACC[SHIFT16]` is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

#### Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

### 53.5.8.3.2 Transmit processing

When `ENETn_TACC[SHIFT16]` is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

### 53.5.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (`ENETn_RSFL` cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than `MAX_FL`
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (`RX_ERR` asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET $n$ \_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### 53.5.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

#### Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### 53.5.8.6 IPv6 support

The following sections describe the IPv6 support.

#### 53.5.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing.

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

#### **53.5.8.6.2 Transmit processing**

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

### **53.5.9 Resets and stop controls**

#### **53.5.9.1 Hardware reset**

To reset the Ethernet module, set ENET $n$ \_ECR[RESET].

#### **53.5.9.2 Soft reset**

When ENET $n$ \_ECR[ETHER\_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.

- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

### 53.5.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

### 53.5.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER\_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

#### 53.5.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET $n$ \_TCR[GTS] is set by software.
- ENET $n$ \_TCR[TFC\_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

#### **53.5.9.4.2 Graceful receive stop (GRS)**

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set

- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

### Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

#### 53.5.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC\_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

## 53.5.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

Figure 53-9. IEEE 1588 functions overview

### 53.5.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to  $(1 \times 10^9) - 1$ . The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

#### 53.5.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

### Figure 53-10. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENETn\_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in `ENETn_ATPER`, defines the modulo when the counter wraps. In a typical implementation, the period is set to  $1 \times 10^9$  so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value  $(\text{Current} + \text{Inc} - (1 \times 10^9))$ , assuming the period is set to  $1 \times 10^9$ .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in `ENETn_ATCOR`, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in `ENETn_ATINC`. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (`ENETn_ATCR[SLAVE] = 1`), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set `ENET $n$ _ATINC[INC]` to the value of the master, since it is used for internal comparisons.

### **53.5.10.2 Transmit timestamping**

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENET $n$ _ATSTMP`. `ENET $n$ _EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENET $n$ _EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENET $n$ _ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

### **53.5.10.3 Receive timestamping**

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

### **53.5.10.4 Time synchronization**

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to  $(1 \times 10^9) - 1$ . In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at  $1 \times 10^9$ .

### 53.5.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

#### 53.5.10.5.1 Input capture

The  $TCCR_n$  capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the  $1588\_TMR_n$  signals. An event will cause the corresponding  $TCSR_n[TF]$  timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the  $TCSR_n[TIE]$  field, an interrupt can be generated.

#### 53.5.10.5.2 Output compare

The  $TCCR_n$  compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the  $TCCR_n$  register, the corresponding flag,  $TCSR_n[TF]$ , is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by  $TCSR_n[TIE]$ , will be generated. The corresponding  $1588\_TMR_n$  output signal will be asserted according to  $TCSR_n[TMODE]$ .

#### 53.5.10.5.3 DMA requests

A DMA request can be enabled by setting  $TCSR_n[TDRE]$ . The corresponding DMA request is generated when the  $TCSR_n[TF]$  timer flag is set. When the DMA has completed, the corresponding  $TCSR_n[TF]$  flag is cleared.

### 53.5.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

### 53.5.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation.

**Table 53-27. Receive FIFO thresholds definition**

| Register                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENET $n$ _RSFL<br>[RX_SECTION_F<br>ULL]  | <p>When the FIFO level reaches the ENET<math>n</math>_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET<math>n</math>_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENET<math>n</math>_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENET<math>n</math>_RSFL (cut-through operation) it should be greater than ENET<math>n</math>_RAEM.</p> |
| ENET $n$ _RAEM<br>[RX_ALMOST_E<br>MPTY]  | <p>When the FIFO level reaches the ENET<math>n</math>_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p> <p>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</p> <p>Set ENET<math>n</math>_RAEM to a minimum of six.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ENET $n$ _RAFL<br>[RX_ALMOST_F<br>ULL]   | <p>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET<math>n</math>_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</p> <p>The corresponding error status is set when the frame is delivered to the application.</p> <p>Set ENET<math>n</math>_RAFL to a minimum of 4.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ENET $n$ _RSEM<br>[RX_SECTION_E<br>MPTY] | <p>When the FIFO level reaches the ENET<math>n</math>_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client.</p> <p>When the FIFO level goes below the value programmed in ENET<math>n</math>_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client.</p> <p>Clearing ENET<math>n</math>_RSEM disables any pause frame generation.</p>                                                                                                                                                                                                                                                                                                    |

Figure 53-11. Receive FIFO overview

### 53.5.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation.

Table 53-28. Transmit FIFO thresholds definition

| Register                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENET $n$ _TAEM<br>[TX_ALMOST_EMPTY]  | When the FIFO level reaches the ENET $n$ _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication.<br><br>Set ENET $n$ _TAEM to a minimum of 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ENET $n$ _TAFL<br>[TX_ALMOST_FULL]   | When the FIFO level approaches the maximum, so that there is no more space for at least ENET $n$ _TAFL number of words, the MAC deasserts its control signal to the application.<br><br>If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.<br><br>Set ENET $n$ _TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion. |
| ENET $n$ _TSEM<br>[TX_SECTION_EMPTY] | When the FIFO level reaches the ENET $n$ _TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.<br><br>When ENET $n$ _TSEM is 0, the signal is never deasserted.                                                                                                                                                                                                                                                                                                                                    |
| ENET $n$ _TFWR                       | When the FIFO level reaches the ENET $n$ _TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Table 53-28. Transmit FIFO thresholds definition

| Register | Description                                                                                                                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | If a complete frame has a size smaller than the ENETn_TFWR threshold, the MAC also transmits the frame to the line.<br><br>To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO. |

Figure 53-12. Transmit FIFO overview

53.5.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENETn\_RCR register fields found here.

Table 53-29. Loopback options

| Register field | Description                                                                                                                                                                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOOP           | Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.<br><br>In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s)) |

Figure 53-13. Loopback options

### 53.5.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENETn\_ECR[1588EN].

#### NOTE

- The legacy buffer descriptor tables show the byte order for big-endian chips. **DBSWP** must be set to 0 after reset to enable big-endian mode.

#### 53.5.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 53-33](#) contains the descriptions for each field.

Table 53-30. Legacy FEC receive buffer descriptor (RxBD)

|            | Byte 0                                 |     |   |     |   |   |   |   | Byte 1 |    |    |    |    |    |    |    |
|------------|----------------------------------------|-----|---|-----|---|---|---|---|--------|----|----|----|----|----|----|----|
|            | 0                                      | 1   | 2 | 3   | 4 | 5 | 6 | 7 | 8      | 9  | 10 | 11 | 12 | 13 | 14 | 15 |

| Offset + 4 | Tx Data Buffer Pointer — high halfword |     |   |     |   |    |                  |   |        |   |    |    |    |    |    |    |
| Offset + 6 | Tx Data Buffer Pointer — low halfword  |     |   |     |   |    |                  |   |        |   |    |    |    |    |    |    |

1. This field is not supported by the uDMA.

## 53.5.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET<sub>n</sub>\_ECR[1588EN].

### NOTE

The enhanced buffer descriptor tables show the byte order for big-endian chips. [DBSWP](#) must be set to 0 after reset to enable big-endian mode.

### 53.5.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 53-33](#) contains the descriptions for each field.

**Table 53-32. Enhanced uDMA receive buffer descriptor (RxBd)**

|            | Byte 0                                 |     |   |     |   |    |    |    | Byte 1 |    |    |    |    |    |    |    |
|------------|----------------------------------------|-----|---|-----|---|----|----|----|--------|----|----|----|----|----|----|----|

| Offset + 0 | 7<br>M   | Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM fields are set to 1.<br>0 The frame was received because of an address recognition hit.<br>1 The frame was received because of promiscuous mode.<br>The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal. |
|            |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|            |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Offset + 0 | 8<br>BC  | Set if the DA is broadcast (FFFF_FFFF_FFFF).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 53-33. Receive buffer descriptor field definitions (continued)**

| Word       | Field                            | Description                                                                                                                                                                                                                                                                                                                             |
|------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + 0 | 9<br>MC                          | Set if the DA is multicast and not BC.                                                                                                                                                                                                                                                                                                  |
| Offset + 0 | 10<br>LG                         | Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.                                                                                        |
| Offset + 0 | 11<br>NO                         | Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set. |
| Offset + 0 | 12                               | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 0 | 13<br>CR                         | Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.                                                                                                                                                   |
| Offset + 0 | 14<br>OV                         | Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.                                                                                         |
| Offset + 0 | 15<br>TR                         | Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.                                                                                                                                           |
| Offset + 2 | 0–15<br>Data Length              | Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.                                                              |
| Offset + 4 | 0–15<br>Data buffer pointer high | Receive data buffer pointer, high halfword <sup>1</sup>                                                                                                                                                                                                                                                                                 |
| Offset + 6 | 0–15<br>Data buffer pointer low  | Receive data buffer pointer, low halfword                                                                                                                                                                                                                                                                                               |
| Offset + 8 | 0<br>ME                          | MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.                                                                                                            |
| Offset + 8 | 1–4                              | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |
| Offset + 8 | 5<br>PE                          | PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.                                                                                                                              |
| Offset + 8 | 6<br>CE                          | Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.                                                                                                      |
| Offset + 8 | 7<br>UC                          | Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.                                                                                                                                                                                          |
| Offset + 8 | 8<br>INT                         | Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb</i> / <i>dma_int_rxfevent</i> .                                                                                                                                                                   |
| Offset + 8 | 9–15                             | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                              |

*Table continues on the next page...*

**Table 53-33. Receive buffer descriptor field definitions (continued)**

| Word        | Field                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Offset + A  | 0–2<br>VPCP              | VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.                                                                                                                                                                                                                                                                                                                                                                                              |
| Offset + A  | 3–9                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + A  | 10<br>ICE                | IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.                                                                                                                                                                                                                                                                                                                                                                               |
| Offset + A  | 11<br>PCR                | Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Offset + A  | 12                       | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + A  | 13<br>VLAN               | VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + A  | 14<br>IPV6               | IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + A  | 15<br>FRAG               | IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Offset + C  | 0–4<br>Header length     | Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> <li>• ICMP/IP: 6 (5 IP header, 1 ICMP header)</li> <li>• UDP/IP: 7 (5 IP header, 2 UDP header)</li> <li>• TCP/IP: 10 (5 IP header, 5 TCP header)</li> </ul> This field is only valid if the L field is set. |
| Offset + C  | 5–7                      | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offset + C  | 8–15<br>Protocol type    | Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + E  | 0–15<br>Payload checksum | Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Offset + 10 | 0<br>BDU                 | Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 53-33. Receive buffer descriptor field definitions**

| Word             | Field | Description |
|------------------|-------|-------------|
| —<br>Offset + 1E |       |             |

- The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

### 53.5.14.2 Enhanced transmit buffer descriptor

**Table 53-34. Enhanced transmit buffer descriptor (TxBD)**

| Offset + 0 | 7–15                             | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + 2 | 0–15<br>Data Length              | Data length, written by user.<br>Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.                                                                                                                                                                                                                                                                             |
| Offset + 4 | 0–15<br>Data buffer pointer high | Tx data buffer pointer, high halfword. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 8. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller.                                                                                                                                                        |
| Offset + 6 | 0–15<br>Data buffer pointer low  | Tx data buffer pointer, low halfword                                                                                                                                                                                                                                                                                                                                                                                                  |
| Offset + 8 | 0                                | Reserved, must be cleared.                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offset + 8 | 1<br>INT                         | Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.                                                                                                                                                                                                                                   |
| Offset + 8 | 2<br>TS                          | Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.                                                                                                                                                                      |
| Offset + 8 | 3<br>PINS                        | Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame. |
| Offset + 8 | 4<br>IINS                        | Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by                                                                                                                                                                                       |

**Table 53-35. Enhanced transmit buffer descriptor field definitions (continued)**

| Word                    | Field          | Description                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                | the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.                                                                                                                               |
| Offset + 8              | 5–15           | Reserved, must be cleared.                                                                                                                                                                                                                                                                                 |
| Offset + A              | 0<br>TXE       | Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set. |
| Offset + A              | 1              | Reserved, must be cleared.                                                                                                                                                                                                                                                                                 |
| Offset + A              | 2<br>UE        | Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.                                                                                                                           |
| Offset + A              | 3<br>EE        | Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.                                                                                                             |
| Offset + A              | 4<br>FE        | Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.                                                                                               |
| Offset + A              | 5<br>LCE       | Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.                                                                                                         |
| Offset + A              | 6<br>OE        | Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.                                                                                                      |
| Offset + A              | 7<br>TSE       | Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.                                                                                                            |

### 53.5.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

### 53.5.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

**Table 53-36. FIFO interface data structure**

|        | 63      | 56 55   | 48 47   | 40 39   | 32 31   | 24 23   | 16 15  | 8 7    | 0 |
|--------|---------|---------|---------|---------|---------|---------|--------|--------|---|
| Word 0 | Byte 7  | Byte 6  | Byte 5  | Byte 4  | Byte 3  | Byte 2  | Byte 1 | Byte 0 |   |
| Word 1 | Byte 15 | Byte 14 | Byte 13 | Byte 12 | Byte 11 | Byte 10 | Byte 9 | Byte 8 |   |
| ...    | ...     |         |         |         |         |         |        |        |   |

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

### Note

On transmit, if ENET $n$ \_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET $n$ \_PAUR and ENET $n$ \_PALR registers.

**Table 53-37. FIFO interface frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–13       | Length/type field       |
| 14–N        | Payload data            |

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 53-38. FIFO interface VLAN frame format**

| Byte number | Field                   |
|-------------|-------------------------|
| 0–5         | Destination MAC address |
| 6–11        | Source MAC address      |
| 12–15       | VLAN tag and info       |
| 16–17       | Length/type field       |
| 18–N        | Payload data            |

### Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

## 53.5.15.2 Data structure examples

Figure 53-14. Normal Ethernet frame 64-bit mapping example

Figure 53-15. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 53.5.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxB[ME] is also set with the last data of the frame.

## 53.5.16 FIFO protection

### 53.5.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII\_TXER) (1 in [Figure 53-16](#)) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII\_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 53-16. Transmit FIFO underflow protection

### 53.5.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

### Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET $n$ \_ECR[ETHER\_EN], to clear the FIFOs and prepare for normal operation again.

### 53.5.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 53-17. Receive FIFO overflow protection

### 53.5.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

| Ethernet speed mode | Ethernet bus clock | Minimum ENET system clock |
|---------------------|--------------------|---------------------------|
| 10 Mbit/s           | 2.5 MHz            | 5 MHz                     |
| 100 Mbit/s          | 25.0 MHz           | 50 MHz                    |

## 53.5.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

### 53.5.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

**Table 53-39. MDIO clause 22 frame structure**

| ST | OP | PHYADR | REGADR | TA | DATA |
|----|----|--------|--------|----|------|
|----|----|--------|--------|----|------|

**Table 53-40. MDIO frame field descriptions**

| Field              | Description                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| ST<br>(2 bits)     | Start indication field, programmed with ENET $n$ _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).        |
| OP<br>(2 bits)     | Opcode defines type of operation. Programmed with ENET $n$ _MMFR[OP].<br>01 Write operation<br>10 Read operation |
| PHYADR<br>(5 bits) | Five-bit PHY device address, programmed with ENET $n$ _MMFR[PA]. Up to 32 devices can be addressed.              |

*Table continues on the next page...*

**Table 53-40. MDIO frame field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REGADR<br>(5 bits) | Five-bit register address, programmed with ENET $n$ _MMFR[RA]. Each PHY can implement up to 32 registers.                                                                                                                                                                      |
| TA<br>(2 bits)     | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| Data<br>(16 bits)  | Data, set by ENET $n$ _MMFR[DATA]. Written to or read from the PHY                                                                                                                                                                                                             |

### 53.5.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

**Table 53-41. MDIO clause 45 frame structure**

|    |    |       |       |    |           |
|----|----|-------|-------|----|-----------|
| ST | OP | PRTAD | DEVAD | TA | ADDR/DATA |
|----|----|-------|-------|----|-----------|

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

**Table 53-42. MDIO clause 45 frame field descriptions**

| Field | Description                                                                                                                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ST    | Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.                                                                                                |
| OP    | Opcode defines if a read or write operation is performed and is programmed with ENET $n$ _MMFR[OP]. See <a href="#">Table 53-43</a> for more information.<br><br>00 Address write<br>01 Write operation<br>10 Read inc. operation |

*Table continues on the next page...*

**Table 53-42. MDIO clause 45 frame field descriptions (continued)**

| Field     | Description                                                                                                                                                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | 11 Read operation                                                                                                                                                                                                                                                              |
| PRTAD     | The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.                                                                                                                                                   |
| DEVAD     | Device address. Up to 32 devices can be addressed (within a port).                                                                                                                                                                                                             |
| TA        | Turnaround time, programmed with ENET $n$ _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| ADDR/DATA | 16-bit address (for address write) or data, set by ENET $n$ _MMFR[DATA], written to or read from the PHY.                                                                                                                                                                      |

**Table 53-43. MDIO Clause 45 Transactions**

| Transaction Type | Description                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address          | A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.                                             |
| Write            | Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.                                                                                                                                             |
| Read             | Data is read from the register identified by the device-internal address.                                                                                                                                                                                        |
| Read inc.        | Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around). |

### 53.5.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET $n$ \_MSCR[MII\_SPEED].

### 53.5.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET $n$ \_MMFR) according to the description provided in MII Management Frame Register (ENET $n$ \_MMFR).

