| 28:30  | DAC_OFST | Data Address Compare Offset<br>Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 31     | —        | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 60.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

#### 60.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of EDBSR0<sub>DAC{R,W}</sub> bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR

hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the  $EDBSR0_{DAC\{R,W\}}$  bits are set and are not masked by  $EDBSRMSK0$ , in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

**Figure 60-19. EDDEAR Register**

## 60.5.2 OnCE Introduction

The e200z4251n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z4251n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd\_enable\_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd\_enable\_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

**Figure 60-20. OnCE TAP Controller and Registers**

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting `EDBCR0_EDM` to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), [OnCE Status Register](#)) by assertion of one or more debug requests, begins a *debug session*. The `jd_debug_b` output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See [OnCE Command Register \(OCMD\)](#)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

### 60.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg\_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg\_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

**Table 60-22. JTAG/OnCE Primary Interface Signals**

| Signal name           | Type | Description                               |
|-----------------------|------|-------------------------------------------|
| j_trst_b              | I    | JTAG test reset                           |
| j_tclk                | I    | JTAG test clock                           |
| j_tms                 | I    | JTAG test mode select                     |
| j_tdi                 | I    | JTAG test data input                      |
| j_tdo                 | O    | Test data out to master controller or pad |
| j_tdo_en <sup>1</sup> | O    | Enables TDO output buffer                 |

1. j\_tdo\_en is asserted when the TAP controller is in the shift\_DR or shift\_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z4251n3) Core Complex Overview.

### 60.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

#### 60.5.4.1 CPU Debug Request (**dbg\_dbgrq**)

The **dbg\_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

#### 60.5.4.2 CPU Debug Acknowledge (**cpu\_dbgack**)

The **cpu\_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

#### 60.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

#### 60.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

### 60.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

#### 60.5.5.1 OnCE Enable (**jd\_en\_once**)

The OnCE enable signal **jd\_en\_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable\_OnCE

commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd\_de\_b** input. Secure systems may choose to leave the **jd\_en\_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j\_en\_once\_regsel** output signal is provided to assist external logic performing security checks.

The **jd\_en\_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update\_DR TAP states. A new value will take affect after one additional **j\_tclk** cycle of synchronization. In addition, **jd\_enable\_once** input signal must not change state during a debug session, or undefined activity may occur.

### 60.5.5.2 OnCE Debug Request/Event (**jd\_de\_b**, **jd\_de\_en**)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE\_b** (not part of the e200z4251n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE\_b** was used to enter the Debug Mode then **DE\_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd\_de\_en** output and samples the **jd\_de\_b** input when OnCE is enabled (**jd\_en\_once** asserted). Assertion of **jd\_de\_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd\_de\_en** output will be asserted for three **j\_tclk** periods to signal an acknowledge. **jd\_de\_en** can be used to enable the open-drain pulldown of the system level **DE\_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE\_b**, the **jd\_de\_en** and **jd\_de\_b** signals may still be used to handshake debug entry.

### 60.5.5.3 OnCE Debug Output (jd\_debug\_b)

The OnCE Debug output **jd\_debug\_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See [OnCE Command Register \(OCMD\)](#) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

### 60.5.5.4 CPU Clock On Input (jd\_mclk\_on)

The CPU Clock On input **jd\_mclk\_on** is used to indicate that the CPU's **m\_clk** input is active. This input signal is expected to be driven by system logic external to the e200z4251n3 core, is synchronized to the **j\_tclk** (scan clock) clock domain, and is presented as a status flag on the **j\_tdo** output during the Shift\_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m\_clk** clock domain.

### 60.5.5.5 Watchpoint Events (jd\_watchpt[0:31])

The **jd\_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to [Table 60-28](#) for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

### 60.5.5.6 Update DR w/go+exit (j\_ocmd\_go\_exit)

This signal indicates the TAP controller is in the Update\_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update\_DR state to cause any CPU currently in debug mode to exit. CPUs which are not in debug mode will ignore the command.

## 60.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

Figure 60-21. OnCE Controller and Serial Interface

### 60.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j\_tdo** output in serial fashion when the Shift\_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

|      |     |   |       |      |      |       |      |   |   |
|------|-----|---|-------|------|------|-------|------|---|---|
| MCLK | ERR | 0 | RESET | HALT | STOP | DEBUG | WAIT | 0 | 1 |
| 0    | 1   | 2 | 3     | 4    | 5    | 6     | 7    | 8 | 9 |

**Figure 60-22. OnCE Status Register**

The following table provides bit definitions for the Once Status Register.

**Table 60-23. OnCE Status Register Bit Definitions**

| Bit(s) | Name  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | MCLK  | MCLK<br><b>m_clk</b> Status Bit<br>0 - Inactive state<br>1 - Active state<br>This status bit reflects the logic level on the <b>jd_mclk_on</b> input signal after capture by <b>j_tclk</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 1      | ERR   | ERROR<br>This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed. |
| 3      | RESET | RESET Mode<br>This bit reflects the <u>inverted</u> logic level on the CPU <b>p_reset_b</b> input after capture by <b>j_tclk</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 4      | HALT  | HALT Mode<br>This bit reflects the logic level on the CPU <b>p_halted</b> output after capture by <b>j_tclk</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 5      | STOP  | STOP Mode<br>This bit reflects the logic level on the CPU <b>p_stopped</b> output after capture by <b>j_tclk</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 6      | DEBUG | Debug Mode<br>This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 7      | WAIT  | Waiting Mode<br>This bit reflects the logic level on the CPU <b>p_waiting</b> output after capture by <b>j_tclk</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 60-23. OnCE Status Register Bit Definitions  
(continued)**

| Bit(s) | Name | Description                              |
|--------|------|------------------------------------------|
| 8      | 0    | Reserved, set to 0 for 1149.1 compliance |
| 9      | 1    | Reserved, set to 1 for 1149.1 compliance |

### 60.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in [Figure 60-23](#). The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

| R/W | GO | EX | RS[0:6] |   |   |   |   |   |   |
|-----|----|----|---------|---|---|---|---|---|---|
| 0   | 1  | 2  | 3       | 4 | 5 | 6 | 7 | 8 | 9 |

Reset - 10'b1000000010 on assertion of **j\_trst\_b** or **m\_por**, or while in the Test\_Logic\_Reset state

**Figure 60-23. OnCE Command Register**

[Table 60-24](#) provides bit definitions for the Once Command Register.

**Table 60-24. OnCE Command Register Bit Definitions**

| Bit(s) | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0      | R/W  | <p>Read/Write Command Bit</p> <p>The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit.</p> <p><b>Note:</b> The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on <b>j_tdo</b> during the first 32 clocks of Shift-DR.</p> <p>0 - Write the data associated with the command into the register specified by RS[0:6]</p> |

|        |      | 1 - Read the data contained in the register specified by RS[0:6]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1      | GO   | <p>Go</p> <p>Go Command Bit</p> <p>If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered.</p> <p>On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR<sub>ERR</sub> bit indicates such an occurrence.</p> <p>If the CPU is not currently in debug mode, then the GO command will be ignored.</p> <p>Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See <a href="#">Exiting Debug Mode and Interrupt Blocking</a>.</p> <p>0 - Inactive (no action taken)</p> <p>1 - Execute instruction in IR</p> |
| 2      | EX   | <p>Exit Command Bit</p> <p>0 - Remain in debug mode</p> <p>1 - Leave debug mode</p> <p>If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored.</p> <p>The processor will leave the debug mode after the TAP controller Update-DR state is entered.</p> <p>Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and EDBCR0<sub>EDM</sub>=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode <i>without</i> execution of an instruction, even though the EX bit was set.</p> <p>Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See <a href="#">Exiting Debug Mode and Interrupt Blocking</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                  |
| 3:9    | RS   | <p>Register Select</p> <p>The Register Select bits define which register is source (destination) for the read (write) operation. <a href="#">Table 60-25</a> indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

[Table 60-25](#) indicates the OnCE register addresses.

1. Causes assertion of the j\_en\_once\_regssel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR<sub>ERR</sub> bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the EDBCR0<sub>EDM</sub> bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0<sub>EDM</sub>. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j\_ocmd\_go\_exit output will be asserted.

### 60.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z4251n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see [MPU Operation During Debug](#)). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd\_en\_once** asserted). The OCR is shown in the following figure.

**Figure 60-24. OnCE Control Register**

The following table provides bit definitions for the OnCE Control Register.

**Table 60-26. OnCE Control Register Bit Definitions**

| Bit(s) | Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 29     | WKUP | Wakeup Request Bit (WKUP)<br><br>This control bit may be used to force the <b>p_wakeup</b> output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the <b>m_clk</b> input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.                                                                                                                                                                                           |
| 30     | FDB  | Force Breakpoint Debug Mode Bit (FDB)<br><br>This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the ' <b>bkpt</b> ' pseudo- instruction will cause the processor to enter debug mode, as if the <b>jd_de_b</b> input had been asserted.<br><br>This bit is qualified with EDBCR0 <sub>EDM</sub> , which must be set for FDB to take effect.<br>Note that this bit has no effect on <b>e_dnh</b> or <b>se_dnh</b> instruction operation. |
| 31     | DR   | CPU Debug Request Control Bit<br><br>This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state.<br><br>0 - No Debug Mode request<br>1 - Unconditional Debug Mode request<br><br>When the DR bit is set the processor will enter Debug mode at the next instruction boundary.                                                                                                                                                                                                                        |

## 60.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z4251n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z4251n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z4251n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m\_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR<sub>WKUP</sub> control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

**Table 60-27. OnCE Register Access Requirements**

| Register name       | Access requirements                         |                                                      |                                                    |                                                       |                                                        | Notes                                                              |

- Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.

## 60.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd\_en\_once** input See [OnCE Enable \(jd\\_en\\_once\)](#).

### 60.5.8.1 External Debug Request During RESET

Holding the **jd\_de\_b** signal asserted during the assertion of **p\_reset\_b**, and continuing to hold it asserted following the negation of **p\_reset\_b** causes the e200z4251n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register **DEBUG** bit, the external command controller should negate the **jd\_de\_b** signal before sending the first command. Note that in this case the e200z4251n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

### 60.5.8.2 Debug Request During RESET

Asserting a debug request by setting the **DR** bit in the **OCR** during the assertion of **p\_reset\_b** and then negating **p\_reset\_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

### 60.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the **DR** bit in the **OCR** during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

### 60.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the **DR** bit in the **OCR** when the chip is in the Waiting state (**p\_waiting** asserted), Halted state (**p\_halted** asserted) or Stopped state (**p\_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m\_clk** has been restored. Note that in this case, the CPU will negate the **p\_waiting**, **p\_halted** and **p\_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m\_clk**, the **p\_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to **OCR<sub>DR</sub>** being set, or **jd\_de\_b** assertion, and will remain set from then until the debug session ends (**jd\_debug\_b** goes from asserted to negated). In addition, the status of the **jd\_mclk\_on** input (after synchronization to the **j\_tclk** clock domain) may be sampled

along with other status bits from the **j\_tdo** outputs during the Shift\_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m\_clk** clock domain.

#### 60.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z4251n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and EDBCR0<sub>EDM</sub>=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

#### 60.5.8.6 Debug Notify Halt Instructions

The **e\_dnh** and **se\_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by EDBCR0<sub>DNH\_EN</sub>, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is *not* conditioned on EDBCR0<sub>EDM</sub>, allowing for debug of software debug handlers as well as other software. For e200z4251n3, when the CPU enters a debug halted state due to a **e\_dnh** or **se\_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e\_dnh** or **se\_dnh** instruction.

#### 60.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

**Figure 60-25. CPU Scan Chain Register (CPUSCR)**

### 60.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

### 60.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

|   |   |   |   |   |   |   |   |   |   |          |          |          |          |          |         |        |    |    |    |    |       |      |         |         |         |         |         |         |         |         |         |         |
|---|---|---|---|---|---|---|---|---|---|----------|----------|----------|----------|----------|---------|--------|----|----|----|----|-------|------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|

**Figure 60-26. Control State Register (CTL)**

#### WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

#### PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

\* — Internal State Bits

*Table continues on the next page...*

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See [OnCE Debug Output \(jd\\_debug\\_b\)](#), which is not part of the normal program execution flow, these bits should be set to a 0.

### PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

### FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the WBBR<sub>lo</sub> to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se\_ instructions, RT for e\_{logical\_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR. For most LSP instructions using rAllrB as a 64-bit source operand, WBBR<sub>hi\_lo</sub> is used to supply the 64-bit source value.

This allows the debug firmware to update processor registers — initialize the WBBR<sub>lo</sub> with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

*Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.*

0= No action.

1= Content of WBBR<sub>lo</sub> or WBBR<sub>hi\_lo</sub> used as operand value

### IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

### IRStat1 — IR Status Bit 1

This control bit is reserved.

### IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

### IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

### IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

### IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

*Table continues on the next page...*

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

#### IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache .

#### IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

#### IRStat8 — IR Status Bit 8

This control bit indicates the Power ISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a Power ISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

#### IRStat9 — IR Status Bit 9

This control bit is reserved.

#### IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

#### IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

#### IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

#### IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

#### IRStat14 — IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0= No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1= An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

### 60.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

#### 60.5.9.4 Write-Back Bus Register (WBBR<sub>low</sub>, WBBR<sub>high</sub>)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. WBBR<sub>low</sub> holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. For LSP instructions which generate 64-bit results, WBBR<sub>low</sub> holds the low-order 32 bits of the result. WBBR<sub>high</sub> holds the updated effective address calculated by a load with update instruction. For LSP instructions which generate 64-bit results, WBBR<sub>high</sub> holds the high-order 32 bits of the result. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into WBBR<sub>low</sub>. The contents of WBBR<sub>low</sub> can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the WBBR<sub>low</sub> to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to [Control State Register \(CTL\)](#) for more detail on the CTL<sub>FFRA</sub> bit.)

WBBR<sub>low</sub> and WBBR<sub>high</sub> are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

#### 60.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used. This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

#### 60.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

## 60.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

## 60.6 Watchpoint Support

e200z4251n3 supports the generation and signalling of watchpoints when operating in internal debug mode ( $\text{DBCR0}_{\text{IDM}}=1$ ) or in external debug mode ( $\text{EDBCR0}_{\text{EDM}}=1$ ).

Watchpoints are indicated with a dedicated set of interface signals. The

**jd\_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred.

Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with  $\text{EDBCR0}_{\text{EDM}}$  or  $\text{DBCR0}_{\text{IDM}}$ .

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The  $\text{DBCRx}$  control fields are used to configure watchpoints, regardless of whether events are enabled in  $\text{DBCR0}$ . Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in  $\text{DBCR4}$ , 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVENT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address.  $\text{MSR}_{\text{DE}}$  has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd\_watchpt[0:31]**) for various development control purposes. (See the "Watchpoint Trace Messaging" section in the Core (e200z4251n3) Nexus 3 Module chapter.)

Note that these signals are **m\_clk** domain signals, not **j\_tclk** domain signals.

The following table shows the **jd\_watchpt[0:31]** output signal assignments to various debug events.

**Table 60-28. Watchpoint Output Signal Assignments**

| Signal Name    | Type   | Description                                                                                                                                                             |
|----------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| jd_watchpt[0]  | IAC1   | Instruction Address Compare 1 watchpoint<br>Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[1]  | IAC2   | Instruction Address Compare 2 watchpoint<br>Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[2]  | IAC3   | Instruction Address Compare 3 watchpoint<br>Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[3]  | IAC4   | Instruction Address Compare 4 watchpoint<br>Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[4]  | DAC1   | Data Address Compare 1 watchpoint<br>Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on DBCR4 <sub>DAC1CFG</sub> settings |
| jd_watchpt[5]  | DAC2   | Data Address Compare 2 watchpoint<br>Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on DBCR4 <sub>DAC2CFG</sub> settings |
| jd_watchpt[6]  | DAC3   | Data Address Compare 3 watchpoint<br>Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on DBCR7 <sub>DAC3CFG</sub> settings |
| jd_watchpt[7]  | DAC4   | Data Address Compare 4 watchpoint<br>Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on DBCR7 <sub>DAC4CFG</sub> settings |
| jd_watchpt[8]  | IAC5   | Instruction Address Compare 5 watchpoint<br>Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[9]  | IAC6   | Instruction Address Compare 6 watchpoint<br>Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[10] | DEVT1  | Debug Event Input 1 watchpoint<br>Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status                                           |
| jd_watchpt[11] | DEVT2  | Debug Event Input 2 watchpoint<br>Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status                                           |
| jd_watchpt[12] | DEVNT0 | Debug Event Output 0 watchpoint<br>Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]        |
| jd_watchpt[13] | DEVNT1 | Debug Event Output 1 watchpoint                                                                                                                                         |

*Table continues on the next page...*

**Table 60-28. Watchpoint Output Signal Assignments  
(continued)**

| Signal Name    | Type    | Description                                                                                                                                                      |
|----------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |         | Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]                                    |
| jd_watchpt[14] | IAC7    | Instruction Address Compare 7 watchpoint<br>Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status                              |
| jd_watchpt[15] | IAC8    | Instruction Address Compare 8 watchpoint<br>Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status                              |
| jd_watchpt[16] | IRPT    | Interrupt watchpoint<br>Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status                                              |
| jd_watchpt[17] | RET     | Return watchpoint<br>Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status                                                   |
| jd_watchpt[18] | CIRPT   | Critical Interrupt watchpoint<br>Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status                                     |
| jd_watchpt[19] | CRET    | Critical Return watchpoint<br>Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status                                         |
| jd_watchpt[20] | DEVNT2  | Debug Event Output 2 watchpoint<br>Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20] |
| jd_watchpt[21] | DEVNT3  | Debug Event Output 3 watchpoint<br>Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21] |
| jd_watchpt[22] | PMEVENT | Performance Monitor Event input watchpoint<br>Asserted whenever <b>p_pm_event</b> transitions from a '0' to a '1' while <b>m_clk</b> is running                  |
| jd_watchpt[23] | PMC0    | Performance Monitor Counter 0 watchpoint<br>Asserted whenever PMC0 triggers an event based on PMLCa0 <sub>PMP</sub>                                              |
| jd_watchpt[24] | PMC1    | Performance Monitor Counter 1 watchpoint<br>Asserted whenever PMC1 triggers an event based on PMLCa1 <sub>PMP</sub>                                              |
| jd_watchpt[25] | PMC2    | Performance Monitor Counter 2 watchpoint<br>Asserted whenever PMC2 triggers an event based on PMLCa2 <sub>PMP</sub>                                              |
| jd_watchpt[26] | PMC3    | Performance Monitor Counter 3 watchpoint<br>Asserted whenever PMC3 triggers an event based on PMLCa3 <sub>PMP</sub>                                              |
| jd_watchpt[27] | MPU     | Memory Protection Unit watchpoint<br>Asserted whenever the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.            |
| jd_watchpt[28] | TRAP    | TRAP watchpoint                                                                                                                                                  |

*Table continues on the next page...*

**Table 60-28. Watchpoint Output Signal Assignments  
(continued)**

| Signal Name    | Type | Description                                                                                               |
|----------------|------|-----------------------------------------------------------------------------------------------------------|
|                |      | Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status               |
| jd_watchpt[29] | DTC1 | Data Trace Control Range 1 watchpoint<br>Asserted whenever an access meets the conditions for DTC Range 1 |
| jd_watchpt[30] | DTC2 | Data Trace Control Range 2 watchpoint<br>Asserted whenever an access meets the conditions for DTC Range 2 |
| jd_watchpt[31] | DTC3 | Data Trace Control Range 3 watchpoint<br>Asserted whenever an access meets the conditions for DTC Range 3 |

## 60.7 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR ([OnCE Control Register \(OCR\)](#)) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR ([OnCE Control Register \(OCR\)](#)) for more detail. When the MPU is disabled for instruction accesses (OCR<sub>I\_DMDIS</sub>) or for data accesses (OCR<sub>D\_DMDIS</sub>), substituted access attribute bits will control operation on respective accesses initiated during debug.

## 60.8 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

## 60.9 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd\_en\_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR<sub>DR</sub>, OCR<sub>WKUP</sub>, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode.
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift\_IR state. The CPUSCR will be shifted out during the Shift\_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the EDBCR0<sub>EDM</sub> bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing  $MSR_{EE}$  and  $MSR_{CE}$ ). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Control State Register \(CTL\)](#)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has re-entered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The  $OCR_{DR}$  control bit should be cleared, leaving the  $OCR_{WKUP}$  bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Control State Register \(CTL\)](#)), with a Go+Exit OnCE Command value.
- The  $OCR_{WKUP}$  bit may then be cleared.

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the  $OCR_{DR}$  with  $OCR_{WKUP}$  asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the  $EDBCR0_{EDM}$  bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should re-write the DBCR0 with all bits including EDM cleared.
- The debugger should clear the  $OCR_{DR}$  bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Control State Register \(CTL\)](#)), with a Go+Exit OnCE Command value.
- The  $OCR_{WKUP}$  bit may then be cleared.

### **Note**

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

# Chapter 61

## JTAG Controller (JTAGC)

### 61.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

#### 61.1.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to the chip-specific configuration information as well as [Register description](#) for more information about the JTAGC registers.

**Figure 61-1. JTAG (IEEE 1149.1) block diagram**

## 61.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 61-5](#) for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS\_AUX\_x instructions
- TEST\_CTRL register
- JTAG\_PASSWORD register
- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

### 61.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

#### 61.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

#### 61.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

### 61.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 61.2 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 61-1. JTAG signal properties**

| Name  | I/O    | Function         | Reset State | Pull |
|-------|--------|------------------|-------------|------|
| TCK   | Input  | Test Clock       | —           | Up   |
| TDI   | Input  | Test Data In     | —           | Up   |
| TDO   | Output | Test Data Out    | High Z      | —    |
| TMS   | Input  | Test Mode Select | —           | Up   |
| JCOMP | Input  | JTAG Compliancy  | —           | Down |

### 61.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 61.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 61.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

### 61.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

### 61.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

## 61.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 61.3.1 Instruction register

The JTAGC block uses a 5-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 00001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                  |   |   |   |   |
|--------|------------------|---|---|---|---|
|        | 4                | 3 | 2 | 1 | 0 |
| R      | 0                | 0 | 0 | 0 | 1 |
| W      | Instruction Code |   |   |   |   |
| Reset: | 0                | 0 | 0 | 0 | 1 |

**Figure 61-2. Instruction register**

### 61.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 61.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

The following table describes the device identification register functions.

**Table 61-2. Device identification register field descriptions**

| Field     | Description                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRN       | Part Revision Number. Contains the revision number of the part. Value is as mentioned in Table - "PRN for existing Masksets" given in Debug section of "Chip configuration" chapter.. |
| DC        | Design Center. Indicates the design center. Value is 0x26.                                                                                                                            |
| PIN       | Part Identification Number. Contains the part number of the device. 0x345.                                                                                                            |
| MIC       | Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.                                                                |
| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.                                                      |

### 61.3.4 TEST\_CTRL Register

The TEST\_CTRL register is a 17-bit shift register path from TDI to TDO selected when the ENABLE\_TEST\_CTRL instruction is active. The TEST\_CTRL register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state.

1. The reset value of TEST\_CTRL is 0x5D

The following table describes the TEST\_CTRL register functions.

**Table 61-3. TEST\_CTRL register field descriptions**

| Field     | Description                                           |
|-----------|-------------------------------------------------------|
| TEST_CTRL | Test Control. Used to control chiptop test functions. |

### 61.3.5 JTAG\_PASSWORD register

The JTAG\_PASSWORD register is a 65-bit shift register path from TDI to TDO selected when the ENABLE\_JTAG\_PASSWORD instruction is active. The default reset value of the JTAG\_PASSWORD register is 65'b0. The JTAG\_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE\_JTAG\_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG\_PASSWORD is 65 'b0.  
1. The reset value of JTAG\_PASSWORD is 65 'b0.

The following table describes the JTAG\_PASSWORD register functions.

**Table 61-4. JTAG\_PASSWORD register field descriptions**

| Field         | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| JTAG_PASSWORD | JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security. |

### 61.3.6 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

## 61.4 Functional description

This section explains the JTAGC functional description.

### 61.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

### 61.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to [ACCESS\\_AUX\\_x instructions](#).

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

**Figure 61-3. Shifting data through a register**

### 61.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 61-4. IEEE 1149.1-2001 TAP controller finite state machine**

### 61.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

### 61.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

### 61.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 61-5. General 5-bit JTAG instructions**

| Instruction            | Code[4:0] | Instruction Summary                                                                                                                                     |
|------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| IDCODE                 | 00001     | Selects device identification register for shift                                                                                                        |
| SAMPLE/PRELOAD         | 00010     | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation                                           |
| SAMPLE                 | 00011     | Selects boundary scan register for shifting and sampling without disturbing functional operation                                                        |
| EXTEST                 | 00100     | Selects boundary scan register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset. |
| Factory debug reserved | 00101     | Intended for factory debug only                                                                                                                         |
| ENABLE_TEST_CTRL       | 00110     | Selects TEST_CTRL register                                                                                                                              |
| ENABLE_JTAG_PASSWORD   | 00111     | Selects JTAG_PASSWORD register                                                                                                                          |
| HIGHZ                  | 01001     | Selects bypass register and three-states all output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset.                   |
| Factory debug reserved | 01010     | Intended for factory debug only                                                                                                                         |
| CLAMP                  | 01100     | Selects bypass register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset.        |

*Table continues on the next page...*

**Table 61-5. General 5-bit JTAG instructions (continued)**

| Instruction            | Code[4:0]         | Instruction Summary                         |
|------------------------|-------------------|---------------------------------------------|
| Factory debug reserved | 01110             | Intended for factory debug only             |
| Factory debug reserved | 01111             | Intended for factory debug only             |
| BYPASS                 | 11111             | Selects bypass register for data operations |
| Reserved <sup>1</sup>  | All other opcodes | Decoded to select bypass register           |

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS\_AUX instructions are described in the chip configuration debug information.

#### 61.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

#### 61.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

### 61.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

### 61.4.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

### 61.4.4.5 ENABLE\_TEST\_CTRL instruction

The ENABLE\_TEST\_CTRL instruction selects the TEST\_CTRL register for connection as the shift path between TDI and TDO.

### 61.4.4.6 ENABLE\_JTAG\_PASSWORD instruction

The ENABLE\_JTAG\_PASSWORD instruction selects the JTAG\_PASSWORD register for connection as the shift path between TDI and TDO.

### 61.4.4.7 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

#### **61.4.4.8 CLAMP instruction**

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### **61.4.4.9 ACCESS\_AUX\_x instructions**

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS\_AUX\_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

#### **61.4.4.10 BYPASS instruction**

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

### **61.4.5 Boundary scan**

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

## 61.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

# Chapter 62

## Nexus Module

### 62.1 Introduction

The e200z4251n3Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

#### 62.1.1 General description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

#### 62.1.2 Terms and definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

**Table 62-1. Terms and definitions**

| Term                             | Description                                                                                                                                                                                                                                           |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IEEE-ISTO 5001                   | Consortium & standard for real-time embedded system design. World wide Web documentation at <a href="http://www.ieee-isto.org/Nexus5001">http://www.ieee-isto.org/Nexus5001</a>                                                                       |
| Auxiliary Port                   | Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.                                                                                                                                                             |
| Branch Trace Messaging (BTM)     | Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.                                                                                                              |
| Data Read Message (DRM)          | External visibility of data reads to memory-mapped resources.                                                                                                                                                                                         |
| Data Write Message (DWM)         | External visibility of data writes to memory-mapped resources.                                                                                                                                                                                        |
| Data Trace Messaging (DTM)       | External visibility of how data flows through the embedded system. This may include DRM and/or DWM.                                                                                                                                                   |
| Data Acquisition Messaging (DQM) | Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.                                                                                                                  |
| JTAG Compliant                   | Device complying to IEEE 1149.1 JTAG standard                                                                                                                                                                                                         |
| JTAG IR & DR Sequence            | JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan. |
| Nexus1                           | The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.                                                       |
| Ownership Trace Message (OTM)    | Visibility of process/function that is currently executing.                                                                                                                                                                                           |
| Public Messages                  | Messages on the auxiliary pins for accomplishing common visibility and controllability requirements                                                                                                                                                   |
| SoC                              | "System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.                                                                        |
| Standard                         | The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.                                                                                                                                                  |
| Transfer Code (TCODE)            | Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.                                                                                                                         |
| Watchpoint                       | A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.                                            |

### 62.1.3 Feature list

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- Auxiliary interface for higher data input
  - Configurable (min/max) Message Data Out pins (**nex\_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex\_mseo\_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex\_rdy\_b**) pin
  - One (1) Watchpoint Event output pin (**evto\_b**)
  - One (1) Event In pin (**nex\_evti\_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex\_sfwcntl\_en**)
- Indicates to the FCCU whether it becomes active during functional mode.

### Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the SoC level). For single Nexus implementations

(not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

### **Note**

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

## 62.1.4 Functional block diagram

Figure 62-1. Nexus 3 functional block diagram

## 62.2 Enabling Nexus 3 operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex\_evti\_b input signal is asserted at the time that j\_trst\_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j\_trst\_b** pin or by cycling through the state machine using the **j\_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex\_mdo[n:0]**, **nex\_mseo[1:0]**, **nex\_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex\_sfwcntl\_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex\_sfwcntl\_en** input. Software can enable the module by a write to any of the module's DCRs when **nex\_sfwcntl\_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j\_trst\_b**, on initial entry into the Test-Logic-Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p\_reset\_b** signal, even when software has control of the module.

## 62.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex\_clk** remains active. In the Stopped state, **nex\_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex\_clk** is active.

## 62.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in [Table 62-2](#).

**Table 62-2. Supported TCODEs**

| Message Name                            | Min Field Size (bits) | Max Field Size (bits) | Field Name | Field Type | Field Description                                                                                                            |
|-----------------------------------------|-----------------------|-----------------------|------------|------------|------------------------------------------------------------------------------------------------------------------------------|
| Debug Status                            | 6                     | 6                     | TCODE      | fixed      | TCODE number = 0                                                                                                             |
|                                         | 4                     | 4                     | SRC        | fixed      | source processor identifier                                                                                                  |
|                                         | 8                     | 8                     | STATUS     | fixed      | Development Status Register (DS[31:24])                                                                                      |
|                                         | 0                     | 30                    | TSTAMP     | variable   | Timestamp value (optionally generated field)                                                                                 |
| Ownership Trace Message                 | 6                     | 6                     | TCODE      | fixed      | TCODE number = 2                                                                                                             |
|                                         | 4                     | 4                     | SRC        | fixed      | source processor identifier                                                                                                  |
|                                         | 1                     | 32                    | PROCESS    | variable   | Task/Process ID tag                                                                                                          |
|                                         | 0                     | 30                    | TSTAMP     | variable   | Timestamp value (optionally generated field)                                                                                 |
| Program Trace - Direct Branch Message   | 6                     | 6                     | TCODE      | fixed      | TCODE number = 3                                                                                                             |
|                                         | 4                     | 4                     | SRC        | fixed      | source processor identifier                                                                                                  |
|                                         | 1                     | 8                     | ICNT       | variable   | # sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow |
|                                         | 0                     | 30                    | TSTAMP     | variable   | Timestamp value (optionally generated field)                                                                                 |
| Program Trace - Indirect Branch Message | 6                     | 6                     | TCODE      | fixed      | TCODE number = 4                                                                                                             |
|                                         | 4                     | 4                     | SRC        | fixed      | source processor identifier                                                                                                  |
|                                         | 1                     | 1                     | MAP        | fixed      | (always set to 0)                                                                                                            |

|                                                         | 0                     | 32                    | CDATA2     | variable   | correlation data field 2- PID info (See <a href="#">Program Correlation Messages</a> .)                                                              |
|                                                         | 0                     | 30                    | TSTAMP     | variable   | Timestamp value (optionally generated field)                                                                                                         |

### Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in [Branch Trace Messaging types](#). If the Branch History method is selected, the shaded TCODEs above will not be messaged out.

[Table 62-3](#) shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

**Table 62-3. Error Code (ECODE) Encoding (TCODE = 8)**

| Error Code | Description                                          |
|------------|------------------------------------------------------|
| xxxxxxx1   | Watchpoint Trace Message(s) Lost                     |
| xxxxxx1x   | Data Trace Message(s) Lost                           |
| xxxxx1xx   | Program Trace Message(s) Lost                        |
| xxx1xxx    | Ownership Trace Message(s) Lost                      |
| xxx1xxxx   | Status Message(s) Lost (Debug Status messages, etc.) |
| xx1xxxxx   | Data Acquisition Message(s) Lost                     |
| x1xxxxxx   | Reserved                                             |
| 1xxxxxxx   | Reserved                                             |

Table 62-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

**Table 62-4. Error Type (ETYPE) Encoding (TCODE = 8)**

| Error Type  | Description                                                                     |
|-------------|---------------------------------------------------------------------------------|
| 0000        | Message Queue Overrun caused one or more messages to be lost                    |
| 0001        | Contention with higher priority messages caused one or more messages to be lost |
| 0010        | Reserved                                                                        |
| 0011        | Reserved                                                                        |
| 0100        | Reserved                                                                        |
| 0101        | Invalid access opcode (Nexus Register unimplemented)                            |
| 0110 - 1111 | Reserved                                                                        |

Table 62-5 shows the encodings used for resource codes for certain messages.

**Table 62-5. Resource Code (RCODE) values (TCODE = 27)**

| Resource Code | Description                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 0000          | Program Trace Instruction counter reached 255 and was reset.                                                                                     |
| 0001          | Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit. |

Table 62-6 shows the event code encodings used for certain messages.

**Table 62-6. Event Code (EVCODE) Encoding (TCODE = 33)**

| Event Code | Description                          |
|------------|--------------------------------------|
| 0000       | Entry into Debug Mode                |
| 0001       | Entry into Low Power Mode (CPU only) |
| 0010-0011  | Reserved for future functionality    |
| 0100       | Disabling Program Trace              |

*Table continues on the next page...*

**Table 62-6. Event Code (EVCODE) Encoding (TCODE = 33) (continued)**

| Event Code | Description                                                                       |
|------------|-----------------------------------------------------------------------------------|
| 0101       | Process ID value is established in PID0/NPIDR via <b>mtspr PID0/NPIDR</b>         |
| 0110-1000  | Reserved for future functionality                                                 |
| 1001       | Begin masking of program trace messages due to $MSR_{PMM}=0$ and $DC4_{PTMARK}=1$ |
| 1010       | Branch and link occurrence (direct branch function call)                          |
| 1011-1111  | Reserved for future functionality                                                 |

[Table 62-7](#) shows the data trace size encodings used for certain messages.

**Table 62-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)**

| DTM Size Encoding | Transfer Size        |
|-------------------|----------------------|
| 0000              | 0 - no data          |
| 0001              | Byte                 |
| 0010              | Halfword (2 bytes)   |
| 0011              | Three bytes          |
| 0100              | Word (4 bytes)       |
| 0101              | Five bytes           |
| 0110              | Six bytes            |
| 0111              | Seven bytes          |
| 1000              | Doubleword (8 bytes) |
| 1001-1111         | Reserved             |

## 62.4 Nexus 3 Programmer's model

This section describes the Nexus 3 programmer's model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See [Nexus 3 Register Access via JTAG/OnCE](#) and [Nexus 3 Register Access via Software](#) for details on Nexus 3 register access.

### Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 62-8. Nexus 3 register map

| Nexus Register                                 | Nexus Access Opcode    | Read/Write | Read Address | Write Address | DCR # <sup>1</sup> |
|------------------------------------------------|------------------------|------------|--------------|---------------|--------------------|
| Client Select Control (CSC)                    | 0x1                    | R          | 0x02         | -             |                    |
| Port Configuration Register (PCR) <sup>3</sup> | PCR_INDEX <sup>2</sup> | R/W        | -            | -             |                    |

- Software access via the **mfdcr** and **mtddcr** instructions use these values for the DCR number. Software writes to these registers via **mtddcr** when **nex\_sfwcntl\_en** is negated are ignored.
- The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.

3. The "PCR\_INDEX" is a parameter determined by the SoC.

### 62.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Nexus Reg# - 0x1; Read-only; Reset - 0x0

**Figure 62-2. Client Select Control (CSC) register**

**Table 62-9. CSC field descriptions**

| Bits     | Description                                             |
|----------|---------------------------------------------------------|
| CSC[7:4] | Reserved for future Nexus Clients (read as 0)           |
| CSC[3:0] | Client Select Control<br>0xx - Nexus client (SoC level) |

### 62.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Nexus Reg# - PCR\_INDEX; Read/Write; Reset - 0x0

**Figure 62-3. Port Configuration Register**

**Table 62-10. PCR field descriptions**

### Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

## 62.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in [Figure 62-4](#) and its fields are described in [Table 62-11](#).

**Figure 62-4. Development Control Register 1**

1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to [Watchpoint Trigger \(WT, PTSTC, PTETC, DTSTC, DTETC\) registers](#) for more information on watchpoint triggering.

Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to [Watchpoint Trigger \(WT, PTSTC, PTETC, DTSTC, DTETC\) registers](#) for more information on watchpoint triggering.

### Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK\_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

## 62.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z4251n3) Core Debug Support chapter.

Development Control Register 2 is shown in [Figure 62-5](#) and its fields are described in [Table 62-12](#).

**Figure 62-5. Development Control Register 2**

**Table 62-12. DC2 field descriptions**

### 62.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in [Figure 62-7](#) and its fields are described in [Table 62-14](#).

**Figure 62-7. Development Control 4 (DC4) register****Table 62-14. DC4 field descriptions**

## 62.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

### 62.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop

triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z4251n3) Core Debug Support chapter.

**Figure 62-9. Watchpoint Trigger (WT) Register**

Table 62-16 details the Watchpoint Trigger register fields.

**Table 62-16. WT field descriptions**

For extended Data Trace end trigger control, the DTETC register is used.

**Figure 62-13. Data Trace End Trigger Control (DTETC) register**

The following table details the DTETC register fields.

**Table 62-20. DTET field descriptions**

| Bits  | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## 62.4.8 Nexus Watchpoint Mask (WMSK) register

The Nexus Watchpoint Mask register controls which watchpoint events are enabled to produce Watchpoint Trace Messages (DC1<sub>TM</sub> must also be programmed to generate Watchpoint Trace Messages).

**Figure 62-14. Watchpoint Mask Register**

The following table details the Watchpoint Trigger register fields.

**Table 62-21. WMSK field descriptions**

| Bits | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 62.4.9 Nexus Overrun Control Register (OVCR)

The Nexus Overrun Control register controls Nexus behavior as the internal message queues fill up. Response options include suppressing selected message types, or stalling processor instruction execution.

**Figure 62-15. Nexus Overrun Control Register**

| Bits  | Name    | Description                                                                                                                                                                                                                                                                                                                                                                   |

Figure 62-16. Nexus Overrun Control Register Fields

### 62.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

### 62.4.11 Data Trace Start Address Registers (DTSA1-4)

The Data Trace Start Address Registers define the start addresses for each trace channel.

**Figure 62-18. Data Trace Start Address 1 (DTSA1) register****Figure 62-19. Data Trace Start Address 2 (DTSA2) register****Figure 62-20. Data Trace Start Address 3 (DTSA3) register**

**Figure 62-21. Data Trace Start Address 4 (DTSA4) register**

## 62.4.12 Data Trace End Address (DTEA1-4) registers

The Data Trace End Address Registers define the end addresses for each trace channel.

**Figure 62-22. Data Trace End Address 1 (DTEA1) register****Figure 62-23. Data Trace End Address 2 (DTEA2) register****Figure 62-24. Data Trace End Address 3 (DTEA3) register****Figure 62-25. Data Trace End Address 4 (DTEA4) register**

Table 62-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

**Table 62-23. Data trace - address range options**

| Programmed values | Range Control Bit Value | Range Selected           |
|-------------------|-------------------------|--------------------------|
| DTSA < DTEA       | 0                       | DTSA -> <- DTEA          |
| DTSA < DTEA       | 1                       | <- DTSA DTEA ->          |
| DTSA > DTEA       | N/A                     | Invalid Range - no trace |
| DTSA = DTEA       | N/A                     | Invalid Range - no trace |

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when  $DTC_{DI}=1$ , all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

62.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per [Table 62-25](#).

Figure 62-26. Read/Write Access Control/Status (RWCS) register

NOTES:

<sup>1</sup>ERR and DV are read-only

Table 62-24. RWCS field description

| Bits        | Name            | Description                                                                                                                                                                                                                                                                                                                                                                       |

### 62.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

**Figure 62-27. Read/Write Access Data (RWD) register**

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. [Table 62-26](#) shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

**Table 62-26. RWD data placement for transfers**

| Transfer Size<br>and byte offset  | RWA(2:0) | RWCS[SZ] | RWD   |       |      |     |
|-----------------------------------|----------|----------|-------|-------|------|-----|
|                                   |          |          | 31:24 | 23:16 | 15:8 | 7:0 |
| Byte                              | x x x    | 0 0 0    | -     | -     | -    | X   |
| Half                              | x x 0    | 0 0 1    | -     | -     | X    | X   |
| Word                              | x 0 0    | 0 1 0    | X     | X     | X    | X   |
| Doubleword                        | 0 0 0    | 0 1 1    |       |       |      |     |
| first RWD pass (low order data)   |          |          | X     | X     | X    | X   |
| second RWD pass (high order data) |          |          | X     | X     | X    | X   |

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

[Table 62-27](#) shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

**Table 62-27. RWD byte lane mapping**

| Transfer Size<br>and byte offset | RWA(2:0) | RWD        |            |            |            |
|----------------------------------|----------|------------|------------|------------|------------|
|                                  |          | 31:24      | 23:16      | 15:8       | 7:0        |

Table Notes:

"-" indicates byte lanes that will contain unused data.

### 62.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

**Figure 62-28. Read/Write Access Address (RWA) register**

## 62.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in [Table 62-8](#).

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See [IEEE 1149.1 \(JTAG\) RD/WR sequences](#).)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see [Table 62-8](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

| Nexus Register Index | Selected from values in <a href="#">Table 62-8</a> |
|----------------------|----------------------------------------------------|
| Read/Write (R/W):    | 0 - Read<br>1 - Write                              |

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
  - a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
  - b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

## 62.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no

possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 62-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the `nex_sfwcntl_en` input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

## 62.7 Nexus message fields

Nexus messages are composed of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

### 62.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

### 62.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the `nex3_ext_src_id[0:3]` input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

### 62.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) = 0x0003FC01, New Address (A2) = 0x0003F365

**Figure 62-29. Relative address generation and recreation**

## 62.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

## 62.7.5 Timestamp field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the `nex_tsen` input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of `nex_tsmode[0:1]` and the timestamp value is based on the `nex_timebase[0:29]` inputs. These signals are first synchronized to the `nex_clk` clock domain, and for `nex_timebase[0:29]`, a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they exit the message queues. Leading zeros in the timestamp value are removed. The table shows the `nex_tsmode[0:1]` encodings used for the timestamp mode.

**Table 62-28. `nex_tsmode[0:1]` timestamp mode encoding**

| <code>nex_tsmode[0:1]</code> | Timestamp Mode                          |
|------------------------------|-----------------------------------------|
| 00                           | Timestamp applied to every message      |
| 01                           | Timestamp applied to every 4th message  |
| 10                           | Timestamp applied to every 16th message |
| 11                           | Timestamp applied to every 64th message |

## 62.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

### **62.8.1 Message Queue Overrun**

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

### **62.8.2 CPU Stall**

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to [Nexus Overrun Control Register \(OVCR\)](#) for complete programming options.

### **62.8.3 Message Suppression**

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in

**Message Queue Overrun.** Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

## 62.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

[Table 62-29](#) lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in [Table 62-29](#).

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM -> DQM -> PCM<sub>PIDMSG</sub> -> OTM -> BTM -> DTM) -> Instruction 1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

**Table 62-29. Message Type Priority and Message Dropped Responses**

| Message Type               | Message                                                 | Priority    | Message Dropped Response |
|----------------------------|---------------------------------------------------------|-------------|--------------------------|
| Error                      | Error                                                   | 0 (highest) | N/A                      |
| WP<br>(Watchpoint Trace)   | WPM<br>(Watchpoint Message)                             | 1           | N/A <sup>1</sup>         |
| DQ<br>(Data Acquisition)   | DQM<br>(Data Acquisition Message)                       | 2           | DQM Error Message        |
| Program Trace<br>(PID MSG) | PCM - PID/NPIDR update<br>(Program Correlation Message) | 2           | OTM Error Message        |

*Table continues on the next page...*

**Table 62-29. Message Type Priority and Message Dropped Responses (continued)**

| Message Type       | Message                                                             | Priority   | Message Dropped Response                    |
|--------------------|---------------------------------------------------------------------|------------|---------------------------------------------|
| OT<br>(Ownership)  | OTM - PID/NPIDR update<br>(Ownership Trace Message)                 | 2          | OTM Error Message <sup>2</sup>              |
| Program Trace      | BTM<br>(Branch Trace Message)                                       | 2          | BTM Error Message,<br>Sync upgrade next BTM |
|                    | Sync<br>(Program Sync Message)                                      | 3          | Sync upgrade next BTM                       |
|                    | RFM<br>(Resource Full for Instruction counter or<br>history buffer) | 4          | BTM Error Message<br>Sync upgrade next BTM  |
|                    | DS<br>(Debug Status Message)                                        | 5          | Sync upgrade next BTM                       |
|                    | PCM<br>(Program Correlation Message)                                | 6          | BTM Error Message<br>Sync upgrade next BTM  |
| DT<br>(Data Trace) | DTM<br>(Data Trace Message)                                         | 7          | Sync upgrade next DTM                       |
| OT<br>(Ownership)  | OTM - Periodic update<br>(Ownership Trace Message)                  | 8 (lowest) | none                                        |

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

### 62.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

### 62.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

### 62.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

### 62.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

### 62.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

## 62.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

| (8 bits)  | (4 bits)   | (6 bits)       |
|-----------|------------|----------------|
| DS[31:24] | Src. Proc. | TCODE (000000) |

Fixed length = 18 bits

**Figure 62-30. Debug Status message format**

# 62.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

**Note**

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see [Table 62-3](#) and [Table 62-4](#)):

|            |            |            |                |
|------------|------------|------------|----------------|
| (6 bits)   | (4 bits)   | (4 bits)   | (6 bits)       |
| Error Code | Error Type | Src. Proc. | TCODE (001000) |

Fixed length = 20 bits

**Figure 62-31. Error message format**

# 62.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

## 62.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

## 62.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z4251n3) processors contain a *Power ISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mf spr/mt spr** instructions.

### Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mf spr/mt spr** instructions. This register is accessible in user or supervisor mode.

**Figure 62-32. Nexus 3 Process ID Register (NPIDR)**

### Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the DC1<sub>OTS</sub> control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and DC1<sub>OTS</sub> indicates PID0 should be used, or when the NPIDR register is written to by the processor and DC1<sub>OTS</sub> indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for

PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.

- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting DC1<sub>POTD</sub>.

Ownership trace information is messaged out in the following format:

| (1-32 bits) | (4 bits)            | (4 bits)   | (6 bits)       |
|-------------|---------------------|------------|----------------|
| Process ID  | PID Index<br>(0000) | Src. Proc. | TCODE (000010) |

Variable length = 15-46 bits

**Figure 62-33. Ownership Trace Message format**

## 62.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the e200z4251n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z4251n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p\_mode[0:3]**, **p\_pstat\_pipe{0,1}[0:5]**).

### 62.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Certain instructions (**zvselh**) generate a pair of predicate bits that are both reported as consecutive bits in the history field. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

### 62.12.1.1 Indirect Branch Message instructions

Table 62-30 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

**Table 62-30. Indirect Branch Message sources**

| Source of Indirect Branch Message          | Instructions / Detail                                                              |
|--------------------------------------------|------------------------------------------------------------------------------------|
| Taken branch relative to a register value  | <b>bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl</b>              |
| System Call / Trap exceptions taken        | <b>se_sc, tw</b>                                                                   |
| Return from interrupts / exceptions        | <b>se_rfi, se_rfci, se_rfdi</b>                                                    |
| Exit from reset with Program Trace Enabled | <b>Indirect branch with Sync, target address is initial instruction, count = 1</b> |

## 62.12.1.2 Direct Branch Message Instructions

Table 62-31 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

**Table 62-31. Direct Branch Message sources**

| Source of Direct Branch Message  | Instructions                                                                             |
|----------------------------------|------------------------------------------------------------------------------------------|
| Taken direct branch instructions | b, ba, bl, bla, bc, bca, bcl, bcla, se_b, se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync |
| Instruction Synchronize          |                                                                                          |

## 62.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. Certain instructions (**zvselh**) generate a pair of predicate bits that are both reported as consecutive bits in the history field.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

## 62.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

## 62.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

### 62.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If  $DC1_{PTM}$  is set to '1', indirect branch information is messaged out in the following format:

|                |                  |                |         |              |                |
|----------------|------------------|----------------|---------|--------------|----------------|
| (1-32 bits)    | (1-32 bits)      | (1-8 bits)     | (1 bit) | (4 bits)     | (6 bits)       |
| Branch History | Relative Address | Sequence Count | (0)     | Source Proc. | TCODE (011100) |

Max length = 83 bits; Min length = 14 bits

**Figure 62-34. Indirect branch message (history) format**

### 62.12.2.2 Indirect branch messages (traditional)

If  $DC1_{PTM}$  is cleared to '0', indirect branch information is messaged out in the following format:

|                  |                |         |              |                |
|------------------|----------------|---------|--------------|----------------|
| (1-32 bits)      | (1-8 bits)     | (1 bit) | (4 bits)     | (6 bits)       |
| Relative Address | Sequence Count | (0)     | Source Proc. | TCODE (000100) |

Max length = 51 bits; Min length = 13 bits

**Figure 62-35. Indirect branch message format**

### 62.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

| (1-8 bits)     | (4 bits)   | (6 bits)       |
|----------------|------------|----------------|
| Sequence Count | Src. Proc. | TCODE (000011) |

Max length = 18 bits; Min length = 11bits

**Figure 62-36. Direct Branch message format**

### Note

When DC1<sub>PTM</sub> is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

## 62.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

### 62.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

### 62.12.3.2 Branch/Predicate Instruction History (HIST)

If DC1<sub>PTM</sub> is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **zvselh** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

**Table 62-32. Branch/Predicate history events**

| Branch/Predicate History Event       | History Bit(s)  | Relevant Instructions                                                                                          |
|--------------------------------------|-----------------|----------------------------------------------------------------------------------------------------------------|
| Not taken register indirect branches | 0               | <b>bcctr</b> , <b>bcctrl</b> , <b>bclr</b> , <b>bclrl</b>                                                      |
| Not taken direct branches            | 0               | <b>b</b> , <b>ba</b> , <b>bc</b> , <b>bca</b> , <b>bla</b> , <b>bcla</b> , <b>bl</b> , <b>bcl</b>              |
| Taken direct branches                | 1               | <b>b</b> , <b>ba</b> , <b>bc</b> , <b>bca</b> , <b>bla</b> , <b>bcla</b> , <b>bl</b> , <b>bcl</b> <sup>1</sup> |
| zvselh instruction                   | 00,01,10, or 11 | <b>zvselh</b>                                                                                                  |

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.<sup>1</sup>

### 62.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

### 62.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 62-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 62-33. RCODE encoding

| RCODE | Description                                                  | RDATA field                                                                                             |
|-------|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| 0000  | Program Trace Instruction counter reached 255 and was reset. | 0xFF                                                                                                    |
| 0001  | Program Trace, Branch / Predicate Instruction History full.  | Branch Hlstory.<br>This type of packet is terminated by a stop bit set to 1 after the last history bit. |

## 62.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to  $MSR_{PMM}='0'$  and  $DC4_{PTMARK}='1'$ .
- When a write to the process ID register selected by  $DC1_{OTS}$  (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to [Table 62-6](#) for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

| (1-32 bits)    | (1-8 bits)     | (2 bits) | (4 bits) | (4 bits)   | (6 bits)       |
|----------------|----------------|----------|----------|------------|----------------|
| Branch History | Sequence Count | CDF*     | EVCOD    | Src. Proc. | TCODE (100001) |

Max length = 56 bits; Min length = 18 bits

\* - CDF=01,  
EVCODE = Any but 0101, 1101

**Figure 62-38. Program Correlation message formats**

### 62.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

### 62.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

### 62.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see [Table 62-34](#)):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex\_evti\_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to  $MSR_{PMM} \rightarrow '1'$  with  $DC4_{PTMARK} = '1'$ .

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

| (1-32 bits)         | (1-8 bits)     | (1 bit) | (4 bits)     | (6 bits)       |
|---------------------|----------------|---------|--------------|----------------|
| Full Target Address | Seq. Count (0) | (0)     | Source Proc. | TCODE (001001) |

Max length = 51 bits; Min length = 13 bits

Exception conditions that result in Program Trace Synchronization are summarized in [Table 62-34](#).

**Table 62-34. Program Trace exception summary**

| Exception Condition       | Exception Handling                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Reset Negation     | At the negation of JTAG reset ( <b>j_trst_b</b> ), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset ( <b>p_reset_b</b> ), if Program Trace is already enabled, a Program Trace Sync Message is sent.                                                                                                                                            |
| Program Trace Enabled     | The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.                                                                                                                                                                                                                                                                                                    |
| Exit from Low Power/Debug | Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.                                                                                                                                                                                                                                                                                                                                  |
| Queue Overrun             | An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message. |

*Table continues on the next page...*

Table 62-34. Program Trace exception summary (continued)

| Exception Condition | Exception Handling                                                                                                                                                                               |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event In            | If the Nexus module is enabled, a <b>nex_evti_b</b> assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature. |

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

62.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see [Table 62-34](#)):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

Figure 62-39. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

| (1-32 bits)    | (1-32 bits)         | (1-8 bits)     | (1 bit) | (4 bits)     | (6 bits)       |
|----------------|---------------------|----------------|---------|--------------|----------------|
| Branch History | Full Target Address | Sequence Count | (0)     | Source Proc. | TCODE (011101) |

Max length = 83 bits; Min length = 14 bits

**Figure 62-40. Indirect Branch History w/ Sync. message format**

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in [Table 62-35](#).

**Table 62-35. Program Trace Exception Summary for w/Sync BTM messages**

| Exception Condition                   | Exception Handling                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Periodic Program Trace Sync.          | A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Sequential Instruction Count Overflow | After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event.<br><br>If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the <i>next</i> Program Trace Direct/Indirect Branch Message.                                                                                                                               |
| Collision Priority                    | All Messages have the following priority: Instruction 0 (WPM → DQM → PCMPIDMSG → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision. |

## 62.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Filtering of Program Trace messages may be performed using the MSR<sub>PMM</sub> bit and the setting of DC4<sub>PTMARK</sub>

**Figure 62-44. Program Trace - Indirect Branch w/ Sync. message**

## 62.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

### 62.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

#### Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z4251n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of the following ways:

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).

### 62.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

#### 62.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

|                |                  |           |         |           |                |
|----------------|------------------|-----------|---------|-----------|----------------|
| (1-64 bits)    | (1-32 bits)      | (4 bits)  | (1 bit) | (4 bits)  | (6 bits)       |
| Data Value(s)* | Relative Address | Data Size | (0)     | Src. Proc | TCODE (000101) |

Max length = 111 bits; Min length = 17 bits

Figure 62-45. Data Write message format

#### 62.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

|                |                  |           |         |           |                |
|----------------|------------------|-----------|---------|-----------|----------------|
| (1-64 bits)    | (1-32 bits)      | (4 bits)  | (1 bit) | (4 bits)  | (6 bits)       |
| Data Value(s)* | Relative Address | Data Size | (0)     | Src. Proc | TCODE (000110) |

Max length = 111 bits; Min length = 17 bits

Figure 62-46. Data Read fessage format

**Note**

\* Core (e200z4251n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p\_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z4251n3)-based CPUs, the doubleword encoding (**p\_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

### 62.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see [Table 62-36](#)):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex\_evti\_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

|             |              |           |         |              |                          |
|-------------|--------------|-----------|---------|--------------|--------------------------|
| (1-64 bits) | (1-32 bits)  | (4 bits)  | (1 bit) | (4 bits)     | (6 bits)                 |
| Data Value  | Full Address | Data Size | (0)     | Source Proc. | TCODE (001101 or 001110) |

Max length = 111 bits; Min length = 17 bits

**Figure 62-47. Data Write/Read with Sync. message format**

Exception conditions that result in Data Trace Synchronization are summarized in [Table 62-36](#).

**Table 62-36. Data Trace Exception summary**

| Exception Condition       | Exception Handling                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Reset Negation     | At the negation of JTAG reset ( <b>j_trst_b</b> ), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.                                                                                                                                                                               |
| Data Trace Enabled        | The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.                                                                                                                                                                                                                                                                                                                              |
| Exit from Low Power/Debug | Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.                                                                                                                                                                                                                                                                                        |
| Queue Overrun             | An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message. |
| Periodic Data Trace Sync. | A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.                                                                                                                                                                                                                             |
| Event In                  | If the Nexus module is enabled, a <b>nex_evti_b</b> assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).                                                                                                                                                                                   |
| Collision Priority        | All Messages have the following priority: Instruction 0 (WPM → DQM → PCM <sub>PIDMSG</sub> → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.                |

## 62.13.3 DTM Operation

### 62.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

### 62.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

### 62.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR<sub>PMM</sub> and DC4<sub>DTMARK</sub>.

### 62.13.3.4 Bus Cycle special cases

**Table 62-37. Bus Cycle Special Cases**

| Special Case                                                                                                                                                                    | Action                                                                                  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Bus cycle aborted                                                                                                                                                               | Cycle ignored                                                                           |
| Bus cycle with data error ( $\overline{TEA}$ )                                                                                                                                  | Data Trace Message discarded                                                            |
| Bus cycle completed without error <sup>1</sup>                                                                                                                                  | Cycle captured & transmitted                                                            |
| AHB bus cycle initiated by Nexus 3                                                                                                                                              | Cycle ignored                                                                           |
| Bus cycle is an instruction fetch                                                                                                                                               | Cycle selectively ignored based on DTC <sub>DI</sub> setting                            |
| Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range                                                               | 1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note) |
| Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range                                  | 1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note) |
| Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error | Data Trace Message discarded                                                            |
| Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range                                  | 1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note) |
| Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error                       | Data Trace Message discarded                                                            |

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

#### Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the

doubleword at address 0, or unless the misaligned access wraps over the end of a circular buffer when using the LSP specialized load or store with circular addressing. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z4251n3) Core Debug Support chapter.)

### Note

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

## 62.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 62-48. Data Trace - Data Write Message

Figure 62-49. Data Trace — Data Read w/ Sync message

## 62.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

### 62.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from  $DEVENT_{DQTAG}$  when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

### 62.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

### 62.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core (e200z4251n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Figure 62-50. Data Acquisition message format

62.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z4251n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the WMSK<sub>WEM</sub> field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (evto\_b) pin for one (1) period of the output clock (nex\_mcko) based on settings in the DC2 and DC3 registers. See Table 62-40 for details on evto\_b.

Watchpoint information is messaged out in the following format:

Figure 62-51. Watchpoint message format

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 62-38. Watchpoint Source Encoding

| Watchpoint Source (1-30 bits)    | Watchpoint Description                                  |
|----------------------------------|---------------------------------------------------------|
| 00000000000000000000000000000000 | - No Watchpoints enabled for Watchpoint Trace Messaging |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1   | - Watchpoint #0 enabled for WTM                         |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1X  | - Watchpoint #1 enabled for WTM                         |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1XX | - Watchpoint #2 enabled for WTM                         |

**Table 62-38. Watchpoint Source Encoding**

| Watchpoint Source (1-30 bits)           | Watchpoint Description         |
|-----------------------------------------|--------------------------------|
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXX        | Watchpoint #3 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXX       | Watchpoint #4 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXXX      | Watchpoint #5 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXXXX     | Watchpoint #6 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXXXXX    | Watchpoint #7 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXXXXXX   | Watchpoint #8 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXXXXXXX  | Watchpoint #9 enabled for WTM  |
| XXXXXXXXXXXXXXXXXXXXXXXXXXXX1XXXXXXXXXX | Watchpoint #10 enabled for WTM |

| X1XXXXXXXXXXXXXXXXXXXX                  | Watchpoint #28 enabled for WTM |
| 1XXXXXXXXXXXXXXXXXXXX                   | Watchpoint #29 enabled for WTM |

## 62.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 62-52. Watchpoint Message & Watchpoint Error message

## 62.16 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p\_d\_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The RWCS<sub>ATTR</sub> field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

### Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

### 62.16.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
  - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#). Configure the bits as follows:
  - Access Control (AC) → 1b'1 (to indicate start access)
  - Map Select (MAP) → 3b'000 (primary memory map)
  - Access Priority (PR) → 2b'11 (highest priority)
  - Read/Write (RW) → 1b'1 (write access)
  - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
  - Access Count (CNT) → 14h'0000 or 14h'0001 (single access)

#### Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data (RWD) register through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
  - Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD register to the memory mapped address in the Read/Write Access Address (RWA) register. The nex\_ahb\_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS register. If the access has completed without error, (ERR=1'b0), Nexus asserts the nex\_rdy\_b pin (see [Table 62-40](#) for details) and clears the ERR bit in the RWCS register. Otherwise, if the access completes with an error, the ERR bit will be set to indicate an error has

occurred, and the **nex\_rdy\_b** pin will not be asserted. Once the DV bit has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

### Note

Only the **nex\_ahb\_start**, and **nex\_rdy\_b** pins, as well as the AC, DV, and ERR bits within the RWCS, provide Read/Write Access status to the external development tool.

## 62.16.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in [Single write access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block then arbitrates for the AHB system bus and transfers the first data value from the RWD register to the memory-mapped address in the Read/Write Access Address (RWA) register. The **nex\_ahb\_start** output is asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS register. Otherwise, the ERR bit is set and the DV bit is cleared to indicate an error has occurred, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Clearing the DV bit indicates that the device is ready for the next access in the block transfer, or that an error has occurred.
3. If the AC bit has not been cleared due to an error, repeat Step 3 in [Single write access](#) until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block write access.

### Note

The actual RWA register value as well as the CNT field within the RWCS register are not changed when executing a block write access. The original values can be read by the external development tool at any time.