To check when the programmed access completes, read the ENET $n$ \_EIR[MII] field.

Figure 53-18. MDIO access overview

### 53.5.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

| Mode              | ECR[SLEEP] | RCR[RMII_10T] | RCR[RMII_MODE] |
|-------------------|------------|---------------|----------------|
| MII - 10 Mbit/s   | 0          | —             | 0              |
| MII - 100 Mbit/s  | 0          | —             | 0              |
| RMII - 10 Mbit/s  | 0          | 1             | 1              |
| RMII - 100 Mbit/s | 0          | 0             | 1              |

#### 53.5.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS\_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

### Figure 53-19. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

**Figure 53-20. RMI receive operation with false carrier**

In RMII transmit mode, TXD[1:0] provides valid data for each REF\_CLK period while TXEN is asserted.

### Figure 53-21. RMI transmit operation

### 53.5.19.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII\_TXCLK rising edge. The MII data enable signal MII\_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII\_TXD[3:0] bus.

Between frames, MII\_TXEN remains deasserted.

**Figure 53-22. MII transmit operation**

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII\_TXER error signal for one clock cycle at any time during the packet transfer.

**Figure 53-23. MII transmit operation — errored frame**

### 53.5.19.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII\_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

Figure 53-24. MII transmit operation — transmission with collision

### 53.5.19.3 MII interface — receive

On receive, all signals are sampled on the MII\_RXCLK rising edge. The MII data enable signal, MII\_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII\_RXD[3:0] bus.

Between frames, MII\_RXDV remains deasserted.

Figure 53-25. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII\_RXER, for at least one clock cycle at any time during the packet transfer.

**Figure 53-26. MII receive operation — errored frame**

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

## **Chapter 54**

# **Reset Generation Module (MC\_RGM)**

## **54.1 Introduction**

### **54.1.1 Overview**

The reset generation module (MC\_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

The following figure shows the MC\_RGM block diagram.

Figure 54-1. MC\_RGM Block Diagram

## 54.1.2 Features

The MC\_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signalling of reset events after each reset sequence (reset status flags)
- conversion of reset events to SAFE mode or interrupt request events

- short reset sequence configuration
- bidirectional reset behavior configuration
- boot mode capture on RESETB deassertion
- configurable escalation of recurring 'functional' resets to 'destructive' reset

### 54.1.3 Reset Sources

The different reset sources are organized into two families: 'destructive' and 'functional'.

- A 'destructive' reset source is associated with an event related to a critical - usually hardware - error or dysfunction. When a 'destructive' reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown. 'Destructive' resets are
  - power-on reset
  - software 'destructive' reset
  - FCCU failure to react reset
  - 'functional' reset escalation
  - temperature sensor 'destructive' reset
  - voltage out of range 'destructive' reset

#### NOTE

POR occurs when the voltage starts from 0 or the voltage drops below the absolute minimum operating level. It remains active until the voltage is above the operating threshold. After that, the device is no longer in the POR state (although the POR flag remains set until software clears it), and other reset events can potentially occur.

- A 'functional' reset source is associated with an event related to a less-critical - usually non-hardware - error or dysfunction. When a 'functional' reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (e.g., debug modules, flash modules) as well as the system memory content is preserved. 'Functional' resets are

- external reset
- start-up self test completed
- software 'functional' reset
- FCCU hard reaction
- FCCU soft reaction
- JTAG 'functional' reset
- temperature sensor 'functional' reset
- voltage out of range 'functional' reset

When a reset is triggered, the MC\_RGM state machine is activated and proceeds through the different phases (i.e., PHASEn states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC\_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC\_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC\_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC\_ME or to an interrupt issued to the core (see ['Functional' Event Reset Disable Register \(MC\\_RGM\\_FERD\)](#) and ['Functional' Event Alternate Request Register \(MC\\_RGM\\_FEAR\)](#)).

## 54.2 External Signal Description

The MC\_RGM interfaces to the bidirectional reset pin RESETB.

## 54.3 Memory Map and Register Definition

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM\_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

### MC\_RGM memory map

| Address offset (hex) | Register name                                                   | Width (in bits) | Access | Reset value | Section/ page                |

#### 54.3.1 'Destructive' Event Status Register (MC\_RGM\_DES)

This register contains the status of the 'destructive' reset sources. It can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode. Register bits are cleared on write '1'.

This register is reset only on power-on.

**54.3.2 ‘Destructive’ Event Reset Disable Register (MC\_RGM\_DERD)**

This register provides dedicated bits to disable particular ‘destructive’ reset sources. It can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode. Each byte can be written only once after a ‘destructive’ or power-on reset.

This register is reset only on power-on.

**WARNING**

It is important to clear the RGM\_DES register before setting any of the bits in the RGM\_DERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

**54.3.3 Destructive' Bidirectional Reset Enable Register (MC\_RGM\_DBRE)**

This register enables the generation of an external reset on 'destructive' reset. It can be accessed in read only in all modes. Since all 'destructive' resets assert RESETB, all the bits in this register are always '0'.

This register is reset only on power-on.

**54.3.4 'Functional' Event Status Register (MC\_RGM\_FES)**

This register contains the status of the 'functional' reset sources, including those configured to not generate a reset sequence. It can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source.

This register is reset only on power-on.

**NOTE**

If a 'functional' reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM\_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good

## Memory Map and Register Definition

practice for software to check whether the RGM\_FES has been properly cleared, and if not, clear it again.

**54.3.5 'Functional' Event Reset Disable Register (MC\_RGM\_FERD)**

This register provides dedicated bits to disable 'functional' reset sources. When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see ['Functional' Event Alternate Request Register \(MC\\_RGM\\_FEAR\)](#)). It can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any 'destructive' reset.

Warning

It is important to clear the RGM\_FES register before setting any of the bits in the RGM\_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address: 0h base + 310h offset = 310h

### 54.3.6 'Functional' Event Alternate Request Register (MC\_RGM\_FEAR)

This register defines an alternate request to be generated when a reset on a 'functional' event has been disabled. The alternate request can be either a SAFE mode request to MC\_ME or an interrupt request to the system. It can be accessed as read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on and any 'destructive' reset.

## 54.3.7 'Functional' Bidirectional Reset Enable Register (MC\_RGM\_FBRE)

This register enables the generation of an external reset on 'functional' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 330h offset = 330h

**54.3.8 'Functional' Event Short Sequence Register (MC\_RGM\_FESS)**

This register defines which reset sequence will be done when a 'functional' reset sequence is triggered. The 'functional' reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

**NOTE**

This could be useful for fast reset sequence, for example to skip flash reset.

It can be accessed as read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 340h offset = 340h

**54.3.9 'Functional' Reset Escalation Threshold Register (MC\_RGM\_FRET)**

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode.

Writing a non-zero value to the FRET field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. See ['Functional' Reset Escalation](#) for details on the 'functional' reset escalation function.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 604h offset = 604h

| 4–7<br>FRET     | 'Functional' Reset Escalation Threshold - If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets which will cause a 'destructive' reset if the RGM_FRET register isn't written to beforehand. |

### 54.3.10 'Destructive' Reset Escalation Threshold Register (MC\_RGM\_DRET)

This register sets the threshold for 'destructive' reset escalation to keep the chip in the reset state until the next power-on reset triggers a new reset sequence. The register can be accessed as read/write in either supervisor mode or test mode. It can be accessed as read-only in user mode.

Writing a non-zero value to the DRET field enables the 'destructive' reset escalation function. Writing any value to this register resets the 'destructive' reset counter. See ['Destructive' Reset Escalation](#) for details on the 'destructive' reset escalation function.

This register is reset only on power-on.

Address: 0h base + 608h offset = 608h

## 54.4 Functional Description

### 54.4.1 Reset State Machine

The main role of the MC\_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in the following table.

**Table 54-1. MC\_RGM Reset Implications**

| Source                                              | What Gets Reset                                                      | External Reset Assertion <sup>1</sup> | Boot Mode Capture         |
|-----------------------------------------------------|----------------------------------------------------------------------|---------------------------------------|---------------------------|
| power-on reset                                      | all                                                                  | yes                                   | yes                       |
| 'destructive' resets                                | all except some clock/reset management                               | yes                                   | yes                       |
| external reset                                      | all except some clock/reset management and debug                     | programmable                          | yes                       |
| 'functional' resets                                 | all except some clock/reset management, STCU, FCCU, and debug        | programmable <sup>2</sup>             | programmable              |
| shortened external or shortened 'functional' resets | flip-flops except some clock/reset management, STCU, FCCU, and debug | programmable <sup>2</sup>             | programmable <sup>3</sup> |

1. 'external reset assertion' means that the RESETB pin is asserted by the MC\_RGM from the start of the reset sequence until the end of reset PHASE3
2. the assertion of the external reset is controlled via the RGM\_FBRE register
3. the boot mode is captured if the external reset is asserted

#### Note

JTAG logic has its own independent reset control and is not controlled by the MC\_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in the following figure.

Figure 54-2. MC\_RGM State Machine

### 54.4.1.1 PHASE0 Phase

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled 'destructive' resets have been processed

- all processes that need to be done in PHASE0 are completed
  - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of 3 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled 'destructive' reset event

#### **54.4.1.2 PHASE1 Phase**

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or 'functional' reset event if it has not been configured to trigger a 'short' sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened 'functional' resets have been processed
- a minimum of 8 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened 'functional' reset event

#### **54.4.1.3 PHASE2 Phase**

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
  - flash initialization
- a minimum of 8 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

#### **54.4.1.4 PHASE3 Phase**

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened 'functional' reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
  - trimming, start-up self test configuration, and FCCU initialization

- a minimum of 40 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened 'functional' reset event
- RESETB is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence

#### 54.4.1.5 IDLE Phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC\_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

#### 54.4.2 'Destructive' Resets

A 'destructive' reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed.

The status flag associated with a given 'destructive' reset event (RGM\_DES.F\_<destructive reset> bit) is set when the 'destructive' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A 'destructive' reset will trigger a reset sequence starting from the beginning of PHASE0.

#### 54.4.3 External Reset

The MC\_RGM manages the external reset coming from RESETB. The detection of a falling edge on RESETB will start the reset sequence.

The status flag associated with the external reset falling edge event (RGM\_FES.F\_EXR bit) is set when the external reset is asserted and the power-on reset is not asserted.

An external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM\_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM\_FESS.SS\_EXR is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the flash.

The MC\_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event
- an external reset event if configured via the RGM\_FBRE register to assert the external reset
- a 'functional' reset event configured via the RGM\_FBRE register to assert the external reset

In this case, RESETB is asserted until all conditions for exiting PHASE3 have been met with the exception of the RESETB assertion check.

In addition, the MC\_RGM asserts RESETB while the start-up self test is being executed.

The RESETB input is disabled immediately as of the RESETB output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4µs after the RESETB output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

#### **54.4.4 'Functional' Resets**

A 'functional' reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given 'functional' reset event (RGM\_FES.F\_<functional reset> bit) is set when the 'functional' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'functional' reset can be optionally disabled by software writing bit RGM\_FERD.D\_<functional reset>.

#### **Note**

The RGM\_FERD register can be written only once between two power-on reset events.

An enabled 'functional' reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM\_FESS register enables the further configuring of the reset sequence triggered by a 'functional' reset. When RGM\_FESS.SS\_<functional reset> is set, the associated 'functional' reset will trigger a

reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a 'functional' reset should not reset the flash module.

See the MC\_ME chapter for details on the STANDBY0 and DRUN modes.

### 54.4.5 Alternate Event Generation

The MC\_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC\_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC\_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM\_FERD and RGM\_FEAR registers as shown in the following table.

**Table 54-2. MC\_RGM Alternate Event Selection**

| <b>RGM_FERD<br/>Bit Value</b> | <b>RGM_FEAR<br/>Bit Value</b> | <b>Generated Event</b> |
|-------------------------------|-------------------------------|------------------------|
| 0                             | X                             | reset                  |
| 1                             | 0                             | SAFE mode request      |
| 1                             | 1                             | interrupt request      |

The alternate event is cleared by deasserting the source of the request (that is, at the reset source that caused the alternate request) and also clearing the appropriate RGM\_FES status bit.

#### Note

SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock; therefore, if the system clock was disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

#### Note

If a masked 'destructive' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC\_RGM will not send any safe mode/interrupt request to the MC\_ME.

### Note

If a masked 'functional' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC\_RGM will not send any safe mode/interrupt request to the MC\_ME.

#### 54.4.6 'Functional' Reset Escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' or external resets has occurred between software writes to the RGM\_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once 'functional' reset escalation has been enabled, the MC\_RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (i.e., entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM\_FRET register and on any power-on or 'destructive' reset. If the counter reaches the value in the RGM\_FRET register's FRET field, the MC\_RGM starts a reset sequence at PHASE0 and asserts the F\_EDR bit in the RGM\_DES register.

#### 54.4.7 'Destructive' Reset Escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM\_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

After 'destructive' reset escalation has been enabled, the MC\_RGM increases a counter on each 'destructive' reset that is enabled to increment the escalator and that causes a reset sequence to be initiated (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM\_DRET register and on any power-on reset. If the counter reaches the value in the RGM\_DRET register's DRET field, the MC\_RGM enters reset PHASE0 and remains there until the next power-on reset occurs.

On a power-on reset, the `dest_rst_escalation` output is deasserted. It is asserted by the MC\_RGM when the counter reaches the value in the RGM\_DRET register's DRET field. It is not deasserted until the next power-on reset.

### 54.4.8 Boot Mode Capturing

The MC\_RGM samples FAB/ABS whenever RESETB is asserted until five 16 MHz internal RC oscillator clock cycles before its deassertion edge. The result of the sampling is used at the beginning of reset PHASE3 for boot mode selection and is retained after RESETB has been deasserted for subsequent boots after reset sequences during which RESETB is not asserted.

#### NOTE

In order to ensure that the boot mode is correctly captured, the application needs to apply the valid boot mode value the entire time that RESETB is asserted and to keep applying it for 5  $\mu$ s after RESETB is deasserted. For non-alternate boot modes, it is recommended to use a dedicated pin for the FAB pin and to keep it asserted to '0' at all times.

#### NOTE

RESETB can be asserted as a consequence of the internal reset generation. This will force re-sampling of the boot mode pins. (See [Table 54-1](#) for details.)

# Chapter 55

## Boot Assist Module (BAM)

### 55.1 Overview

The Boot Assist Module (BAM) is a block of read-only memory containing VLE code which is executed according to the boot mode of the device. The code stored in the BAM is not executed when booting in Single Chip mode, except when entering the "Static mode" in case no valid bootable section has been found.

The BAM downloads code into internal SRAM through the following serial protocols and executes it afterwards:

- UART (using LINFlexD)
- CAN (using FlexCAN)

Depending on the selected boot mode (see [Entering boot modes](#)), any download is performed with a fixed baud rate.

### 55.2 Features

The BAM provides the following features:

- Programmable 64-bit password protection for serial boot mode
- Serial boot loads the application boot code from a FlexCAN or LINFlexD bus into internal SRAM
- Censorship protection for internal flash module

### 55.3 Memory map

The BAM code resides in 8 KB of ROM mapped from address 0xFFFF\_C000. The address space and memory used by the BAM is shown in the following table.

**Table 55-1. BAM memory organization**

| Entity                                     | Address                 |
|--------------------------------------------|-------------------------|
| BAM entry point                            | 0xFFFF_C000             |
| RAM area used by the BAM code (do not use) | 0x4000_0000–0x4000_00FF |
| Downloaded code base address               | 0x4000_0100             |

The RAM location where to download the code can be any 8 byte-aligned location in the SRAM starting from the address 0x4000\_0100.