### 62.16.3 Single read access

1. Initialize the Read/Write Access Address (RWA) register through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
  - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#). Configure the bits as follows:
  - Access Control (AC) → 1b'1 (to indicate start access)
  - Map Select (MAP) → 3b'000 (primary memory map)
  - Access Priority (PR) → 2b'11 (highest priority)
  - Read/Write (RW) → 1b'0 (read access)
  - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
  - Access Count (CNT) → 14h'0000 or 14h'0001 (single access)

#### Note

An Access Count (CNT) of 14h'0000 or 14h'0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The `nex_ahb_start` output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex\_rdy\_b** pin (see [Table 62-40](#) for detail on **nex\_rdy\_b**). Otherwise, if the access has completed with an error, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred. The **nex\_rdy\_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit is cleared in either case.
4. The data can then be read from the Read/Write Access Data register (RWD) through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#).

**Note**

Only the **nex\_ahb\_start** and **nex\_rdy\_b** pins as well as the AC, DV, and ERR bits within the RWCS register provide Read/Write Access status to the external development tool.

**62.16.4 Block read access**

1. For a block read access, follow Steps 1 and 2 outlined in [Single read access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The **nex\_ahb\_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex\_rdy\_b** pin (see [Table 62-40](#) for detail on **nex\_rdy\_b**). Otherwise, if the access has completed with an error, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex\_rdy\_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS register, and asserts the **nex\_rdy\_b** pin (see [Table 62-40](#) for detail on **nex\_rdy\_b**). Otherwise, if the access has completed with an error, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex\_rdy\_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the RWD register through the access method outlined in [Nexus 3 Register Access via JTAG/OnCE](#).
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in [Single read access](#) until the CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block read access.

**Note**

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

**Note**

The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

## 62.16.5 Error handling

The Nexus 3 module handles various error conditions as follows:

### 62.16.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p\_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write error

### 62.16.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.

- a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
- b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

### 62.16.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

|                    |            |                |
|--------------------|------------|----------------|
| (5 bits)           | (4 bits)   | (6 bits)       |
| Error Code (00011) | Src. Proc. | TCODE (001000) |

Fixed length = 15 bits

Figure 62-53. Error message format1

## 62.17 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

### 62.17.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex\_evti\_b** and one (1) **nex\_mseo\_b** or two (2) **nex\_mseo\_b[1:0]**. It also implements a configurable number of **nex\_mdo[n:0]** pins, (1) **nex\_rdy\_b** pin, (1) **evto\_b** pin, and one (1) clock output pin (**nex\_mcko**), as well as additional configuration pins described in [Table 62-40](#). The output pins are synchronized to the Nexus 3 output clock (**nex\_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see [Nexus 3 Register Access via JTAG/OnCE](#) for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core (e200z4251n3) Core Debug Support chapter.

**Table 62-39. JTAG Pins for Nexus 3**

| JTAG Pins       | Input/<br>Output | Description of JTAG Pins (included in Nexus 1)                                                                                                                                                                                                                        |
|-----------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>j_tdo</b>    | O                | The Test Data Output ( <b>j_tdo</b> ) pin is the serial output for test instructions and data. <b>j_tdo</b> is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. <b>j_tdo</b> changes on the falling edge of <b>j_tclk</b> . |
| <b>j_tdi</b>    | I                | The Test Data Input ( <b>j_tdi</b> ) pin receives serial test instruction and data. TDI is sampled on the rising edge of <b>j_tclk</b> .                                                                                                                              |
| <b>j_tms</b>    | I                | The Test Mode Select ( <b>j_tms</b> ) input pin is used to sequence the OnCE controller state machine. <b>j_tms</b> is sampled on the rising edge of <b>j_tclk</b> .                                                                                                  |
| <b>j_tclk</b>   | I                | The Test Clock ( <b>j_tclk</b> ) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.                                                                                                                             |
| <b>j_trst_b</b> | I                | The Test Reset ( <b>j_trst_b</b> ) input pin is used to asynchronously initialize the JTAG/OnCE controller.                                                                                                                                                           |

The auxiliary pins are used to send and receive messages and are described in [Table 62-40](#).

**Table 62-40. Nexus 3 Auxiliary pins**

| Auxiliary pins         | Input/<br>Output | Description of auxiliary pins                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nex_mcko</b>        | O                | Message Clock Out ( <b>nex_mcko</b> ) is a free running output clock to development tools for timing of <b>nex_mdo[n:0]</b> & <b>nex_mseo_b[1:0]</b> pin functions. <b>nex_mcko</b> is programmable through the DC1 Register.                                                                                                                                                                                                                                                                                                                           |
| <b>nex_mdo[n:0]</b>    | O                | Message Data Out ( <b>nex_mdo[n:0]</b> ) are output pins used for OTM, BTM, and DTM. External latching of <b>nex_mdo[n:0]</b> shall occur on the rising edge of the Nexus3 clock ( <b>nex_mcko</b> ).                                                                                                                                                                                                                                                                                                                                                   |
| <b>nex_mseo_b[1:0]</b> | O                | Message Start/End Out ( <b>nex_mseo_b[1:0]</b> ) are output pins that indicate when a message on the <b>nex_mdo[n:0]</b> pins has started, when a variable length packet has ended, and when the message has ended. External latching of <b>nex_mseo_b[1:0]</b> shall occur on the rising edge of the Nexus3 clock ( <b>nex_mcko</b> ). One or two pin MSEO functionality is determined at integration time per SOC implementation.                                                                                                                     |
| <b>nex_ahb_start</b>   | O                | AHB Start ( <b>nex_ahb_start</b> ) is an output pin used to indicate to the external tool or SoC that the Nexus block is requesting the next Read/Write Access on the system bus. If Nexus is enabled, this signal is asserted upon an acknowledged request to start an AHB system bus transfer (Nexus read or write) and is pulsed asserted for one <b>nex_clk</b> clock period, corresponding to the first clock of the address phase of the transfer. Upon exit from system reset or if Nexus is disabled, <b>nex_ahb_start</b> remains de-asserted. |
| <b>nex_rdy_b</b>       | O                | Ready ( <b>nex_rdy_b</b> ) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, <b>nex_rdy_b</b> remains deasserted.                                                                              |
| <b>evto_b</b>          | O                | Event Out ( <b>evto_b</b> ) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. <b>evto_b</b> is held asserted for one (1) cycle of <b>nex_mcko</b> : <ol style="list-style-type: none"> <li>1. One (or more) watchpoints has occurred (from Nexus1) &amp; EOC = 2'b00</li> </ol>                                                                                                                                                                                                     |

*Table continues on the next page...*

**Table 62-40. Nexus 3 Auxiliary pins (continued)**

| Auxiliary pins             | Input/<br>Output | Description of auxiliary pins                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            |                  | 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>nex_evti_b</b>          | I                | Event In ( <b>nex_evti_b</b> ) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): <ol style="list-style-type: none"> <li>1. Program Trace &amp; Data Trace synchronization messages (provided Program Trace &amp; Data Trace are enabled &amp; EIC = 2'b00).</li> <li>2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).</li> </ol> |
| <b>nex_ext_src_id[0:3]</b> | I                | <b>nex_ext_src_id[0:3]</b> is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.                                                                                                                                                                                                                                                                                                                 |
| <b>nex_sfwcntl_en</b>      | I                | <b>nex_sfwcntl_en</b> is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.                                                                                                                                                                                          |

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to [Auxiliary port arbitration](#) for detail on Nexus port arbitration.

**Table 62-41. Nexus port arbitration signals**

| Nexus port arbitration pins | Input/<br>Output | Description of arbitration pins                                                                                                                                                                                                                                                                                                       |
|-----------------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nex_aux_req[1:0]</b>     | O                | Nexus Auxiliary Request ( <b>nex_aux_req[1:0]</b> ) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See <a href="#">Table 62-43</a> .) |
| <b>nex_aux_busy</b>         | O                | Nexus Auxiliary Busy ( <b>nex_aux_busy</b> ) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.                                                                                                                 |
| <b>nar_aux_grant</b>        | I                | Nexus Auxiliary Grant ( <b>nar_aux_grant</b> ) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.                                                                                                                                                             |
| <b>ext_multi_nex_sel</b>    | I                | Multi-Nexus Select ( <b>ext_multi_nex_sel</b> ) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).                                                                                  |

## 62.17.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in [Table 62-42](#). Both single and dual pin cases are shown.

**nex\_mseo\_b[1:0]** is used to signal the end of variable-length packets, and not fixed length packets. **nex\_mseo\_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex\_mcko**).

Single pin MSEO is not supported on the MPC5744P.

**Table 62-42. MSEO pin(s) protocol**

| nex_mseo_b function           | Single nex_mseo_b data (serial) | Dual nex_mseo_b[1:0] data |
|-------------------------------|---------------------------------|---------------------------|
| Start of message              | 1-1-0                           | 11-00                     |
| End of message                | 0-1-1-(more 1's)                | 00 (or 01)-11-(more 1's)  |
| End of variable length packet | 0-1-0                           | 00-01                     |
| Message transmission          | 0's                             | 00's                      |
| Idle (no message)             | 1's                             | 11's                      |

Figure 62-54 illustrates the state diagram for single pin MSEO transfers.

**Figure 62-54. Single pin MSEO transfers**

Note that the "End Message" state does not contain valid data on the **nex\_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex\_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex\_mseo\_b** pin before the actual end of message.

Figure 62-55 illustrates the state diagram for dual pin MSEO transfers.

Figure 62-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust than the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

### Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

## 62.18 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

For example, if the **nex\_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex\_mdo[n:0]** must be packed with a 0.

## 62.19 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level. The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in [Table 62-43](#) below. The Nexus 3 module will receive a 1-bit grant signal (**nar\_aux\_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in [Pin protocol](#). The Nexus 3 module will maintain control of the port, by asserting the **nex\_aux\_busy** signal, until the  $\overline{\text{MSEO}}$  state machine reaches the "End Message" state.

**Table 62-43. MDO Request Encodings**

| Request level | MDO request encoding<br>(nex_aux_req[1:0]) | Condition of queue               |
|---------------|--------------------------------------------|----------------------------------|
| No Request    | 00                                         | No message to send               |
| Low Priority  | 01                                         | Message queue less than 1/2 full |
| —             | 10                                         | Reserved                         |
| High Priority | 11                                         | Message queue 1/2 full or more   |

## 62.20 Examples

The following are examples of Program Trace and Data Trace Messages.

[Table 62-44](#) illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. [Table 62-45](#) illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex\_mdo[n:0]** pins are ignored in the single MSEO case.

**Table 62-44. Indirect Branch Message Example (2 MDO / 1 MSEO)**

| Clock | nex_mdo[1:0] |     | nex_mseo_b | State                         |
|-------|--------------|-----|------------|-------------------------------|
| 0     | X            | X   | 1          | Idle (or end of last message) |
| 1     | T1           | T0  | 0          | Start Message                 |
| 2     | T3           | T2  | 0          | Normal Transfer               |
| 3     | T5           | T4  | 0          | Normal Transfer               |
| 4     | S1           | S0  | 0          | Normal Transfer               |
| 5     | S3           | S2  | 0          | Normal Transfer               |
| 6     | I0           | MAP | 0          | Normal Transfer               |
| 7     | I2           | I1  | 0          | Normal Transfer               |
| 8     | I4           | I3  | 1          | End Packet                    |
| 9     | A1           | A0  | 0          | Normal Transfer               |
| 10    | A3           | A2  | 0          | Normal Transfer               |
| 11    | A5           | A4  | 0          | Normal Transfer               |
| 12    | A7           | A6  | 1          | End Packet                    |
| 13    | 0            | 0   | 1          | End Message                   |
| 14    | T1           | T0  | 0          | Start Message                 |

**Table 62-45. Indirect branch message example (8 MDO / 2 MSEO)**

| Clock | nex_mdo[7:0] |    |    |    |    |             |    |    | nex_mseo_b[1:0] |   | State                         |
|-------|--------------|----|----|----|----|-------------|----|----|-----------------|---|-------------------------------|
| 0     | X            | X  | X  | X  | X  | X           | X  | X  | 1               | 1 | Idle (or end of last message) |
| 1     | S1           | S0 | T5 | T4 | T3 | T2          | T1 | T0 | 0               | 0 | Start Message                 |
| 2     | I4           | I3 | I2 | I1 | I0 | M<br>A<br>P | S3 | S2 | 0               | 1 | End Packet                    |
| 3     | A7           | A6 | A5 | A4 | A3 | A2          | A1 | A0 | 1               | 1 | End Packet/End Message        |
| 4     | S1           | S0 | T5 | T4 | T3 | T2          | T1 | T0 | 0               | 0 | Start Message                 |

Table 62-46 and Table 62-47 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

**Table 62-46. Direct branch message example (2 MDO / 1 MSEO)**

| Clock | nex_mdo[1:0] |    | nex_mseo_b | State                         |
|-------|--------------|----|------------|-------------------------------|
| 0     | X            | X  | 1          | Idle (or end of last message) |
| 1     | T1           | T0 | 0          | Start Message                 |
| 2     | T3           | T2 | 0          | Normal Transfer               |
| 3     | T5           | T4 | 0          | Normal Transfer               |
| 4     | S1           | S0 | 0          | Normal Transfer               |
| 5     | S3           | S2 | 0          | Normal Transfer               |
| 6     | I1           | I0 | 1          | End Packet                    |
| 7     | 0            | 0  | 1          | End Message                   |

**Table 62-47. Direct branch message example (8 MDO / 2 MSEO)**

| Clock | nex_mdo[7:0] |    |    |    |    |    |    |    | nex_mseo_b[1:0] |   | State                         |
|-------|--------------|----|----|----|----|----|----|----|-----------------|---|-------------------------------|
| 0     | X            | X  | X  | X  | X  | X  | X  | X  | 1               | 1 | Idle (or end of last message) |
| 1     | S1           | S0 | T5 | T4 | T3 | T2 | T1 | T0 | 0               | 0 | Start Message                 |
| 2     | 0            | 0  | 0  | 0  | I1 | I0 | S3 | S2 | 1               | 1 | End Packet/End Message        |
| 3     | S1           | S0 | T5 | T4 | T3 | T2 | T1 | T0 | 0               | 0 | Start Message                 |

Table 62-48 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and Table 62-49 illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

**Table 62-48. Data write message example (8 MDO / 1 MSEO)**

| Clock | nex_mdo[7:0] |    |    |    |    |    |    |    | nex_mseo_b | State                         |
|-------|--------------|----|----|----|----|----|----|----|------------|-------------------------------|
| 0     | X            | X  | X  | X  | X  | X  | X  | X  | 1          | Idle (or end of last message) |
| 1     | S1           | S0 | T5 | T4 | T3 | T2 | T1 | T0 | 0          | Start Message                 |
| 2     | A0           | Z3 | Z2 | Z1 | Z0 | 0  | S3 | S2 | 1          | End Packet                    |
| 3     | D7           | D6 | D5 | D4 | D3 | D2 | D1 | D0 | 0          | Normal Transfer               |
| 4     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1          | End Packet                    |
| 5     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1          | End Message                   |

**Table 62-49. Data write message example (8 MDO / 2 MSEO)**

| Clock | nex_mdo[7:0] |    |    |    |    |    |    |    | nex_mseo_b[1:0] |   | State                         |
|-------|--------------|----|----|----|----|----|----|----|-----------------|---|-------------------------------|
| 0     | X            | X  | X  | X  | X  | X  | X  | X  | 1               | 1 | Idle (or end of last message) |

## 62.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the MPC5744P Data Sheet.

## 62.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

### 62.22.1 JTAG sequence for accessing internal Nexus registers

**Table 62-50. Accessing internal Nexus 3 registers via JTAG/OnCE**

| Step # | TMS Pin | Description                                                                                  |
|--------|---------|----------------------------------------------------------------------------------------------|
| 1      | 1       | IDLE -> SELECT-DR_SCAN                                                                       |
| 2      | 0       | SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)                |
| 3      | 0       | CAPTURE-DR -> SHIFT-DR                                                                       |
| 4      | 0       | (7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr. |
| 5      | 1       | SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)                                      |
| 6      | 1       | EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)               |
| 7      | 1       | UPDATE-DR -> SELECT-DR_SCAN                                                                  |
| 8      | 0       | SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)                |
| 9      | 0       | CAPTURE-DR -> SHIFT-DR                                                                       |
| 10     | 0       | (31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value     |
| 11     | 1       | SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)                             |
| 12     | 1       | EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)              |
| 13     | 0       | UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)       |

### 62.22.2 JTAG sequence for read access of memory-mapped resources

**Table 62-51. Accessing memory-mapped resources (reads)**

| Step # | TCLK clocks | Description                                                                |
|--------|-------------|----------------------------------------------------------------------------|
| 1      | 13          | Nexus Command = write to Read/Write Access Address Register (RWA)          |
| 2      | 37          | Write RWA (initialize starting read address — data input on TDI)           |
| 3      | 13          | Nexus Command = write to Read/Write Control/Status Register (RWCS)         |
| 4      | 37          | Write RWCS (initialize read access mode and CNT value — data input on TDI) |
| 5      | —           | Wait for falling edge of <b>nex_rdy_b</b> pin                              |
| 6      | 13          | Nexus Command = read Read/Write Access Data Register (RWD)                 |
| 7      | 37          | Read RWD (data output on TDO)                                              |
| 8      | —           | If CNT > 0, go back to Step #5                                             |

### 62.22.3 JTAG sequence for write access of memory-mapped resources

**Table 62-52. Accessing memory-mapped resources (writes)**

| Step # | TCLK clocks | Description                                                                 |
|--------|-------------|-----------------------------------------------------------------------------|
| 1      | 13          | Nexus Command = write to Read/Write Access Control/Status Register (RWCS)   |
| 2      | 37          | Write RWCS (initialize write access mode and CNT value - data input on TDI) |
| 3      | 13          | Nexus Command = write to Read/Write Address Register (RWA)                  |
| 4      | 37          | Write RWA (initialize starting write address - data input on TDI)           |
| 5      | 13          | Nexus Command = read Read/Write Access Data Register (RWD)                  |
| 6      | 37          | Write RWD (data output on TDO)                                              |
| 7      | —           | Wait for falling edge of <b>nex_rdy_b</b> pin                               |
| 8      | —           | If CNT > 0, go back to Step #5                                              |

# Chapter 63

## Nexus Crossbar Multi-Master Client (NXMC)

### 63.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.

#### 63.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on internal triggers.

- Nexus Auxiliary port for higher data throughput
  - 4 MDO (Message Data Out) pins
  - Two  $\overline{\text{MSEO}}$  (Message Start/End Out) pins
  - One  $\overline{\text{EVTO}}$  (Watchpoint Event) pin
  - One  $\overline{\text{EVTI}}$  (Event In) pin
  - One MCKO (Message Clock Out) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

## 63.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NPC. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One  $\overline{\text{EVTI}}$
- One  $\overline{\text{EVTO}}$
- Two  $\overline{\text{MSEO}}$
- 4 MDOs
- One MCKO

These pins are described in [Table 63-2](#).

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see [IEEE 1149.1 \(JTAG\) Test Access Port](#) for details). A separate JTAG TAP controller is instantiated within the NXMC. The following table describes the JTAG pins.

**Table 63-1. JTAG pins for NXMC**

| JTAG port | Input/ output | Description                                                                                                                                                                                                               |
|-----------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TDO       | O             | The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK. |
| TDI       | I             | The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.                                                                   |
| TMS       | I             | The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.                                         |
| TCK       | I             | The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.                                                                                                  |
| TRST      | I             | The Test Reset ( $\overline{\text{TRST}}$ ) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.                                      |

**Table 63-2. NXMC auxiliary pins**

| Auxiliary port | Input/output | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MCKO           | O            | Message Clock Out (MCKO) is a Nexus generated output clock to development tools for timing of MDO and MSEO pin functions. MCKO is programmable through the DC Register.                                                                                                                                                                                                                       |
| MDO[4:0]       | O            | Message Data Out (MDO[4:0]) are output pins used for DTM and WPM (watch point message). External sampling of MDO by the development tool shall occur on rising edge of the Nexus clock (MCKO).                                                                                                                                                                                                |
| MSEO[1:0]      | O            | Message Start/End Out (MSEO) are output pins which indicate when a message on the MDO pins has started, when a variable length packet has ended, and when the message has ended. External sampling of MSEO shall occur on rising edge of the Nexus clock (MCKO).                                                                                                                              |
| EVTO           | O            | <p>Event Out (EVTO) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register:</p> <ul style="list-style-type: none"> <li>one of the internal or external watchpoints has occurred and EOC = 2'b00</li> <li>system-level debug mode was entered (ipg_debug) and EOC = 2'b01</li> </ul> <p>EVTO is held asserted for one cycle.</p> |
| EVTI           | I            | Event In (EVTI) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see <a href="#">Enabling NXMC operation</a> ), assertion initiates data trace synchronization messages (provided data trace is enabled).                                                                                                                                      |

### 63.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in the following table. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

**Table 63-3. Supported public TCODEs**

| Message name                           | Min packet size (bits) | Max packet size (bits) | Packet name | Packet type | Packet description                                         |
|----------------------------------------|------------------------|------------------------|-------------|-------------|------------------------------------------------------------|
| <b>Data Trace - Data Write Message</b> | 6                      | 6                      | TCODE       | fixed       | TCODE number = 58                                          |
|                                        | 4                      | 4                      | SRC         | fixed       | Source processor identifier (multiple Nexus configuration) |
|                                        | 4                      | 4                      | MASTER      | fixed       | Indicates which master (ID) initiated the data access      |
|                                        | 3                      | 3                      | DSZ         | fixed       | Data size (See <a href="#">Table 63-4</a> )                |
|                                        | 1                      | 32                     | U-ADDR      | variable    | Unique portion of the data write address                   |
|                                        | 8                      | 64                     | DATA        | fixed       | Data write value (size fixed based on DSZ field)           |

*Table continues on the next page...*

**Table 63-3. Supported public TCODEs (continued)**

| Message name                                   | Min packet size (bits) | Max packet size (bits) | Packet name | Packet type | Packet description                                             |
|------------------------------------------------|------------------------|------------------------|-------------|-------------|----------------------------------------------------------------|

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

## 63.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See [IEEE 1149.1 \(JTAG\) Test Access Port](#) for details. The complete list of registers is shown in this table.

**Table 63-7. NXMC registers**

| Nexus register                                 | Nexus access opcode (hex) | Read/write | Read address (hex) | Write address (hex) |
|------------------------------------------------|---------------------------|------------|--------------------|---------------------|
| Development Control 1 (DC1)                    | 2                         | R/W        | 04                 | 05                  |
| Development Control 2 (DC2)                    | 3                         | R/W        | 06                 | 07                  |
| Watchpoint Trigger (WT)                        | B                         | R/W        | 16                 | 17                  |
| Data Trace Control (DTC)                       | D                         | R/W        | 1A                 | 1B                  |
| Data Trace Start Address1 (DTSA1)              | E                         | R/W        | 1C                 | 1D                  |
| Data Trace Start Address2 (DTSA2)              | F                         | R/W        | 1E                 | 1F                  |
| Data Trace End Address1 (DTEA1)                | 12                        | R/W        | 24                 | 25                  |
| Data Trace End Address2 (DTEA2)                | 13                        | R/W        | 26                 | 27                  |
| Breakpoint/Watchpoint Control Register1 (BWC1) | 16                        | R/W        | 2C                 | 2D                  |
| Breakpoint/Watchpoint Control Register2 (BWC2) | 17                        | R/W        | 2E                 | 2F                  |
| Breakpoint/Watchpoint Address Register1 (BWA1) | 1E                        | R/W        | 3C                 | 3D                  |
| Breakpoint/Watchpoint Address Register2 (BWA2) | 1F                        | R/W        | 3E                 | 3F                  |

### 63.4.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. This table shows the format of the DC1.

|           | 31 | 30 | 29 | 28  | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4   | 3 | 2 | 1  | 0 |
|-----------|----|----|----|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|-----|---|---|----|---|
| R         | 0  | 0  | 0  | EOC |    |    | 0  | 0  | W  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | C  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | EIC |   |   | TM |   |
| W         |    |    |    |     |    |    |    |    | E  |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |     |   |   |    |   |
| Res<br>et | 0  | 0  | 0  | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0   | 0 | 0 | 0  | 0 |

The DC1 is described in this table.

**Table 63-8. DC1 register field description**

| Field | Description                                                                                                                                    |

|       | XXXXX1XX Internal Watchpoint #2 triggers $\overline{\text{EVTO}}$ |
|       | XXXXXX1X Reserved                                                 |
|       | XXXXXXX1 Reserved                                                 |
| 23:0  | Reserved for future functionality (read as 0)                     |

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.

### 63.4.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable.

The WT bits can be used to produce an address related window for triggering trace messages. This table shows the format of the WT register.

|       |    |    |    |    |    |    |     |    |    |     |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|-----|----|----|-----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

### 63.4.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. This table shows the format of the DTC register.

|     | 31   | 30   | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19  | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |
|-----|------|------|----|----|----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|
| R   |      |      |    |    | 0  | 0  | 0  | M  | 0  | 0  |    |    |     |    |    |    |    | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | R | R | 0 | 0 | 0 | 0 | 0 | 0 |

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

### 63.4.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. This table shows the format of the DTSA1 and DTSA2 registers.

|       |                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|--------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|       | 31                       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | DATA TRACE START ADDRESS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0                        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

### 63.4.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. This table shows the format of the DTEA1 and DTEA2 registers.

|       |                        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|       | 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R     | DATA TRACE END ADDRESS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| W     |                        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Reset | 0                      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

This table illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

**Table 63-12. Data trace address range options**

| Programmed values | Range control bit value | Range selected                                 |
|-------------------|-------------------------|------------------------------------------------|
| $DTSA \leq DTEA$  | 0                       | $DTSA \rightarrow \leftarrow DTEA$             |
| $DTSA \leq DTEA$  | 1                       | $\leftarrow DTSA \rightarrow DTEA \rightarrow$ |
| $DTSA > DTEA$     | N/A                     | Invalid range—no trace                         |

#### Note

DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

### 63.4.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. This table shows the format of the BWC1 register.

| R    |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    | B    |    |    |    |      |    |   |   |      |   |   |   |   |   |   |   |   |   |   |   |  |
|------|----|----|----|------|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|------|----|---|---|------|---|---|---|---|---|---|---|---|---|---|---|--|
| W    |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    | W    |    |    |    |      |    |   |   |      |   |   |   |   |   |   |   |   |   |   |   |  |
| T1   |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    | T1   |    |    |    |      |    |   |   |      |   |   |   |   |   |   |   |   |   |   |   |  |
| 31   | 30 | 29 | 28 | 27   | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15   | 14 | 13 | 12 | 11   | 10 | 9 | 8 | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |   |   |   |  |
| BWE1 |    |    |    | BRW1 |    |    |    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | BWR1 |    |    |    | BWE1 |    |   |   | BRW1 |   |   |   | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|      |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |      |    |   |   |      |   |   |   |   |   |   |   |   |   |   |   |  |
| Res  |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    | et   |    |    |    |      |    |   |   |      |   |   |   |   |   |   |   |   |   |   |   |  |
| 0    | 0  | 0  | 0  | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0    | 0  | 0  | 0  | 0    | 0  | 0 | 0 | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |   |   |   |   |  |

The BWC1 register is described in this table.

**Table 63-13. BWC1 field description**

| Field         | Description                                                                                                                                                                                 |

| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0 |  |  |  |  |  |  |  |  |  |  |  | 0     |  | 0      |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0    |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |       |  |   |  |  |  |  |  |  |  |  |  |  |  |       |  |        |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

The BWC2 register is described in this table.

**Table 63-14. BWC2 field description**

| Field         | Description                                                                                                                                                                                 |

### 63.4.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. This table shows the format of the BWA1 and BWA2 registers.

### 63.4.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in [Table 63-7](#). For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

## 63.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of  $\overline{\text{TRST}}$  and system reset de-assertion. The JTAG ID register should be read by the tool after negation of  $\overline{\text{TRST}}$  and should be programmed before deassertion of system reset.

### 63.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in [NXMC register access via JTAG](#).

### 63.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the  $\overline{\text{TRST}}$  pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

### 63.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the  $\overline{\text{TRST}}$  pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

### 63.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR).

Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in [Table 63-7](#).

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see [Table 63-7](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown below.

**Table 63-15. JTAG DR field description for Nexus register access**

| Field                | Description                                        |
|----------------------|----------------------------------------------------|
| Nexus Register Index | Selected from values in <a href="#">Table 63-7</a> |
| Read/Write (R/W)     | 0 Read<br>1 Write                                  |

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.

- a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
- b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

## **63.6 Functional description**

The following sections describe the functionality of the NXMC module.

### **63.6.1 Data trace**

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

#### **63.6.1.1 Data trace messaging (DTM)**

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

#### **63.6.1.2 DTM message formats**

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

### 63.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. Data write message and data read message information is messaged out in the format shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

**Table 63-16. DTM message format for DATA width = 64 bits**

| 8/16/32/64 bits | 1–32 bits | 3 bits | 4 bits | 4 bits | 6 bits                   |
|-----------------|-----------|--------|--------|--------|--------------------------|
| DATA            | U-ADDR    | DSZ    | MASTER | SRC    | TCODE (111010 or 111011) |

### 63.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

### 63.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 000000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 000000000000011).

Error information is messaged out in the format shown in this figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

**Table 63-17. DTM error message format (fixed length = 28 bits)**

| 14 bits | 4 bits | 4 bits | 6 bits         |
|---------|--------|--------|----------------|
| ECODE   | ETYPE  | SRC    | TCODE (001000) |

**NOTE**

The internal queue FIFO is very small. This causes FIFO overflows whenever Trace is enabled on any of the AHB clients and the AHB master module generates >4 burst accesses. If the customer is experiencing a lot of overflow error messages the amount of data snooped by the NXMC should be reduced.

**63.6.1.2.4 Data trace synchronization messages**

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see [Table 63-19](#)):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message. This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly.

Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in the following figure. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

**Table 63-18. Data write/read with synchronization message format**

| 8-64 bits | 1–32 bits | 3 bits | 4 bits | 4 bits | 6 bits                   |
|-----------|-----------|--------|--------|--------|--------------------------|
| DATA      | F-ADDR    | DSZ    | MASTER | SRC    | TCODE (111100 or 111101) |

Exception conditions that result in data trace synchronization are summarized in this table.

**Table 63-19. Data trace exception summary**

| Exception condition                 | Exception handling                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Reset Negation               | At the negation of JTAG reset (TRST), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.                                                                                                                                                                             |
| Data Trace Enabled                  | The first data trace message (after data trace has been enabled) is a synchronization message.                                                                                                                                                                                                                                                                                                                        |
| Exit from Low Power/Debug           | Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.                                                                                                                                                                                                                                                                             |
| Queue Overrun                       | An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message. |
| Periodic Data Trace Synchronization | A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.                                                                                                                                                                                                           |
| Event In                            | If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).                                                                                                                                                                |
| Collision Priority                  | All messages have the following priority: Error > WPM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.                                                                        |

### 63.6.1.3 Enabling data trace messaging operation

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).

- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

### **Note**

When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

#### **63.6.1.4 DTM queueing**

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

### **Note**

If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > DTM).

#### **63.6.1.5 Relative addressing**

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in this figure.

**Message Generation:**

$$A1 = 0000\ 0000\ 0000\ 0011\ 1111\ 1100\ 0000\ 0001$$

$$A2 = 0000\ 0000\ 0000\ 0011\ 1111\ 0011\ 0110\ 0101$$

$$A1 \oplus A2 = 0000\ 0000\ 0000\ 0000\ 0000\ 1111\ 0110\ 0100$$

$$\text{Address Message (M1)} = 1111\ 0110\ 0100$$
**Address Re-creation:**

$$A1 \oplus M1 = A2$$

$$A1 = 0000\ 0000\ 0000\ 0011\ 1111\ 1100\ 0000\ 0001$$

$$M1 = 0000\ 0000\ 0000\ 0000\ 0000\ 1111\ 0110\ 0100$$

$$A2 = 0000\ 0000\ 0000\ 0011\ 1111\ 0011\ 0110\ 0101$$
**Figure 63-1. Relative addressing example****63.6.1.6 Data trace windowing**

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

**63.6.1.7 System bus cycle special cases**

The system bus cycle special cases are shown in this table.

**Table 63-20. System Bus cycle special cases**

| Special case                             | Action                         |
|------------------------------------------|--------------------------------|
| System bus cycle with data error         | Data trace message discarded   |
| System bus cycle completed without error | Cycle captured and transmitted |
| System bus cycle is an instruction fetch | Cycle ignored                  |

### 63.6.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in [Data write and data read messages](#) for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

## 63.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

### 63.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

#### Note

In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in [System bus multi-master tracing](#)).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in [Table 63-21](#) and [Table 63-22](#).

**Table 63-21. Watchpoint message format (fixed length = 18 bits)**

| 8 bits           | 4 bits | 6 bits         |
|------------------|--------|----------------|
| WPHIT (RRRRXXXX) | SRC    | TCODE (001111) |

**Table 63-22. Watchpoint source description**

| Watchpoint source (8-bits) | Watchpoint description                  |
|----------------------------|-----------------------------------------|
| RRRRXXX1 <sup>1</sup>      | External Watchpoint #1 (device defined) |
| RRRRXX1X                   | External Watchpoint #2 (device defined) |
| RRRRX1XX                   | Internal Watchpoint #1 (BWA1 match)     |
| RRRR1XXX                   | Internal Watchpoint #2 (BWA2 match)     |

1. R = reserved for future use (insert 0s).

### 63.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

**Functional description**

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in this figure.

**Table 63-23. Error message format (fixed length = 28 bits)**

| 14 bits | 4 bits | 4 bits | 6 bits         |
|---------|--------|--------|----------------|
| ECODE   | ETYPE  | SRC    | TCODE (001000) |

# Chapter 64

## Nexus Port Controller (NPC)

### 64.1 Introduction

The following figure is a block diagram of the Nexus Port Controller (NPC) block.

**Figure 64-1. Nexus Port Controller Block Diagram**

#### 64.1.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2001 standard. The blocks share input and output ports that interface with the

development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

## 64.1.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of  $\overline{\text{EVTO}}$
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus blocks based on JCOMP input, and power-on reset status
- System clock status indication via MDO[0] following power-on reset
- Controls arbitration for ownership of the Nexus Aurora Link (NAL) in Aurora Link mode

## 64.1.3 Modes of operation

The NPC block uses the JCOMP input, and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

### 64.1.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, JCOMP is not set for Nexus access or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state.

Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset or JCOMP not set for NPC operation only)
- Registers default back to their reset values

### 64.1.3.2 Disabled-Port Mode

In disabled-port mode, output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through  $\overline{\text{EVT0}}$ .

### 64.1.3.3 Reduced-Port Mode

Reduced-port mode (RPM) is entered by asserting the MCKO\_EN bit and negating the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

### 64.1.3.4 Aurora Link Mode

In Aurora Link mode, trace data is transmitted through the Nexus Aurora Link (NAL) instead of the auxiliary port. For SoCs that support a Nexus Aurora Link, the FPM bit in the PCR functions as the Aurora Link enable, leaving RPM as the only available mode for data transmission via the auxiliary port. Aurora Link Mode is enabled by setting the MCKO\_EN and FPM bits and selecting a non-zero value for the ALC\_NUM\_LN bits in the PCR. The MCKO\_DIV value should be set to select a clock frequency equal to the system clock frequency (MCKO\_DIV = 000).

## 64.2 External signal description

### 64.2.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table. Pull information for the JTAG signals can be found in the JTAG chapter.

**Table 64-1. NPC Signal Properties**

| Name   | Port      | Function                                | Reset State         |
|--------|-----------|-----------------------------------------|---------------------|
| EVTO_B | Nexus     | Event Out pin                           | 0b1                 |
| JCOMP  | JTAG      | JTAG Compliancy and TAP Sharing Control | —                   |
| MDO    | Auxiliary | Message Data Out pins                   | 0 <sup>1</sup>      |
| MSEO   | Auxiliary | Message Start/End Out pins              | 0b11                |
| TCK    | JTAG      | Test Clock Input                        | —                   |
| TDI    | JTAG      | Test Data Input                         | —                   |
| TDO    | JTAG      | Test Data Output                        | High Z <sup>2</sup> |
| TMS    | JTAG      | Test Mode Select Input                  | —                   |

1. Following a power-on reset, MDO[0] remains asserted until power-on reset is exited and the system clock achieves lock.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

### 64.2.2 Detailed signal descriptions

This section describes each of the signals listed in [Table 64-1](#) in more detail. Note that the JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

#### 64.2.2.1 EVTO\_B — Event Out

Event Out ( $\overline{\text{EVTO}}$ ) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The  $\overline{\text{EVTO}}$  output of the NPC is generated based on the values of the individual  $\overline{\text{EVTO}}$  signals from all Nexus blocks that implement the signal.

### 64.2.2.2 JCOMP — JTAG Compliancy

The JCOMP signal provides the ability to share the TAP. The NPC TAP controller remains in reset until it is enabled using the JCOMP signal.

### 64.2.2.3 MDO — Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

### 64.2.2.4 MSEO\_B — Message Start/End Out

Message Start/End Out ( $\overline{\text{MSEO}}$ ) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample  $\overline{\text{MSEO}}$  on the rising edge of MCKO.

### 64.2.2.5 TCK — Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

### 64.2.2.6 TDI — Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

### 64.2.2.7 TDO — Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

### 64.2.2.8 TMS — Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

## 64.3 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

The following table shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers.

Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

**Table 64-2. NPC registers**

| Index | Register                            |
|-------|-------------------------------------|
| 0     | Device ID Register (DID)            |
| 126   | Aurora Configuration Register (ACR) |
| 127   | Port Configuration Register (PCR)   |

### 64.3.1 Register descriptions

This section consists of NPC register descriptions.

#### 64.3.1.1 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 64.3.1.2 Instruction register

The NPC block uses a 4-bit instruction register as shown in the following table. The instruction register is accessed via the SELECT\_IR\_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS\_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                                 |   |   |   |
|--------|---------------------------------|---|---|---|
|        | 3                               | 2 | 1 | 0 |
| R      | Previous Instruction Opcode     |   |   |   |
| W      | Instruction Opcode              |   |   |   |

### 64.3.1.3 Nexus Device ID (DID) Register

The device identification register, shown in the following figure, allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the output port.

|       |                            |    |    |    |                            |    |    |    |    |    |                            |    |    |    |    |                          |  |

The PCR, shown in the figure above, is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

The PCR register may be rewritten by the debug tool subsequent to the enabling of the NPC for low power debug support. In this case, the debug tool may set and clear the LP\_DBG and LPn\_SYN bits, but must preserve the original state of the remaining bits in the register. While enabling the low power mode handshake (setting LP\_DBG), the debugger should simultaneously set the LPn\_SYN bit. At the end of low-power mode handshake, the LP\_DBG and LPn\_SYN should be set again if further handshakes between the device and debugger are required.

**NOTE**

The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Supported devices set these bits before a pending entry into low power mode. After reading the bit as set, the debug tool then clears the bit to acknowledge to the device that it may enter the low power mode.<br>0 Low power mode entry acknowledged<br>1 Low power mode entry pending |
| 0   | Reserved |                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 64-8. MCKO\_DIV Values**

| MCKO_DIV[2:0] | MCKO Frequency       |
|---------------|----------------------|
| 0             | SYS_CLK <sup>1</sup> |
| 1             | SYS_CLK/2            |
| 2             | Reserved             |
| 3             | SYS_CLK/4            |
| 4             | Reserved             |
| 5             | Reserved             |
| 6             | Reserved             |
| 7             | Reserved             |

1. SYS\_CLK setting for MCKO frequency should only be used if this setting does not violate the maximum operating frequency of the auxiliary port pins.

### 64.3.1.5 Aurora Configuration Register (ACR)

| Register index: 126 |                 |    |    |    |    |    |    |    |                 |    |    |    |    |    |    |    |
|---------------------|-----------------|----|----|----|----|----|----|----|-----------------|----|----|----|----|----|----|----|
|                     | 31              | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23              | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| R                   | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| W                   |                 |    |    |    |    |    |    |    |                 |    |    |    |    |    |    |    |
| Reset               | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|                     | 15              | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7               | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| R                   | LVDS_RXOPT[3:0] |    |    |    | 0  | 0  | 0  | 0  | LVDS_TXOPT[7:0] |    |    |    |    |    |    |    |
| W                   |                 |    |    |    |    |    |    |    |                 |    |    |    |    |    |    |    |
| Reset               | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0               | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

The ACR, shown in the figure above, is used to configure the RXOPT and TXOPT settings of the LVDS receive and transmit pads.

**Table 64-10. ACR Field Descriptions**

| Bit   | Name            | Description                                                                                         |
|-------|-----------------|-----------------------------------------------------------------------------------------------------|
| 15:12 | LVDS_RXOPT[3:0] | Configures LVDS receive pad options rxopt3, rxopt2, rxopt1, rxopt0                                  |
| 7:0   | LVDS_TXOPT[7:0] | Configures LVDS transmit pad options txopt7, txopt6, txopt5, txopt4, txopt3, txopt2, txopt1, txopt0 |

## 64.4 Functional Description

### 64.4.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the output port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO\_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO\_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

For SoCs that support message transmission via the Nexus Aurora Link, asserting the MCKO\_EN and FPM bits and setting the NUM\_ALC\_LN bits to a non-zero value enables NAL data transmission. Transmission of data via the auxiliary port is enabled only by selecting the RPM configuration in this case.

The following table describes the NPC reset configuration options.

**Table 64-11. NPC reset configuration options**

| Power On Reset status asserted? | JCOMP asserted high | MCKO_EN bit of the Port Configuration Register | FPM bit of the Port Configuration Register | NUM_ALC_LN bits of the PCR > 0 | Configuration     |
|---------------------------------|---------------------|------------------------------------------------|--------------------------------------------|--------------------------------|-------------------|
| yes                             | X                   | X                                              | X                                          | X                              | Reset             |
| no                              | no                  | X                                              | X                                          | X                              | Reset             |
| no                              | yes                 | 0                                              | X                                          | X                              | Disabled          |
| no                              | yes                 | 1                                              | 0                                          | X                              | Reduced Port Mode |
| no                              | yes                 | 1                                              | 1                                          | yes                            | Aurora Link Mode  |

## 64.4.2 Auxiliary Output Port

The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

### 64.4.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the  $\overline{\text{MSE0}}$  functions. The  $\overline{\text{MSE0}}$  pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and  $\overline{\text{MSE0}}$  are sampled on the rising edge of MCKO.

The following figure illustrates the state diagram for  $\overline{\text{MSE0}}$  transfers. All transitions not included in the figure are reserved, and must not be used.

Figure 64-2.  $\overline{\text{MSEO}}$  Transfers (for 2-bit  $\overline{\text{MSEO}}$ )

### 64.4.2.2 Output Messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register on the MDO pins. The device ID message can also be sent out serially through TDO.

Figure 64-3 describes the device ID output message that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

| Message Name                                   | Min. Packet Size (bits) | Max Packet Size (bits) | Packet Type | Packet Name | Packet Description                                                |
|------------------------------------------------|-------------------------|------------------------|-------------|-------------|-------------------------------------------------------------------|
| Device ID Message                              | 6                       | 6                      | fixed       | TCODE       | Value = 1                                                         |
|                                                | 32                      | 32                     | fixed       | ID          | DID register contents                                             |
| Aurora Link Overrun Error Message <sup>1</sup> | 6                       | 6                      | fixed       | TCODE       | Value = 8                                                         |
|                                                | 4                       | 4                      | fixed       | SRC         | Nexus Aurora Link SRC value. Set during SoC integration via plug. |
|                                                | 5                       | 5                      | fixed       | ECODE       | Value = 01000. Error code indicating overrun of NAL FIFO.         |

NOTES:

- <sup>1</sup> The Aurora Link Overrun Error Message only transmits when there is a NAL overrun in Nexus Aurora Link Mode. This message is not valid in modes where data is transmitted via the auxiliary port.

**Figure 64-3. NPC output messages**

### 64.4.2.3 Rules of Message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. The following figure shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

**Figure 64-4. Transmission Sequence of Messages**

### 64.4.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 test access port (TAP) for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller. .

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in [Figure 64-6](#) . The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in [Figure 64-7](#).

The instructions implemented by the NPC TAP controller are listed in the following table. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

**Table 64-12. Implemented Instructions**

| Instruction Name | Private/Public | Opcode | Description                                                                       |
|------------------|----------------|--------|-----------------------------------------------------------------------------------|
| NEXUS-ENABLE     | public         | 0x0    | Activate Nexus controller state machine to read and write NPC registers.          |
| BYPASS           | private        | 0xF    | NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset. |

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

**Figure 64-5. Shifting Data Into Register**

### 64.4.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or setting JCOMP to a value other than the NPC enable encoding resets the NPC TAP controller. When not in power-on reset, the NPC TAP controller is enabled by driving JCOMP with the NPC enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 64-6. IEEE 1149.1-2001 TAP Controller State Machine**

### 64.4.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the output port or shifted out serially by accessing the Nexus Device ID register through the TAP.

Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled for auxiliary port mode. Transmission of the device identification message serially via the TAP is achieved by performing a read of the register contents as described in [Selecting a Nexus Client Register](#). The device identification message is not transmitted on the Aurora Link in Aurora Link mode, and it can be retrieved only via the TAP in that mode.

### 64.4.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 64-7](#), transitions to the REG\_SELECT state. The Nexus controller has three states: idle, register select, and data access. [Table 64-13](#) illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 64-7. NEXUS Controller State Machine

Table 64-13. Loading NEXUS-ENABLE instruction

| Clock | TMS | IEEE 1149.1 State | Nexus State | Description                                   |
|-------|-----|-------------------|-------------|-----------------------------------------------|
| 0     | 0   | RUN-TEST/IDLE     | IDLE        | IEEE 1149.1-2001 TAP controller in idle state |
| 1     | 1   | SELECT-DR-SCAN    | IDLE        | Transitional state                            |
| 2     | 1   | SELECT-IR-SCAN    | IDLE        | Transitional state                            |

Table continues on the next page...

**Table 64-13. Loading NEXUS-ENABLE instruction  
(continued)**

| Clock  | TMS | IEEE 1149.1 State | Nexus State | Description                                                                                                                   |
|--------|-----|-------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| 3      | 0   | CAPTURE-IR        | IDLE        | Internal shifter loaded with current instruction                                                                              |
| 4      | 0   | SHIFT-IR          | IDLE        | TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction. |
| 3 TCKS |     |                   |             |                                                                                                                               |
| 8      | 1   | EXIT1-IR          | IDLE        | Last bit of instruction shifted in                                                                                            |
| 9      | 1   | UPDATE-IR         | IDLE        | NEXUS-ENABLE loaded into instruction register                                                                                 |
| 10     | 0   | RUN-TEST/IDLE     | REG_SELECT  | Ready to be read/write Nexus registers                                                                                        |

#### 64.4.3.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG\_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following table. The read/write control bit is set to 1 for writes and 0 for reads.

| MSB                  | LSB |
|----------------------|-----|
| 7-bit register index | R/W |

**Figure 64-8. IEEE 1149.1 Controller Command Input**

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the JTAG shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

**Table 64-14. Write to a 32-Bit Nexus Client Register**

| Clock   | TMS | IEEE 1149.1 State | Nexus State | Description                                                                                          |
|---------|-----|-------------------|-------------|------------------------------------------------------------------------------------------------------|
| 0       | 0   | RUN-TEST/IDLE     | REG_SELECT  | IEEE 1149.1-2001 TAP controller in idle state                                                        |
| 1       | 1   | SELECT-DR-SCAN    | REG_SELECT  | First pass through SELECT-DR-SCAN path                                                               |
| 2       | 0   | CAPTURE-DR        | REG_SELECT  | Internal shifter loaded with current value of controller command input.                              |
| 3       | 0   | SHIFT-DR          | REG_SELECT  | TDO becomes active, and write bit and 6 bits of register index shifted in.                           |
| 7 TCKs  |     |                   |             |                                                                                                      |
| 11      | 1   | EXIT1-DR          | REG_SELECT  | Last bit of register index shifted into TDI                                                          |
| 12      | 1   | UPDATE-DR         | REG_SELECT  | Controller decodes and selects register                                                              |
| 13      | 1   | SELECT-DR-SCAN    | DATA_ACCESS | Second pass through SELECT-DR-SCAN path                                                              |
| 14      | 0   | CAPTURE-DR        | DATA_ACCESS | Internal shifter loaded with current value of register                                               |
| 15      | 0   | SHIFT-DR          | DATA_ACCESS | TDO becomes active, and outputs current value of register while new value is shifted in through TDI  |
| 31 TCKs |     |                   |             |                                                                                                      |
| 47      | 1   | EXIT1-DR          | DATA_ACCESS | Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.                     |
| 48      | 1   | UPDATE-DR         | DATA_ACCESS | Value written to register                                                                            |
| 49      | 0   | RUN-TEST/IDLE     | REG_SELECT  | Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register. |

#### 64.4.4 Nexus JTAG Port Sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

#### 64.4.5 MCKO Control

MCKO is an output clock to the development tools used for the timing of  $\overline{\text{MSEO}}$  and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO\_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO\_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO\_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO\_GT bit in the PCR is written to a logic 1.

### 64.4.6 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the  $\overline{\text{EVTO}}$  output between all Nexus clients that produce an  $\overline{\text{EVTO}}$  signal. The NPC assumes incoming  $\overline{\text{EVTO}}$  signals will be asserted for one system clock period. After receiving a single clock period of asserted  $\overline{\text{EVTO}}$  from any Nexus client, the NPC latches the result, and drives  $\overline{\text{EVTO}}$  for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives  $\overline{\text{EVTO}}$  for two system clock periods.  $\overline{\text{EVTO}}$  sharing is active as long as the NPC is not in reset.

### 64.4.7 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus blocks. If JCOMP is negated, an internal reset is asserted, indicating that all Nexus modules should be held in reset.

### 64.4.8 System Clock Locked Indication

Following a power-on reset, MDO[0] can be monitored to provide the lock status of the system clock. MDO[0] is driven to a logic 1 until the system clock achieves lock after exiting power-on reset. Once the system clock is locked, MDO[0] is negated and tools may begin Nexus configuration. Loss of lock conditions that occur subsequent to the exit of power-on reset and the initial lock of the system clock do not cause a Nexus reset, and therefore do not result in MDO[0] driven high.

### 64.4.9 Data Transmission via Nexus Aurora Link

The NPC supports data transmission over a high-speed serial Nexus Aurora Link (NAL). The NPC's role in Aurora Link data transmission is to route trace data to the NAL while continuing to manage arbitration between Nexus clients for the right to transmit data. In

addition, the NPC monitors the NAL transmit queue and will halt further data transmission from Nexus clients if the queue is in danger of an overrun condition. In the event of an overrun condition, the NPC transmits a standard Nexus error message.

Once the PCR is configured for Aurora Link Mode (MCKO\_EN bit set, FPM bit set, ALC\_NUM\_LN set to non-zero value), the NPC waits for the NAL to acknowledge it is ready to receive data before starting data transmission. All data transmitted in Aurora Link mode is transmitted in frames, with each frame consisting of 8192 bytes of data. The first beat of each frame is accompanied by the assertion of the start of frame control signal, and the last beat of each frame is accompanied by the assertion of the end of frame control signal. Each beat of valid NAL data from the NPC is also accompanied by the assertion of the NAL data valid message signal.

Data received by the NAL is held in a FIFO until it can be sent out on the Aurora Link. The NPC keeps track of the NAL FIFO fill level. To help prevent an overrun of the NAL FIFO, the NPC holds off further grants to all clients if the NAL FIFO is filled above the watermark level. In the event that the NAL FIFO is overrun with data, the NPC transmits its FIFO overrun error message shown in [Figure 64-3](#).

## 64.5 Initialization/Application Information

### 64.5.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.

2. Read the register value with a second pass through the SELECT-DR-SCAN path.  
Data shifted in is ignored.

See the IEEE-ISTO 5001-2001 standard for more detail.

# Chapter 65

## Nexus Aurora Link (NAL)

### 65.1 Introduction

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. The following figure details the NAL block diagram. The number of lanes,  $n$ , is 2.

**Figure 65-1. NAL block diagram**

Debug data in the Nexus format from multiple clients is collected by the Nexus Port Controller (NPC) ; messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS

drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NPC/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. The table below lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

**Table 65-1. NAL and NAP feature summary**

| Sub-Component                | Feature                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 65.2 Transmit operation

During transmit operation, the NPC collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NPC places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol

Each payload is transferred from the NPC to the NPC/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each end symbol packet transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

**NOTE**

Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

### 65.3 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

### 65.4 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

**Note**

Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL\_GCR).

The following steps enable static training:

1. Write 80000000h to NAL\_GCR
2. Write 00000000h to NAL\_GCR
3. Write 80783C0Fh to NAL\_TCR
4. Write 80000000h to NAL\_GCR
5. Write 00000000h to NAL\_GCR
6. Write A0408000h to NPC\_PCR

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage.

Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

## **65.5 Clock compensation considerations**

The Aurora Protocol Specification describes clock compensation as a means for the link to compensate for clock rate differences between the transmitter and receiver. The spec requires that a clock compensation be inserted at a minimum every 10000 symbol pairs; this should allow the link to accommodate up to a 200 ppm difference in clock rates.

Due to the fact that the NAL is restricted to only inserting clock-compensation sequences after an end-of-frame, it may not be possible to always meet the Aurora spec requirement. However, there are ways to control the framing of data through the link and insure that satisfactory performance is maintained. There are two types of scenarios that can prevent an adequate number of clock compensation sequences from being generated: the sparse data case and the unframed data case. In the sparse data case, there are long periods of time when no data is flowing through the link; no data means no frames. In the unframed case, there is plenty of data, but this data is not framed, and so again, clock-compensation never gets a chance to make it out.

The unframed case is simplest to address. The NPC can either operate in framed or unframed mode. In unframed mode, an end-of-frame is only injected when the NPC runs out of data (as soon as new data is collected, it is sent out accompanied with a start-of-frame; if the NPC is configured in this mode, the clock-compensation spec can easily be violated. However, in framed mode, an end-of-frame/start-of-frame pair is injected after every 256 data transmissions. Here, each frame consists of 256 x AW symbol pairs. Inside the APE, a clock-compensation counter keeps track of how much data has been transmitted to the ALC since the last clock-compensation sequence; once the counter hits 7424, clock-compensation will be sent on the next end-of-frame.

On the other hand, even if the NPC is in framing mode, there is little that can be done if the NPC has no data to send. In the sparse data scenario, the NAL could end up transmitting idles for an undetermined number of cycles while waiting for the NPC to

provide new data. However, a user can get around this problem by insuring that the NPC always has at least some minimal amount of data to send. There are several ways to do this:

- If full-duplex infrastructure is available, then the simplest thing to do is for the debugger to monitor the TX data stream from the NAL for long idle periods. If the link has been idle for longer than some minimal amount of time (say 8000 symbol pairs), then the debugger could send in a read request through the aurora-in RX port -- a quick NRR read of the dev\_id register would be ideal for this purpose. The NPC would then return the requested data, accompanied by a start-of-frame/end-of-frame pair, which the NAL could then tag with clock-compensation. See the NPC block guide for more details on aurora-in NRR access.
- If full-duplex is not available, then the debugger could still force the NPC to send the dev\_id message by going through the JTAG/SAP port and setting the NPC SRESET bit. Reinitializing the NPC puts it back into its startup state, wherein it will invariably send device ID before doing anything else. The only drawbacks to this approach are its long latency (going through JTAG) and the fact that NPC must be correctly reconfigured after every SRESET.
- Another approach is to use periodic watchpoints to insure that the data stream never falls completely silent for more than some predefined count. Most nexus clients, including the NPC itself, can generate a watchpoint sync message based on an external or internal trigger. By hooking one of these triggers up to a counter (a performance-monitor, event-processing unit debug counter can be used for this purpose), we can insure that, even if there is no other trace data traffic, there will at least be periodic watchpoint messages which can be used to trigger clock compensation. The drawback here is that it requires devoting one of the debug counters for clock compensation, but this may not always be a problem: one of the proposed methods of correlating nexus timestamps from different asynchronous domains is to use the same sort of periodic sync trigger to force all asynchronous clients to send a stamped watchpoint message at (roughly) the same time. This asynchronous sync trigger can also be used for clock compensation.

## 65.6 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. These registers are not memory-mapped and can only be accessed via the JTAG interface.

**Table 65-2. NAL memory map**

| Offset | Register name                           | Width (in bits) | Access | Reset value |
|--------|-----------------------------------------|-----------------|--------|-------------|
| 0h     | NAL General Status Register (NAL_GSR)   | 32              | R      | See section |
| 8h     | NAL General Control Register (NAL_GCR)  | 32              | R/W    | 0000_0000h  |
| Ch     | NAL Training Control Register (NAL_TCR) | 32              | R/W    | 0000_0000h  |

## 65.6.1 Nexus Aurora Link General Status Register (NAL\_GSR)

The NAL\_GSR is a read only register that describes the status of the NAL. See the chip-specific NAL information for the NAL\_GSR reset value.

|     |    |    |       |    |    |    |    |    |    |    |    |    |          |    |    |    |

**Table 65-3. NAL\_GSR field descriptions (continued)**

| Field | Description                                      |
|-------|--------------------------------------------------|
| 0     | Aurora Status.                                   |
| AS    | 0 Aurora is not enabled.<br>1 Aurora is enabled. |

## 65.6.2 NAL General Control Register (NAL\_GCR)

The NAL\_GCR configures the behavior of the APE. It can be programmed to reset the Aurora channel, or to configure simplex/duplex initialization and to enable debug features.

## Chapter 66

# Nexus Aurora PHY (NAP)

### 66.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Port Controller (NPC) Port Configuration Register (NPC\_PCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.

Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

#### Note

The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

The following figure shows a high level block diagram of the High Speed Nexus Interface and the NAP.

Figure 66-1. High speed Nexus interface block diagram

### 66.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

### 66.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NPC\_PCR setting; functional operation is enabled by the NPC.

### 66.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

### 66.1.2.2 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

### 66.1.2.3 Transmit

During Nexus trace output operation, it is the responsibility of the NPC to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 2 transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

## 66.2 External signal description

The external signals of the NAP are listed in the following table. Each of the NAP signals consists of a positive and negative differential pair.

**Table 66-1. NAP signals**

| Signal Name           | Direction | Description                              |
|-----------------------|-----------|------------------------------------------|
| PHY_CLOCK (CLKP/CLKN) | Input     | NAP clock input from external debug tool |

*Table continues on the next page...*

**Table 66-1. NAP signals (continued)**

| Signal Name          | Direction | Description            |
|----------------------|-----------|------------------------|
| TX Data0 (TX0P/TX0N) | Output    | NAP Tx data for lane 0 |
| TX Data1 (TX1P/TX1N) | Output    | NAP Tx data for lane 1 |

## 66.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NPC\_PCR which is described in the NPC Chapter.

## 66.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

### 66.4.1 Data symbol character accumulator

The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

### 66.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

The following figure shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

Figure 66-2. Serializer timing diagram

### 66.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

## 66.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NPC\_PCR to configure the number of lanes and LVDS pads.

# Chapter 67

## Cyclic Redundancy Check (CRC) Unit

### 67.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

### 67.2 Main features

- 3 contexts for the concurrent CRC computation are supported
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- Three hard-wired polynomials (CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

#### 67.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN

## Block diagram

- CRC-16-CCITT
- CRC-32 Ethernet (see note below)

### NOTE

Although the CRC-32 Ethernet polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the Ethernet protocol (IEEE 802).

## 67.3 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to [Main features](#) for number of contexts in this module.

Figure 67-1. CRC top level diagram

## 67.4 External signal description

The CRC module does not generate any external signals.

### 67.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers

- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:

- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC\_CFG and CRC\_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC\_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC\_CSTAT or CRC\_OUTP registers immediately following (next clock cycle) a write operation to the CRC\_CSTAT, CRC\_INP, or CRC\_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

## 67.5 CRC memory map and registers

CRC memory map

|       | This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation. |

**67.6 Functional description**

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC\_INP).

The data stream is generally executed by  $n$  concurrent DMA data transfers (mem2mem) where  $n$  is less or equal to the number of contexts.

The standard generator polynomials are given in [Equation 56 on page 2681](#), [Equation 57 on page 2681](#), and [Equation 58 on page 2681](#) for the CRC computation of each context. Two separate registers are available: CRC\_INP for writing data and CRC\_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

**Equation 56. CRC8 VDA CAN**

$$x^{16} + x^{12} + x^5 + 1$$

**Equation 57. CRC-CCITT (x.25 protocol)**

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

**Equation 58. CRC-32 (Ethernet protocol)**

**Figure 67-2. CRC-CCITT engine concept scheme**

The initial seed value of the CRC can be programmed by initializing the CRC\_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in [Figure 67-2](#) for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in [Input Register \(CRC\\_INP<sub>n</sub>\)](#), is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC\_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in [Figure 67-3](#).

Figure 67-3. CRC computation flow

## 67.7 Use cases

### 67.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has  $n$  channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context  $x$ , channel  $x$ ) by CPU
2. Payload transfer from the MEM to the CRC module (CRC\_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel  $x$ )
3. CRC signature copy from the CRC module (CRC\_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel  $x$ )

Figure 67-4. DMA-CRC transmission sequence

### 67.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

#### Use cases

- SWAP\_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP\_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP\_BITWISE has priority over SWAP\_BYTEWISE when both are applied together.
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP\_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP\_BITWISE bit.

# Chapter 68

## Memory Error Management Unit (MEMU)

### 68.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- System RAM
- Peripheral RAM
- Flash memory

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single Bit error in the data part that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Multiple bit error that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same

word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.

- Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the chip-specific MEMU information.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral RAM ECC
- Flash memory ECC

Each instance has two reporting tables. Correctable errors are reported in one table, and the uncorrectable errors are reported in the other.

See [Design overview](#) for the reporting block details.

## 68.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per the following reporting blocks (the number of error sources are chip-specific; see the chip-specific MEMU information):
  - System RAM ECC and MBIST
  - Peripheral RAM ECC
  - Flash memory ECC
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral RAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.

- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

### 68.3 Block diagram

Figure 68-1. MEMU block diagram

### 68.4 Design overview

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See [Handling overflows \(Multiple error reporting\)](#), for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

### 1. Synchronizer block

For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

### 2. Error Processing block

This block is used to process the incoming errors coming from the device.

- Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.
- All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.
- While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.

- While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique
- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles ( $\leq 5$  unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

### 3. Reporting table

This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. `..._CERR_STS` or `..._UNCERR_STS`). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

The reporting table sizes are chip-specific; see the chip-specific MEMU information.

### 4. Register block

The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 68-2. MEMU error buffer uniqueness check flow chart

Figure 68-3. MEMU reporting table uniqueness check flow chart

## 68.5 External signal description

MEMU has no external signals.

## 68.6 Memory map and register definition

This section describes the registers on this module.

### 68.6.1 Overview

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

#### NOTE

The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

#### NOTE

The memory map in this section shows all the possible registers on this module and the associated offsets (which vary depending on the number of registers actually implemented). The actual availability, number and addresses of registers, and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                          |
| 16<br>SWR         | Software Reset bit.<br>Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle.<br><br>0 No reset.<br>1 Reset asserted. |
| 17–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                          |

**68.6.3 Error flag register (MEMU\_ERR\_FLAG)**

Bits in the ERR\_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR\_CE, PR\_UCE, F\_CE, F\_UCE, SR\_CE, and SR\_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR\_UCO, SR\_CEO, F\_UCO, F\_CEO, PR\_UCO, and PR\_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Bits SR\_UCO, SR\_CEO, F\_UCO, F\_CEO, PR\_UCO, and PR\_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Access: User read/write

**MEMU\_ERR\_FLAG field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. |
|       | This field will also be set to 1 if the input ASYNC FIFOs overflow.                                                                                                                                                                                                                                                                                |
| 0     | No Overflow.                                                                                                                                                                                                                                                                                                                                       |
| 1     | Overflow in the internal error processing buffer detected.                                                                                                                                                                                                                                                                                         |

**68.6.4 Debug register (MEMU\_DEBUG)**

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Access: User read/write

Address: 0h base + Ch offset = Ch

|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>OFLW | Overflow Bit.<br>Each bit corresponds to an error source and is asserted when any of the conditions mentioned in <a href="#">Handling overflows (Multiple error reporting)</a> occurs. |

## 68.7 Functional description

In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

### 68.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = '1' for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:

1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (i.e. duplicate entries).

### 68.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

|                                                                                                                  |       | Address [A:0] | Bad Bit [B:0] | Valid |
|------------------------------------------------------------------------------------------------------------------|-------|---------------|---------------|-------|

| .....                                                                                                            |       |               |               |       |
|                                                                                                                  | N     |               |               |       |
|                                                                                                                  | 1     |               |               |       |
| Uncorrectable                                                                                                    |       | (B+1){1'b1}   |               |       |
| Flags                                                                                                            |       |               |               |       |
| Overflow Source Bits [C:0]                                                                                       |       |               |               |       |
| Address - The address associated with the table entry.                                                           |       |               |               |       |
| Bad Bit - As needed a binary encoding of the single bit error that is false.                                     |       |               |               |       |
| Valid - A user clearable bit that indicates that the row is valid                                                |       |               |               |       |
| Flags - Indications of important events that occurred.                                                           |       |               |               |       |
| Overflow Source Bits - A one hot encoding of the Source channel or channels that resulted in the overflow event. |       |               |               |       |

**Figure 68-4. Generic representation of the reporting table of one MEMU reporting block**

### 68.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Error buffer overflow—More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
  - More than 2 errors detected at same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not "guarantee" that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Error Overflow—Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
  - An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
3. The Overflows will be stored in the bit-wise order i.e., if the error bit 31 reports an error, the bit 31 of the overflow register will be set to '1'.

# Chapter 69

## Fault Collection and Control Unit (FCCU)

### 69.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of hardware checker (for example, RCCU) results
- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
  - No reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase

- The FCCU's configuration is lockable:
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into FCCU\_TRANS\_LOCK register (that is, other than 0xBC). Key to lock the FCCU permanently is 0xFF, written in the FCCU\_PERMNT\_LOCK register.
- One of the error out pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.
- After power on, the EOUT signals have high impedance.<sup>1</sup> They show operational state only on software request.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T<sub>min</sub>, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).
- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 CLKSAFE cycles.

The FCCU circuitry is checked at the start-up by the self-checking procedure. The FCCU is operative with the default configuration immediately after the completion of the self-checking procedure. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

### 69.1.1 Acronyms and abbreviations

| Term  | Description                  |
|-------|------------------------------|
| CF    | Critical fault               |
| CPU   | Central processing unit      |
| EOUT  | Error out                    |
| FOSU  | FCCU output supervision unit |
| FSM   | Finite state machine         |
| INTC  | Interrupt controller         |
| intf  | Interface                    |
| IRQ   | Interrupt request            |
| MC_ME | Mode entry module            |

*Table continues on the next page...*

1. Actual value depends on device specific setting at pad level.

| Term | Description                     |
|------|---------------------------------|
| NCF  | Noncritical fault               |
| NMI  | Nonmaskable interrupt           |
| RCC  | Redundancy control checkers     |
| RCCU | Redundancy control checker unit |
| SoC  | System-on-chip                  |
| STCU | Self-test control unit          |
| SW   | Software                        |
| WKPU | Wake-up unit                    |

## 69.2 Main features

- Management of non-critical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)
- External reaction (fault state): EOOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
  - long functional reset request pulse
  - short functional reset request pulse
  - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock

## 69.3 Block diagram

The following figure is a top-level diagram of the FCCU module.

Figure 69-1. FCCU block diagram

This table describes the FCCU submodules.

Table 69-1. FCCU submodules

| Submodule                              | Description                                                                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REG intf                               | Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers                                                      |
| HNSHK blocks (master and slave blocks) | Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock) |
| FSM unit                               | Implements the main functions of the FCCU. The FSM also includes the: <ul style="list-style-type: none"><li>• Watchdog timer (WDG)</li><li>• Alarm timer (ALRT)</li></ul>           |
| FAULT intf                             | Implements the interface for the fault conditioning and management                                                                                                                  |
| EOUTx units                            | Implement the output stage to manage the EOUT interfaces                                                                                                                            |

## 69.4 Signal description

### 69.4.1 Signals

This table describes the signals on the boundary of FCCU.

| Signal                     | Direction | Function                                                                                                                                                                                                                             | Active level | Clock              |
|----------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------------|
| <b>Clock and reset</b>     |           |                                                                                                                                                                                                                                      |              |                    |
| CLKSYS                     | Input     | System Clock—Supplies the primary clock.                                                                                                                                                                                             | Rising edge  | —                  |
| CLKSAFE0                   | Input     | Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).                                                                   | Rising edge  | —                  |
| CLKSAFE1                   | Input     | Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).                                                                   | Rising edge  | —                  |
| <b>EOUT interface</b>      |           |                                                                                                                                                                                                                                      |              |                    |
| EOUT[1:0]                  | Output    | Error Output—Indicate to off-chip logic that a fault has occurred. For more information, see <a href="#">EOUT interface</a> .                                                                                                        | Programmable | CLKSAFE0, CLKSAFE1 |
| <b>WKPU interface</b>      |           |                                                                                                                                                                                                                                      |              |                    |
| NMIWKPU                    | Input     | WKPU Nonmaskable Interrupt Request—Receives nonmaskable interrupt requests from the WKPU module.                                                                                                                                     | Low          | CLKSYS             |
| WAKEWKPU                   | Output    | Wake WKPU—Wakes the WKPU module to bring the chip out of dormant state when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).                            | High         | CLKSAFE0, CLKSAFE1 |
| <b>Interrupt interface</b> |           |                                                                                                                                                                                                                                      |              |                    |
| NMIOUT                     | Output    | Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]). | Low          | CLKSYS             |

## 69.5 Functional description

### 69.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- **HW recoverable fault:** the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- **SW recoverable fault:** the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

This table describes the types of resets.

| Reset type       | Function                                                                |
|------------------|-------------------------------------------------------------------------|
| Destructive      | Initializes the entire chip as the result of a power-failure condition. |
| Long functional  | Initializes the digital circuitry except for FCCU and STCU2.            |
| Short functional | Initializes the digital circuitry except for OCOTP, FCCU, and STCU2.    |

For more information on each type of reset, see the MC\_RGM and reset chapters.

### 69.5.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- **Configuration:** Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU\_TRANS\_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU\_PERMNT\_LOCK register.

After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration by writing either to TRANS\_LOCK or PERMT\_LOCK, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

All pending faults that occur during Configuration state result in both of the following:

- Highest-priority state transition
- Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- **Normal:** This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

- unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
- unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
- masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.
- Fault: FCCU moves into Fault state when one of the following condition occurs:
  - timeout related to a noncritical fault when FCCU is in Alarm state
  - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed only to the Safety Core

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

Figure 69-2. FCCU state diagram

### 69.5.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any non-critical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

## 69.5.4 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a non-critical FAULT management (ALARM state), see [Figure 69-3](#) and [Figure 69-4](#), is as follows:

- non-critical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)
  - FCCU state transition ALARM → NORMAL

**Figure 69-3. Non-critical FAULT (ALARM state) recovery (a)**

**Figure 69-4. Non-critical FAULT (ALARM state) recovery (b)**

A typical sequence related to a FAULT management (ALARM → FAULT state), see [Figure 69-5](#), is as follows:

- non-critical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT
  - NMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
  - system state transition: SAFE → RUN

**Figure 69-5. FAULT (ALARM → FAULT state) recovery**

### 69.5.5 NMI/WKPU interface

NMIOUT is connected to all processor cores on the chip but is masked when any one of the following is true:

- An FCCU asynchronous reset is in progress.
- The chip is in RESET mode.
- The chip has automatically entered DRUN mode from RESET mode and software has not yet requested another mode.

This figure shows the logical scheme.

Figure 69-6. NMI/WKPU scheme

### 69.5.6 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR. This feature is optionally programmable using MC\_RGM.

## Functional description

**Figure 69-7. STCU-FCCU (case 1)**

**Figure 69-8. STCU-FCCU (case 2)**

**Figure 69-9. STCU-FCCU (case 3)**

### 69.5.7 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT[1:0]) as a failure indication to the external world. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (FCCU\_CFG[FOM]):

- Dual-Rail
- Time-Switching

- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

| Attribute          | Field                         | Setting used in the example diagrams and tables that follow |
|--------------------|-------------------------------|-------------------------------------------------------------|
| Switching mode     | FCCU_CFG[SM]                  | Slow                                                        |
| Polarity selection | FCCU_CFG[PS]                  | For the faulty indication, EOUT1 is high, and EOUT0 is low. |
| Derived prescaler  | FCCU_CFG[FOPE], FCCU_CFG[FOP] | 0                                                           |

With a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time  $T_{min}$ , even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked when software has set the error signal to high. During the  $T_{min}$  by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the  $T_{min}$  interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within  $T_{min}$  after a first one, the  $T_{min}$  counter is restarted.

These resets influence the state of the failure indication pins:

- Power on reset
- Destructive reset (including when an FOSU timeout occurs due to FCCU failing to react)
- Chip pin reset (RESET\_B)

Other resets should not influence the state of the failure indication pins.

**NOTE**

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

**NOTE**

FCCU remains in Normal state when a fault is disabled; therefore, <i>NA</i> (not applicable) appears in the following table.

**NOTE**

The following table is valid only after software has enabled the EOUT signals (FCCU\_CFG[FCCU\_SET\_AFTER\_RESET]).

**Table 69-2. FCCU error pin behavior on state transitions**

| Fault signaling state | Transition from Normal to Fault state |                  |           | Normal+Configuration states |                  |           | Transition from Normal to Alarm state |                  |           |
|-----------------------|---------------------------------------|------------------|-----------|-----------------------------|------------------|-----------|---------------------------------------|------------------|-----------|
|                       | with Fault disabled   enabled         |                  |           |                             |                  |           | with Fault disabled   enabled         |                  |           |
|                       | Internal error pin                    | Error pin enable | Error pad | Internal error pin          | Error pin enable | Error pad | Internal error pin                    | Error pin enable | Error pad |
| Disabled              | NA   OK                               | NA   1           | NA   OK   | OK                          | 1                | OK        | NA   OK                               | NA   1           | NA   OK   |
| Enabled               | NA   NOK                              | NA   1           | NA   NOK  | OK                          | 1                | OK        | NA   OK                               | NA   1           | NA   OK   |

**NOTE**

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

### 69.5.7.1 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in [Table 69-3](#) and the related timing diagram is given in [Figure 69-10](#) and [Figure 69-11](#).

**Table 69-3. Dual-rail encoding**

| Logical state | Dual-rail encoding (output pins EOUT[1:0]) | Note     |
|---------------|--------------------------------------------|----------|
| non-faulty    | 10                                         | toggling |
| non-faulty    | 01                                         |          |
| faulty        | 00                                         | toggling |
| faulty        | 11                                         |          |

*Table continues on the next page...*

**Table 69-3. Dual-rail encoding (continued)**

| Logical state | Dual-rail encoding (output pins EOUT[1:0]) | Note        |
|---------------|--------------------------------------------|-------------|
| reset         | Hi impedance <sup>1</sup>                  | no toggling |
| configuration | same as NORMAL                             | toggling    |

1. Final value depends on the SoC setting at pad level.

As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as "high impedance".

### Note

Figure 69-10 and Figure 69-11 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

**Figure 69-10. Dual-rail protocol (slow switching mode)****Figure 69-11. Dual-rail protocol (fast switching mode)**

### 69.5.7.2 Time-switching protocol

The encoding scheme is given in [Table 69-4](#) and the related timing diagram is given in [Figure 69-12](#).

**Table 69-4. Time-switching encoding**

| Logical state | Time-switching encoding (output pins EOUT[1:0]) | Note        |
|---------------|-------------------------------------------------|-------------|
| non-faulty    | 10                                              | toggling    |
| non-faulty    | 01                                              |             |
| faulty        | 10                                              | no toggling |
| reset         | high-Z <sup>1</sup>                             | no toggling |
| configuration | same as NORMAL                                  | toggling    |

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency specified by the CFG[FOP].

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".<sup>2</sup>

**Note**

[Figure 69-12](#) is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

**Figure 69-12. Time-switching protocol**

2. Actual value depends on device specific settings at pad level.

### 69.5.7.3 Bi-stable protocol

The encoding scheme is given in [Table 69-5](#) and the related timing diagram is given in [Figure 69-13](#).

**Table 69-5. Bi-stable encoding**

| Logical state | Bi-stable encoding (output pins EOUT[1:0]) | Note        |
|---------------|--------------------------------------------|-------------|
| non-faulty    | 01                                         | no toggling |
| faulty        | 10                                         | no toggling |
| reset         | high-Z <sup>1</sup>                        | no toggling |
| configuration | same as NORMAL                             | no toggling |

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".<sup>3</sup>

#### Note

[Figure 69-13](#) is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

**Figure 69-13. Bi-stable protocol**

### 69.5.8 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

3. Actual value depends on device specific settings at pad level.

## 69.6 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don't read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don't write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don't write to FCCU\_TRANS\_LOCK or FCCU\_PERMNT\_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU\_TRANS\_LOCK and FCCU\_PERMNT\_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible NCF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

**FCCU memory map**

### 69.6.1 Control (FCCU\_CTRL)

The FCCU\_CTRL register allows the following operations to be executed:

- moving the FCCU state from the NORMAL state into the CONFIG state
- moving the FCCU state from the CONFIG state into the NORMAL state
- reading or to clear the NCF status register
- reading the FCCU FSM status register
- reading or to clear the FCCU freeze registers
- reading the ALARM timer
- reading the Watchdog timer

Some critical operations require a key as defined in the FCCU\_CTRLK register.

Address: 0h base + 0h offset = 0h

**69.6.2 Control Key (FCCU\_CTRLK)**

The FCCU\_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU\_CTRLK register.
2. Write the FCCU\_CTRL register (operations OP1 or OP2 ).

**NOTE**

The FCCU\_CTRLK and FCCU\_CTRL registers must be written with consecutive instructions. Both registers must be written as 32-bit values. Do not use read-modify-write instructions, such as bit field instructions, to modify these registers.

The FCCU\_CTRLK register is not readable, a 0000\_0000h value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Address: 0h base + 4h offset = 4h

69.6.3 Configuration (FCCU\_CFG)

Defines the global configuration for FCCU.

NOTE

This register is writable only when FCCU is in Configuration state.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the EOUT fault-indication timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the EOUT fault-indication timer expires (FCCU stops indicating a fault on the EOUT signals).

Address: 0h base + 8h offset = 8h

\* Notes:

- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

### FCCU\_CFG field descriptions

| Field                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–6<br>Reserved           | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 7<br>FCCU_SET_AFTER_RESET | <p>This bit controls the enable of the EOUT signals after reset lifts. After power-on the EOUT signals shall be in a high-impedance state.</p> <p><b>NOTE:</b> The actual value depends on the chip settings at the pad level. They will go to normal state only on software request, that is, this field is set to 1. It is software's responsibility to write 1 to this field; otherwise, the error pin stays in a high-impedance state after reset lifts and FCCU is not functioning.</p> <p>0 FCCU's error indication stops functioning and the EOUT signals are in a high-impedance state (the actual value depends on the chip settings at the pad level).</p> <p>1 Write to start FCCU functioning.</p>                                                                                                                                                                                                                                 |
| 8–9<br>FCCU_SET_CLEAR     | <p>Error pin state can be controlled by these bits<br/>These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z.</p> <p><b>NOTE:</b> Actual value depends on the SoC settings at pad level.</p> <p>Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves Configuration state. After this is in effect, software maintains priority over FCCU FSM except for the case of 11 mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10.</p> <p>00 FCCU acts independent of above software control</p> <p>01 Both error signals are set to low.</p> <p>10 FCCU acts independent of above software control.</p> <p>11 Both error signals are set to high (write not possible when FCCU is already in the T_min timer phase or if FCCU enters Fault state by capture of a fault).</p> |
| 10–11<br>Reserved         | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**FCCU\_CFG field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>The following equation defines the signaling frequency in terms of the CLKSAFE frequency (<math>\text{CLKSAFE}_{\text{freq}}</math>) and the derived prescaler:</p> $\text{EOUT}_{\text{freq}} = \text{CLKSAFE}_{\text{freq}} / ((\{\text{FOPE}, \text{FOP}\} + 1) \times 2 \times 2048)$ <p>The following values and meanings are for the derived (7-bit) prescaler, not FOP alone. The meanings show the derived prescaler followed by the corresponding value by which the input clock frequency is then divided.</p> <p>0000000: 0; divide by <math>2 \times 2048</math> (4096)</p> <p>0000001: 1; divide by <math>4 \times 2048</math> (8192)</p> <p>0000010: 2; divide by <math>6 \times 2048</math> (12,288)</p> <p>...</p> <p>1111101: 125; divide by <math>252 \times 2048</math> (516,096)</p> <p>1111110: 126; divide by <math>254 \times 2048</math> (520,192)</p> <p>1111111: 127; divide by <math>256 \times 2048</math> (524,288)</p> <p><b>NOTE:</b> The value of FOP after a Configuration-state timeout is 001000b (divide by <math>18 \times 2048</math>, or 36,864).</p> |

**69.6.4 Noncritical Fault Configuration (FCCU\_NCF\_CFGn)**

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

**NOTE**

These registers are writable only when FCCU is in Configuration state.

This table shows the noncritical-fault configuration-register channels.

**Table 69-6. Noncritical-fault configuration-register channels**

| Address offset | Register name | Channel range (x)<br>(bit location [0:31]) |
|----------------|---------------|--------------------------------------------|
| 1Ch            | FCCU_NCF_CFG0 | NCFC[31:0]                                 |
| 20h            | FCCU_NCF_CFG1 | NCFC[63:32]                                |
| 24h            | FCCU_NCF_CFG2 | NCFC[95:64]                                |

Address: 0h base + 1Ch offset + (4d × i), where i=0d to 2d

## 69.6.5 Noncritical Fault State Configuration (FCCU\_NCFS\_CFGn)

The FCCU\_NCFS\_CFGx registers contain the configuration of each non-critical fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

### NOTE

These registers are writable only when the FCCU is in the CONFIG state.

### NOTE

Do not configure the same channel for both a RESET reaction in the FCCU\_NCFS\_CFGn register and an NMI reaction in the FCCU\_NMI\_ENn register at the same time.

[Table 69-7](#) shows FCCU configuration register channels.

**Table 69-7. FCCU NCFS configuration register channels**

| Address offset | Register name  | Channel range (x) |
|----------------|----------------|-------------------|
| 4Ch            | FCCU_NCFS_CFG0 | NCFSCx[15:0]      |
| 50h            | FCCU_NCFS_CFG1 | NCFSCx[31:16]     |
| 54h            | FCCU_NCFS_CFG2 | NCFSCx[47:32]     |
| 58h            | FCCU_NCFS_CFG3 | NCFSCx[63:48]     |
| 5Ch            | FCCU_NCFS_CFG4 | NCFSCx[79:64]     |

Address: 0h base + 4Ch offset + (4d × i), where i=0d to 4d

## 69.6.6 Noncritical Fault Status (FCCU\_NCF\_Sn)

The FCCU\_NCF\_Sx register contains the latched fault indication collected from the non-critical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU\_NCF\_Ex register and the respective enable bit for the timeout is set in the FCCU\_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU\_NCF\_Ex register and the respective enable bit for the timeout is disabled in the FCCU\_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU\_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU\_NCF\_Sx register is encoded respectively into the N2FF\_STATUS or A2FF\_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU\_NCF\_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU\_NCFK register.

2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU\_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
4. Read the FCCU\_NCF\_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

### NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU\_NCF\_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the FCCU\_NCF\_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU\_NCF\_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU\_NCFK register
- to attempt to clear a HW recoverable fault

Table 69-8 shows FCCU NCF status register channels.

**Table 69-8. FCCU NCF status register channels**

| Address offset | Register name | Channel range (x)<br>(bit location [0:31]) |

## 69.6.7 Noncritical Fault Key (FCCU\_NCFK)

The FCCU\_NCFK register implements the key access to clear the status flags of the FCCU\_NCF\_Sx register.

The status bits of the FCCU\_NCF\_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU\_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU\_NCF\_Sx clear operation.

The FCCU\_NCFK register is not readable; a 0000\_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

| Field        | Description                         |
|--------------|-------------------------------------|
| 0–31<br>NCFK | Non-critical fault key = AB34_98FEh |

## 69.6.8 Noncritical Fault Enable (FCCU\_NCF\_En)

The FCCU\_NCF\_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU\_NCF\_Sn register is set (for debugging purposes), only the reaction is masked.

### NOTE

These registers are writable only when the FCCU is in the CONFIG state.

### NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU\_IRQ\_ALARM\_ENn).

Table 69-9 shows FCCU NCFE enable register channels.

**Table 69-9. FCCU NCF enable register channels**

| Address offset | Register name | Channel range (x)<br>(bit location [0:31]) |
|----------------|---------------|--------------------------------------------|

### 69.6.9 Noncritical Fault Timeout Enable (FCCU\_NCF\_TOEn)

The FCCU\_NCF\_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective non-critical fault is enabled ( NCFEx and NCFTOEx are set). In case the respective timeout is disabled ( NCFTOEx is cleared) and the non-critical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related non-critical fault is asserted. The timer (preset with the timeout value defined by FCCU\_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

#### NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 69-10 shows FCCU NCF timeout enable register channels.

**Table 69-10. FCCU NCF timeout enable register channels**

| Address offset | Register name | Channel range (x)<br>(bit location [0:31]) |
|----------------|---------------|--------------------------------------------|
| A4h            | FCCU_NCF_TOE0 | NCFTOE[31:0]                               |

\* Notes:

- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

#### FCCU\_NCF\_TOEn field descriptions

| Field           | Description                                                                                                                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>NCFTOEx | <p>Fault timeout enable</p> <p>See Table 69-10 for register offset to channel number relationship.</p> <p>0 FCCU moves into the FAULT state if the respective fault is enabled</p> <p>1 FCCU moves into the ALARM state if the respective fault is enabled</p> |

69.6.10 Noncritical Fault Timeout (FCCU\_NCF\_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state. The alarm timeout value should be programmed to be less than FOSU\_COUNT, or destructive resets may be generated by FOSU timeouts.

NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

- \* Notes:
- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

FCCU\_NCF\_TO field descriptions

| Field      | Description                                                        |
|------------|--------------------------------------------------------------------|
| 0–31<br>TO | Noncritical Fault Timeout<br>Timeout = (TO) × T <sub>RC16MHz</sub> |

69.6.11 Configuration-State Timeout (FCCU\_CFG\_TO)

The FCCU\_CFG\_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the timeout, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. The description for a configuration register will contain a NOTE that it is writable only in the CONFIG state. The watchdog timeout is clocked

with CLKSAFE. The default timeout value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

### NOTE

The FCCU\_CFG\_TO register is writable in any state excluding the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog timeout the FCCU\_CFG\_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

### NOTE

When the configuration watchdog timer expires, FCCU changes the value of this register to its reset value.

## 69.6.12 IO Control (FCCU\_EINOUT)

The FCCU\_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU\_CFG.FOM)

Register descriptions

- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU\_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

Table 69-11 shows Bi-stable encoding.

Table 69-11. Bi-stable encoding

| Mode = FCCU_CFG.FOM | EOUT[0] | EOUT[1] |
|---------------------|---------|---------|
| Test1               | output  | output  |
| Test2               | output  | input   |
| Test0               | input   | output  |

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU\_EINOUT register.

Address: 0h base + BCh offset = BCh

**69.6.13 Status (FCCU\_STAT)**

The FCCU\_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the FCCU status (FCCU\_STAT register).

**69.6.14 NA Freeze Status (FCCU\_N2AF\_STATUS)**

The N2AF\_STATUS register contains a unique code to identify the "non-critical fault" source ( fccu\_ncf[x] ) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF\_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the N2AF\_STATUS register.

The SW application executes the N2AF\_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

**69.6.15 AF Freeze Status (FCCU\_A2FF\_STATUS)**

The A2FF\_STATUS register contains a unique code to identify the timeout trigger ( non-critical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF\_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the A2FF\_STATUS register.

The SW application executes the FCCU\_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).

All the freeze registers are cleared by this operation.

**69.6.16 NF Freeze Status (FCCU\_N2FF\_STATUS)**

The N2FF\_STATUS register contains a unique code to identify the source of the non-critical fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes. The SW application executes the N2FF\_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the N2FF\_STATUS register.

The SW application executes the N2FF\_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

## 69.6.17 FA Freeze Status (FCCU\_F2A\_STATUS)

The F2AF\_STATUS register contains a unique code to identify the source of the non-critical fault (fccu\_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF\_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the F2AF\_STATUS register.

The SW application executes the F2AF\_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

## 69.6.18 Noncritical Fault Fake (FCCU\_NCFF)

The FCCU\_NCFF register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked. The FCCU\_NCFF is a write-only register with a set of codes corresponding to each non-critical fault injection.

69.6.19 IRQ Status (FCCU\_IRQ\_STAT)

The FCCU\_IRQ\_STAT register provides the FCCU interrupt status related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG\_TO\_STAT bit of the FCCU\_IRQ\_STAT register is set and the CFG\_TO\_IEN bit of the FCCU\_IRQ\_EN register is also set. It is cleared when a 1 is written to the CFG\_TO\_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU\_IRQ\_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h

### 69.6.20 IRQ Enable (FCCU\_IRQ\_EN)

The FCCU\_IRQ\_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

## Register descriptions

The configuration timeout interrupt is asserted if the CFG\_TO\_STAT bit of the FCCU\_IRQ\_STAT register is set and the CFG\_TO\_IEN bit of the FCCU\_IRQ\_EN register is also set.

Address: 0h base + E4h offset = E4h

## 69.6.21 XTMR (FCCU\_XTMR)

The FCCU\_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked by CLKSAFE.

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU\_CTRL.OPR field:
  - OP17
  - OP19
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the FCCU\_XTMR register.

Table 69-12 shows Timer state/value.

**Table 69-12. Timer state/value**

| TIMER | CONFIG state | NORMAL state  | ALARM state | FAULT state       |
|-------|--------------|---------------|-------------|-------------------|
| ALARM | 00000000h    | Initial value | Running     | Idle/End of count |
| CFG   | Running      | 0001FFFFh     | 0001FFFFh   | 0001FFFFh         |

Address: 0h base + E8h offset = E8h

| 28–31<br>MCS0     | Mode Controller State 0—Indicates the most recent (current) chip mode.                                                                                                                                                                                                                                                                                                |

**69.6.23 Transient Lock (FCCU\_TRANS\_LOCK)**

The FCCU\_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.

Address: 0h base + F0h offset = F0h

|       |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |

69.6.24 Permanent Lock (FCCU\_PERMNT\_LOCK)

The FCCU\_PERMNT\_LOCK register is used for locking configuration permanently by writing FFh. This register is available only in supervisor mode. The permanent lock can only be removed by applying a reset (not necessarily power on reset). This register is write only.

Address: 0h base + F4h offset = F4h

FCCU\_PERMNT\_LOCK field descriptions

| 23–31<br>PERMNTKEY | Transition Locking Key value<br>FFh: Configuration Locked<br>Any other value: No Change |

69.6.25 Delta T (FCCU\_DELTA\_T)

The FCCU\_DELTA\_T register is used for programming the value of delta\_T constant, in microseconds.

NOTE

This register can be written only when the FCCU is in CONFIG state.

NOTE

Reserved bits should always be written as all 0's.

Address: 0h base + F8h offset = F8h

69.6.26 IRQ Alarm Enable (FCCU\_IRQ\_ALARM\_EN<sub>n</sub>)

These registers enable the corresponding IRQ alarm.

Table 69-13 shows FCCU IRQ alarm enable register channels.

**Table 69-13. FCCU IRQ alarm enable register channels**

| Address offset | Register name      | Channel range (x)<br>(bit location [0:31]) |
|----------------|--------------------|--------------------------------------------|
| 0FCh           | FCCU_IRQ_ALARM_EN0 | IRQENE[31:0]                               |
| 100h           | FCCU_IRQ_ALARM_EN1 | IRQENE[63:32]                              |
| 104h           | FCCU_IRQ_ALARM_EN2 | IRQENE[95:64]                              |

### NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + FCh offset + (4d × i), where i=0d to 2d

## 69.6.27 NMI Enable (FCCU\_NMI\_ENn)

These registers enable the NMI.

### NOTE

Do not configure the same channel for both a RESET reaction in the FCCU\_NCFS\_CFGn register and an NMI reaction in the FCCU\_NMI\_ENn register at the same time.

Table 69-14 shows FCCU NMI enable register channels.