### **Caution**

Do not use the RAM area used by the BAM code as indicated in the preceding table.

## **55.4 Functional description**

### **55.4.1 Entering boot modes**

The device detects the boot mode based on external pins and device status. The following sequence applies (see the following figure):

1. To boot either from FlexCAN or LINFlexD, the device must be forced into an Alternate Boot Loader Mode via the FAB (Force Alternate Boot Mode) pin which must be asserted before initiating the reset sequence. The type of alternate boot mode is selected according to the ABS (Alternate Boot Selector) pins (see the following table).
2. If FAB is not asserted, the device boots from the first flash-memory sector which contains a valid boot signature.
3. If no flash memory sector contains a valid boot signature, the device will go into static mode.

Figure 55-1. Boot mode selection

Table 55-2. Hardware configuration to select boot mode

| FAB | ABS[2,0] | Standby-RAM<br>Boot Flag | Boot ID | Boot Mode |
|-----|----------|--------------------------|---------|-----------|
| 1   | 00       | 0                        | -       | UART      |
| 1   | 01       | 0                        | -       | CAN       |

## 55.4.2 Boot through BAM

### 55.4.2.1 Executing BAM

Single chip boot mode (selecting the first bootable flash memory sector) is managed by hardware and BAM does not participate in it.

BAM is executed only in one or both of the following cases:

- Serial boot mode has been selected by Force Alternate Boot (FAB) pin.
- Hardware has not found a valid Boot ID in any flash memory boot locations.

If one of these conditions is true, the device fetches code at location 0xFFFF\_C000 and the BAM application starts.

55.4.2.2 BAM software flow

The following figure describes the BAM logic flow.

Figure 55-2. BAM logic flow

The first action is to save the initial device configuration. In this way it is possible to restore the initial configuration after downloading the new code but before executing it. This allows the new code to be executed as the device was just coming out of reset.

The SSCM\_STATUS[BMODE] field indicates which boot has to be executed (see the following table).

If BMODE field shows either a single chip value (011) or the reserved values, the boot mode is not considered valid and the BAM pushes the device into static mode.

In all other cases data is downloaded in serial boot mode and saved into the correct SRAM location.

Table 55-3. Fields of SSCM\_STATUS register read by BAM to detect the chosen boot mode

| Field | Description                                                        |
|-------|--------------------------------------------------------------------|
| BMODE | BMODE Device Boot Mode<br>001 CAN Serial Boot Loader using FlexCAN |

**Table 55-3. Fields of SSCM\_STATUS register read by BAM to detect the chosen boot mode**

| Field | Description                                |
|-------|--------------------------------------------|
|       | 010 UART Serial Boot Loader using LINFlexD |
|       | 011 Single Chip                            |
|       | other values are reserved                  |

Then, the initial device configuration is restored and the code jumps to the address provided for the downloaded code. At this point BAM has just finished its task.

If there is any error (that is, communication error, wrong boot selected, etc.), BAM restores the default configuration and puts the device into static mode. Static mode means the device enters the low power mode SAFE and the processor executes a wait instruction. It is needed if the device can not boot in the mode which was selected. During BAM execution and after, the mode reported by the field S\_CURRENT\_MODE of the register ME\_GS in the module MC\_ME Module is "DRUN".

### 55.4.2.3 BAM resources

BAM uses/initializes the following MCU resources:

- MC\_ME and MC\_CGM modules to initialize mode and clock sources
- CAN\_0, LINFlex\_0 and their pins when performing serial boot mode
- SWT is disabled in case of a serial boot mode or when entering static mode
- PIT for some time measurement when performing serial boot mode
- SSCM to check the boot mode and during password check (see [Table 55-3](#))
- External oscillator (XOSC)
- SIUL to perform programming of the required GPIO pins

The frequency of the external oscillator defines the baud rate for serial interfaces used to download the user application. For a LINFlexD transmission, the selected baud rate is  $f_{XOSC} / 832$ . For a FlexCAN transmission, the selected baud rate is  $f_{XOSC} / 40$ .

### 55.4.2.4 Download and execute the new code

From high level perspective, the download protocol follows these steps:

1. Transmit 64-bit password.
2. Transmit start address, size of downloaded code in bytes and VLE bit.
3. Transmit download data.
4. Execute code from start address.

Each step must be completed before the next step starts.

The communication is done in half duplex manner; any transmission from the host is followed by the MCU transmission.

- Host sends data to MCU and starts waiting
- MCU echoes to host the data received
- Host verifies if echoes are correct
  - if data is correct, the host can continue to send data
  - if data is not correct, the host stops to transmit and MCU must be reset

All multi-byte data structures are sent with MSB first.

A more detailed description of these steps follows.

### **NOTE**

There must be no stringent timeout condition while the host waits for the echoed data from the MCU; especially after step 2. After receiving the actual size of the data to be transmitted, the BAM must initialize the memory receiving the transmitted data with 64 bit writes to avoid ECC errors due to uninitialized memory.

#### **55.4.2.5 Download 64-bit password and password check**

The first 64 bits received represent the password. This password is sent to the Password Check procedure which verifies whether it is correct. The actual processing of the provided password by the Password Check procedure is described in the following table. The Password Check procedure performs the check with a time limiting condition that ensures no more than one check occurs within a certain timeframe. The corresponding timeout by the hardware performing the check works in parallel to the actual download to minimize the download time. In case of secured flash memory, after the timer that locks the hardware checking the password expires:

- If the correct password was supplied, flash memory is now unsecured and BAM continues its task.
- If an incorrect password was supplied, flash memory is still secured; BAM puts the device into static mode.

**Table 55-4. Password Check procedure**

| Flash Secured | Public Password | Password requested                                                        | Comment                                                                    |
|---------------|-----------------|---------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Yes           | No              | Password must match the password recorded in the corresponding DCF client | Flash is unsecured when providing the correct private password.            |
| Yes           | Yes             | FEED_FACE_CAFE_BEEF                                                       | Flash is unsecured when providing the correct public password.             |
| No            | No              | (password is not verified)                                                | There is no benefit in checking the password, since the Flash is readable. |
| No            | Yes             | FEED_FACE_CAFE_BEEF                                                       | Password is checked, Flash is already unsecured                            |

### 55.4.2.6 Download start address, VLE bit and code size

The next 8 bytes received by the MCU contain a 32-bit Start Address, the VLE mode bit and a 31-bit code Length as shown in the following figure.

The VLE bit (Variable Length Instruction) is used to indicate for which instruction set the code has been compiled. The BAM supports the download of VLE code.

The Start Address defines where the received data will be stored and where the MCU will branch after the download is finished. The two LSB bits of the Start Address are ignored by the BAM program, such that the loaded code should be 32-bit word aligned.

The Code Length defines the number of data bytes to be loaded.

**Figure 55-3. Start address, VLE bit and download size in bytes**

### 55.4.2.7 Download data

Each byte of data received is stored into device's SRAM, starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until the number of bytes of data received matches the number of bytes specified in the previous protocol step.

Since the SRAM is protected by a 64-bit wide Error Correction Code (ECC), the BAM performs a series of 64 bit writes to initialize the SRAM are required for the downloaded data. The actual writes are performed in chunks of 32-bit writes. If the last byte received does not fall onto a 32-bit boundary, the BAM fills it with 0 bytes.

Since the SRAM is protected by 32-bit wide Error Correction Code (ECC), BAM always writes bytes into SRAM grouped into 32-bit words. If the last byte received does not fall onto a 32-bit boundary, the BAM fills it with 0 bytes.

Finally a "dummy" word (0x0000\_0000) is written to avoid a possible ECC error during core prefetch.

### 55.4.2.8 Execute code

The BAM program waits for the last echo message transmission being completed.

Then it restores the initial MCU configuration and jumps to the code loaded at Start Address which was received in step 2 of the protocol.

At this point BAM has finished its tasks and MCU is controlled by new code executing from SRAM.

## 55.4.3 UART Boot

### 55.4.3.1 Configuration

Boot using the UART protocol is implemented by LINFlex\_0 module. Pins used are:

- LINFlex\_TX corresponds to pin B[2]
- LINFlex\_RX corresponds to pin B[3].

The LINFlexD controller is configured to operate at a baud rate of  $f_{XOSC} / 832$ , using 8 bit data frame without parity bit and 1 stop bit.

**Figure 55-4. LINFlexD bit timing in UART mode**

### 55.4.3.2 Protocol

The following table summarizes the protocol and BAM action during this boot mode.

**Table 55-5. UART boot mode download protocol**

| Protocol step | Host sent message                               | BAM response message                            | Action                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1             | 64-bit password (MSB first)                     | 64-bit password                                 | Password checked for validity and compared against stored password.                                                                                                                                                                              |
| 2             | 32-bit store address                            | 32-bit store address                            | Load address is stored for future use.                                                                                                                                                                                                           |
| 3             | VLE bit +<br>31-bit number of bytes (MSB first) | VLE bit +<br>31-bit number of bytes (MSB first) | Size of download is stored for future use.<br>Verify VLE bit.                                                                                                                                                                                    |

These words are saved into SRAM starting from the "Load address".<br>"Load address" increments until the number of data received and stored matches the size as specified in the previous step. |
| 5             | none                                            | none                                            | Branch to downloaded code                                                                                                                                                                                                                        |

## 55.4.4 CAN Boot

### 55.4.4.1 Configuration

Boot using the CAN protocol is implemented by FlexCAN\_0 module. Pins used are:

- CAN\_TX corresponds to pin B[0]
- CAN\_RX corresponds to pin B[1].

Boot from FlexCAN uses the system clock driven by the external oscillator.

The FlexCAN controller is configured to operate at a baud rate = system clock frequency/40.

It uses the standard 11 bit identifier format detailed in FlexCAN 2.0A specification.

FlexCAN controller bit timing is programmed with 10 time quanta, and the sample point is 2 time quanta before the end, as shown in the following figure.

1 time Quantum = 4 system clock periods

Figure 55-5. FlexCAN bit timing

### 55.4.4.2 Protocol

The following table summarizes the protocol and BAM action during this boot mode. All data is transmitted byte wise.

Table 55-6. FlexCAN boot mode download protocol

| Protocol step | Host sent message                                                                | BAM response message                                                             | Action                                                                                                   |
|---------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| 1             | FlexCAN ID 0x011+<br>64-bit password                                             | FlexCAN ID 0x001+<br>64-bit password                                             | Password checked for validity and compared against stored password.                                      |

### 55.4.5 Inhibiting BAM operation

Under certain circumstances, you may want to inhibit BAM operation. To do this, set to 1 the RAE field in the SSCM\_ERROR register. After this change, any attempt to access the memory range occupied by the BAM results in an access error.

### 55.4.6 Interrupts

No interrupts are generated or enabled by the BAM.

# Chapter 56

## System Status and Configuration Module (SSCM)

### 56.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

#### 56.1.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

Figure 56-1. SSCM block diagram

## 56.1.2 Glossary

The table below shows a glossary of terms used through out the text.

**Table 56-1. Glossary**

| Term   | Definition                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0011b  | Binary numbers                                                                                                                                                          |
| 0Fh    | Hexadecimal numbers                                                                                                                                                     |
| Pin    | External physical connection.                                                                                                                                           |
| Signal | Electronic construct whose state or change in state conveys information.                                                                                                |
| X      | In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care. |
| y      | y is used for a place holder of 1 hex digit for unknown values.                                                                                                         |

## 56.1.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
- Debug Status Port enable and selection
- Bus abort enable/disable
- Peripheral abort enable/disable

## 56.1.4 Modes of operation

The SSCM operates identically in all system modes.

## 56.2 External signal description

The SSCM provides a set of pins for the debug port (see Debug Status Port Register (DEBUGPORT) for details).

## 56.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

### NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal (that is, you should not make any transfer that is not aligned to burst size boundary).

### NOTE

SSCM does not generate transfer errors in all memory holes.

### SSCM memory map

| Address offset (hex) | Register name                                       | Width (in bits) | Access | Reset value                 | Section/page                |
|----------------------|-----------------------------------------------------|-----------------|--------|-----------------------------|-----------------------------|
| 0                    | SSCM System Status (SSCM_STATUS)                    | 16              | R      | <a href="#">See section</a> | <a href="#">56.3.1/2222</a> |
| 2                    | SSCM System Memory and ID Register (SSCM_MEMCONFIG) | 16              | R      | <a href="#">See section</a> | <a href="#">56.3.2/2224</a> |
| 6                    | SSCM Error Configuration Register (SSCM_ERROR)      | 16              | R/W    | 0000h                       | <a href="#">56.3.3/2225</a> |
| 8                    | SSCM Debug Status Port Register (SSCM_DEBUGPORT)    | 16              | R/W    | 0000h                       | <a href="#">56.3.4/2225</a> |
| 20                   | User Option Status Register (SSCM_UOPS)             | 32              | R      | <a href="#">See section</a> | <a href="#">56.3.5/2227</a> |
| 28                   | Processor Start Address Register (SSCM_PSA)         | 32              | R      | <a href="#">See section</a> | <a href="#">56.3.6/2227</a> |

## 56.3.1 SSCM System Status (SSCM\_STATUS)

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

|       |       |     |      |     |      |     |     |    |
|-------|-------|-----|------|-----|------|-----|-----|----|
| Bit   | 0     | 1   | 2    | 3   | 4    | 5   | 6   | 7  |
| Read  | 0     | CER | CERS | 0   | NXEN | PUB | SEC | 0  |
| Write |       | w1c | w1c  |     |      |     |     |    |
| Reset | 0     | 0   | 0    | 0   | *    | *   | *   | 0  |
| Bit   | 8     | 9   | 10   | 11  | 12   | 13  | 14  | 15 |
| Read  | BMODE |     |      | VLE | 0    | 0   | 0   |    |
| Write |       |     |      |     |      |     |     |    |
| Reset | *     | *   | *    | *   | 0    | 0   | 0   | 0  |

\* Notes:

- VLE field: Reset value depends on the associated option bits in flash memory.
- BMODE field: Reset value depends on the device status after leaving reset.
- SEC field: Reset value depends on the device status after leaving reset.
- PUB field: Reset value depends on the device status after leaving reset.
- NXEN field: Reset value depends on the device status after leaving reset.

### SSCM\_STATUS field descriptions

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                     |
| 1<br>CER      | Configuration Error<br><br>This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error. If a non-permanent error is detected, this bit can be cleared by writing a 1. Refer to <a href="#">CERS-DCF Mechanism</a> section.<br><br>0 No configuration problem detected by the SSCM<br>1 Device configuration is not correct |
| 2<br>CERS     | Configuration Error for Safe DCF Clients<br><br>This field indicates that the SSCM has detected a configuration error during reset while loading the Safe DCF Clients (DCF client with SPRD ADDR enabled, Triple Voting Enabled). If a non-permanent error is detected, this bit can be cleared by writing a 1. Refer to <a href="#">CERS-DCF Mechanism</a> section.<br><br>0 No configuration problem detected by the SSCM<br>1 Device configuration is not correct        |
| 3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                     |

56.3.2 SSCM System Memory and ID Register (SSCM\_MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Address: 0h base + 2h offset = 2h

56.4 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

56.4.1 DCF mechanism

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST\_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. [Table 56-3](#) shows the DCF start record. The start record must be placed at UTEST\_OFFSET to indicate to the device that the following data records should be processed.

Table 56-3. DCF start record

|            |
|------------|
| 0:31       |
| 05AA 55AFh |
| 0:31       |
| 0000 0000h |

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See [Table 56-4](#). In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

**Table 56-4. Format of a DCF data record**

|             |            |      |      |
|-------------|------------|------|------|
| 0:31        |            |      |      |
| WDATA[31:0] |            |      |      |
| 0:14        | 15:29      | 30   | 31   |
| CS[14:0]    | ADDR[16:2] | PRTY | STOP |

The stop record indicates that processing should stop. The general format of the stop record is shown in [Table 56-5](#). Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

**Table 56-5. DCF stop record**

|      |    |
|------|----|
| 0:30 | 31 |
| rsvd | 1  |
| 0:31 |    |
| rsvd |    |

If  $n$  data records are to be stored in UTEST, the data structure must be as shown in [Table 56-6](#).