**Table 69-14. FCCU NMI enable register channels**

| Address offset | Register name | Channel range (x)<br>(bit location [0:31]) |
|----------------|---------------|--------------------------------------------|
| 10Ch           | FCCU_NMI_EN0  | NMIENE[31:0]                               |

## FCCU\_EOUT\_SIG\_ENn field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>EOUTENx | <p>Fault-Output (EOUT) Signaling Enable</p> <p>Writable only when FCCU is in Configuration state. Controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x) when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]). Fault-output signaling is always enabled for the associated channel, regardless of the value of this field, when FCCU is configured for any other fault-output mode.</p> <p><b>NOTE:</b> To ensure that the FOSU module is aware that fault-output signaling is enabled as a reaction for the associated noncritical fault channel (so that FOSU doesn't mistakenly generate a destructive chip reset), you must set this field to enabled when FCCU is configured for any mode other than Bistable fault-output mode.</p> <p>For the mapping of the EOUTENx fields among registers, see the earlier table in this register description.</p> <p>0 Disabled<br/>1 Enabled</p> |

## 69.7 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU\_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC\_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU, which is asserted on power-on, 'destructive', and external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

#### **NOTE**

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

**Figure 69-14. FOSU connections to the FCCU and MC\_RGM**

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU\_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

### NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU\_COUNT, or destructive resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

## 69.8 Use cases and limitations

### 69.8.1 Misconfigurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enabling a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario

Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.

4. If the user programs the FCCU for a higher timeout value than what is hardcoded for FOSU, then FCCU reacts later than what FOSU would be expecting and, as a result, FOSU will generate destructive reset request on its timeout.

### 69.8.2 Recommendations to configure FCCU

1. After a power on, 'destructive', or long external reset, where both system and FCCU are reset, the following steps could be followed to configure FCCU:
  - a. Check and clear any pending fault status
  - b. Verify FCCU is in NORMAL state, else repeat step(a) above
  - c. Configure FCCU
2. After a short external or any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
  - a. If active, wait for the Error out T\_min to expire
  - b. Check and clear fault status
  - c. Error pin moves to "non faulty" state, once fault status is cleared and T\_min expires
  - d. Verify FCCU is in NORMAL state, else repeat step(a) above
  - e. Read and verify value in FCCU\_NCF\_Ex
  - f. Reconfigure FCCU, if necessary

# Chapter 70

## Self-Test Control Unit (STCU2)

### 70.1 Introduction

The Self-Test Control Unit (STCU2) controls the execution of the built-in self-test of the MPC5744P.

The built-in self-test supports in the application:

- Memory (RAM/ROM) Built-In Self-Test (MBIST) at startup and shutdown.
- Scan-based Logic BIST for digital logic (LBIST), which is divided into multiple partitions, at startup and shutdown.

The following table summarizes the three self-test modes. For detailed descriptions of the modes, see [Use cases and limitations](#).

**Table 70-1. STCU2 self-test modes**

| Self-test mode        | Description                                                                                           | Availability                      |
|-----------------------|-------------------------------------------------------------------------------------------------------|-----------------------------------|
| Normal self-test mode | MBIST for all memories with a checkerboard/inverted checkerboard algorithm<br>LBIST on all partitions | In startup mode and shutdown mode |
| Long self-test mode   | MBIST for all memories with the reduced RAM and ROM algorithm<br>LBIST on all partitions              | Only during shutdown mode         |
| Diagnostic mode       | MBIST for all memories with the full RAM and ROM algorithm<br>LBIST on all partitions                 | Only during shutdown mode         |

In application mode, the STCU2 initiates self-test execution:

- after Power-on Reset (POR)
- after external reset (if triggered as long-functional reset)
- after destructive reset
- when initiated by software

The STCU2 communicates any fault information to the Fault Control and Collection Unit (FCCU) and to the Reset Generation Module (MC\_RGM).

The startup self-test is implemented by Freescale. The user can choose either to run normal self-test execution during startup of the device or to bypass the startup self-test execution by programming the appropriate records in the UTEST flash memory.

The shutdown self-test sequence is user programmable and must be started by the user application on demand. This self-test can be executed at less critical times in the application. After the self-test is executed during shutdown, a long functional reset is initiated, and the self-test results are accessible.

The STCU2 includes the SSCM DCF bus to load the self-test parameters from flash memory—consisting of both the test flash memory, which is programmed by Freescale, and the UTEST flash, which is user-programmable—during the startup self-test phase.

## **70.2 Functional description**

### **70.2.1 FCCU interface**

The FCCU interface is the hardware flag mechanism towards the system that indicates detection of an STCU2 critical fault and/or an STCU2 non-critical fault during the self-test sequence.

The FCCU interface allows the user application to check the integrity of the critical fault and non-critical fault connection lines between the STCU2 and the FCCU. See the description of FCCU fault injection mechanism to understand how this set/clear mechanism works.

### **70.2.2 Watchdogs**

The STCU2 implements three different watchdog ensure that operations are finished in time.

#### **70.2.2.1 Initialization sequence**

The STCU2 has two initialization operating modes: program the self-test sequence and run it or bypass completely the self-test sequence. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded Watchdog time-out flags the wrong behavior.

### 70.2.2.2 LBIST and MBIST scheduling

If the selected LBISTs or MBISTs are not completed during the self-test's assigned time, the current execution of LBISTs or MBISTs is interrupted and a failure is flagged in:

- STCU\_ERR\_STAT[WDTO] and STCU\_MBEL or STCU\_LBE for a startup self-test
- STCU\_ERR\_STAT[WDTOSW] and STCU\_MBELSW or STCU\_LBESW for a shutdown self-test

#### NOTE

The only sequence possible is to run MBISTs first and then LBISTs.

### 70.2.2.3 Write access time-out

The access on the STCU2 registers during the self-test configuration phase (both shutdown and startup) is protected by a security key mechanism to prevent any unwanted write access, as described in the STCU\_SKC register description. In addition to this safety feature, there is a hardware Watchdog that, after 4096 STCU2 clock cycles, locks access. In that event, the user must re-apply the STCU\_SKC keys.

### 70.2.3 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters during the startup sequence without CPU intervention after a reset trigger event initializes the STCU2.

## 70.3 Register description: configuration registers

Use these registers to configure self-tests.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

These registers of the STCU2 module are accessible (read/write) in each access mode: user or supervisor.

The following read operations (contiguous byte enables) are supported:

- Word (32-bit) data read operations to any registers

- Low and high half-word (16-bit, data[31:16] or data[15:0]) data read operations to any registers
- Byte (8-bit, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/half-word/word (free byte enables or other operations) on each register
- Any write operation on Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Security keys have not been applied
- Any write operation performed on read-only registers

Write operations to fields marked as reserved do not generate the transfer error.

**70.3.1 STCU2 Run Software Register (STCU\_RUNSW)**

This register initiates the shutdown self-test.

The reset value of this register can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to this register for each shutdown self-test.

**70.3.2 STCU2 SK Code Register (STCU\_SKC)**

The STCU\_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 for shutdown self-test the software (IPS bus) must apply the following sequence:

1. write key1 into the STCU\_SKC register
2. write key2 into the STCU\_SKC register

A byte write operation is not allowed because the full key must be recognized as one unit.

See [Table 70-4](#) for the key values to write to this register for each shutdown self-test.

The reset value of this register can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

The STCU\_SKC register is not readable. A read operation always returns the value 00000000h.

### NOTE

After the self-test sequence has been completed, the SSCM interface is no longer available.

In case of invalid access or sequence (key1 and key2 must be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked. To unlock the access, re-apply the sequence.

If the STCU2 register access lasts for longer than 4096 cycles, the STCU2 write access is locked as described in [Write access time-out](#). In this case, to re-enable the write access to the STCU2, apply the sequence again.

In case it is required to extend the STCU2 register access cycles before the hard-coded WDG time-out expires, apply only key2. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, do not apply key1. If it is applied, a transfer error on the IPS or SSCM bus is asserted depending on the selected source, and the STCU2 write access is locked. To unlock the access, re-apply the sequence.

### 70.3.3 STCU2 Configuration Register (STCU\_CFG)

This register includes global configuration controls for the STCU2.

The reset value of this register can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to this register for each shutdown self-test.

### 70.3.4 STCU2 Watchdog Register Granularity (STCU\_WDG)

This register defines the time budget of LBIST and MBIST execution.

The reset value of this register can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to this register for each shutdown self-test.

### 70.3.5 STCU2 Shutdown LBIST Reset Management (STCU\_LBRMSW)

The STCU\_LBRMSW register enables and ensures the correct reset sequence after shutdown self-test execution.

The reset value of this register can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to this register for each shutdown self-test.

### 70.3.6 STCU2 LBIST Control Register (STCU\_LBn\_CTRL)

The STCU\_LBn\_CTRL register defines the control settings of the corresponding LBIST.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to each register for each shutdown self-test.

### 70.3.7 STCU2 LBIST PC Stop Register (STCU\_LBn\_PCS)

The STCU\_LBn\_PCS register contains pattern-related information.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to each register for each shutdown self-test.

### 70.3.8 STCU2 Shutdown LBIST MISR Expected Low Register (STCU\_LBn\_MISRELSW)

The STCU\_LBn\_MISRELSW register contains MISR signature-related information.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to each register for each shutdown self-test.

### 70.3.9 STCU2 Shutdown LBIST MISR Expected High Register (STCU\_LBn\_MISREHSW)

The STCU\_LBn\_MISREHSW register contains MISR signature-related information.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to each register for each shutdown self-test.

### 70.3.10 STCU2 MBIST Control Register (STCU\_MBn\_CTRL)

The STCU\_MBn\_CTRL register contains control settings for the corresponding MBIST.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to each register for each shutdown self-test.

## 70.4 Register description: clock configuration register

DCL memory map

| Address offset (hex) | Register name                       | Width (in bits) | Access | Reset value                 | Section/page                |
|----------------------|-------------------------------------|-----------------|--------|-----------------------------|-----------------------------|
| FFC0_0104            | Different Clock register (DCL_IPS0) | 32              | R/W    | <a href="#">See section</a> | <a href="#">70.4.1/2785</a> |

### 70.4.1 Different Clock register (DCL\_IPS0)

This register selects different clock configurations for the self-test.

The reset value of this register can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

See [Table 70-4](#) for the value to write to this register for each shutdown self-test.

## 70.5 Register description: status registers

Read these registers to determine the status and results of executed self-tests.

The reset value of each of these registers can vary by device version and due to various dependencies, such as flash memory configuration or the result (pass/fail) of MBISTs and LBISTs.

These registers of the STCU2 module are accessible in each access mode: user or supervisor.

The following read operations (contiguous byte enables) are supported:

- Word (32-bit) data read operations to any registers
- Low and high half-word (16-bit, data[31:16] or data[15:0]) data read operations to any registers
- Byte (8-bit, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/half-word/word (free byte enables or other operations) on each register
- Any write operation on Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Security keys have not been applied
- Any write operation performed on read-only registers

Write operations to fields marked as reserved do not generate the transfer error.

### 70.5.1 STCU2 Error Register (STCU\_ERR\_STAT)

The STCU\_ERR\_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the self-test execution.

The CFSF and NCFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the figure and as follows:

- If you select the byte write capability to write only the CFSF and NCFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides CFSF/NCFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the CFSF/NCFSF single bit set/clean capability.

Address: 0h base + 24h offset = 24h

| Bit   | 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11      | 12     | 13 | 14     | 15     |
|-------|----|----|----|----|----|----|----|----|----|----|----|---------|--------|----|--------|--------|
| R     | 0  |    |    |    |    |    | 0  | 0  |    | 0  |    | LOCKESW | WDTOSW | 0  | ENGESW | INVPSW |

**70.5.6 STCU2 Startup MBIST Status Low Register (STCU\_MBSL)**

The STCU\_MBSL register includes the results corresponding to the execution of the startup MBIST.

The size of the register depends on the number of BISTed RAMs/ROMs.

Address: 0h base + 44h offset = 44h

|       |    |    |    |    |    |       |       |       |       |       |       |       |       |       |       |       |

| 31<br>MBS0 | Startup status of the MBIST0<br>This bit has no significance.<br>The MBIST0 logic involves the BAM ROM. The 4N checkerboard algorithm (as it is processed during normal startup self-tests) is not executed on MBIST0.        |

**70.5.7 STCU2 Startup MBIST End Flag Low Register (STCU\_MBEL)**

The STCU\_MBEL register includes the End Flag related to the execution of the startup MBIST.

The size of the register depends on the number of BISTed RAMs/ROMs.

## 70.5.8 STCU2 Shutdown MBIST Status Low Register (STCU\_MBSLSW)

The STCU\_MBSLSW register includes the results corresponding to the execution of the shutdown MBIST.

Address: 0h base + 5Ch offset = 5Ch

| Bit   | 0  | 1  | 2  | 3  | 4  | 5       | 6       | 7       | 8       | 9       | 10      | 11      | 12      | 13      | 14      | 15      |

The 4N checkerboard algorithm (as it is processed during normal shutdown self-tests) does not run on MBIST0. This bit is meaningful only after execution of a long self-test mode or of the diagnostic self-test mode.</p> <p>0 MBIST execution still ongoing<br/>1 MBIST execution finished</p> |

## 70.6 Use cases and limitations

The STCU2 module is designed to give a high degree of flexibility by providing multiple self-test types. The following tables summarize the provided STCU2 self-test operations.

### NOTE

Make sure that the flash is in IDLE state before starting LBIST (Self Test) operation.

**Table 70-2. Startup self-test**

| Self-test                | Coverage                         | BIST details                                                                       | Execution time                  |
|--------------------------|----------------------------------|------------------------------------------------------------------------------------|---------------------------------|
| No self-test execution   | No coverage                      | No LBIST<br>No MBIST                                                               | 0 ns                            |
| Normal startup self-test | Coverage of $\geq 90\%$ stuck-at | LBIST on all partitions<br>MBIST for all memories with a 4N checkerboard algorithm | Max. 18 ms total execution time |

**Table 70-3. Shutdown self-tests**

| Self-test                     | Stuck-at coverage                                                       | Transition coverage                                                                                          | LBIST details           | MBIST details                                                           | Execution time                  |
|-------------------------------|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|-------------------------|-------------------------------------------------------------------------|---------------------------------|
| Normal shutdown self-test     | $\geq 90\%$ on all partitions                                           | $\geq 60\%$ on partition C0<br>$\geq 60\%$ on partition C1<br>No transition coverage on partitions P0 and P1 | LBIST on all partitions | MBIST for all memories with a 4N checkerboard algorithm                 | Max. 51 ms total execution time |
| Long shutdown self-test       |                                                                         |                                                                                                              |                         | MBIST on all memories with reduced RAM and ROM algorithm (without ASOF) | Max. 68 ms total execution time |
| Diagnostic shutdown self-test | $\geq 90\%$ on partition C0<br>$\geq 90\%$ on partitions C1, P0, and P1 | $\geq 60\%$ on partition C0<br>$\geq 60\%$ on partition C1<br>No transition coverage on partitions P0 and P1 |                         | MBIST on all memories with full RAM and ROM algorithm                   |                                 |

### 70.6.1 Startup self-test sequence

If the normal startup self-test mode is chosen, the system startup sequence includes the following activities if any of the STCU reset conditions is valid.

1. The STCU is configured via DCF during reset phase 3.
2. After the exit from reset phase 3, the STCU powers a self-test setup phase.
3. Self-test executes / MBIST phase
4. Self-test executes / LBIST phase
5. The STCU collects all BIST results and stores them internally.
6. The STCU arranges a long functional reset.

### 70.6.2 Startup self-test mode selection

This chip offers two startup self-test variants.

- No self-test execution
- Normal startup self-test

For correct system behavior one of these modes must be configured. To configure one of these modes, program particular DCF records in the UTEST flash memory.

To configure "No self-test execution": Store the following DCF record as the first record in the UTEST flash memory.

```
00000400h
00080000h
```

To configure "Normal startup self-test": Store the following DCF record as the first record in the UTEST flash memory.

```
00000301h
00080000h
```

#### NOTE

During startup self-tests, once the STCU2 registers are configured they cannot be overridden.

## 70.6.3 Shutdown self-test sequence

This is the typical mode of using the STCU2 module during the application run.

### 70.6.3.1 Preparation before initiating an STCU shutdown self-test

Before you initiate the execution of an STCU shutdown self-test, you must complete the following prerequisite procedure to prepare the chip.

1. End the currently running application, including graceful termination of peripherals as required by the application.
2. Configure FlexRay and CAN clock sources and divider for self-test:
  - a. Configure FRAY\_PLL\_CLK clock as PLL0 PHI divided by 2:  
MC\_CGM\_AC1\_DC0[DIV]=1h.
  - b. Select FRAY\_PLL\_CLK as the FRAY\_CLK clock source:  
FR\_MCR[CLKSEL]=1.
  - c. Select CAN\_PLL\_CLK as the CAN\_CLK clock source:  
CAN\_CTRL1[CLKSRC]=1.
3. Ensure PBRIDGE clock is not over clocked (maximum frequency is 50MHz) when SYS\_CLK is switched to 200MHz.
  - Configure PBRIDGE\*\_CLK as SYS\_CLK (system clock) divided by 4:  
MC\_CGM\_SC\_DC0[DIV]=3h.
4. Configure DRUN to turn off PLL1 (to save power), turn off PLL0 so PLL0 can be re-configured for the required 200MHz self-test clock frequency, turn on the XOSC as it is needed to provide the PLL0 reference clock during self-test, and select IRCOSC to source SYS\_CLK:
  - a. Select IRCOSC as the SYS\_CLK clock source:  
MC\_ME\_DRUN\_MC[SYSCLK]=0000b.
  - b. Enable XOSC: MC\_ME\_DRUN\_MC[XOSCON]=1 (will be required for PLL0).
  - c. Disable PLL0: MC\_ME\_DRUN\_MC[PLL0ON]=0.
  - d. Disable PLL1: MC\_ME\_DRUN\_MC[PLL1ON]=0.
  - e. Gate off all peripheral clocks because they should not be running:  
MC\_ME\_RUN\_PC0[DRUN]=0, MC\_ME\_PCTLn[RUN\_CFG]=000b.

5. Activate new configuration by performing mode change to DRUN:  
MC\_ME\_MCTL[TARGET\_MODE]=0011b (see the MC\_ME chapter for mode change request details).
6. Configure PLL0 for required 200MHz self-test frequency:
  - a. Configure PLL0 to provide 200MHz at its PHI output: PLLDIG\_PLL0DV (values depend on XOSC frequency).
  - b. Select XOSC as PLL0's reference clock: MC\_CGM\_AC3\_SC[SELCTL]=1.
7. Configure DRUN mode to turn on PLL0 and select PLL0 PHI to source SYS\_CLK:
  - a. Enable XOSC: MC\_ME\_DRUN\_MC[XOSCON]=1.
  - b. Enable PLL0: MC\_ME\_DRUN\_MC[PLL0ON]=1.
  - c. Disable PLL1: MC\_ME\_DRUN\_MC[PLL1ON]=0.
  - d. Select PLL0 PHI as the SYS\_CLK clock source:  
MC\_ME\_DRUN\_MC[SYSCLK]=0010b.
8. Activate new configuration by performing mode change to DRUN:  
MC\_ME\_MCTL[TARGET\_MODE]=0011b (see the MC\_ME chapter for mode change request details).
9. Select PLL0 PHI to source all auxiliary clocks used during self-test:
  - a. Select PLL0 PHI as the MOTC\_CLK, SGEN\_CLK, and ADC\_CLK clock source: MC\_CGM\_AC0\_SC[SELCTL]=2h.
  - b. Select PLL0 PHI as the LFAST PLL clock source:  
MC\_CGM\_AC5\_SC[SELCTL]=2h.

### 70.6.3.2 Shutdown self-test initiation procedure

To initiate a shutdown self-test, execute the following steps for the desired self-test mode. All accesses must be processed without interruption. The values to write to each register appear in [Table 70-4](#).

1. Configure the STCU\_SKC register by first writing the key1 value and then writing the key2 value.
2. Configure the STCU\_MBn\_CTRL registers.
3. Configure the STCU\_CFG register.

4. Configure all STCU\_LBn\_CTRL registers.
5. Configure all STCU\_LBn\_PCS registers.
6. Configure all STCU\_LBn\_MISRELSW registers.
7. Configure all STCU\_LBn\_MISREHSW registers.
8. Configure the STCU\_WDG register.
9. Configure the STCU\_LBRMSW register.
10. Configure the DCL\_IPS0 register.
11. Configure the STCU\_RUNSW register. This access immediately starts the shutdown self-test execution.

### NOTE

During shutdown self-tests, once the STCU2 registers are configured they cannot be overridden via IPS until the self-testing is complete.

The following table identifies the values to write to the STCU registers to configure each type of shutdown self-test.

**Table 70-4. STCU register configuration for shutdown self-tests**

| STCU register | Shutdown self-tests                  |      |            |
|---------------|--------------------------------------|------|------------|
|               | Normal                               | Long | Diagnostic |
| SKC           | Key1: 0x753F924E<br>Key2: 0x8AC06DB1 |      |            |
| MB0_CTRL      | 0x91000000                           |      |            |
| MB1_CTRL      | 0x98000000                           |      |            |

### 70.6.3.3 Shutdown self-test execution sequence

1. The user configures the STCU by following the self-test initiation procedure.

2. The STCU powers a self-test setup phase.
3. Self-test executes / MBIST phase
4. Self-test executes / LBIST phase
5. The STCU collects all BIST results and stores them internally.
6. The STCU arranges a long functional reset.

## 70.7 MBIST partitioning

The following table describes the mapping between the MBIST number, as the STCU2 captures it, and the appropriate memory in the design.

**Table 70-5. MBIST mapping**

| MBIST number | Memory in design     |
|--------------|----------------------|
| MBIST0       | BAM ROM              |
| MBIST1       | DMA RAM              |
| MBIST2       | System RAM 1         |
| MBIST3       | System RAM 0         |
| MBIST4       | System RAM 3         |
| MBIST5       | System RAM 2         |
| MBIST6       | System RAM 5         |
| MBIST7       | System RAM 4         |
| MBIST8       | DLMEM 1              |
| MBIST9       | DLMEM 0              |
| MBIST10      | iCache Data Memory 3 |
| MBIST11      | iCache Data Memory 2 |
| MBIST12      | iCache Data Memory 1 |
| MBIST13      | iCache Data Memory 0 |
| MBIST14      | iCache Tag Memory    |
| MBIST15      | dCache Data Memory 3 |
| MBIST16      | dCache Data Memory 2 |
| MBIST17      | dCache Data Memory 1 |
| MBIST18      | dCache Data Memory 0 |
| MBIST19      | dCache Tag Memory    |
| MBIST20      | FlexCAN RAM 2        |
| MBIST21      | FlexCAN RAM 1        |
| MBIST22      | FlexCAN RAM 0        |
| MBIST23      | FlexRay LRAM 1       |

*Table continues on the next page...*

**Table 70-5. MBIST mapping (continued)**

| MBIST number | Memory in design |
|--------------|------------------|
| MBIST24      | FlexRay LRAM 0   |
| MBIST25      | FlexRay DRAM     |
| MBIST26      | ENET Memory      |

## 70.8 LBIST partitioning

The following table describes the mapping among:

- the LBIST number, as the STCU captures it
- the device partition corresponding to the number
- all modules that take part in the appropriate LBIST

**Table 70-6. LBIST mapping**

| LBIST number | Device partition | Modules participating in LBIST                                                                                                                                 |
|--------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LBIST0       | Partition C0     | z4 Main Core_0<br>PFLASHC<br>Flash memory<br>NPC<br>NXMC0 and NXMC1<br>MEMU<br>XBAR<br>DSMC<br>DMA<br>EIM<br>INTC<br>NAL<br>NAP<br>PRAMC<br>SWT<br>SMPU<br>STM |

# Chapter 71

## Register Protection (REG\_PROT)

### 71.1 Overview

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Register Protection (REG\_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE/AIPS-Lite). This is shown in the following figure.

Figure 71-1. REG\_PROT Block Diagram

## 71.2 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

## 71.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.

## 71.4 External signal description

There are no external signals.

## 71.5 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in the following figure.

**Figure 71-2. REG\_PROT Memory Diagram**

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.
- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

## 71.5.1 Memory map

Following is the memory map for a module which is protected via a REG\_PROT module.

**Table 71-1. Generic Protected Module Memory Map**

| Offset          | Use                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| 0x0000          | Module Register 0 (MR0)                                                                                                 |
| 0x0001          | Module Register 1 (MR1)                                                                                                 |
| 0x0002          | Module Register 2 (MR2)                                                                                                 |
| 0x0003 - 0x17FF | Module Register 3 (MR3) - Module Register 6143(MR6143)                                                                  |
| 0x1800 - 0x1FFF | Reserved                                                                                                                |
| 0x2000          | Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)                                                                    |
| 0x2001          | Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)                                                                    |
| 0x2002 - 0x37FF | Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143) |
| 0x3800          | Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3                                                                    |
| 0x3801          | Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7                                                                    |
| 0x3802 - 0x3DFF | Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 -Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143 |
| 0x3E00 - 0x3FFB | Reserved                                                                                                                |
| 0x3FFC          | Global Configuration Register (GCR)                                                                                     |

### Note

Reserved registers in area #1 will be handled as specified in the protected module's documentation.

## 71.5.2 Register descriptions

This section describes in address order all the REG\_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

**Figure 71-3. Register description**

### 71.5.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG\_PROT module.

### 71.5.2.2 Module register and set soft lock bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBRn.SLBm, according to the mapping described in the Soft Lock Bit Register section.

## 71.6 Memory map and registers

**REG\_PROT memory map**

| Address offset (hex) | Register name                                | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|----------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 3800                 | Soft Lock Bit Register n (REG_PROT_SLBRn)    | 8               | R/W    | 00h         | <a href="#">71.6.1/2825</a> |
| 3FFC                 | Global Configuration Register (REG_PROT_GCR) | 32              | R/W    | 0000_0000h  | <a href="#">71.6.2/2827</a> |

### 71.6.1 Soft Lock Bit Register *n* (REG\_PROT\_SLBRn)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area #1.

**Table 71-2. Soft Lock Bits vs. Protected Address**

| Soft Lock Bit | Protected address |
|---------------|-------------------|
| SLBR0.SLB0    | MR0               |
| SLBR0.SLB1    | MR1               |
| SLBR0.SLB2    | MR2               |
| SLBR0.SLB3    | MR3               |
| SLBR1.SLB0    | MR4               |
| SLBR1.SLB1    | MR5               |
| SLBR1.SLB2    | MR6               |

*Table continues on the next page...*

**Table 71-2. Soft Lock Bits vs. Protected Address (continued)**

| Soft Lock Bit | Protected address |
|---------------|-------------------|
| SLBR1.SLB3    | MR7               |
| SLBR2.SLB0    | MR8               |
| ...           | ...               |

**NOTE**

- As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.
- Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address: 0h base + 3800h offset = 3800h

| Bit   | 0   | 1   | 2   | 3   | 4    | 5    | 6    | 7    |
|-------|-----|-----|-----|-----|------|------|------|------|
| Read  | 0   | 0   | 0   | 0   | SLB0 | SLB1 | SLB2 | SLB3 |
| Write | WE0 | WE1 | WE2 | WE3 |      |      |      |      |
| Reset | 0   | 0   | 0   | 0   | 0    | 0    | 0    | 0    |

**REG\_PROT\_SLBRn field descriptions**

| Field     | Description                                                                                                                         |

## 71.7 Functional description

The following sections describe the functional characteristics of the Register Protection module.

### 71.7.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depends on the SoC and/or module.

For all addresses (peripheral registers) that are protected there are SLBRn.SLBm bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBRn.SLBm bit is always 0b0 no matter what software is writing to.

## 71.7.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBRn.SLBm bit needs to be changed. This can be done using the following methods:

- Modify the SLBRn.SLBm directly by writing to area #4
- Set the SLBRn.SLBm bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

### 71.7.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBRn.SLBm bit has a mask bit SLBRn.WEm which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

The following figure shows two modification examples. In the left example there is a write access to the SLBRn register specifying a mask value which allows modification of all SLBRn.SLBm bits. The example on the right specifies a mask which only allows modification of the bits SLBRn.SLB[3:1].

**Figure 71-4. Change lock settings directly via Area #4**

The previous figure shows four registers that can be protected 8-bit wise. The following figures show registers with 16- and 32-bit protection respectively:

## Functional description

**Figure 71-5. Change lock settings for 16-bit protected addresses**

On the right side of the previous figure it is shown that the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[1] also. This is done as the address reflected by SLBRn.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBRn.WE[0] must be set while SLBRn.WE[1] does not matter. As the enable bits SLBRn.WE[3:2] are cleared the lock bits SLBRn.SLB[3:2] remain unchanged.

In the example on the left side of the previous figure the data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] and the data written to SLBRn.SLB[2] is mirrored to SLBRn.SLB[3] as for both registers the write enables are set.

The next figure shows a 32-bit wise protected register. When SLBRn.WE[0] is set the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[3:1] also. Otherwise SLBRn.SLB[3:0] remains unchanged.

**Figure 71-6. Change lock settings for 32-bit protected addresses**

The following figure shows a mixed protection size configuration:

**Figure 71-7. Change lock settings for mixed protection**

The data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBRn.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBRn.SLB[3] is written to SLBRn.SLB[3].

### 71.7.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. For example:

**Figure 71-8. Enable Locking Via Mirror Module Space (Area #3)**

When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (see the left part of [Figure 71-5](#)).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of [Figure 71-5](#)).

The following figure shows an example where some addresses are protected and some are not:

**Figure 71-9. Enable locking for protected and unprotected addresses**

In the previous figure addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

### Note

Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

### 71.7.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in [Change lock settings directly via Area #4](#) and [Enable locking via mirror module space \(Area #3\)](#) is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

### 71.7.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to [Figure 71-2](#)

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.

6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

# Chapter 72

## Wakeup Unit (WKPU)

### 72.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Wakeup Unit (WKPU) supports one external source that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. The figure below shows the WKPU block diagram and its interfaces to other system components.

Figure 72-1. WKPU and connected system components

### 72.2 Features

The WKPU supports these features:

- Non-maskable Interrupt support with:

## External signal description

- One external NMI source
- One analog glitch filter
- Independent interrupt destination for each core:
  - Non-maskable interrupt
  - Critical interrupt
  - Machine check request
- Active edge selection control for events to each core
- Configurable system wakeup triggering from NMI source(s)

## 72.3 External signal description

The WKPU has signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

## 72.4 WKPU memory map and register definition

This section provides a detailed description of all registers accessible in the WKPU module.

### NOTE

Reserved registers will read as 0, writes will have no effect.  
Transfer error will be generated when trying to access completely reserved register space.

### WKPU memory map

| Address offset (hex) | Register name                         | Width (in bits) | Access | Reset value                 | Section/ page               |

### 72.4.1 NMI Status Flag Register (WKPU\_NSR)

This register holds the non-maskable interrupt status flags.

**NOTE**

This register is accessible by 8-, 16-, and 32-bit read/write operations.

Access: User read/write

Address: 0h base + 0h offset = 0h

**72.4.2 NMI Configuration Register (WKPU\_NCR)**

This register holds the configuration bits for the non-maskable interrupt settings.

**NOTE**

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing a 0 to both NREE[n] and NFEE[n] disables the NMI functionality completely (i.e., no system wakeup or interrupt will be generated on any pad activity).

Access: User read/write

Address: 0h base + 8h offset = 8h

## 72.5 Functional description

This section provides a functional description of the WKPU.

### 72.5.1 Non-maskable interrupts

The WKPU supports the generation of 3 types of interrupts per NMI input to the SoC. The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, though it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

**NOTE**

Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

**NOTE**

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

Figure 72-2. NMI pad diagram

### 72.5.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see [NMI Configuration Register \(WKPU\\_NCR\)](#)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

#### Note

After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI. Please see chip specific section for details on NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See [NMI Configuration Register \(WKPU\\_NCR\)](#) for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see [NMI Status Flag Register \(WKPU\\_NSR\)](#)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (i.e. has not yet been cleared).

#### Note

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

During an NMI ISR, on wakeup of the SoC from an NMI, any writes to ECC-protected memory must have the correct ECC.

# Appendix A

## Protected Registers

The following table identifies registers that are protected on this device.

**Table A-1. Protected registers**

| Module | Register | Size | Offset | Address    | Protect size |
|--------|----------|------|--------|------------|--------------|
| ADC0   | MCR      | 32   | 0x0    | 0xFBE00000 | 32-bit       |

#### B.2 Introduction changes

|                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"><li>• In <a href="#">Table 2-1</a>, ADC Analog Reference voltage updated as "3.15 V to 5.5 V".</li></ul> |
|--------------------------------------------------------------------------------------------------------------------------------------------|

#### B.3 Embedded Memory changes

|                                                                                  |
|----------------------------------------------------------------------------------|
| <ul style="list-style-type: none"><li>• No substantial content changes</li></ul> |
|----------------------------------------------------------------------------------|

## B.4 Signal Description changes

- In [Table 4-7](#) short signal description of:
  - Port pin I[5] is changed from "LFAST PLL Phase 0 clock on negative terminal" to "SIPI/LFAST PLL Phase 0 clock on negative terminal"
  - Port pin C[12] is changed from "LFAST PLL Phase 0 clock on positive terminal" to "SIPI/LFAST PLL Phase 0 clock on positive terminal"
- In [LVDS pins/balls](#) deleted 'Debug LFAST' from footnote in table.

## B.5 Memory Map changes

- In [Table 5-1](#), added footnote in DMAMUX\_0 and DMAMUX\_1 entries at PCTL 36 and PCTL 146 respectively
- In [Table 5-6](#), In DCF Records row :
  - Updated End address column to 0x004009FF
  - Updated Allocated size (bytes) column to 2048
- In [Table 5-1](#), the Reserved row from 0xFFC08000 to 0xFFC0C003 address is now split into two separate rows:
  - 0xFFC08000 to 0xFFC0BFFF - Reserved
  - 0xFFC0C000 to 0xFFC0C003 - Generic Control Register

## B.6 Functional Safety changes

- No substantial content changes

## B.7 Chip Configuration changes

- Rewrote [FCCU chip-specific register reset values](#), formerly titled "FCCU register default values." Added rows for the FCCU\_CFG\_TO and FCCU\_NCF\_TO registers. Because the information about the reset value of FCCU\_CFG after a configuration timeout is now covered in the register description, deleted the related information in the row for the FCCU\_CFG register. Corrected the reset value of FCCU\_NCFS\_CFG0 from 0002\_0000h to 0000\_0000h.
- Reset value of SSCM\_MEMCONFIG[MREV] is changed from 1h to 2h in [SSCM\\_MEMCONFIG reset value](#) section.
- Added [Motor control configurations](#) as a new section
- In [Table 7-33](#)
  - Added footnote to NCF[14]
  - Previous errata e7858 integrated into reference manual, added footnote to NCF[26]
  - Updated the signal description for NCF[33]
  - Removed "Default Functional Reset (Short, Long, None)" column from this table and added a note: "Functional reset is not generated by any of the fault by default (after reset)."
  - Updated Signal description column for various NCF's.
- In [Table : Corresponding error sources for OFLWn registers](#), added footnote in "Core I-Cache - MEMU\_SYS\_RAM\_OFLW0: bit 1" and "Core D-Cache - MEMU\_SYS\_RAM\_OFLW0: bit 2" rows.
- In [Platform Configuration Module \(PCM\)](#) :
  - Reset value of PCM\_IAHB\_BE1 register changed to 0007\_0707h.

- Reset value of PCM\_IAHB\_BE2 register changed to 0007\_0707h.
- In PCM\_IAHB\_BE1 register : Access for the reserved bit fields [5:7], [21:23] and [29:31] are changed to R/W.
- In PCM\_IAHB\_BE2 register : Access for the reserved bit fields [13:15] and [29:31] are changed to R/W.
- PCM\_IAHB\_BE1[PRE] changed to Reserved bit.
- PCM\_IAHB\_BE2[PRE] changed to Reserved bit.
- Added Note in [Periodic Interrupt Timer \(PIT\) configuration](#) section
- In [System Status and Configuration Module \(SSCM\) configuration](#) added a note "UART and SCI are used interchangeably in the document beyond this point."
- In [Table 7-16](#), removed the redundant Reserved rows from the table for better readability
- In [Table 7-12](#), updated OPACR value for SAR ADC\_0 to 127
- In [Ethernet \(ENET\) configuration](#) :
  - Previous errata e7251 integrated into reference manual : added a Note
  - Added a new paragraph : "The ENET module's RMII\_CLK can be output ...."
  - Added a new sub section : Generic Control Register
- Added a footnote in [Figure 7-8](#)
- Added a Note in [Flash Memory Controller \(PFLASH\) configuration](#) section
- In [Debug](#) section, added [Table 7-34](#)
- Updated [Software Watchdog Timer \(SWT\) configuration](#) section
- Updated [Table 7-3](#)
- Updated paragraph text in [Fault inputs](#) section
- Previous errata e8229 integrated into reference manual : added a new section [FCCU chip-specific glitch-filter guidelines](#)

## B.8 Reset changes

- No substantial content changes

## B.9 DCF Records changes

- In [DCF clients available in the SOC](#) section : Updated table

## B.10 Device Security changes

- No substantial content changes

## B.11 Debug changes

- Previous errata e8014 integrated into reference manual, added a note in [Introduction](#) section.
- In [DID register reset and parameter values](#), added a new maskset bullet point as: Maskset N15P: 29B4501Dh

## Power Management changes

- Added a new section [Device identification register reset values](#).
- Previous errata e6726 integrated into reference manual : In [Features](#), added Note - "MCKO may be gated one clock period early when ...."

## B.12 Power Management changes

- In **Power-on Reset** the slow ramp up / ramp down of battery supply and following VDD is changed from 0.5 V / min. to 0.9 V / sec.

## B.13 Clocking changes

- Updated [Figure 13-1](#), to show PLL1 as a source for AUX Clock Selector 0.
  - Updated [Figure 13-3](#) :BIU clock input signal connection changed from MOTC\_CLK to PGBRIDGEEx\_CLK for CTU and SGEN blocks.
- 
- Previous errata e8227 integrated into reference manual, added note in [Peripheral clocks](#) section.
  - Updated paragraph text in [Clock monitoring](#)
  - In [Clock generation](#), added a Note.

## B.14 e200z4 Core Complex Overview changes

- No substantial content changes

## B.15 Core description module changes

- **Table 15-4 :**
  - Correction: se\_lbz latency is 2 (was previously stated as 22)
  - Clarification: Footnote added to se\_lwz latency ("Aligned")
  - Clarification: Footnote added to se\_sth latency ("Aligned")
  - Clarification: Footnote added to se\_stw latency ("Aligned")
- **Table 15-5 :**
  - Clarification: Footnote added to divwo[.] latency ("With early-out capability, timing is data-dependent.")
  - Clarification: Footnote added to divwu[.] latency ("With early-out capability, timing is data-dependent.")
  - Clarification: Footnote added to divwuof[.] latency ("With early-out capability, timing is data-dependent.")
  - Clarification: Footnote added to e\_lhau latency ("Aligned.")
  - Clarification: Footnote added to lhax latency ("Aligned.")
  - Clarification: Footnote added to lhbrx latency ("Aligned.")
  - Clarification: Footnote added to e\_lhz latency ("Aligned.")
  - Clarification: Footnote added to e\_lhzu latency ("Aligned.")
  - Clarification: Footnote added to lhuzx latency ("Aligned.")
  - Clarification: Footnote added to lhzx latency ("Aligned.")
  - Clarification: Footnote added to lwbrx latency ("Aligned.")
  - Clarification: Footnote added to e\_lwz latency ("Aligned.")

- Clarification: Footnote added to e\_lwzu latency ("Aligned.")
  - Clarification: Footnote added to lwzux latency ("Aligned.")
  - Clarification: Footnote added to lwzx latency ("Aligned.")
  - Clarification: Footnote added to mfdcr latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to mfspr (DEBUG, CACHE, LMEM < MPU) latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to mpure latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to mpuwe latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to msync latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to mtmsr latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to mtspr (DEBUG, CACHE, LMEM < MPU) latency ("Plus additional synchronization time.")
  - Clarification: Footnote added to e\_sth latency ("Aligned.")
  - Clarification: Footnote added to sthbrx latency ("Aligned.")
  - Clarification: Footnote added to e\_sthu latency ("Aligned.")
  - Clarification: Footnote added to sthux latency ("Aligned.")
  - Clarification: Footnote added to sthx latency ("Aligned.")
  - Clarification: Footnote added to e\_stw latency ("Aligned.")
  - Clarification: Footnote added to stwbrx latency ("Aligned.")
  - Clarification: Footnote added to e\_stwu latency ("Aligned.")
  - Clarification: Footnote added to stwux latency ("Aligned.")
  - Clarification: Footnote added to stwx latency ("Aligned.")
  - [Table 15-6](#) :
    - Clarification: Footnote added to efsmsub throughput ("Destination register is also a source register, so for full throughput, back-to-back operations must use a different destination register.")
    - Clarification: Footnote added to efsnmadd throughput ("Destination register is also a source register, so for full throughput, back-to-back operations must use a different destination register.")
    - Clarification: Footnote added to efsnmsub throughput ("Destination register is also a source register, so for full throughput, back-to-back operations must use a different destination register.")
  - [Table 15-8](#) :
    - Clarification: Footnote added to throughput ("Timing is data-dependent.")
  - [Table 15-18](#) :
    - For Reserved bits 8:11, 13:14, 19:24, and 28, changed footnote number from 2 to 1
  - [Instruction timing](#) :
    - Changes to Instruction class cycle counts ([Table 15-3](#)):
      - "Description" column heading changed to "Throughput"
      - "Integer: compare" latency is 1 (previously was no value)
      - "Integer: compare" throughput is 1 (previously was no value)
      - Extraneous row (Branch with Latency 3/2/1) deleted
    - Changes to Instruction timing by mnemonic—16-bit instructions ([Table 15-4](#)):
      - Correction: Previously, se\_cmpl instruction appeared twice. Second instance changed to se\_cmpli
    - Changes to Instruction timing by mnemonic—32-bit instructions ([Table 15-5](#)):
      - Correction: Extraneous ">" suffix deleted from addco[.] instruction
      - Correction: e\_sc latency value is 4 (previously stated as 1).
      - Correction: Latency value for mtspr (except DEBUG, msr, hid0/1) is 1 (previously stated as "i").
  - [Machine State Register \(MSR\)](#) :
    - Bits added to register figure and field descriptions table:
      - SPV (SP/Embedded FP/Vector available)
      - WE (Wait State (Power management) enable)
      - FP (Floating-Point Available)
      - FE0 (Floating-point exception mode 0)
      - FE1 (Floating-point exception mode 1)
      - IS (Instruction Address Space)
      - DS (Data Address Space)
- NOTE:**
- None of the above bits are functional. They were previously shown as reserved bits but are redefined to clearly show any deviations from Book III-E of the Power ISA version 2.06 specification.
- [Dual-issue operation](#) :

## SIUL2 module changes

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <ul style="list-style-type: none"><li>Removed bullet beginning with, "Operation at a 1-to-1 clock frequency..." from <a href="#">Features</a>.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## B.18 XBIC module changes

|                                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"><li><a href="#">Overview</a> : Removed content which is not useful to customer.</li></ul> |
|-----------------------------------------------------------------------------------------------------------------------------|

- [Features](#) : Removed bullet beginning with "hready, hresp0, and hresp2..."
- [Functional description](#) : Section has been rewritten. Removed "XBIC H Matrix Definition" table.
- [Block diagram](#) :
  - Replaced cross references to figures with "the following diagram."
  - In XBIC system block diagram, corrected label on top green signal to "hready, hresp0, hresp2".
  - Removed figure, "XBIC block diagram".
- Changed "last transfer" to "first transfer" in XBIC\_EAR register description.
- Minor editing.
- [XBIC Error Status Register \(XBIC\\_ESR\)](#) : Previous errata e8310 integrated into the RM: Added note to register description.
- [XBIC Error Address Register \(XBIC\\_EAR\)](#) : Previous errata e8310 integrated into the RM: Added note to register description.

## B.19 AIPS module changes

- Edited [General operation](#).

## B.20 SMPU module changes

- In [Figure 20-1](#) of [Block diagram](#) section: in upper right corner, changed "Internal peripheral bus" to "Register access"
- In [Features](#) section:
  - Removed what was the first list item: "Support for a maximum of 16 program-visible 128-bit region descriptors, accessible as four 32-bit words each. "
  - Changed first (formerly second) list item from "Each region descriptor defines an arbitrarily-sized space, aligned anywhere in memory" to "Arbitrarily sized protection regions alignable anywhere in memory."
  - Moved first five list items to highest level in list hierarchy
- For [Error Address Register, Bus Master n \(SMPU\\_EARn\)](#) changed reset value from "Undefined at reset" to 0000\_0000h
- For [Error Detail Register, Bus Master n \(SMPU\\_EDRn\)](#) changed reset value from "Undefined at reset" to 0000\_0080h
- In [Hit determination](#) section:
  - Replaced Boolean equation for hit determination with new sentence: "When RGDn\_Word3[VLD] is 1, a region hit occurs when the requested address is between the start address (RGDn\_Word0[SRTADDR]) and the end address (RGDn\_Word1[ENDADDR]), inclusive."
  - Changed first Note from "The SMPU does not verify that ENDADDR >= SRTADDR" to "If ENDADDR < SRTADDR, no hit occurs."
- Changed title of [Final evaluation and error terminations](#) section (formerly was "Putting it all together and error terminations")

## B.21 INTC module changes

- In [Interrupt sources](#), changed "chapter that describes how modules are configured and connected" to "chip-specific INTC information".
- In [TIMERn](#), changed INUM to IRQ.
- In [Block diagram](#), revised the stem sentence and figure title to indicate that the diagram is an example of a four-processor configuration, and that the actual number of supported processors is given in the chip-specific INTC information.

## eDMA module changes

- In [Features](#), ensured that the bulleted list shows only those processors supported on this chip.
- Revised [Memory map and register definition](#) to show only those registers and fields actually present on this chip.
- In [Features](#), changed "monitor the latency of up to 4 interrupt sources per corresponding Processor" to "monitor the latency of interrupt sources for a corresponding Processor".
- In [Memory map and register definition](#), changed "Although INTC\_SSIn are 8 bits wide..." to "Although INTC\_SSICRn are 8 bits wide...".
- In [Memory map and register definition](#) :
  - Added [Figure 21-2](#) and surrounding text explaining write restrictions for PSRn and SSICRn.
  - In [INTC Priority Select Register \(INTC\\_PSRn\)](#) and [INTC Software Set/Clear Interrupt Register \(INTC\\_SSICRn\)](#), added "See [Figure 21-2](#) for limitations on writing to this register."

## B.22 eDMA module changes

- Changed description for value b101 of TCD\_ATTR[SSIZE] to "32-byte burst (4 beats of 64 bits)".
- [eDMA initialization](#) : Changed "ERQ register" to "ERQH and ERQL registers" in bullet 5.
- Made several editorial corrections and improvements.
- Made editorial change to [Features](#) : "data packet" to "transferred data".
- Added note to DMA\_DCHMIDn[EMI] bit field description.
- [Fault reporting and handling](#) : Added note re. cancel transfer request. Added note re. channel priority errors.
- [Block parts](#) : Changed "16 bytes of register storage" to "a data buffer" in Data path description.
- Added note to DMA\_CR[CLM] description re. restriction on use of continuous link mode.
- In section "Peak transfer rates", added a note stating "All architectures will not meet the assumptions listed above. See the SRAM configuration section for more information."
- [Features](#) : Removed bullet beginning with, "Support to cancel transfers..."
- Made editorial changes in [Fault reporting and handling](#).
- Editorial changes.
- Removed "(INTC)" from [Interrupt Request Register \(DMA\\_INT\)](#) description.
- Changed the following descriptive names of registers and fields:
  - TCD Minor Byte Count (Minor Loop Disabled) to TCD Minor Byte Count (Minor Loop Mapping Disabled).
  - TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) to TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled).
  - TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) to TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled).
  - Link Channel Number to Minor Loop Link Channel Number (DMA\_TCDn\_CITER\_ELINKYES[LINKCH]).
  - Link Channel Number to Major Loop Link Channel Number (DMA\_TCDn\_CSR[MAJORLINKCH]).
- Edited [Introduction](#).
- Edited note in UCE field description in [Error Status Register \(DMA\\_ES\)](#).
- [Dynamic channel linking](#) : Added cross-reference to TCD structure.
- Edited [Features](#).
- Edited [CLM](#) description.
- [Error Status Register \(DMA\\_ES\)](#) : Added two causes of channel errors to list in register description.

## B.23 DMAMUX module changes

- Removed the address information of CHCFG1 register (base address + 0x01) and CHCFG8 (base address + 0x08) from the section "Enabling and configuring sources."

## B.24 EIM module changes

- Edited throughout
  - In [Memory map and register definition](#) introduction text, changed register mnemonic from "Word" to "WORD"
  - [Error Injection Channel Descriptor, Word1 \(EIM\\_EICHDn\\_WORD1\)](#)
    - Changed name of field from Upper Data Mask (UDATA\_MASK) to Data Mask Bytes 0-3 (B0\_3DATA\_MASK), and changed references to the field accordingly
    - In [B0\\_3DATA\\_MASK](#) description, added text: "For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 0-3 of the read data bus, see the chip-specific EIM information."
  - [Error Injection Channel Descriptor, Word2 \(EIM\\_EICHDn\\_WORD2\)](#)
    - Changed name of field from Lower Data Mask (LDATA\_MASK) to Data Mask Bytes 4-7 (B4\_7DATA\_MASK), and changed references to the field accordingly
    - In [B4\\_7DATA\\_MASK](#) description, added text: "For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 4-7 of the read data bus, see the chip-specific EIM information."
  - [Functional description](#)
    - Added a Note: "When the use case for a channel requires writing any EICHD\_WORD register, write the EICHD\_WORD register before executing the two-stage enable mechanism. A successful write to any EICHD\_WORD register clears the corresponding EICHEN[EICHEN] field."
- 
- [Overview](#)
    - Added Note preceding diagram: "The following diagram shows an example EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus."
    - To title of [Figure 24-1](#) added: "(64-bit read data bus and 8-bit checkbit bus)"
  - [Memory map and register definition](#)
    - Reorganized first paragraph into subsection titled "Programming model access"
    - Completely revised second paragraph and reorganized it into subsection titled "Error injection channel descriptor: function and structure"
    - For [Error Injection Channel Enable register \(EIM\\_EICHEN\)](#) edited and reorganized register and field descriptions and renamed field from EICHEN to EICH0EN
    - Renamed registers and changed references to them accordingly:
      - EICHD\_WORD0 to EICHD0\_WORD0
      - EICHD\_WORD1 to EICHD0\_WORD1
      - EICHD\_WORD2 to EICHD0\_WORD2
    - For [CHKBIT\\_MASK](#) in [Error Injection Channel Descriptor, Word0 \(EIM\\_EICHDn\\_WORD0\)](#) added text to field description: "The width of the field for the channel is defined in the chip-specific EIM information."
    - Incorporated editorial changes in descriptions of [Error Injection Channel Descriptor, Word1 \(EIM\\_EICHDn\\_WORD1\)](#) and [Error Injection Channel Descriptor, Word2 \(EIM\\_EICHDn\\_WORD2\)](#)
    - Revised descriptions of [B0\\_3DATA\\_MASK](#) field in [Error Injection Channel Descriptor, Word1 \(EIM\\_EICHDn\\_WORD1\)](#) and [B4\\_7DATA\\_MASK](#) field in [Error Injection Channel Descriptor, Word2 \(EIM\\_EICHDn\\_WORD2\)](#)
  - Edited all content in [Functional description](#)
- 
- In [Memory map and register definition](#) changed first sentence:
    - from: "The EIM provides an IPS programming model mapped to a standard 16 KB slot for an on-platform peripheral."
    - to: "The EIM provides an IPS programming model mapped to an on-platform peripheral slot."
- 
- [Memory map and register definition](#)
    - Minor editorial changes: in each list item of first two unordered lists, capitalized first letter of first word
- 
- [Memory map and register definition](#)
    - Edited and reorganized text in [Error injection channel descriptor: function and structure](#)

## B.25 PLLDIG changes

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

- Updated figure [Figure 25-1](#) to show correct modulation depth.
- In [PLL1DIG PLL1 Fractional Divide Register \(PLL1DIG\\_PLL1FD\)](#)
  - Replaced DTHDIS field with Reserved field at offset 15.

## B.26 CMU changes

- [CLKMN1 supervisor](#)
  - Updated NOTE to read "(HFREF<sub>Actual</sub> = (HFREF<sub>Ideal</sub> ÷ 0.95))" instead of "(HFREF<sub>Actual</sub> = (HFREF<sub>Ideal</sub> + 2) × 1.05)".
  - Added "The actual LFREF value will be 762 when the accuracy is taken into consideration (LFREF<sub>Actual</sub> = (LFREF<sub>Ideal</sub> ÷ 1.05))." to the NOTE.
- [Main features](#)
  - Updated second bullet to "CLKMN0\_RMT monitoring with respect to CLKMT0\_RMN ÷ 2<sup>CSR[RCDIV]</sup> clock."
- Added CMU\_ prefix in front of register/field names that did not previously include it.
- [CMU Frequency Display Register \(CMU\\_FDR\)](#)
  - Updated register description placing items in a bullet list.
- [CMU Interrupt Status Register \(CMU\\_ISR\)](#)
  - Updated Note in register description, "All flags in the CMU\_ISR are set..."
  - Updated bitfield description [FHHI](#)
  - Updated bitfield description [FLLI](#)
- [Frequency meter](#)
  - Added "[FD]" to end of CMU\_FDR throughout where it was not previously included.
- [CMU Interrupt Status Register \(CMU\\_ISR\)](#)
  - Updated the Note in the [OLRI](#) bitfield description, "When attempting to enter STOP mode..."

## B.27 MC\_CGM changes

- Previous errata e7103 integrated into reference manual, added a note "If the current system clock source.....of the switch." in SELSTAT bit of [System Clock Select Status Register \(MC\\_CGM\\_SC\\_SS\)](#) register.
- Previous errata e7250 integrated into reference manual, added a note "Always write.....registers." and changed bit access from RO to RW in DE bit of [System Clock Divider 0 Configuration Register \(MC\\_CGM\\_SC\\_DC0\)](#) register.
- Updated the bit-width of MC\_CGM\_AC0\_SC[SELCTL] to [5:7] and added the clock source availability for PLL1 PHI at 100b.
- Updated the bit-width of MC\_CGM\_AC0\_SS[SELSTAT] to [5:7] and added the clock source availability for PLL1 PHI at 100b.
- Added Note in MC\_CGM\_AC0\_SC register description.

## B.28 XOSC changes

- No substantial content changes
- [XOSC Control Register \(XOSC\\_CTL\)](#)
  - Updated XOSC\_CTL[I\_OSC] field access.

## B.29 IRCOSC changes

- [Frequency trimming calculation](#)
  - Updated table contents replacing  $\delta F_{\text{var\_SW}}$  with  $\delta f_{\text{TRIM}}$ .
  - Updated all instances of "F" with "f" to represent frequency.

## B.30 PRAMC module changes

- [SRAM controller memory map and register definition](#) :
  - Note added regarding caution required when reconfiguring platform RAM controller during device operation
- [e2eECC considerations on less-than-64-bit write transactions](#) :
  - Added to end of section: "Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module."
- [Less than 64-bit writes](#) :
  - Added single bit and multi bit error signals to Read-modify-write data path figure
  - Changed hardware signal names to names that describe signal function more clearly
- [Optional read wait-state](#) :
  - All references to the PRCR1 register changed to "PRCRx". This is only an editorial change--there is no change to any register name or function.
- [Read and write operations \(formerly "Read / Write introduction"\)](#) :
  - Section completely rewritten

## B.31 Flash memory controller module changes

- [Functional description](#) :
  - Deleted from first sentence: "As shown in the block diagram"
- [ECC on data flash accesses](#) :
  - Editorial changes
  - Clarification: Following note added: "EEPROM should be avoided for storage of executable code."
- [Platform Flash Remap Descriptor Enable Register \(PFLASH\\_PFCRDE\)](#) :
  - Clarification: Only CRD0EN - CRD7EN fields (bits 0 - 7) are valid for this device because it can have a maximum of 8 overlay regions. The remaining bits are read only zero reserved bits.
- [Platform Flash Remap Control Register \(PFLASH\\_PFCRCR\)](#) :
  - Correction: PFLASH\_PFCRCR[SAFE\_CAL] field description updated to state the correct reduced number of calibration regions available if SAFE\_CAL=1. When the SAFE\_CAL field is set, the number of available calibration regions is reduced by half. For this device, if SAFE\_CAL=1, the number of calibration regions available is reduced to 4.
- [Platform Flash Configuration Register 1 \(PFLASH\\_PFCR1\)](#) :
  - Clarification: The PFLASH\_PFCR1[P0\_BFEN] field can only be updated when PFLASH\_PFCR3[BFEN\_LK]=0.
- [Platform Flash Configuration Register 3 \(PFLASH\\_PFCR3\)](#) :
  - Reserved field at bit 15 deleted
  - New field added at bit15: BFEN\_LK. This field must be set to 0 before the PFCR1[P0\_BFEN] field can be updated.

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <ul style="list-style-type: none"> <li>• <b>Platform Flash Configuration Register 1 (PFLASH_PFCR1) :</b> <ul style="list-style-type: none"> <li>• Clarification: Following statement added to PFLASH_PFCR1[APC] field description: "For valid RWSC and APC combinations please refer to the device data sheet.</li> <li>• Following note in PFLASH_PFCR1[APC] field description reformatted into note list: "A value of '1' in the most significant bit causes the flash controller to function in retrograde/legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup."</li> <li>• Added to note list in PFLASH_PFCR1[APC] field description: "Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet."</li> </ul> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                       |

## c55fmc module changes

- Clarification: Updated portion of PFLASH\_PFCR1[RWSC] field description that points to data sheet for valid values to state, "For valid RWSC and APC combinations please refer to the device data sheet. (was "The required settings are documented in the device data sheet")
- Clarification: Following statement in PFLASH\_PFCR1[RWSC] field description reformatted as item in note list for emphasis: "Higher operating frequencies require non-zero settings for this field for proper flash operation"
- Clarification: Added to note list in PFLASH\_PFCR1[RWSC] field description: "Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet"

## B.32 c55fmc module changes

- **Features :**
  - Clarification: Feature "Triple Voted Flops for flash functions requiring high reliability" changed to, "Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control"
- **Over-Program Protection 0 register (C55FMC\_OPP0) :**
  - Correction: Two most significant bits of the register always reset to 0 (previously shown as dependent on chip configuration)
  - Clarification: Footnote in register diagram replaced with footnotes stating that the reset value of each field (LOWOPP and MIDOPP) varies among devices
- **Over-Program Protection 1 register (C55FMC\_OPP1) :**
  - Correction: Sixteen most significant bits of the register always reset to 0 (previously shown as varying among devices)
  - Clarification: Footnote in register diagram replaced with footnote stating that the reset value of the HIGHOPP field varies among devices
- **Over-Program Protection 2 register (C55FMC\_OPP2) :**
  - Clarification: Footnote in register diagram replaced with footnote stating that the reset value of the A256KOPP field varies among devices
- **Over-Program Protection 3 register (C55FMC\_OPP3) :**
  - Correction: Sixteen most significant bits of the register always reset to 0 (previously shown as varying among devices)
  - Clarification: Footnote in register diagram replaced with footnote stating that the reset value of the A256KOPP field varies among devices

## B.33 Flash OTP changes

- No substantial content changes

## B.34 DSMC module changes

- No substantial content changes

## B.35 ADC Configuration changes

- In [CTU interface](#), added Note: "CTU Clock (MC\_CLK) and ADC\_CLK should either be same and synchronous or CTU can also operate with ADC\_CLK being an integer plus half (1.5, 2.5, 3.5, ...) of MC\_CLK clock."
- Added a new topic [ADC channel conversion](#) under [ADC pin muxing](#)

## B.36 ADC module changes

- [Features](#) :
  - Added list of channels for each group of ADC channels.
- In [Normal conversion](#) :
  - Added list of channels for each group of ADC channels.
- In [Presampling channel enable](#) :
  - Added list of channels for each group of ADC channels.
- In [Injected conversion](#) :
  - Added list of channels for each group of ADC channels.
- In [Analog watchdog setting](#) :
  - Added list of channels for each group of ADC channels.
- [ADC clock prescaler and sample time settings](#) :
  - Added list of channels for each group of ADC channels.
- [Self test \(Quick-Check/Safety mode\)](#) :
  - Clarification: ADC self test step 1, "Supply self-test (analog supply)", was previously described as "Measures the analog supply for the ADC". Changed to: "Measures the analog supply voltage (VDDA) and divides the result by the bandgap voltage (result from Algorithm S step 0). The VDDA conversion result is written to ADC\_STDR1[TCDATA]. The final result (after division) consists of an integer portion and a fractional portion, both of which are written to the ADC\_STDR2 register."
  - Comment added regarding pre- and post-conversion scaling of the analog supply voltage that results in the least significant bits of the VDDA conversion result always being '0'.
- [Self Test Data Register 1 \(ADC\\_STDR1\)](#) :
  - Updated register description: "The ADC\_STDR1 register contains the most current result data for conversions executed during ADC self test. Additionally, the register contains status bits to indicate whether result data has been read and whether existing conversion data has been overwritten by a newer result."
  - Note added: "For Algorithm S step 1, the result data contained in this register is not the final step 1 result. The step 1 data is the conversion of the analog supply (VDDA). This VDDA conversion result is divided by the Algorithm S step 0 conversion data and the result is written to the ADC\_STDR2 register."
  - Detailed note added regarding pre- and post-conversion scaling of the analog supply voltage that results in the least significant bits of the VDDA conversion result always being '0'.
- [Calibration, BIST Control and status Register \(ADC\\_CALBISTREG\)](#) :
  - Default register reset value changed to C037\_0670h (was 2037\_06F0h)
- [Conversion Timing Register 0 \(ADC\\_CTR0\)](#) :
  - Default register reset value value changed to 0000\_0014h (was 0000\_0016h)
- [Conversion Timing Register 1 \(ADC\\_CTR1\)](#) :
  - Default register reset value value changed to 0000\_0014h (was 0000\_0016h)
- [Self Test Analog Watchdog Register 0 \(STAW0R\)](#) :
  - Correction: The ADC\_STAW0R[THRL] register field description has been updated to state that if the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA] < THRL. Previously stated that the input was expected in 2's complement format and that the error bit would be set if (Absolute value of STDR1[TCDATA]) > (Absolute value of THRL). The value entered is NOT interpreted as 2' complement.
  - Correction: The ADC\_STAW0R[THRH] register field description has been updated to state that if the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA] > THRH. Previously stated that the

## ADC module changes

input was expected in 2's complement format and that the error bit would be set if (Absolute value of STDR1[TCDATA]) > THRH.. The value entered is NOT interpreted as 2' complement.