**Table 56-6. Series of DCF records in UTEST**

| ADDR<br>offset | DATA        |            |      |        |
|----------------|-------------|------------|------|--------|
| 00h            | 05AA 55AFh  |            |      |        |
| 04h            | 0000 0000h  |            |      | STOP=0 |
| 08h            | WDATA[31:0] |            |      |        |
| 0Ch            | CS[14:0]    | ADDR[16:2] | PRTY | STOP=0 |
| 10h            | WDATA[31:0] |            |      |        |
| 14h            | CS[14:0]    | ADDR[16:2] | PRTY | STOP=0 |
| ...            | ...         |            |      |        |
| $8n - 1 + 0h$  | reserved    |            |      |        |
| $8n - 1 + 4h$  | reserved    |            |      | 1      |
| $8n + 0h$      |             |            |      |        |
| $8n + 4h$      |             |            |      |        |

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in [Figure 56-2](#).

**Figure 56-2. Appending DCF records**

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0000\_0001h then the PRTY field needs to be set to 1, so that the total number of 1s is even.)

#### NOTE

When programming DCF records, ensure that programming is not interrupted and can complete without error.

### 56.4.2 CERS-DCF Mechanism

The figure below shows that a faulty DCF record has been loaded between the original DCF record set and the final DCF record set. When a faulty DCF record is encountered, the SSCM\_STATUS[CERS] field indicates that the device configuration is not correct. In a situation like the one shown below, CERS can be cleared by writing 1 to it, as long as the final DCF record set is correct.

If there is an error in the final set of loaded DCF records, CERS cannot be cleared. This situation indicates that the final DCF record set has at least one error. To fix this, the user should update flash memory after the faulty DCF record with a correct DCF record of the same type. For example, if the faulty DCF record is DCF2, then the correct DCF record should also be DCF2.

Figure 56-3. DCF Error and CERS Handling

### 56.4.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Single Chip (SC) - The device will boot from the first bootable section of the flash memory main array.
- Serial Boot (SBL) - The device will download boot code from either SCI or CAN interface and then execute it.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location) then the device will enter static mode.

### 56.4.4 Hardware configuration

The device will detect the boot mode based on external pins and device status. The following sequence applies:

- If the FAB (Force Alternate Boot Mode) pin is set to boot in serial mode the device can be forced into an Alternate Boot Loader Mode. The type of alternate boot mode is selected according to the ABS (Alternate Boot Selector) pins (See [Table 56-7](#)). For details of the serial boot modes please refer to the BAM/System Boot chapter.
- If the device identifies a flash memory sector with a valid boot sector, it will boot from the lowest sector. (See [Figure 56-4](#).)
- If none of the flash memory sectors contains a valid boot signature, the device will go into static mode.

**Table 56-7. Hardware Configuration**

| FAB | ABS 2, 0 | Boot ID   | Boot Mode        |
|-----|----------|-----------|------------------|
| 1   | 0 0      | –         | Serial Boot SCI  |
| 1   | 0 1      | –         | Serial Boot CAN  |
| 0   | –        | valid     | SC (Single Chip) |
| 0   | –        | not found | Static Mode      |

**NOTE**

All combinations not listed in the table above are not supported.

## 56.4.5 Single Chip boot sector search

### 56.4.5.1 Potential boot sectors

As shown in [Figure 56-4](#) in single chip mode, several locations are searched for a valid boot ID. The lowest sector that starts with a valid boot ID is used to boot the device.

For the flash memory locations that are searched on this device, see the chip-specific details about boot locations in flash memory.

**Figure 56-4. Flash memory partitioning and RCHW search**

### 56.4.5.2 Reset Configuration Half-Word

Each boot sector in flash memory contains the Reset Configuration Half-Word (RCHW) at offset 00h. If the RCHW field `BOOT_ID` holds the value 5Ah then the sector is considered bootable. In addition, there is a flag which indicates that the code is VLE code. (If a device only supports VLE code for future compatibility the flag must always be set to 1.) All other bits are reserved.

|       | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7   | 8       | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
|-------|---|---|---|---|---|---|---|-----|---------|---|----|----|----|----|----|----|
| R     | 0 | 0 | 0 | 0 | 0 | 0 | 0 | VLE | BOOT_ID |   |    |    |    |    |    |    |
| W     |   |   |   |   |   |   |   |     |         |   |    |    |    |    |    |    |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0   | 0       | 0 | 0  | 0  | 0  | 0  | 0  | 0  |

 = Reserved

Once the device detects that it needs to boot from flash memory, and finds a valid `BOOT_ID`, it will boot from the application start address at offset 04h within the boot sector.

**NOTE**

When programming any of the locations in the RCHW list, ensure that programming is not interrupted and can complete without error. When erasing any block containing any of the locations in the RCHW list, ensure that the erase is not interrupted (especially by reset or loss of power).

**56.4.5.3 Boot and alternate boot sectors**

Some applications require an alternate boot sector so that the main boot can be erased and reprogrammed in the field.

When an alternate boot is needed, the user can create two bootable sectors; the lowest sector shall be the main boot sector and the highest shall be the alternate boot sector. The alternate boot sector does not need to be consecutive to the main boot sector.

This scheme ensures that there is always one active boot sector by erasing one of the boot sectors only:

- Sector is activated (that is, program a valid BOOT\_ID instead of FFh as initially programmed).
- Sector is deactivated by writing 0 to some bits of the BOOT\_ID field (bit 1 and/or bit 3, and/or bit 4, and/or bit 6).

**56.4.6 Serial boot loader mode****56.4.6.1 Serial boot loader mode - public password enabled**

In Serial Boot Loader Mode, if public serial access is allowed, the MCU executes BAM code which will check for a valid public password on the chosen interface. The interface will be selected via FAB and ABS pins.

- Nexus/JTAG available
- Boot from BAM
- Flash memory main array and shadow block access disabled

### 56.4.6.2 Serial boot loader mode - flash memory password enabled

It's possible to boot in Serial Boot Loader Mode when serial access with password is selected. The MCU executes BAM code which will check for a valid flash memory password on the chosen interface. If the password is known, full access to the device is enabled.

- Nexus/JTAG available
- Boot from BAM
- Flash memory main array and UTEST block access possible

### 56.4.7 Security

The censorship mechanism implemented on the device is intended to increase the protection against unauthorized access to the device. The mechanisms employed does not provide a guarantee of a secure device. It can only be deemed effective if used in conjunction with an appropriately robust software and documentation infrastructure to assist in guarding against unauthorized access to device resources.

When the Flash is censored, the MCU is in the Secured state. This feature intends to prevent the unauthorized read and write of memory contents. Which device features are enabled or disabled is determined by the chip mode and security state in effect.

The user needs to keep in mind that part of the security must lie with the application code. As an extreme example: it would be possible to generate application code that dumps the contents of the internal program - obviously this code would defeat the purpose of security. However there may be good reasons to provide a back door in the application code. Care must be taken when implementing these backdoors, since they allow paths of attack to break security on the device.

#### 56.4.7.1 Securing the microcontroller

The device can be secured by adding a Non-Volatile System Censorship Information (NVSCI) record to the DCF record list in the UTEST Flash block ([Table 56-8](#)).

**Table 56-8. NVSCI DCF record**

|                     |                    |
|---------------------|--------------------|
| 0:31                |                    |
| Serial Boot Control | Censorship Control |
| 0:31                |                    |
| 0100_000Ch          |                    |

A value of 55AAh in the censorship control word of the NVSCI record determines that the device is unsecured, any other value determines that the device is secured.

By factory default the device has been programmed with a DCF record in UTEST with the value 55AA\_55AAh. (For the function of the Serial Boot Control word see [Serial access security](#).)

The device supports a backdoor to unsecure the device via a 64 bit password, which is programmed in two records (Non-Volatile Password Low (NVPWDL) and Non-Volatile Password High (NVPWDH)). ([Table 56-9](#) and [Table 56-10](#)).

**Table 56-9. NVPWDH DCF record**

|               |
|---------------|
| 0:31          |
| Password High |
| 0:31          |
| 0100_0008h    |

**Table 56-10. NVPWDL DCF record**

|              |
|--------------|
| 0:31         |
| Password Low |
| 0:31         |
| 0100_0004h   |

By default there is no backdoor password. In order to define one the two DCF records need to be added to the list.

To protect against voltage manipulations, each 16-bit halfword needs to contain both 1's and 0's. Below are examples for legal and illegal passwords:

| Illegal Passwords    | Legal Passwords      |
|----------------------|----------------------|
| 0000_0000_0000_0000h | 0001_0010_0100_1000h |
| FFFF_FFFF_FFFF_FFFFh | FFFE_FFFE_FFFE_FFFEh |
| FFFF_0000_FFFF_FFFFh | FFF0_000F_0FFF_0FFFh |
| 0000_0000_0000_FFFFh | 1000_1000_1000_FFFEh |
| AAAA_AAAA_AAAA_0000h | AAAA_AAAA_AAAA_0001h |

To deactivate the backdoor password ("swallowing the key") the records can be programmed to have the data value 0000\_0000\_0000\_0000h.

However once this is done neither the manufacturer nor the user can unlock device security again, other than by triggering a factory erase mechanism. Of course, application code can still implement a different backdoor scheme if there are special requirements which are not covered by the available mechanism.

### 56.4.7.2 Unsecuring the microcontroller

To unsecure a secured device, the backdoor password needs to be provided. This can be done by booting in SBL mode and providing the backdoor password via the serial bootloader protocol (please refer to the BAM chapter) or via JTAG command.

If SBL mode was used in conjunction with the backdoor password, the password comparison result will only be known after a delay - this is in order to avoid brute-force attacks. The data can be downloaded into SRAM during this delay.

#### Note

The scheme used here does not prohibit a malicious listener from capturing the password of a valid serial download, since the key is not in encrypted form. The user must take appropriate measures to protect against access by third parties during a valid download.

If the password is correct, the device is temporarily unsecured. In this state the a new backdoor password can be programmed by adding NVPWD records or new application data can be programmed into the flash memory.

It's also possible to unlock the device via JTAG. For this the device needs to be held in reset by asserting the external reset input. Once the flash memory has completed it's internal sequence, the JTAG register CENSOR\_CTRL can be written with the password in bits 63:0 and with bit 64 set to 1. The password comparator will compare the password and unsecure the device if it's correct, if serial access with the backdoor password is allowed, and if the device hasn't swallowed the key. (Only one transition on bit 64 from 0 to 1 is allowed.) The debugger needs to wait until the device is unlocked, after that a breakpoint can be set if desired, and the debugger can release the reset. The device will remain unsecured until the next reset event occurs.

#### NOTE

When external reset which is configured to generate long functional reset is applied, device will become secure until correct password is loaded by DCF again. Hence debugger will get disconnected on occurrence of long external reset.

### 56.4.7.3 Software unsecure

Since the security state of the device is determined solely by a set of DCF records in the UTEST block, any application may choose to implement a software unsecure method, through any interface.

### 56.4.8 Serial access security

If booted in SBL mode, the device can be accessed via a serial interface. It is possible to use either the public or backdoor password in SBL mode. The setting of the Serial Boot Control word in the NVSCI record determines which password will be used (see [Hardware configuration](#)). If it contains the value 55AAh, and the device is secured, the backdoor password must be used. If it contains any other value, the public password must be used.

#### NOTE

Any password is allowed if the device is unsecured.

Access to flash memory depends on the configuration of both the Serial Boot Control and Censorship Control fields in the NVSCI. An unsecured device always allows access to flash memory regardless of the Serial Boot Control field configuration. The flash memory will not be visible if public password access is used with a secured device. If backdoor password access is used, device security is disabled and flash memory will be visible.

The application may wish to prohibit access via the serial connection. On a secured device, this can be accomplished by programming Serial Boot Control field to 55AAh, which mandates the use of the backdoor password, or programming the NVPWD records so the password is 0000\_0000\_0000\_0000h making the backdoor password invalid (swallowing the key) (see [Table 56-10](#) and [Table 56-9](#)).

However, it should be carefully evaluated whether this scenario is desirable. If programmed as described above, there is no longer the possibility of allowing the manufacturer to run diagnostics on a returned device apart from erasing the flash memory. Also, it will not be possible to update application software. This does not apply if the user decides to implement an alternative backdoor scheme in software (see [Software unsecure](#)).

## 56.5 Initialization and application information

### **56.5.1 Reset**

The reset state of each individual bit appears in the detailed register descriptions.

## **56.6 Additional safety measures**

### **56.6.1 Spurious reset protection**

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM, but not other modules) by gating the state machines status with the expected status of the MC\_RGM. If a spurious reset occurs, the SSCM will not interfere with the flash memory bus or overwrite configuration registers. However, internal SSCM status will be lost.

# Chapter 57

## Power Management Controller block (PMC)

### 57.1 Introduction

#### 57.1.1 PMC Introduction

The power management controller (PMC) consists of two blocks: analog block and a digital block. This describes the digital block of the PMC.

The PMC block, shown below, contains all of the registers and digital logic to generate all of the enable signals, trim control bits, power on resets (PORs), and test mode logic for the analog block. The PMC digital logic also controls the PMC analog outputs that are to be sensed by the Analog-to-Digital Converter (ADC) module.

The PMC digital logic also provides the enable signals, trim bits and other registers for the temperature sensors.

Custom interfaces are provided to each of:

- The Reset Generation Module (MC\_RGM) block, which receives low voltage detect (LVD) values that are used for phase transition conditions during POR.
- The Flash memory, via the SSCM (and DCF client blocks), provides trim values for use during initial POR.

**Figure 57-1. Digital PMC block diagram**

## 57.1.2 Features

The PMC module provides:

- Configuration and control information to the analog PMC block.
- An interface with the TCU block for test related controls.

- An interface with Flash memory for retrieval of trim/control information, during POR, for HVDs, LVDs, regulators, and band gap filters.
- Necessary status and indication information to the MC\_RGM block during power up.
- Configuration and monitoring of the two temperature sensors.
- Interrupt or reset generation for HVDs and LVDs (based on the configuration).
- Host access, via the IPS bus, to all register controls, configurations, and status.
- Self test logic for the LVDs and HVDs.
- Software triggered fault injection to the FCCU for LVDs, HVDs, temperature sensors, and LVD self test.

## 57.2 Memory Map and Registers

The PMC includes many registers for configuring, monitoring, and trimming the regulators and the LVD/HVD monitors.

**PMC memory map**

| Address offset (hex) | Register name                                            | Width (in bits) | Access | Reset value | Section/ page                |

**57.2.2 Regulator Voltage Status Register (PMC\_RSSR)**

This status register contains the status of the indicated supply. This indicates the present state of the voltage detect events for each of the supplies. Each of the voltage detect signals for a give voltage are combined to form a single bit.

The following figure indicates the combined supply status generation logic for various LVDs and HVDs for a voltage level. Not that the LVD/HVD signals coming from analog is first synchronized on the system clock before generating the status.

The figure below indicates the combined supply status generation logic for various LVDs and HVDs for a voltage level. Not that the LVD/HVD signals coming from analog is first synchronized on the system clock before generating the status.

Figure 57-2. Supply Status Generation Logic

**57.2.4 Interrupt Enable Register (PMC\_IER)**

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Status Registers (ESR\_0). These bits indicate whether an interrupt occurs when the voltage event is seen. A '0' indicates that no interrupt is to be sent, and a '1' indicates that an interrupt is to occur when the voltage detect event occurs. These bits are enabled via a write of one to the MSB of this register (IE\_EN). After this, these bits can be read or written at any time.

**NOTE**

If an interrupt is enabled for an LVD/HVD, the FCCU fault corresponding to the LVD/HVD must be disabled in the FCCU.

## Memory Map and Registers

## 57.2.5 Event Status Register 0 (PMC\_ESR\_0)

This status register contains the latched status of the Voltage detect events. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the writing '1'). These bits are read only, and they are cleared by writing a one to the corresponding ESR register.

**57.2.6 Reset Event Enable 0 (PMC\_REE\_0)**

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event.

## Memory Map and Registers

The register's reset value applies until the portion of the boot sequence that loads a value for the register from a DCF record in the UTEST area of flash memory. The user can change the loaded value by programming a new DCF record in the UTEST area. If the loaded value programs any flag bit to be enabled (set to 1), the bit cannot be disabled (cleared to 0) by software through IPS programming.

**57.2.7 Reset Event Selection 0 (PMC\_RES\_0)**

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event.

**NOTE**

If a functional reset is enabled for an LVD/HVD, the FCCU fault corresponding to the LVD/HVD must be disabled in the FCCU. The user should configure a functional reset for an

LVD/HVD only for debugging purposes and never for any actual application.

57.2.8 FCCU Fault Injection Register (PMC\_FIR)

This FCCU Fault Injection register enables the user s/w to artificially generate FCCU faults corresponding to various Events, namely LVD, HVD, TEMP SENS and Self Test. A write '1' to these bits generates a single cycle pulsed fault to the FCCU block, this bit automatically gets cleared in the next cycle.

Address: 0h base + 70h offset = 70h

## 57.2.9 Temperature Event Status register (PMC\_ESR\_TD)

This Event Status Register indicates the present and past state of the two temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Address: 0h base + 100h offset = 100h

**57.2.10 Temperature Reset Event Enable register (PMC\_REE\_TD)**

This Reset Event Enable register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

The register's reset value applies until the portion of the boot sequence that loads a value for the register from a DCF record in the UTEST area of flash memory. The DCF record for this register is PMC\_LVD\_MISC. The user can change the loaded value by programming a new DCF record for PMC\_LVD\_MISC in the UTEST area. If the loaded value programs any flag bit to be enabled (set to 1), the bit cannot be disabled (cleared to 0) by software through IPS programming.

**NOTE**

Programming a new value for PMC\_LVD\_MISC in the UTEST area of flash memory requires special care. In addition to the TEMPn\_m bits, this DCF record contains the LVD trim values for the ADC, FLASH, IO, and OSC 3.3 V supplies. For these LVD trim bits, the user must not change the values in the factory-programmed DCF record for PMC\_LVD\_MISC.

1. Before programming a new value for PMC\_LVD\_MISC, read the factory-programmed value of the DCF record.

2. When programming a new DCF record for  
PMC\_LVD\_MISC:

- Change only the values of the desired TEMP<sub>n</sub>\_m bits.
- Ensure that all other bits have the same values as in the factory-programmed value of PMC\_LVD\_MISC.

**57.2.11 Temperature Reset Event Selection register (PMC\_RES\_TD)**

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the temperature sensor event causes either a destructive or functional reset to be generated when the selected temperature passes the trigger event.

The register's reset value applies until the portion of the boot sequence that loads a value for the register from a DCF record in the UTEST area of flash memory. The user can change the loaded value by programming a new DCF record in the UTEST area.

**57.2.12 Temperature detector configuration register (PMC\_CTL\_TD)****NOTE**

To disable a temperature sensor, program both TS<sub>n</sub>\_DOUT\_EN and TS<sub>n</sub>\_AOUT\_EN for that temperature sensor to 0. To enable a temperature sensor, write 1 to either or both of these fields.

Address: 0h base + 10Ch offset = 10Ch

| 001101                   | LVD_CORE_HOT                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                 |      |        |                 |        |          |        |          |        |          |        |          |        |          |        |            |        |           |        |         |        |         |        |        |        |          |        |          |        |              |        |          |
| 001110                   | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                 |      |        |                 |        |          |        |          |        |          |        |          |        |          |        |            |        |           |        |         |        |         |        |        |        |          |        |          |        |              |        |          |

## 57.3 Analog PMC interface

The digital block uses the analog PMC interface to configure trim values for the regulators and LVDs that are in the analog block.

## 57.4 Temperature Sensor Interface Logic

The digital PMC block provides control and configuration information to the two temperature sensors. This information includes digital and analog enables, and trim values. A user adjustable trim control is also provided to fine tune the trimming (for more detail, see the detailed description of the Temperature Sensor module).

## 57.5 Power On Reset (MC\_RGM Phase Gates)

The interface with the MC\_RGM block is used during the power on sequence and startup. It provides various phase gates, thereby enabling the MC\_RGM to properly complete the reset sequence.

It also provides functional and destructive reset sources, based on the configuration. Two types of resets are generated, based on LVD and HVD faults and the corresponding REE and RES enables:

- functional, and
- destructive.

The temperature sensor provides another reset source, based on the under/over temperature faults and the corresponding REE and RES enables.

## 57.6 Flash interface (DCF)

During power up, trim values for the regulators, LVDs, and HVDs are read from Flash memory by the SSCM, and are then provided to the digital PMC via the DCF interface.

The reset event enable (REE) configurations that are stored in Flash memory are also provided to the PMC via the DCF interface. These REEs configurations are used, by default, to generate various resets to the RGM.

## 57.7 FCCU Interface

The digital block generates various fault indications to the FCCU block:

- Separate corresponding, active-high, fault indications are generated whenever an LVD or HVD defect is detected in the analog block.
- A fault indication is generated when a self test task results in a failure.
- A fault condition is generated whenever over-temperature or under-temperature events occur in the temperature sensor.

The figures below show the exact logic for the generation fault indications to FCCU block.

MPC5744P Reference Manual, Rev. 6, 06/2016

<sup>1</sup> See “FCCU Fault Injection Register 0(FIR) for details.

## 57.8 LVD/HVD self test mechanism

The PMC implements an LVD/HVD self test mechanism for use in satisfying safety goals. The digital block assists and controls the analog block during its performance of the self test.

Currently, three self test modes (described in the following sections) are supported by the analog block (based on the mode specified by the VD\_UTST[ST\_MODE] register bit).

The self test status and result are provided in the VD\_UTST[ST\_DONE, ST\_RESULT] register fields, respectively.

### 57.8.1 Default Mode

The self test is always performed during startup (power on). The self test starts during the phase 3 MC\_RGM state, when the SSCM has completed reads from the flash memory (that is, asserts ‘sscm\_done’ signal). A counter is provided that starts from zero and increments by one after an 8  $\mu$ s time gap.

Meanwhile, the LVD/HVD indication from the analog block is latched in the VD\_UTST register. At the end of the self test (that is, when all of the LVDs/HVDs have been tested), the VD\_UTST[ST\_DONE] status bit is set to '1' and all of the bits in the VD\_UTST register are checked for '1'. One or more bits not set to '1' generates a fault indication to the FCCU block, and the VD\_UTST[ST\_RESULT] register bit is set to '0'. In the case where all of the register bits are set to '1', the test is considered to be PASSED, the VD\_UTST[ST\_RESULT] register bit is set to '1', and no fault indications are provided to the FCCU.

#### NOTE

The total run time of the LVD self test is equal to: 'time required per LVD (8  $\mu$ s)' multiplied by 'number of LVDs (14)' = 112  $\mu$ s. Some of the 14 self tests are internal self tests that are listed as reserved in the description of VD\_UTST[VD\_ST\_CTRL].

## 57.8.2 Software triggered self test

This mode is entered by software by writing '01' to the VD\_UTST[ST\_MODE] register 2-bit field. The complete self test, as is performed in default mode, is repeated. The difference is that the self test in this mode is initiated by the host while the self test in default mode is started automatically during power on.

### NOTE

The LVD self test Time Window Register (STTW) has to be configured appropriately (based on the clock frequency used), before initiating software triggered self test. For example, the configuration for a 100MHz system clock and a 8us window should be 800 (decimal).

## 57.8.3 Single VD test

This mode is entered by software writing 10b to the 2-bit VD\_UTST[ST\_MODE] field, which results in the assertion of the pmc\_lvd\_self\_test input. The test completes after the prescribed time gap has elapsed. The PASS/FAIL result is then updated based on whether or not the corresponding LVD output trips.

### NOTE

The LVD Self Test Time Window Register (STTW) must to be configured appropriately as in Software triggered self test mode.

### NOTE

During the running of the LVD self test, all of the LVD and HVD outputs are masked that are also under self test (see the LVD/HVD list in the definition of VD\_UTST[VD\_ST\_CTRL]). Therefore, they have no effect on POR generation, or in any reset and/or fault generation.

## **Chapter 58**

# **Power Control Unit (MC\_PCU)**

## **58.1 Introduction**

### **58.1.1 Overview**

The power control unit (MC\_PCU) acts as a bridge for mapping the PMC peripheral to the MC\_PCU address space.

The following figure depicts the MC\_PCU block diagram.

Figure 58-1. MC\_PCU Block Diagram

### 58.1.2 Features

The MC\_PCU includes the following features:

- maps the PMC registers to the MC\_PCU address space

## 58.2 External Signal Description

The MC\_PCU has no connections to any external pins.

## 58.3 Memory Map and Register Definition

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU\_PSTAT register may be accessed as a word at address 0x0040, as a half-word at address 0x0042, or as a byte at address 0x0043.

**MC\_PCU memory map**

| Address offset (hex) | Register name                                          | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|--------------------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Power Domain #0 Configuration Register (MC_PCU_PCONF0) | 32              | R      | 0000_05FFh  | <a href="#">58.3.1/2284</a> |
| 40                   | Power Domain Status Register (MC_PCU_PSTAT)            | 32              | R      | 0000_0001h  | <a href="#">58.3.2/2286</a> |

58.3.1 Power Domain #0 Configuration Register (MC\_PCU\_PCONF0)

This register defines for power domain #0 whether it is on or off in each chip mode. It can be read in user and supervisor mode. Because power domain #0 is always on, none of this register's bits are programmable. This register is available for completeness reasons.

Address: 0h base + 0h offset = 0h

## **Chapter 59**

# **Mode Entry Module (MC\_ME)**

## **59.1 Introduction**

### **59.1.1 Overview**

The MC\_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

The following figure shows the MC\_ME block diagram.

Figure 59-1. MC\_ME Block Diagram

### 59.1.2 Features

The MC\_ME includes the following features:

- control of the available modes by the ME\_ME register
- definition of various chip mode configurations by the ME\_<mode>\_MC registers
- control of the actual chip mode by the ME\_MCTL register
- capture of the current mode and various resource status within the contents of the ME\_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME\_RUN\_PC0...7, ME\_LP\_PC0...7, and ME\_PCTLn registers
- additional core clock gating and boot address control based on the ME\_CCTLn and ME\_CADDRn registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

### 59.1.3 Modes of Operation

The MC\_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC\_ME are divided into system and user modes. The system modes are modes such as RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as RUN0...3, HALT0, and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0...3 are the chip software running modes.

The following table describes the MC\_ME modes.

**Table 59-1. MC\_ME Mode Descriptions**

| Name     | Description                                                                                                                                                                                                                                                                                                           | Entry                                                                                                          | Exit                                                                                                                    |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| RESET    | This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules. | system reset assertion from MC_RGM                                                                             | system reset deassertion from MC_RGM                                                                                    |
| DRUN     | This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAM when present is executed in DRUN mode.                                                                    | system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0...3                            | system reset assertion, RUN0...3, TEST via software, SAFE via software or hardware failure.                             |
| SAFE     | This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.                                                                                                                   | hardware failure, software request from DRUN, TEST, and RUN0...3                                               | system reset assertion, DRUN via software                                                                               |
| TEST     | This is a chip-wide service mode which is intended to provide a control environment for chip software testing.                                                                                                                                                                                                        | software request from DRUN                                                                                     | system reset assertion, DRUN via software                                                                               |
| RUN0...3 | These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.                                                                                                                     | software request from DRUN or other RUN0...3, interrupt event from HALT0, interrupt or wakeup event from STOP0 | system reset assertion, SAFE via software or hardware failure, DRUN and other RUN0...3 modes, HALT0, STOP0 via software |
| HALT0    | This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals like clock sources, flash, main regulator, etc. for efficient power management at the cost of higher wakeup latency.                                                  | software request from RUN0...3                                                                                 | system reset assertion, SAFE on hardware failure, RUN0...3 on interrupt event                                           |
| STOP0    | This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.                                                                            | software request from RUN0...3                                                                                 | system reset assertion, SAFE on hardware failure, RUN0...3 on interrupt event or wakeup event                           |

## 59.2 External Signal Description

The MC\_ME has no connections to any external pins.

## 59.3 Memory Map and Register Definition

The MC\_ME contains registers for:

- mode selection and status reporting

- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME\_RUN\_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

### MC\_ME memory map

**59.3.2 Mode Control Register (MC\_ME\_MCTL)**

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME\_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME\_<mode>\_MC registers must respect this for successful mode requests.

**NOTE**

Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Address: 0h base + 4h offset = 4h

| 16–31<br>KEY       | <p>Control key — These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key.</p> <p>KEY: 0101101011110000 (0x5AF0)</p> <p>INVERTED KEY: 1010010100001111 (0xA50F)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 59.3.3 Mode Enable Register (MC\_ME\_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET\_FUNC, SAFE, DRUN, RUN0, and RESET\_DEST modes are always enabled.

Address: 0h base + 8h offset = 8h

59.3.6 Invalid Mode Transition Status Register (MC\_ME\_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Address: 0h base + 14h offset = 14h

59.3.7 Debug Mode Transition Status Register (MC\_ME\_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME\_GS.S\_MTRANS may be taking longer than expected. NOTE The ME\_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME\_DMTS bits may still be asserted after the mode transition has completed.

Address: 0h base + 18h offset = 18h

**MC\_ME\_RESET\_MC field descriptions (continued)**

| Field | Description                                                        |
|-------|--------------------------------------------------------------------|
| 1110  | reserved                                                           |
| 1111  | system clock is disabled in TEST mode, reserved in all other modes |

**59.3.9 TEST Mode Configuration Register (MC\_ME\_TEST\_MC)**

This register configures system behavior during TEST mode.

**NOTE**

Byte write accesses are not allowed to this register.

**WARNING**

Although the IRCON bit is writable, writing a '0' to this bit will not turn off the 16 MHz internal RC oscillator is always in use. Writing a '0' to this bit will cause the mode transition to not complete, since it will wait forever for the 16 MHz internal RC oscillator to become free.

Address: 0h base + 24h offset = 24h

**59.3.11 DRUN Mode Configuration Register (MC\_ME\_DRUN\_MC)**

This register configures system behavior during DRUN mode.

**NOTE**

Byte write accesses are not allowed to this register.

**NOTE**

The following configuration values are set according to the chip configuration: XOSCON

## Memory Map and Register Definition

Address: 0h base + 2Ch offset = 2Ch

### MC\_ME\_DRUN\_MC field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

MC\_ME\_DRUN\_MC field descriptions (continued)

| Field | Description                                                        |
|-------|--------------------------------------------------------------------|
| 1110  | reserved                                                           |
| 1111  | system clock is disabled in TEST mode, reserved in all other modes |

59.3.12 RUN0 Mode Configuration Register (MC\_ME\_RUN0\_MC)

This register configures system behavior during RUN0 mode.

NOTE

Byte write accesses are not allowed to this register.

Address: 0h base + 30h offset = 30h

**MC\_ME\_RUN0\_MC field descriptions**

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                          |
| 1–3<br>PWRLVL     | Power level — These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.                                                                                                                                                                                                            |
| 4–7<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                          |
| 8<br>PDO          | I/O output power-down control — This bit controls the output power-down of I/Os.<br><br>0 No automatic safe gating of I/Os used and pads power sequence driver is enabled<br>1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional. |
| 9–10<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                          |

**59.3.17 STOP0 Mode Configuration Register (MC\_ME\_STOP0\_MC)**

This register configures system behavior during STOP0 mode.

**NOTE**

Byte write accesses are not allowed to this register.

**59.3.60 CORE0 Address Register (MC\_ME\_CADDR0)**

This registers gives the boot address for main and checker cores and a bit for controlling whether main and checker cores are to be reset on the next mode change that has main and checker cores configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (that is, while the S\_MTRANS bit of the ME\_GS register = '1'). A write access to this register during this time will result in the ICONF\_CC flag in the ME\_IS register being asserted.

**NOTE**

The reset value of the ADDR field of the ME\_CADDR0 is determined by the chip configuration and boot mode.

Address: 0h base + 1E0h offset = 1E0h

### MC\_ME\_CADDR0 field descriptions

| Field          | Description                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–29<br>ADDR   | Core Address — This field is used by main and checker cores as the boot address (32-bit word aligned) when main and checker cores next exits reset.             |
| 30<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                         |
| 31<br>Reserved | This field is reserved.<br>This read/write field is reserved, and must always be written with the value '0'. Writing a '1' will lead to unpredictable behavior. |

## 59.4 Functional Description

### 59.4.1 Mode Transition Request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME\_MCTL. But the in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME\_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET\_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET\_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME\_<mode>\_MC register. The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S\_CURRENT\_MODE bit field and the S\_MTRANS bit of the global status register ME\_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please refer to [Mode Transition Interrupts](#).

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as RUN0...3 → RUN0...3, DRUN → DRUN, SAFE → SAFE, and TEST → TEST are considered valid mode transition requests. As soon as

the mode request is accepted as valid, the S\_MTRANS bit is set till the status in the ME\_GS register matches the configuration programmed in the respective ME\_<mode>\_MC register.

### Note

Software should poll the S\_MTRANS bit in the ME\_GS register after requesting a transition to HALT0 or STOP0 modes.

Figure 59-2. MC\_ME Mode Diagram

## 59.4.2 Modes Details

### 59.4.2.1 RESET Mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0...3, or TEST mode when the TARGET\_MODE bit field of the ME\_MCTL register is written with either "0000" for a 'functional' reset or "1111" for a 'destructive' reset
- from any mode due to a system reset by the MC\_RGM because of some non-recoverable hardware failure in the system (see the MC\_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME\_RESET\_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

### 59.4.2.2 DRUN Mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0...3, SAFE, or TEST mode when the TARGET\_MODE bit field of the ME\_MCTL register is written with "0011"

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME\_DRUN\_MC register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME\_DRUN\_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs

#### Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

### 59.4.2.3 SAFE Mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET\_MODE bit field of the ME\_MCTL register is written with "0010"
- from any mode except RESET due to a SAFE mode request generated by the MC\_RGM because of some potentially recoverable hardware failure in the system (see the MC\_RGM chapter for details)

#### Note

If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME\_SAFE\_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

#### Note

If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either

- re-initialize the chip via the DRUN mode, or
- completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME\_SAFE\_MC register should be set. The input levels remain unchanged.

#### 59.4.2.4 TEST Mode

The chip enters this mode on the following events:

- from the DRUN mode when the TARGET\_MODE bit field of the ME\_MCTL register is written with "0001"

As soon as any of the above events has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME\_TEST\_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to "1111", and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

#### Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

#### 59.4.2.5 RUN0...3 Modes

The chip enters one of these modes on the following events:

- from the DRUN or another RUN0...3 mode when the TARGET\_MODE bit field of the ME\_MCTL register is written with "0100...0111"
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0...3 mode transition request is generated. The mode configuration information for these modes is provided by the ME\_RUN0...3\_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

### **Note**

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

## **59.4.2.6 HALT0 Mode**

The chip enters this mode on the following events:

- from one of the RUN0...3 modes when the TARGET\_MODE bit field of the ME\_MCTL register is written with "1000".

As soon as any of the above events has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME\_HALT0\_MC register. This mode is quite configurable, and the ME\_HALT0\_MC register should be programmed according to the system needs. The flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

If a HALT0 mode transition request is generated at the same time that an interrupt request occurs there is a possibility that the system may hang requiring a power-on reset to recover. The application software should avoid the conditions where this system hang is possible. Before entering HALT0 mode the application software should disable all interrupts. If this is not easily manageable by software then the software should ensure that any transaction which can potentially generate an interrupt should be finished and all interrupts serviced before requesting HALT0 transition. As a result the wake up source from HALT0 mode should always be executed by an external interrupt and not from internal interrupts from the peripheral modules.

This mode is intended as a first-level low-power mode with

- the core clocks frozen the additional core clocks frozen
- XBAR masters cannot operate in system HALT0 mode as they are clock gated. Also, NPC should be enabled if mode transition is initiated while debugger is connected
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (i.e., within a few system clock cycles of an interrupt event)

### Note

It is good practice for software to ensure that the S\_MTRANS bit in the ME\_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0...3 mode configuration has been fully restored before executing critical code.

#### 59.4.2.7 STOP0 Mode

The chip enters this mode on the following events:

- from one of the RUN0...3 modes when the TARGET\_MODE bit field of the ME\_MCTL register is written with "1010".

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME\_STOP0\_MC register. This mode is fully configurable, and the ME\_STOP0\_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the primary PLL
- the secondary PLL

The flash memory can be put in power-down mode as needed.

If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted—with the resulting mode being the current mode—and an invalid mode transition interrupt is generated. The reason for this interrupt is S\_MRIG (Mode request ignored): If a transition to SAFE (on SAFE mode request) is in progress, a transition request to STOP0 mode also generates an S\_MRIG (Mode request ignored)

interrupt. In case of a transition to DRUN (on reset), no interrupt is generated. Before attempting to enter STOP0 mode, properly disable all interrupts not intended to be used as wakeup events in software.

If a STOP0 mode transition request is generated at the same time that an interrupt request occurs there is a possibility that the system may hang requiring a power-on reset to recover. The application software should avoid the conditions where this system hang is possible. Before entering STOP0 mode the application software should disable all interrupts. If this is not easily manageable by software then the software should ensure that any transaction which can potentially generate an interrupt should be finished and all interrupts serviced before requesting STOP0 transition. As a result the wake up source from STOP0 mode should always be executed by an external wake-up/interrupt and not from internal interrupts from the peripheral modules.

This mode is intended as an advanced low-power mode with:

- the core clock frozen
- the additional core clocks frozen
- XBAR masters cannot operate in system STOP0 mode as they are clock gated. Also, NPC should be enabled if mode transition is initiated while debugger is connected
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (e.g., allow for system clock source to be re-started)

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

### **Note**

It is good practice for software to ensure that the S\_MTRANS bit in the ME\_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0...3 mode configuration has been fully restored before executing critical code.

### 59.4.3 Mode Transition Process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

#### 59.4.3.1 Target Mode Request

The target mode is requested by accessing the ME\_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET\_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to [Mode Transition Interrupts](#) for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET\_MODE bit field of the ME\_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S\_MTRANS of the ME\_GS register.

A RESET mode requested via the ME\_MCTL register is passed to the MC\_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC\_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME\_MCTL register from all software running modes or by the MC\_RGM after the detection of system hardware failures, which may occur in any mode.

#### 59.4.3.2 Target Mode Configuration Loading

On completion of the [Target Mode Request](#) step, the target mode configuration from the ME\_<target mode>\_MC register is loaded to start the resources (voltage sources, clock sources, flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in the following table. A '√' indicates that a given resource is configurable for a given mode.

**Table 59-2. MC\_ME Resource Control Overview**

| Resource | Mode   |             |         |             |             |                |                 |
|----------|--------|-------------|---------|-------------|-------------|----------------|-----------------|
|          | RESET  | TEST        | SAFE    | DRUN        | RUN0...3    | HALT0          | STOP0           |
| IRC      | on     | √<br>on     | on      | on          | on          | on             | on              |
| XOSC     | off    | √<br>off    | off     | √<br>off    | √<br>off    | √<br>off       | √<br>off        |
| PLL0     | off    | √<br>off    | off     | √<br>off    | √<br>off    | √<br>off       | off             |
| PLL1     | off    | √<br>off    | off     | √<br>off    | √<br>off    | √<br>off       | √<br>off        |
| FLASH    | normal | √<br>normal | normal  | √<br>normal | √<br>normal | √<br>low-power | √<br>power-down |
| MVREG    | on     | on          | on      | on          | on          | on             | on              |
| PDO      | off    | √<br>off    | √<br>on | off         | off         | off            | √<br>off        |

### 59.4.3.3 Peripheral Clocks Disable

On completion of the [Target Mode Request](#) step and the system clock frequency ramp-down of the [System Clock Switching](#) step, the MC\_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME\_RUN\_PC0...7 and ME\_LP\_PC0...7, and the peripheral control registers ME\_PCTL*n*

#### Note

The MC\_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC\_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC\_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC\_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please refer to [Peripheral Clock Gating](#) for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

#### 59.4.3.4 Processor Low-Power Mode Entry

If, on completion of the [Peripheral Clocks Disable](#) step, the mode transition is to the HALT0,STOP0 mode, the MC\_ME requests each processor to enter its stopped state. Each processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If, on completion of the [Peripheral Clocks Disable](#) step, the mode transition is from a non-low-power mode to another non-low-power mode, the MC\_ME requests each processor which is configured in the ME\_CCTL $n$  registers to be disabled to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

#### 59.4.3.5 Processor Clocks Disable

If, on completion of the [Processor Low-Power Mode Entry](#) step, and all processors which are configured in the ME\_CCTL $n$  registers to be disabled are in their appropriate stopped state, the MC\_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

#### Warning

Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

### 59.4.3.6 System Clock Disable

If, on completion of the [Processor Clocks Disable](#) step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

### 59.4.3.7 Clock Sources Switch-On

On completion of the [Processor Low-Power Mode Entry](#) step, the MC\_ME switches on all clock sources based on the <clock source>ON bits of the ME\_<current mode>\_MC and ME\_<target mode>\_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator
- the 4-40 MHz crystal oscillator
- the primary PLL
- the secondary PLL

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S\_<clock source> bits of ME\_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

### 59.4.3.8 Flash Module Switch-On

On completion of the step, if the flash needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME\_<current mode>\_MC and ME\_<target mode>\_MC registers, the MC\_ME requests the flash to exit from its low-power/power-down mode. When the flash is available for access, the S\_FL A bit field of the ME\_GS register is updated to "11" by hardware.

## Warning

It is illegal to switch the FLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC\_ME, however, does not prevent this nor does it flag it.

### 59.4.3.9 Pad Outputs-On

On completion of the step, if the PDO bit of the ME\_<target mode>\_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- the I/O pads power sequence driver is switched on

### 59.4.3.10 Peripheral Clocks Enable

Based on the current and target chip modes, the peripheral configuration registers ME\_RUN\_PC0...7, ME\_LP\_PC0...7, and the peripheral control registers ME\_PCTLn, the MC\_ME enables the clocks for selected modules as required. This step is executed only after the process is completed, and if the value of the PWRLVL field of the ME\_<target mode>\_MC register is process is completed.

### 59.4.3.11 System and Processor Clocks Enable

On completion of the [Flash Module Switch-On](#) step, the MC\_ME enables the non-processor system clock and the clocks of all processors that are configured in the ME\_CCTLn registers to be disabled in the current mode and to be running in the target mode.

If the value of the PWRLVL field of the ME\_<target mode>\_MC register is different from that of the ME\_<current mode>\_MC register, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the [System Clock Switching](#) process is completed.

### 59.4.3.12 Processor Low-Power Mode Exit

On completion of the [System and Processor Clocks Enable](#) step, the MC\_ME requests all processors which are configured in the ME\_CCTL $n$  registers to be disabled in the current mode and to be running in the target mode.

### 59.4.3.13 System Clock Switching

Based on the SYSCLK bit field of the ME\_<current mode>\_MC and ME\_<target mode>\_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S\_IRC bit of the ME\_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the 4-40 MHz crystal osc. takes effect only after the S\_IRC bit of the ME\_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the S\_XOSC bit of the ME\_GS register is set by hardware (i.e., the 4-40 MHz crystal oscillator has stabilized).
- The target clock configuration for the secondary PLL takes effect only after the S\_PLL0 bit of the ME\_GS register is set by hardware (i.e., the primary PLL has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with "1111". This is possible only in the TEST mode.

If the value of the PWRLVL field of the ME\_<target mode>\_MC register not equal to that of the ME\_<current mode>\_MC register's, a progressive clock switching is performed in the MC\_CGM to reduce the impact of a sudden increase or drop in the power consumption of the device. The MC\_ME requests progressive clock switching and indicates the direction of the switching (ramp-up vs. ramp-down) via the clk\_sys\_sw\_req and clk\_sys\_sw\_ctl[2:0] outputs. If progressive clock switching has been requested, the system clock switching process is not completed until the MC\_CGM has indicated that the progressive clock switching has finished by deasserting the clk\_sys\_sw\_busy input ME\_CLK\_SYS\_PCS.

The current system clock configuration can be observed by reading the S\_SYSCLK bit field of the ME\_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the [Clock Sources Switch-On](#) process has completed if the target system clock source is one of the following:
  - the 16 MHz internal RC oscillator
  - the 4-40 MHz crystal oscillator
  - the primary PLL
  - the Secondary system clock source 1
- the [Peripheral Clocks Disable](#) process has completed in order not to change the system clock frequency before peripherals close their internal activities the [Peripheral Clocks Enable](#) process has completed

An overview of system clock source selection possibilities for each mode is shown in the following table. A '√' indicates that a given clock source is selectable for a given mode.

**Table 59-3. MC\_ME System Clock Selection Overview**

| System Clock Source      | Mode           |                |                |                |                |                |                |
|--------------------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
|                          | RESET          | TEST           | SAFE           | DRUN           | RUN0...3       | HALT0          | STOP0          |
| 16 MHz int. RC osc.      | √<br>(default) | √<br>(default) | √<br>(default) | √<br>(default) | √<br>(default) | √<br>(default) | √<br>(default) |
| 4-40 MHz crystal osc.    |                | √              |                | √              | √              | √              | √              |
| primary PLL (PHI)        |                | √              |                | √              | √              | √              | √              |
| secondary PLL            |                | √              |                | √              | √              |                |                |
| system clock is disabled |                | √ <sup>1</sup> |                |                |                |                |                |

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

#### 59.4.3.14 Pad Switch-Off

If the PDO bit of the ME\_<target mode>\_MC register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

This step is executed only after the [Peripheral Clocks Disable](#) process has completed.

### 59.4.3.15 Clock Sources (with no Dependencies) Switch-Off

Based on the chip mode and the <clock source>ON bits of the ME\_<mode>\_MC registers, if a given clock source is to be switched off, the MC\_ME requests the clock source to power down and updates its availability status bit S\_<clock source> of the ME\_GS register to '0'. The following clock sources are switched off at this step:

- the 16 MHz internal RC oscillator, if it is not currently being used as the reference clock for PLL0 (the IRCOSC can be turned off only during TEST mode)
- the 4 MHz to 40 MHz crystal oscillator, if it is not currently being used as the reference clock for either PLL0 or PLL1
- the primary PLL, if it is not currently being used as the reference clock for PLL1
- the secondary PLL

For the clock sources related to the system clock, this step is executed only after the [System Clock Switching](#) process has completed.

### 59.4.3.16 Clock Sources (with Dependencies) Switch-Off

Based on the chip mode and the <clock source>ON bits of the ME\_<mode>\_MC registers, if a given clock source is to be switched off and all clock sources that need this clock source to be on have been switched off, the MC\_ME requests the clock source to power down and updates its availability status bit S\_<clock source> of the ME\_GS register to '0'. The following clock sources are switched off at this step:

- the 16 MHz internal RC oscillator, if it is currently being used as the reference clock for PLL0 (the IRCOSC can be turned off only during TEST mode)
- the 4 MHz to 40 MHz crystal oscillator, if it is currently being used as the reference clock for either PLL0 or PLL1
- the primary PLL, if it is currently being used as the reference clock for PLL1

This step is executed only after

- the [System Clock Switching](#) process has completed in order not to lose the current system clock during mode transition
- the [Clock Sources \(with no Dependencies\) Switch-Off](#) process has completed in order to, for example, prevent unwanted clock transitions

### 59.4.3.17 Flash Switch-Off

Based on the FLAON bit field of the ME\_<current mode>\_MC and ME\_<target mode>\_MC registers, if the flash is to be put in its low-power or power-down mode, the MC\_ME requests the flash to enter the corresponding power mode and waits for the flash to acknowledge. The exact power mode status of the flash is updated in the S\_FLA bit field of the ME\_GS register. This step is executed only when the [Processor Clocks Disable](#) and [System Clock Disable](#) processes have completed.

### 59.4.3.18 Current Mode Update

The current mode status bit field S\_CURRENT\_MODE of the ME\_GS register is updated with the target mode bit field TARGET\_MODE of the ME\_MCTL register when :

- all the updated status bits in the ME\_GS register match the configuration specified in the ME\_<target mode>\_MC register
- power sequences are done
- clock disable/enable process is finished
- processor low-power mode (stop) entry and exit processes are finished

#### Note

SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME\_GS.S\_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S\_MTRANS bit of the ME\_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME\_DMTS register can indicate which process is still in progress.

Figure 59-3. MC\_ME Transition Diagram

### 59.4.4 Protection of Mode Configuration Registers

While programming the mode configuration registers ME\_<mode>\_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz internal RC oscillator is selected as the system clock, IRC must be on.
- If the 4 MHz to 40 MHz crystal oscillator clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.
- If the 16 MHz internal RC oscillator is selected as the reference for PLL0 (via the MC\_CGM\_AC3\_SC register in the MC\_CGM) and PLL0 is on, IRCOSC must be on.
- If the 4 MHz to 40 MHz crystal oscillator is selected as the reference for PLL0 (via the MC\_CGM\_AC3\_SC register in the MC\_CGM) and PLL0 is on, XOSC must be on.
- If the 4 MHz to 40 MHz crystal oscillator is selected as the reference for PLL1 (via the MC\_CGM\_AC4\_SC register in the MC\_CGM) and PLL1 is on, XOSC must be on.
- If the primary PLL is selected as the reference for PLL1 (via the MC\_CGM\_AC4\_SC register in the MC\_CGM) and PLL1 is on, PLL0 must be on.

#### Note

Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC\_ME.

- Configuration "00" for the FLAON bit field is reserved.
- System clock configurations marked as 'reserved' may not be selected.
- Configuration "1111" for the SYSCLK bit field is allowed only for the TEST mode, and only in this case may all system clock sources be turned off.

Warning

If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

59.4.5 Mode transition and progressive clock switching

The MC\_ME initiates a progressive clock switching via MC\_CGM whenever the ME\_<current mode>\_MC.PWRLVL field is different from ME\_<target mode>\_MC.PWRLVL bit field. Broadly, the mode transition process can be divided into three steps with respect to progressive clock switching - RAMP DOWN, LOAD CHANGE and RAMP UP. One or more of these steps may not be needed based on the current and target mode configurations. The clock switching (from current system clock source to target system clock source) can happen before or after the LOAD CHANGE step.

Figure 59-4. MC\_ME mode transition process with PCS

The table below shows the different ways the mode transition process can complete.

**Table 59-4. Mode transition steps**

| Pwrlvl    | Source clock | Target clock | Mode transition steps                           |
|-----------|--------------|--------------|-------------------------------------------------|
| Same      | IRC          | Non-IRC      | LoadChange -> ClockSwitch                       |

## 59.4.6 Mode Transition Interrupts

The MC\_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

### 59.4.6.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME\_<mode>\_MC registers violating the protection rules mentioned in the [Protection of Mode Configuration Registers](#), the interrupt pending bit I\_ICONF of the ME\_IS register is set and an interrupt request is generated if the mask bit M\_ICONF of the ME\_IM register is '1'.

In addition, during a mode transition, if a clock source has been configured in the ME\_<target mode>\_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME\_RUN\_PC0...7/ME\_LP\_PC0...7 and ME\_PCTLn registers, the interrupt pending bit I\_ICONF\_CU of the ME\_IS register is set and an interrupt request is generated if the mask bit M\_ICONF\_CU of the ME\_IM register is '1'.

If an attempt to write to one of the ME\_CADDRn registers is made after a mode change request has been made via the second write to the ME\_CTL register and before the completion of that mode transition as indicated by the S\_MTRANS bit in the ME\_GS register deasserting, the interrupt pending bit I\_ICONF\_CC of the ME\_IS register is set and an interrupt request is generated if the mask bit M\_ICONF\_CC of the ME\_IM register is '1'.

### 59.4.6.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC\_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new mode request is considered to be invalid, and the S\_SEA bit of the ME\_IMTS register is set.
- If the TARGET\_MODE bit field of the ME\_MCTL register is written with a value different from the specified mode values (i.e., a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S\_NMA bit of the ME\_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME\_MCTL register.
- If some of the chip modes are disabled as programmed in the ME\_ME register, their respective configurations are considered reserved, and any access to the ME\_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S\_DMA bit of the ME\_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME\_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S\_MRI of the ME\_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME\_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition to a mode other than SAFE mode is in progress (the S\_MTRANS bit of the ME\_GS register is '1'), the mode transition illegal status bit S\_MTI of the ME\_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME\_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occur while a mode transition to the SAFE mode is in progress (the S\_MTRANS bit of the ME\_GS register is '1'), the mode request ignored status bit S\_MRIG of the ME\_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME\_MCTL register. Otherwise, the write operation is ignored.

### Note

As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME\_IMTS register in the order from highest to lowest is S\_SEA, S\_NMA, S\_DMA, S\_MRI, S\_MRIG, and S\_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0...3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software-determined 'reasonable' amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

### CAUTION

Depending on the cause of an incomplete mode transition, aborting by requesting the parent mode might not succeed. In this case, software must request a change to either SAFE or RESET mode, because the cause of the lockup is most likely a hardware fault.

- Self-transition requests (e.g., RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (i.e., S\_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0...3 mode properly (i.e., all status bits of the ME\_GS register match with configuration bits in the ME\_<mode>\_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I\_IMODE of the ME\_IS register is set, and an interrupt request is generated if the mask bit M\_IMODE of the ME\_IM register is '1'.

### 59.4.6.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC\_RGM due to a hardware failure, the interrupt pending bit I\_SAFE of the ME\_IS register is set, and an interrupt is generated if the mask bit M\_SAFE of ME\_IM register is '1'.

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC\_RGM (see the MC\_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC\_RGM also sets the interrupt pending bit I\_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (i.e., programming of ME\_MCTL register).

### 59.4.6.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (i.e., the S\_MTRANS bit of ME\_GS register transits from '1' to '0'), the interrupt pending bit I\_MTC of the ME\_IS register is set, and an interrupt request is generated if the mask bit M\_MTC of the ME\_IM register is '1'. The interrupt bit I\_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

## 59.4.7 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME\_RUN\_PC0...7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0...3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN\_CFG bit field of the ME\_PCTL $n$  registers.

The low-power peripheral configuration registers ME\_LP\_PC0...7 are chosen only during the low-power modes HALT0 and STOP0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP\_CFG bit field of the ME\_PCTL $n$  registers.

Any modifications to the ME\_RUN\_PC0...7, ME\_LP\_PC0...7, and ME\_PCTL $n$  registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the chip enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG\_F bit of the associated ME\_PCTL $n$  register is set. Otherwise, the peripheral clock gating status depends on the RUN\_CFG and LP\_CFG bits.

### 59.4.8 Application Example

The following figure shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

**Figure 59-5. MC\_ME Application Example Flow Diagram**

# Chapter 60

## Core Debug Support

### 60.1 Overview

Internal debug support in the e200z4251n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *Power ISA 2.06*. e200z4251n3 supports a subset of these defined facilities. In addition to the facilities defined in *Power ISA 2.06*, e200z4251n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

#### 60.1.1 Software Debug Facilities

e200z4251n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 (DBCR0<sub>IDM</sub>). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR<sub>DE</sub>, these recorded exceptions cause Debug interrupts to occur. When DBCR0<sub>IDM</sub> is cleared (and EDBCR0<sub>EDM</sub> is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when DBCR0<sub>IDM</sub> is cleared (or is overridden by EDBCR0<sub>EDM</sub> being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

#### 60.1.1.1 Power ISA 2.06 Compatibility

The e200z4251n3 core implements a subset of the *Power ISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

#### 60.1.2 Additional Debug Facilities

In addition to the debug functionality defined in *Power ISA 2.06*, e200z4251n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See [Sharing Debug Resources by Software/Hardware](#).) A data trace port is also provided.

##### 60.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z4251n3 core. This port provides information corresponding to each read or write access

completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z4251n3) Nexus 3 Module chapter. The data trace port will report aligned accesses, and most misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0. Also, for accesses generated by a LSP load/store instruction using circular addressing mode which crosses a buffer boundary, the two portions of the misaligned access will be reported separately, since otherwise it is not possible to correctly correlate the data with the initial access address.

### 60.1.3 Hardware Debug Facilities

The e200z4251n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard IEEE 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z4251n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 (EDBCR0<sub>EDM</sub>), which is also aliased to DBCR0<sub>EDM</sub>. Setting EDBCR0<sub>EDM</sub> overrides the Internal Debug Mode enable bit DBCR0<sub>IDM</sub> unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting EDBCR0<sub>EDM</sub>=1, the control registers and resources described in [Debug registers](#) are reserved for use by the external debugger. The same events described in [Software Debug Events and Exceptions](#) are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR<sub>DE</sub>, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. EDBCR0<sub>EDM</sub>, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m\_clk**) be running in order to perform write accesses from the external hardware debugger.

### 60.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When EDBCR0<sub>EDM</sub> is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when DBCR0<sub>IDM</sub>=1 will cause a debug interrupt to occur when enabled with MSR<sub>DE</sub>. Hardware-owned resources which set EDBSR0 bits when EDBCR0<sub>EDM</sub>=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, (EDBCR0<sub>EDM</sub>=1 and EDBRAC0<sub>IDM</sub>=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

#### 60.1.4.1 Simultaneous Hardware and Software Debug Event Handling

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handling to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z4251n3 debug resources.

Figure 60-1. e200z4251n3 Debug Resources

## 60.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ( $\text{DBCR0}_{\text{IDM}}=1$ ) and not overridden by external debug mode ( $\text{EDBCR0}_{\text{EDM}}$  must either be cleared or corresponding resources must be allocated to software debug by the settings in  $\text{EDBRAC0}$ ). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers ( $\text{DBCR0}$ – $8$ ). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than  $\text{MRR}$ ,  $\text{DAC\_OFST}$ , or  $\text{VLES}$ ), if Debug interrupts are enabled by  $\text{MSR}_{\text{DE}}$ , a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when  $MSR_{DE}=0$  and  $DBCRO_{IDM}=1$ . In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of  $MSR_{DE}$ . A Debug interrupt will be delayed until  $MSR_{DE}$  is later set to '1'.

When a Debug Status Register bit is set while  $MSR_{DE}=0$ , an Imprecise Debug Event flag ( $DBSR_{IDE}$ ) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the  $MSR_{DE}$  bit. A **mtmsr** or **mtdbcr0** which causes both  $MSR_{DE}$  and  $DBCRO_{IDM}$  to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *Power ISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z4251n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in [External debug event](#).
- The Performance Monitor Interrupt event PMI which is described in [Performance Monitor Interrupt debug event](#).

The e200z4251n3 debug configuration supports most of these event types. Unsupported *Power ISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

### 60.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR<sub>DE</sub>. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

### 60.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR<sub>DE</sub>. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the DBSR<sub>DAC{R,W}</sub> bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the DBSR<sub>DAC{R,W}</sub> bits are set.

#### Note

In contrast to the *Power ISA 2.06* definition, Data Address Compare events on e200z4251n3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting DBSR<sub>IDE</sub>) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the DBSR<sub>DAC\_OFST</sub> field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the DBSR<sub>IDE</sub> bit will be set. In addition to occurring when DBCR0<sub>IDM</sub>=1, this circumstance can also occur when EDBCR0<sub>EDM</sub>=1 and the event is hardware-owned, in which case EDBSR0<sub>IDE</sub> will be set.

### Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

### Note

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

### Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

**Note**

DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

**Note**

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

**Note**

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

### 60.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the DBSR<sub>DAC\_OFST</sub> field when the DVC DAC status is recorded.

[Table 60-1](#) outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to

this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in [Table 60-1](#), the DAC\_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC\_OFST and DSRR0 values will point beyond the values shown.

**Table 60-1. DAC events and Resultant Updates**

| 1st load/store class instruction | 2nd instruction (load/store class unless otherwise specified) | 3rd instruction (load/store class unless otherwise specified) | Result                                                                                                                                                                                                                                                                                   |
|----------------------------------|---------------------------------------------------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DSI, no DAC                      | —                                                             | —                                                             | Take DSI exception, no DBSR update. Update ESR.                                                                                                                                                                                                                                          |
| DSI, with DACx                   | —                                                             | —                                                             | Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.                                                                                                                                               |

### 60.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1

may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR<sub>DE</sub>. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

### Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

## 60.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled (DBCR0<sub>TRAP</sub>=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR<sub>DE</sub>. When a Trap debug event occurs, the DBSR<sub>TRAP</sub> bit is set to 1 to record the debug exception.

## 60.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled (DBCR0<sub>BRT</sub>=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR<sub>DE</sub>=1. Branch Taken debug events are not recognized if MSR<sub>DE</sub>=0 at the time of execution of the branch instruction and thus DBSR<sub>ID</sub>E can not be set by a Branch Taken

debug event. When a Branch Taken debug event is recognized, the  $\text{DBSR}_{\text{BRT}}$  bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in  $\text{DSRR0}$ .

## 60.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ( $\text{DBCR0}_{\text{ICMP}}=1$ ), execution of any instruction is completed, and  $\text{MSR}_{\text{DE}}=1$ . If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The *se\_sc* instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized,  $\text{DBSR}_{\text{ICMP}}$  is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in  $\text{DSRR0}$ .

Instruction Complete debug events are not recognized if  $\text{MSR}_{\text{DE}}=0$  at the time of execution of the instruction, thus  $\text{DBSR}_{\text{IDE}}$  is not generally set by an ICMP debug event.

One circumstance may cause the  $\text{DBSR}_{\text{ICMP}}$  and  $\text{DBSR}_{\text{IDE}}$  bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed ( $\text{SRR0}$  points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and  $\text{DBSR}_{\text{IDE}}$  is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with  $\text{SRR0}$  pointing to the instruction following the instruction that generated the EFPU Round exception, and  $\text{DSRR0}$  will point to the Round exception handler. In addition to occurring when  $\text{DBCR0}_{\text{IDM}}=1$ , this circumstance can also occur when  $\text{EDBCR0}_{\text{EDM}}=1$  and the event is hardware-owned, in which case  $\text{EDBSR0}_{\text{IDE}}$  will be set.

### Note

Instruction complete debug events are not generated by the execution of an instruction that sets  $\text{MSR}_{\text{DE}}$  to '1' while  $\text{DBCR0}_{\text{ICMP}}=1$ , nor by the execution of an instruction that sets  $\text{DBCR0}_{\text{ICMP}}$  to '1' while  $\text{MSR}_{\text{DE}}=1$ .

## 60.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ( $\text{DBCR0}_{\text{IRPT}}=1$ ) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using  $\text{SRR0}/1$ ) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of  $\text{MSR}_{\text{DE}}$ . When an Interrupt Taken debug event occurs, the  $\text{DBSR}_{\text{IRPT}}$  bit is set to 1 to record the debug exception. The value saved in  $\text{DSRR0}$  will be the address of the non-critical interrupt handler.

## 60.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ( $\text{DBCR0}_{\text{CIRPT}}=1$ ) and a critical interrupt occurs. Only critical class interrupts (an interrupt using  $\text{CSRR0}/1$ ) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of  $\text{MSR}_{\text{DE}}$ . When a Critical Interrupt Taken debug event occurs, the  $\text{DBSR}_{\text{CIRPT}}$  bit is set to 1 to record the debug exception. The value saved in  $\text{DSRR0}$  will be the address of the critical interrupt handler.

## 60.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ( $\text{DBCR0}_{\text{RET}}=1$ ) and an attempt is made to execute an **se\_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of  $\text{MSR}_{\text{DE}}$ . When a Return debug event occurs, the  $\text{DBSR}_{\text{RET}}$  bit is set to 1 to record the debug exception.

If  $\text{MSR}_{\text{DE}}=0$  at the time of the execution of the **se\_rfi** (i.e. before the MSR is updated by the **se\_rfi**), then  $\text{DBSR}_{\text{IDE}}$  is also set to 1 to record the imprecise debug event.

If  $\text{MSR}_{\text{DE}}=1$  at the time of the execution of the **se\_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se\_rfi** instruction.

## 60.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ( $\text{DBCR0}_{\text{CRET}}=1$ ) and an attempt is made to execute an **se\_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of  $\text{MSR}_{\text{DE}}$ . When a Critical Return debug event occurs, the  $\text{DBSR}_{\text{CRET}}$  bit is set to 1 to record the debug exception.

If  $MSR_{DE}=0$  at the time of the execution of the **se\_rfc**i (i.e. before the MSR is updated by the **se\_rfc**i), then  $DBSR_{IDE}$  is also set to 1 to record the imprecise debug event.

If  $MSR_{DE}=1$  at the time of the execution of the **se\_rfc**i, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se\_rfc**i instruction.

### 60.2.11 External debug event

An External debug event ( $DEVT1$ ,  $DEVT2$ ) occurs if External debug events are enabled ( $DBCR0_{DEVT1}=1$  or  $DBCR0_{DEVT2}=1$ ), and the respective **p\_devt1** or **p\_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of  $MSR_{DE}$ . When an External debug event occurs,  $DBSR_{DEVT\{1,2\}}$  is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m\_clk** is active.

### 60.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p\_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of  $MSR_{DE}$ . When an Unconditional debug event occurs, the  $DBSR_{UDE}$  bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

### 60.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ( $PMGC0_{UDI}=1$ ), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of  $MSR_{DE}$ . When a Performance Monitor Interrupt debug event occurs,  $DBSR_{PMI}$  is set to '1' to record the debug exception. This debug event is an asynchronous event.

## 60.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit (EDBCR0<sub>EDM</sub>) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If EDBCR0<sub>EDM</sub> is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspir** instruction, other than the EDBCR0<sub>EDM</sub> bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

### 60.3.1 Debug Address and Value Registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are

not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, ..., and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, ... . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z4251n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfscr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

### 60.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z4251n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se\_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

### 60.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z4251n3 adds some implementation specific bits to this register, as seen in the following figure.

|     |     |     |   |      |     |      |      |      |      |      |      |      |      |    |     |      |      |      |      |       |       |    |    |       |      |    |    |    |    |    |    |

SPR - 308: Read/Write: Reset<sup>1</sup> - 0x0

**Figure 60-3. Debug Control Register 0 (DBCR0) register**

#### Note

<sup>1</sup> DBCR0<sub>EDM</sub> is affected by **j\_trst\_b** or **m\_por** assertion, and remains reset while in the Test\_Logic\_Reset state, but is not affected by **p\_reset\_b**. All other bits are reset by processor reset **p\_reset\_b** if DBCR0<sub>EDM</sub>=0, as well as unconditionally by **m\_por**. If DBCR0<sub>EDM</sub>=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p\_reset\_b**, and only software-owned resources indicated by EDBRAC0 and the DBCR0<sub>RST</sub> field will be reset by **p\_reset\_b**. The DBCR0<sub>RST</sub> field will always be reset by **p\_reset\_b** regardless of the value of DBCR0<sub>EDM</sub>.

The following provides bit definitions for Debug Control Register 0.

**Table 60-6. DBCR0 field descriptions**

| Bit | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### 60.3.2.2 Debug Control Register 1 (DBCR1)

Debug Control Register 1 is used to configure Instruction Address Compare operation. The DBCR1 register is shown in the following figure.

|        |        |        |        |        |   |        |        |        |        |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

SPR - 309; Read/Write; Reset<sup>1</sup> - 0x0

**Figure 60-4. DBCR1 Register**

#### Note

<sup>1</sup> Reset by processor reset **p\_reset\_b** if EDBCR0<sub>EDM</sub>=0, as well as unconditionally by **m\_por**. If EDBCR0<sub>EDM</sub>=1, EDBRAC0 masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 1.

**Table 60-7. DBCR1 field descriptions**

| Bit | Name   | Description                                        |
|-----|--------|----------------------------------------------------|
| 0:1 | IAC1US | Instruction Address Compare 1 User/Supervisor Mode |

### 60.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation. The DBCR2 register is shown in the following figure.

SPR - 310; Read/Write; Reset<sup>1</sup> - 0x0

**Figure 60-5. DBCR2 Register**

## Note

<sup>1</sup> Reset by processor reset **p\_reset\_b** if  $\text{EDBCR0}_{\text{EDM}}=0$ , as well as unconditionally by **m\_por**. If  $\text{EDBCR0}_{\text{EDM}}=1$ ,  $\text{EDBRAC0}$  masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by  $\text{EDBRAC0}$  will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 2.

**Table 60-8. DBCR2 Bit Definitions**

| Bit | Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table 60-8. DBCR2 Bit Definitions (continued)**

| Bit   | Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       |         | 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 60-8. DBCR2 Bit Definitions**

| Bit | Name | Description                                                                          |
|-----|------|--------------------------------------------------------------------------------------|
|     |      | xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. |
|     |      | xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2. |

### 60.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.

**Figure 60-6. DBCR4 Register**

#### Note

<sup>1</sup> DBCR4 is reset by processor reset **p\_reset\_b** if **EDBCR0\_EDM=0**, as well as unconditionally by **m\_por**. If **EDBCR0\_EDM=1**, **EDBRAC0** masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by **EDBRAC0** will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 4.

**Table 60-9. DBCR4 field description**

| Bit | Name  | Description                                                                                                                                                                                                                                                                                                                                                         |
|-----|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | —     | Reserved                                                                                                                                                                                                                                                                                                                                                            |
| 1   | DVC1C | Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition.<br>0 Normal DVC1 operation.<br>1 Inverted polarity DVC1 operation |

### 60.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

**Figure 60-7. DBCR5 Register**

#### Note

<sup>1</sup> Reset by processor reset **p\_reset\_b** if EDBCR0<sub>EDM</sub>=0, as well as unconditionally by **m\_por**. If EDBCR0<sub>EDM</sub>=1, EDBRAC0 masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 5.

**Table 60-10. DBCR5 field descriptions**

| Bit(s) | Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

IAC7 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC7 or is greater than or equal to the value specified in IAC8. IAC8 debug events do not occur. IAC7US and IAC7ER settings are used. |
| 26:31  | —      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 60.3.2.6 Debug Control Register 6 (DBCR6)

Debug Control Register 6 is used to extend instruction address compare matching functionality. DBCR6 is shown in the following figure.

**Figure 60-8. DBCR6 Register****Note**

<sup>1</sup> DBCR6 is reset by processor reset **p\_reset\_b** if EDBCR0<sub>EDM</sub>=0, as well as unconditionally by **m\_por**. If EDBCR0<sub>EDM</sub>=1, EDBRAC0 masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 6.

**Table 60-11. DBCR6 field descriptions**

| Bit   | Name   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:3   | IAC1XM | Instruction Address Compare 1 Extended Mask Control. IAC1XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2.<br>0000 No additional masking when DBCR1[IAC12M]=00<br>0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC1 when comparing the storage address with the value in IAC1 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported.<br>1101 - 1111 Reserved |
| 4:7   | IAC2XM | Instruction Address Compare 2 Extended Mask Control. IAC2XM allows for binary power of 2 address range compares for IAC2 without requiring the use of IAC1.<br>0000 No additional masking when DBCR1[IAC12M]=00<br>0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC2 when comparing the storage address with the value in IAC2 for exact address compare (DBCR1[IAC12M]=00). Ranges up to 4 KB are supported.<br>1101 - 1111 Reserved |
| 8:11  | IAC3XM | Instruction Address Compare 3 Extended Mask Control. IAC3XM allows for binary power of 2 address range compares for IAC1 without requiring the use of IAC2.<br>0000 No additional masking when DBCR1[IAC34M]=00<br>0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC3 when comparing the storage address with the value in IAC3 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported.<br>1101 - 1111 Reserved |
| 12:15 | IAC4XM | Instruction Address Compare 4 Extended Mask Control. IAC4XM allows for binary power of 2 address range compares for IAC4 without requiring the use of IAC3.<br>0000 No additional masking when DBCR1[IAC34M]=00<br>0001 - 1100 Exact Match Bit Mask. Number of low order bits masked in IAC4 when comparing the storage address with the value in IAC4 for exact address compare (DBCR1[IAC34M]=00). Ranges up to 4 KB are supported.                         |

### 60.3.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in the following figure.

SPR - 596; Read/Write; Reset<sup>1</sup> - 0x0

**Figure 60-9. DBCR7 Register**

## Note

<sup>1</sup> DBCR7 is reset by processor reset **p\_reset\_b** if  $EDBCR0_{EDM}=0$ , as well as unconditionally by **m\_por**. If  $EDBCR0_{EDM}=1$ , EDBRAC0 masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 7.

**Table 60-12. DBCR7 Field Descriptions**

| Bit   | Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 60.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.

**Figure 60-10. DBCR8 Register****Note**

<sup>1</sup> Reset by processor reset **p\_reset\_b** if EDBCR0<sub>EDM</sub>=0, as well as unconditionally by **m\_por**. If EDBCR0<sub>EDM</sub>=1, EDBRAC0 masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p\_reset\_b**.

The following table provides bit definitions for Debug Control Register 8.

**Table 60-13. DBCR8 Bit Definitions**

| Bit(s) | Name   | Description                                                                                                                                                                                                                                                                                                                                                                         |

### 60.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtsprDBSR,RS**.

Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no

effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ( $DBCR0_{IDM}=1$ ). When debug interrupts are enabled ( $MSR_{DE}=1$ ,  $DBCR0_{IDM}=1$  and  $EDBCR0_{EDM}=0$ , or  $MSR_{DE}=1$ ,  $DBCR0_{IDM}=1$ ,  $EDBCR0_{EDM}=1$  and software is allocated resource(s) via  $EDBRAC0$ ), a set bit in DBSR other than MRR, DAC\_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ( $EDBCR0_{EDM}=1$  and  $EDBRAC0_{IDM}=1$ ), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.

|     |     |     |      |     |      |      |     |   |      |      |    |     |     |    |       |       |     |     |       |      |      |          |    |    |    |    |    |    |    |    |    |

| 22     | DEVT2    | External Debug Event 2 Debug Event<br>Set to 1 if a DEVT2 debug event occurred                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 23     | PMI      | Performance Monitor Interrupt Debug Event<br>Set to 1 if a Performance Monitor Interrupt event occurred with PMGC0 <sub>UDI</sub> =1                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 24     | MPU      | Memory Protection Unit Debug Event<br>Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence. |
| 25     | CIRPT    | Critical Interrupt Taken Debug Event<br>Set to 1 if a Critical Interrupt Taken debug event occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 26     | CRET     | Critical Return Debug Event<br>Set to 1 if a Critical Return debug event occurred                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 27     | VLES     | VLE Status<br>Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 28:30  | DAC_OFST | Data Address Compare Offset<br>Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and DBSR <sub>IDE</sub> is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.                                                                                                                                                                                                                                          |
| 31     | —        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 60.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the  $DBSR_{DAC\{R,W\}}$  bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the  $DBSR_{DAC\{R,W\}}$  bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

| Data Effective Address                    |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------------------------------------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

### 60.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when  $EDBCR0_{EDM}$  is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when  $EDBCR0_{EDM}=1$ . EDBRAC0 settings are ignored when  $EDBCR0_{EDM}=0$ .

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if  $DBCR0_{IDM}=1$  update DBSR, causing debug interrupts to occur if  $MSR_{DE}=1$ . EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled ( $MSR_{DE}=1$   $DBCR0_{IDM}=1$  and  $EDBCR0_{EDM}=0$ , or  $MSR_{DE}=1$ ,  $DBCR0_{IDM}=1$  and  $EDBCR0_{EDM}=1$  and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC\_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled (EDBCR0<sub>EDM</sub>=1). When EDBCR0<sub>EDM</sub>=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC\_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If EDBCR0<sub>EDM</sub>=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.

|   |     |     |     |      |     |      |      |      |      |      |      |      |       |      |    |     |      |      |      |      |       |       |     |     |       |      |     |     |    |    |    |

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p\_reset\_b** when EDBCR0<sub>EDM</sub>=1. Only software-owned bits or fields as shown in Table 60-16 are affected in this case, except that DBCR0<sub>RST</sub> and DBCR0<sub>MRR</sub> are updated by assertion of **p\_reset\_b** regardless of the value of EDBCR0<sub>EDM</sub> or EDBRAC0.

### 60.3.4 Debug Event Select Register (DEVENT)

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p\_devnt\_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p\_devnt\_out[0:3]**, a corresponding **jd\_watchpt[x]** output is asserted as well to indicate a watchpoint has

occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The DEVENT<sub>DEVNT</sub> register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z4251n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.

**Figure 60-14. DEVENT Register**

### Note

<sup>1</sup> Reset by processor reset **p\_reset\_b** if EDBCR0<sub>EDM</sub>=0, as well as unconditionally by **m\_por**. If EDBCR0<sub>EDM</sub>=1, EDBRAC0 masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p\_reset\_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p\_reset\_b**.

The following table provides bit definitions for the Debug Event Register.

**Table 60-17. DEVENT Bit Definitions**

| Bit(s) | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### 60.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z4251n3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

Figure 60-15. DDAM Register

#### Note

<sup>1</sup> Reset by processor reset **p\_reset\_b** if  $\text{EDBCR0}_{\text{EDM}}=0$ , as well as unconditionally by **m\_por**. If  $\text{EDBCR0}_{\text{EDM}}=1$ , **EDBRAC0** masks off hardware-owned resources from reset by **p\_reset\_b** and only software-owned resources indicated by **EDBRAC0** will be reset by **p\_reset\_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 60-18. DDAM Bit Definitions

| Bit(s) | Name | Description                                                                                   |

## 60.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in [Table 60-9](#). Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the DBCR4<sub>DAC1CFG</sub> field to '1000' or the DBCR8<sub>DAC3CFG</sub> field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the DBCR4<sub>DAC1CFG</sub> field is set to '1000' with DBCR2<sub>DAC1US</sub> set to '00' or '10', or the DBCR7<sub>DAC3CFG</sub> field is set to '1000' with DBCR8<sub>DAC3US</sub> set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the DBCR4<sub>DAC1CFG</sub> field is set to '1000' with DBCR2<sub>DAC1US</sub> set to '00' or '01', or the DBCR7<sub>DAC3CFG</sub> field is set to '1000' with DBCR8<sub>DAC3US</sub> set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the EDBSR0<sub>IDE</sub> status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses,

an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in [Table 60-9](#) and [Table 60-12](#) in [Debug Control and Status registers](#). Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

## 60.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the EDBCR0<sub>EDM</sub>/DBCR0<sub>EDM</sub> bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When EDBCR0<sub>EDM</sub> is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of [Software Debug Events and Exceptions](#) refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

### Note

On the initial setting of EDBCR0<sub>EDM</sub> to '1', other bits in DBCR0 will remain unchanged. After EDBCR0<sub>EDM</sub> has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR<sub>DR</sub> control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

### Note

It is intended for the CPU to remain in external debug mode (EDBCR0<sub>EDM</sub>=1) in order to single step or perform other debug mode entry/ reentry via the OCR<sub>DR</sub>, by performing go+noexit commands, or by assertion of the **jd\_de\_b** signal.

### Note

EDBCR0<sub>EDM</sub> operation will be blocked if OnCE operation is disabled (**jd\_en\_once** negated) regardless of whether it is set or cleared. This means that if EDBCR0<sub>EDM</sub> was previously set, and then **jd\_en\_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m\_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the EDBCR0<sub>EDM</sub> bit. Register read data is synchronized back to the **j\_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is

performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

## 60.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

### 60.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e\_dnh**, **se\_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e\_dni**, **se\_dni**).

EDBCR0 is not accessible by software. However, the state of EDBCR0<sub>EDM</sub> is reflected as a read-only bit in DBCR0<sub>EDM</sub> to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

**Figure 60-16. EDBCR0 Register**

#### Note

<sup>1</sup> EDBCR0 is affected (reset) by **j\_trst\_b** or **m\_por** assertion, and remains reset while in the Test\_Logics\_Reset state, but is not affected by **p\_reset\_b**.

The following table provides bit definitions for External Debug Control Register 0.

Table 60-19. EDBCR0 Bit Definitions

| Bit(s) | Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Internal debug events not mapped into external debug events.</p> <p>1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0.</p> <p>When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset <b>p_reset_b</b>. This allows the debugger to set up hardware debug events which remain active across a processor reset.</p>                                   |
| 1      | DNH_EN  | <p><b>dnh</b> Instruction Enable</p> <p>0 - execution of <b>e_dnh</b> and <b>se_dnh</b> instructions cause illegal instruction exceptions to occur.</p> <p>1 - execution of <b>e_dnh</b> and <b>se_dnh</b> instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| 2:6    | ---     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 7      | DNI_CTL | <p><b>dni</b> Instruction Control</p> <p>0 - When the <b>dni</b> resource is owned by hardware, the MSR<sub>DE</sub> bit is cared, and when MSR<sub>DE</sub>=0, execution of <b>e_dni</b> and <b>se_dni</b> instructions are nop'ed and no entry into debug mode occurs.</p> <p>1 - When the <b>dni</b> resource is owned by hardware, the MSR<sub>DE</sub> bit is don't-cared, and execution of <b>e_dni</b> and <b>se_dni</b> instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR<sub>DE</sub>.</p> <p>Note that this control bit is only used when the dni resource is owned by hardware via control in EDBRAC0<sub>DNI</sub>, and thus also only when EDM=1</p> |
| 8:31   | ---     | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 60.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

|     |     |     |   |      |     |      |      |     |   |      |      |    |     |     |    |       |       |     |     |       |      |      |          |    |    |    |    |    |    |    |    |

| 22     | DEVT2    | External Debug Event 2 Debug Event<br>Set to 1 if a hardware-owned DEVT2 debug event occurred                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 23     | PMI      | Performance Monitor Interrupt Debug Event<br>Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}=0$ regardless of the setting of $PMGC0_{UDI}$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 24     | MPU      | Memory Protection Unit Debug Event<br>Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence. |
| 25     | CIRPT    | Critical Interrupt Taken Debug Event<br>Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 26     | CRET     | Critical Return Debug Event<br>Set to 1 if a hardware-owned Critical Return debug event occurred                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 27     | VLES     | VLE Status<br>Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH\_EN}$ . Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