- Throughout [Memory Map/Register Definition](#) :
    - Changed Vref to VREF
    - Spelling corrections
    - Formatting changes
  - [Self Test Analog Watchdog Register 0 \(ADC\\_STAW0R\)](#) :
    - Register description updated
    - Clarification. Note added to ADC\_STAW0R[THRH] and ADC\_STAW0R[THRL] field descriptions: "The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments."
    - ADC\_STAW0R[AWDE] field description updated
    - ADC\_STAW0R[WDTE] field description updated
  - [Self Test Status Register 3 \(ADC\\_STSR3\)](#) :
    - Correction: Equation in ADC\_STSR3[DATA0] field changed to "Test channel data = VREF/VBGAP" (was "...VBGAP/VREF")
  - [Self Test Analog Watchdog Register 1A \(ADC\\_STAW1AR\)](#) :
    - Register description updated
    - Clarification. Note added to ADC\_STAW1AR[THRH] and ADC\_STAW1AR[THRL] field descriptions: "The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments."
  - [Self Test Analog Watchdog Register 1B \(ADC\\_STAW1BR\)](#) :
    - Register description updated
    - Clarification. Note added to ADC\_STAW1BR[THRH] and ADC\_STAW1BR[THRL] field descriptions: "The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments."
  - [Self Test Analog Watchdog Register 2 \(ADC\\_STAW2R\)](#) :
    - Register description updated
    - Clarification. Note added to ADC\_STAW2R[THRL] field description: "The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments."
  - [Self Test Analog Watchdog Register 4 \(ADC\\_STAW4R\)](#) :
    - Register description updated
    - Clarification. Note added to ADC\_STAW4R[THRH] and ADC\_STAW4R[THRL] field descriptions: "The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments."
    - ADC\_STAW4R[AWDE] field description updated
    - ADC\_STAW4R[WDTE] field description updated
  - [Self Test Analog Watchdog Register 5 \(ADC\\_STAW5R\)](#) :
    - Register description updated
    - Clarification. Note added to ADC\_STAW5R[THRH] and ADC\_STAW5R[THRL] field descriptions: "The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments."
- 
- In [Calibration \(High Accuracy mode\)](#), removed "For example, if the ADC is calibrated with a 3.3V reference and operated with a 5V reference, it must be recalibrated".
- 
- Editorial updates throughout chapter.
  - [Conversion data processing](#)
    - Updates throughout section.

- In bitfield [JECH](#) of ISR
    - Added NOTE, "If there is no channel selected in the ADC\_JCMRn register(s)..." to field description.
  - In bitfield [ECH](#) of ISR.
    - Added NOTE, "If there is no channel selected in the ADC\_JCMRn register(s)..." to field description.
  - [Offset and Gain User Register \(ADC\\_OFSGNUSR\)](#)
    - Removed "[15 bit accurate]" from the field descriptions of OFFSET\_USER and GAIN\_USER.
    - Added note "A detailed description of the use of OFSGNUSR..." to register description.
  - [User-defined offset and gain values](#) and its subsections
    - Significant updates throughout.
  - [Conversion time](#)
    - Changed title to 'Conversion time' from 'Compare phase time'
    - Significant updates throughout.
- 
- [NSTART](#)
    - Added Note to the MCR[NSTART] bitfield description, "This bit cannot be set (1) when PWDN = 1. This bit is always cleared when PWDN = 1."
- 
- Register CTR0 ([Conversion Timing Register 0 \(ADC\\_CTR0\)](#))
    - Added Note "The Bandgap voltage sampling time is controlled..." to the CTR0[INPSAMP] field description ([INPSAMP](#)).
- 
- [Self Test Status Register 2 \(ADC\\_STSR2\)](#) :
    - Correction: OVFL bit is read-only (previously was shown as R/W)
- 
- [Presampling channel enable](#)
    - Updated "VDD\_HV\_ADV (Power High voltage Supply for ADC, SGEN)" to "VDD\_HV\_ADV/8 (Power High voltage Supply for ADC, SGEN divided by 8)" in table [Table 36-1](#).
- 
- In bitfield [PRECONV](#) of PSCR
    - Added "This bit has no effect on conversion of a channel..." to the field description.
- 
- [Presampling channel enable](#)
    - Updated formatting of table [Table 36-2](#), added table title, and added a cross reference to the table in the preceding text.
    - Updated formatting of table [Table 36-1](#), added table title, and added a cross reference to the table in the preceding text.
    - Added cross reference in first paragraph to the PSCR register.
- 
- [Main Configuration Register \(ADC\\_MCR\)](#)
    - Updated the field access of Reserved field at bit location 6 ([Reserved](#)) to RW.
    - Added Note to Reserved bit field 6 description ([Reserved](#)) "User must not overwrite default value of this field."
- 
- [Calibration \(High Accuracy mode\)](#)
    - Updated content throughout.
- 
- [Parts of the ADC](#)
    - Removed "TEST Interface" bidirectional i/o from [Figure 36-1](#).
- 
- [Parts of the ADC](#)
    - Updated 'ADC high-level block diagram' [Figure 36-1](#) removing the text "and external" from "(to on-chip and external mux)". It now reads "(to on-chip mux)"
- 
- Removed the text "BCTU" throughout section "Memory Map/Register Definition".
- 
- [Crosstriggering Unit interface](#)
    - Changed the signal name 'ctu\_push' to 'ctu\_EOC' in [Figure 36-4](#).
  - [OPMODE](#)
    - Updated field and field values descriptions.
- 
- [Features](#)
    - Reformatted bullet "Modes of operation".
- 
- [Self Test Analog Watchdog Register 4 \(ADC\\_STAW4R\)](#)
    - Updated field description of [THRH](#).
    - Updated field description of [THRL](#).
  - [Self Test Analog Watchdog Register 5 \(ADC\\_STAW5R\)](#)

## Temperature Sensor changes

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## B.37 Temperature Sensor changes

|                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"><li>In <a href="#">Temperature formula</a>, removed the equations for K1, K2, K3, K4, and dependent content.</li><li>In <a href="#">Temperature formula</a>, removed the "Calibration Points" figure and its introductory sentence.</li></ul> |
| <ul style="list-style-type: none"><li>Editorial changes and rephrased text in <a href="#">Introduction</a>, <a href="#">Functional Description</a> and <a href="#">Temperature threshold detection (digital output generation)</a>.</li></ul>                                   |
| <ul style="list-style-type: none"><li>"Temperature Sensor" title is changed as "Temperature Sensor (TSENS)".</li></ul>                                                                                                                                                          |

## B.38 SGEN changes

|                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"><li>In <a href="#">Status Register (SGEN_STAT)</a>, changed access type of <a href="#">SGEN_STAT[SERR]</a> from Read/write to Write one to clear.</li></ul> |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## B.39 eTimer module changes

|                                                                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"><li>Removed the word "other" from the <a href="#">ETIMER_CHn_HOLD</a> register description and <a href="#">HOLD</a> field description.</li></ul>                                                           |
| <ul style="list-style-type: none"><li><a href="#">Channel Block Diagram</a><ul style="list-style-type: none"><li>Added "eTimer Channel Block Diagram" image that removed the 'Fault' input on the 'OFLAG Control' block.</li></ul></li></ul> |
| <ul style="list-style-type: none"><li>In <a href="#">Channel n Status Register (ETIMER_CHn_STS)</a>, access for bits [6:15] has been changed from Read/write to Write one to clear.</li></ul>                                                |
| <ul style="list-style-type: none"><li>Editorial cleanup throughout chapter.</li></ul>                                                                                                                                                        |

## B.40 FlexPWM module changes

- Added register access information to all register descriptions.
- Made editorial improvements throughout chapter.
- [Submodule n Status Register \(FlexPWM\\_SUB0\\_STS\)](#) :
  - Access type for following fields changed to write 1 to clear (was R/W): REF, RF, CFX1, CFX0, CMPF
  - Added reserved register at address offset 0x14A
- Added point "Capture is supported only for X channels not A and B channels" in Features section

## B.41 CTU module changes

- In CTU\_CR section note, added CTU\_ODIS to the list of bits that can be read and set by software.
- Changed registers CTU\_TGSCRR, CTU\_FDCR, and CTU\_CNTRNGR to 16 bits wide.
- Revised CTU\_EFR[ICE] field description.
- In [ADC commands list](#), revised note to clarify command list execution.
- In [ADC command list format](#), revised command sequencing description to clarify the concept of a single command list.
- Previous errata e8137 integrated into the RM: In CTU\_EFR and CTU\_IFR register sections, added note to clarify flag behavior at reset.
- Revised CTU\_IFR register description to read "The IFR register bits are cleared . . ." (was "The EFR register bits are cleared . . .").
- Editorial changes and improvements.
- In [ADC command list format](#), revised "Command list sequencing" figure and corresponding figure description.
- In [ADC results FIFOs](#), changed text to "The CTU FIFOs are fixed depth" (was "The CTU supports several...").
- In [Error Flag Register \(CTU\\_EFR\)](#), revised note ("The ERRCMP field reads 0...") (was "The Tn\_OE fields read 0...").
- Previous errata e7338 integrated into the RM: added note ("If the system attempts to access...") to "Memory Map and Registers" section.

## B.42 STM module changes

- In [Functional description](#)
  - Incorporated minor edits
- For reserved fields of following registers, added text to each field description: "This field is reserved."
  - [STM Control Register \(STM\\_CR\)](#)
  - [STM Channel Control Register \(STM\\_CCRn\)](#)
  - [STM Channel Interrupt Register \(STM\\_CIRn\)](#)

## B.43 SWT module changes

- Memory Map and Registers: incorporated various edits

## PIT module changes

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <ul style="list-style-type: none"><li>In <a href="#">Table 45-10</a> of <a href="#">Rx FIFO structure</a></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

- Added "Format" to first column of first row
- Changed notation of bit ranges (in parentheses) for RXIDA, RXIDB\_n, and RXIDC\_n

## B.46 Zipwire module changes

- In [Zipwire interconnections](#) : Updated bullet from "Tx and Rx connections to the pads via the SIUL and the MSCR registers" to "Tx and Rx configuration is controlled by LFAST Control registers".
- Removed "LFAST clocking" section.
- In [Architecture](#) : Removed paragraph text "The LVDS pads are shared with other I/O and GPIO."

## B.47 SIPI module changes

- In [ARR register](#) added a note "This register is writeable only when SIPI\_MCR[INIT] = 1." Also removed sentence, "This register can be read or written anytime." from register description.
- In [CCR0\[WRT\]](#), removed a note "Only transfers with channel 2 can write 1 to this bit. All other channels forces SIPI\_CCRn[ST] = 0. The SIPI\_CCR2[WRT] and SIPI\_CCR2[ST] bits must be set for streaming." from the WRT bit field of CCR0-CCR3 registers.
- Added bit field brief description of WRT bit in CCR2 register.
- Updated bit field access for SIPI\_ACR[ADCNT] and SIPI\_ACR[Reserved] to read write.

## B.48 LFAST module changes

- Editorial changes.
- Removed reference to 312/320 MHz and referred to as high data rate. Updated in:
  - [External signals](#) section.
  - [LFAST operating data rates](#) section.
  - [Features](#) section.
  - [Auto correlation](#) section.
  - [Figure 48-6](#) figure.
  - [LFAST Speed Control Register \(LFAST\\_SCR\)](#) : Updated description for bit-value 1 of RDR and TDR bit.
- Editorial changes.
- Removed table from [LFAST operating data rates](#) section.
- LVRXOP bit in LFAST LVDS Control Register (LFAST\_LCR) is split into 3 individual bits:
  - LVRXOP[2] changed to LVRXOP\_TR.
  - LVRXOP[1] changed to Reserved.
  - LVRXOP[0] changed to LVRXOP\_BR.
- Updated the access value of LVLPEN bit to Read/Write in LFAST LVDS Control Register (LFAST\_LCR).
- Updated the description of [LVCKSS] bit in LFAST LVDS Control Register (LFAST\_LCR).
- In [Memory map and register definition](#), added note "Read/Write accesses to all unimplemented registers and write accesses to Read only register will return a Transfer Error."
- Updated the register-access value of [LFAST Rx ICLC Interrupt Status Register \(LFAST\\_RIISR\)](#) register from R/W to W1C.

## B.49 SPI module changes

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## B.51 SRX/SENT module changes

|                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>In <a href="#">Features</a> changed sentence from "Supports compensation for variation in SENT Tx Clock up to <math>\pm 25\%</math> and adjusts its measurement for drift and jitter in the Transmitter and Receiver clocks per channel" to "Supports compensation for</li> </ul> |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

variation in SENT Tx Clock up to  $\pm 25\%$  and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel".

- In [Slow Serial Message Ready Status Register \(SRX\\_SMSG\\_RDY\)](#) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
  - In [Fast Message Ready Status Register \(SRX\\_FMSG\\_RDY\)](#) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
  - In [Initialization sequence](#), Note removed as it was taken care of via ERR007425
  - In [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
  - In [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
  - In [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#), changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
  - In [Slow Serial Message Ready Interrupt Enable Register \(SRX\\_SRDY\\_IE\)](#) changed Note to "Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver".
  - In [Input programmable filter](#) updated value of FIL\_CNT for the example shown and updated the diagram
  - In [CRC check](#) removed Note
  - In [Fast Message Ready Status Register \(SRX\\_FMSG\\_RDY\)](#) removed a Note
  - In [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CHn\\_CLK\\_CTRL\)](#) added a Note to the field CM\_PRSC
  - In [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CHn\\_CLK\\_CTRL\)](#) changed sentence from "The generated Receiver Clock is compensated for variations, clock drift and jitter that might occur in the Sensor Tx Clock" to "The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock".
  - In [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#) changed SMSG\_OFLW bitfield description.
  - In [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_CONFIG\)](#) changed description of field values of bitfield SRX\_CHn\_CONFIG[FCRC\_TYPE] and SRX\_CHn\_CONFIG[SCRC\_TYPE].
  - In [Adjustment for variation in sensor \(Tx\) clock](#) deleted note that starts with "At ambient ...".
  - In [Receiver diagnostics](#) changed bullet point from "Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or XOR-based" to "Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended."
  - In [Nibble value check](#) changed introductory sentence from "As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 ticks:" to "As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):".
  - In [CRC check](#) changed text in introductory paragraph from "XOR-based CRC implementation" to "new recommended CRC implementation".
  - In [Pause pulse diagnostic](#) update changed table caption and deleted FMSG\_OFLW row.
  - In [High frequency receiver clock \(protocol clock\) requirements](#) modified entire content within this heading.
- |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## MC\_RGM changes

- [Collision detection and handling — half-duplex operation only](#) : Added Warning regarding use of Ethernet PHYs that support the "heartbeat" feature.
- Changed both MAC frame format overview figures in [Ethernet MAC frame formats](#).
- Changed field description of ENET\_ATCR[CAPTURE ].
- Edited introductory text in [Memory map/register definition](#).
- Edited description for Overrun in [Enhanced receive buffer descriptor](#).
- Edited [Overview](#) and removed "10/100" in last paragraph.
- Editorial changes.
- [Timer Period Register \(ENET\\_ATPER\)](#) : Added note to PERIOD description about value.
- [MII Speed Control Register \(ENET\\_MSCR\)](#) :
  - Changed "internal module clock" to "internal module clock (i.e., IPS bus clock)".
  - Edited MII clock frequency calculation example.
  - In header of "Programming Examples for MSCR" table, changed "Internal MAC clock frequency" to "Internal module clock frequency".
- [Receive FIFO overflow](#) : In MII Receive portion of diagram, changed "MII\_RXEN" to "MII\_RXDV".
- [MDIO clock generation](#) : Changed "internal bus clock" to "internal bus clock (i.e., IPS bus clock)".

## B.54 MC\_RGM changes

- No substantial content changes

## B.55 BAM changes

- No substantial content changes

## B.56 SSCM module changes

- Updated [Features](#) list
- In [CERS](#) bit description, added "If a non-permanent error is detected, this bit can be cleared by writing a 1."
- In [Table 56-8](#) updated 0:31 | 0100\_000Ah to 0:31 | 0100\_000Ch
- In [Boot mode functionality](#) in SBL bullet removed text "(support for the FlexRay interface is planned on future devices)".
- In [Hardware configuration](#) removed table column "standby RAM boot flag".
- In [Securing the microcontroller](#) added "DCF" to the table titles for [Table 56-8](#), [Table 56-9](#), and [Table 56-10](#).
- In [Boot and alternate boot sectors](#) updated second bullet.
- In [CER](#) removed "(with PARITY enabled)" from the bit description.
- In [CERS](#) added cross-reference to [CERS-DCF Mechanism](#).
- In [SSCM System Status \(SSCM\\_STATUS\)](#) register's [CER](#) field description, changed first sentence and added sentence:
  - was: "This field indicates that the SSCM has detected a configuration error during reset while loading DCF clients."
  - now: "This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error."

If REE_TD[TEMP1_3] is also asserted, a system reset is generated, which clears IER[TS1_3IE] and negate the interrupt request. If REE_TD[TEMP1_3] is asserted and a destructive reset is selected (via RES_TD[TEMP1_3] being 0), then a destructive reset is generated. If RES_TD[TEMP1_3] is set, then a functional reset is generated."</li> </ul> </li> <li>In <a href="#">Temperature Event Status register (PMC_ESR_TD)</a> for TEMP1_3_OP, TEMP1_2_OP, TEMP1_0_OP, TEMP0_3_OP, TEMP0_2_OP, and TEMP0_0_OP fields:           <ul style="list-style-type: none"> <li>In description of these fields, added sentences about field dependencies that were removed from corresponding TEMPn_m description (following sample is from TEMP1_3_OP description): "If IER[TS1_3IE] is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP1_3] is also asserted, a system reset is generated, which clears IER[TS1_3IE] and negates the interrupt request. If REE_TD[TEMP1_3] is asserted and a destructive reset is selected because RES_TD[TEMP1_3] is 0, then a destructive reset is generated; if RES_TD[TEMP1_3] is 1, then a functional reset is generated."</li> </ul> </li> </ul> |
| <ul style="list-style-type: none"> <li>In <a href="#">Temperature Reset Event Enable register (PMC_REE_TD)</a> description, added Note and changed second paragraph:           <ul style="list-style-type: none"> <li>from: "These bits are loaded from flash memory during the boot sequence. If the values loaded from flash memory are 1, enabling the reset event, these bits cannot be cleared to 0 to disable the event."</li> <li>to: "The register's reset value applies until the portion of the boot sequence that loads a value for the register from a DCF record in the UTEST area of flash memory. The DCF record for this register is PMC_LVD_MISC. The user can change the loaded value by programming a new DCF record for PMC_LVD_MISC in the UTEST</li> </ul> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## MC\_PCU changes

area. If the loaded value programs any flag bit to be enabled (set to 1), the bit cannot be disabled (cleared to 0) by software through IPS programming."

- In [Temperature Reset Event Selection register \(PMC\\_RES\\_TD\)](#) description, added new second paragraph: "The register's reset value applies until the portion of the boot sequence that loads a value for the register from a DCF record in the UTEST area of flash memory. The user can change the loaded value by programming a new DCF record in the UTEST area."
- In [Reset Event Enable 0 \(PMC\\_REE\\_0\)](#) description:
  - Removed from first paragraph: "These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared)."
  - Added new second paragraph: "The register's reset value applies until the portion of the boot sequence that loads a value for the register from a DCF record in the UTEST area of flash memory. The user can change the loaded value by programming a new DCF record in the UTEST area. If the loaded value programs any flag bit to be enabled (set to 1), the bit cannot be disabled (cleared to 0) by software through IPS programming."
- For following [Reset Event Enable 0 \(PMC\\_REE\\_0\)](#) fields, clarified voltage-detect event to which each field applies:
  - [VD6RE\\_C](#)
  - [VD4RE\\_C](#)
  - [VD3RE\\_H](#)
  - [VD3RE\\_C](#)
- For [Event Status Register 0 \(PMC\\_ESR\\_0\)](#) field [VD4\\_C](#)
  - Changed first sentence of field description from "This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage cold point supply" to "This read-only bit is the high-voltage status flag associated with the voltage level detect for the high-voltage cold point supply."
  - In description of field value 1, changed "HVD occurrence detected on the low voltage supply" to "HVD occurrence detected on the high-voltage supply."

## B.58 MC\_PCU changes

- No substantial content changes

## B.59 MC\_ME changes

- Previous errata e6574 integrated into reference manual:
  - In [HALT0 Mode](#), added a new paragraph "If a HALT0 mode transition request is generated at the same time that an interrupt request occurs ....."
  - In [STOP0 Mode](#), added a new paragraph "If a STOP0 mode transition request is generated at the same time that an interrupt request occurs ....."
- In [HALT0 Mode](#), added a new bullet "XBAR masters cannot operate in system HALT0 mode as they are clock gated. Also, NPC should be enabled if mode transition is initiated while debugger is connected."
- In [STOP0 Mode](#), added a new bullet "XBAR masters cannot operate in system STOP0 mode as they are clock gated. Also, NPC should be enabled if mode transition is initiated while debugger is connected."
- Added a new section: [Mode transition and progressive clock switching](#)
- In [System Clock Switching](#), updated paragraph "If the value of the PWRLVL field of the ME ..."

## B.60 Core Debug Support changes

- No substantial content changes

## B.61 JTAGC module changes

- No substantial content changes

## B.62 Core Nexus Module changes

- [Nexus Development Control Register 4 \(DC4\)](#) :
  - Corrected broken link.
  - Removed footnote from "DC4 field descriptions" table.
- Replaced nex\_evto\_b with evto\_b throughout chapter.
- Added missing TSTAMP sub-row to each Message Name row in [Table 62-2](#) table.
- [Data Acquisition Trace event](#) : in figure, corrected "TCODE(011011)" to "TCODE(000111)".
- Added [Timestamp field \(TSTAMP\)](#).
- [Data Trace Messaging \(DTM\)](#) : Changed "in one of three ways." to "in one of the following ways."

## B.63 NXMC module changes

- Previous errata e7974 integrated into the Reference Manual: Added Note in [DTM overflow error messages](#), "The internal queue FIFO is very small. This causes FIFO overflows whenever Trace is enabled on any of the AHB clients and the AHB master module generates >4 burst accesses. If the customer is experiencing a lot of overflow error messages the the amount of data snooped by the NXMC should be reduced."
- Editorial change in DTM overflow error messages section

## B.64 NPC module changes

- Updated PCR[FPM] description from "1 Reserved" to "1 Aurora mode enabled" .
- In [Port Configuration Register \(PCR\)](#), added "Nexus" to PCR[FPM] description.
- Updates throughout: removed various instances of "auxiliary", changed "auxiliary" to "output", changed "Auxiliary" to "Nexus" and removed text "As an alternative to data transmission on the Nexus auxiliary port".
- In [Port Configuration Register \(PCR\)](#) :
  - Added text "Set to 000 when Nexus Aurora mode is enabled" to PCR[MCKO\_DIV] description.
  - Updated PCR[FPM] description.
- In [Port Configuration Register \(PCR\)](#), added text "While enabling the low power mode handshake (setting LP\_DBG), the debugger should simultaneously set the LPn\_SYN bit. At the end of low-power mode handshake, the LP\_DBG and LPn\_SYN should be set again if further handshakes between the device and debugger are required." to second paragraph.

## B.65 NAL changes

- No substantial content changes

## B.66 Nexus Aurora Phy changes

- No substantial content changes

## B.67 CRC module changes

- Title corrected for section "Register programming".
- Added information about register access level at the end of each register description.
- Editorial changes.
- In CRC\_CFGn[SWAP], updated bit description text from "The swap operation is a bit-by-bit rotation of the content" to "The swap operation is a bit-by-bit swapping of the content".
- In CRC\_CFGn[INV], removed the bit-description text "in case of CRC-CCITT polynomial, the inversion operation is applied on the 16 least-significant bits."
- Updated title of Signal description section to [External signal description](#).
- In [Block diagram](#), updated reference to [Main features](#) section to see the number of contexts of CRC.

## B.68 MEMU changes

- In [Memory map and register definition](#), added register access level information to all register descriptions.
- Previous errata e8145 integrated into this reference manual: In [System RAM uncorrectable error reporting table address register \(MEMU\\_SYS\\_RAM\\_UNCERR\\_ADDR\)](#), in the ERR\_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted."
- Previous errata e8145 integrated into this reference manual: In [Peripheral RAM uncorrectable error reporting table address register \(MEMU\\_PERIPH\\_RAM\\_UNCERR\\_ADDR\)](#), in the ERR\_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted."
- Previous errata e8145 integrated into this reference manual: In [Flash memory uncorrectable error reporting table address register \(MEMU\\_FLASH\\_UNCERR\\_ADDR\)](#), in the ERR\_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted."
- Editorial changes.
- In [Introduction](#) and [Features](#) :
  - Standardized the names of the error-reporting categories for consistency:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Changed "see the Device Configuration chapter that describes how modules are configured and connected" to "see the chip-specific MEMU information."

- In [Design overview](#), changed "see the Device Configuration chapter that describes how modules are configured and connected" to "see the chip-specific MEMU information."
- In [Flash memory correctable error reporting table status register \(MEMU\\_FLASH\\_CERR\\_STS<sub>n</sub>\)](#), in the BAD\_BIT field description, changed "bit position in RAM" to "bit position in flash memory".
- Revised [Figure 68-2](#) and [Figure 68-3](#).
- In [System RAM uncorrectable error reporting table address register \(MEMU\\_SYS\\_RAM\\_UNCERR\\_ADDR\)](#), added "This field must be read-only when its corresponding valid bit (SYS\_RAM\_UNCERR\_STS[VLD]) = 0." to the ERR\_ADD field description.
- In [Peripheral RAM uncorrectable error reporting table address register \(MEMU\\_PERIPH\\_RAM\\_UNCERR\\_ADDR\)](#), added "This field must be read-only when its corresponding valid bit (PERIPH\_RAM\_UNCERR\_STS[VLD]) = 0." to the ERR\_ADD field description.
- In [Flash memory uncorrectable error reporting table address register \(MEMU\\_FLASH\\_UNCERR\\_ADDR\)](#), added "This field must be read-only when its corresponding valid bit (FLASH\_UNCERR\_STS[VLD]) = 0." to the ERR\_ADD field description.
- In [Design overview](#), deleted "The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block."
- In [Overview](#), deleted the paragraph beginning with "The Control, Error Flag, and Debug".

## B.69 FCCU module changes

- [EOUT interface](#)
  - Reorganized the sentence about resets' effect on failure indication pins as two sentences and a list
  - In the list, added "FOSU time-out reset" as a reset type that influences the state of failure indication pins
- Changed reset value of FCCU\_CTRL register from 0x0000\_0000 to 0x0000\_00C0. (OPS field changed from 00b to 11b.)
- In NCF Fake Register (FCCU\_NCFF), changed register description.
- INTRODUCTION SECTION - Removed phrase "(after the boot)"
- INTRODUCTION SECTION - Change "Internal reactions (independently configurable for each NCF):" to "Configurable internal reactions for each NCF:"
- INTRODUCTION SECTION - Change "External reaction (failure is reported to the outside world via one or more output pins)" to "External reactions via configurable output pins"
- INTRODUCTION SECTION - Removed phrase "without CPU intervention".
- INTRODUCTION SECTION - Removed phrase "for application/test/debugging purposes"
- INTRODUCTION SECTION - Changed "FCCU is designed for assuming that the system clock is faster than the IRC clock" to "The FCCU is designed to function when the system clock is faster than the IRC clock."
- FSM description - Change "After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked)." to "After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked."
- In the FCCU\_CTRL register description, change note "There should not be any other operation in between the above steps." to "The FCCU\_CTRL and FCCU\_CTRL registers must be written with consecutive instructions. Both registers must be written as 32-bit values. Do not use read-modify-write instructions, such as bit field instructions, to modify these registers."
- In section FCCU\_DELTA\_T, FCCU\_IRQ\_ALARM\_EN<sub>n</sub>, FCCU\_NMI\_EN<sub>n</sub>, FCCU\_EOUT\_SIG\_EN<sub>n</sub> descriptions: Changed, "This register can be written only when the FCCU is in CONFIG state." to Note.
- In FCCU\_CFG\_TO description changed "oscillator" to "IRCOSC". Changed part of description to Note.
- For FCCU\_NCF\_CFG<sub>n</sub>, FCCU\_NCFS\_CFG<sub>n</sub>, FCCU\_NCF\_En, FCCU\_NCF\_TOEn and MCS registers: Changed the reset value of the registers from 0x0000\_0000 to X. Added the following footnote to each register: The reset value is chip-specific. See the chip-specific FCCU information. Added the following note to register descriptions: The reset value is chip-specific. See the chip-specific FCCU information. For all configuration registers, made the following text into a note: These registers can be written only when the FCCU is in CONFIG state.
- INTRODUCTION -- Changed bullet item "Configurable and graded fault control" to "Configurable fault control"
- INTRODUCTION -- In bullet item "Permanently locked until next reset .....", Changed "FCCU\_TRANS\_LOCK" to "FCCU\_PERMNT\_LOCK"

## FCCU module changes

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>INTRODUCTION -- Changed "failure indication" to "error out"</li> <li>MAIN features -- Changed "Failure indication" to "Error indication"</li> <li>FSM description -- Changed reference to state diagram.</li> <li>FSM description -- Changed "Following one of the following events" to "Following state transitions occur on one of the following event"</li> <li>Corrected notation for binary numbers.</li> <li>FCCU state diagram -- Changed block text on CONFIG state from "AND NOT (configuration locked)" to "AND (configuration unlocked)"</li> <li>FCCU state diagram -- Added block text to ALARM state -- "Actual text in diagram is "Any Fault Pending AND FCCU_IRQ_ALARM_ENn""</li> <li>EOUT interface -- Throughout section changed uppercase "ERROR" to "FAULT".</li> </ul> |
| <ul style="list-style-type: none"> <li>At the end of EOUT interface section, added NOTE on state of EOUT pads.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <ul style="list-style-type: none"> <li>FCCU_CTRL register, FILTER_WIDTH field -- Changed 10 bit description from "filters glitches up to 100 µs for 20 MHz IRC clock" to "filters glitches up to 100 µs". | <ul style="list-style-type: none"> <li>In <a href="#">EOUT interface</a> : <ul style="list-style-type: none"> <li>Edited the section for style, usage, grammar, clarity, and structure, which included reordering some information and moving some information to the appropriate register descriptions.</li> <li>Changed <i>Destructive reset</i> to <i>Destructive reset (including when an FOSU timeout occurs due to FCCU failing to react)</i>.</li> <li>Deleted the list item <i>FOSU timeout reset</i>.</li> <li>Changed <i>The FCCU provides up to two bidirectional signals (EOUT interface)</i> to <i>The FCCU provides up to two bidirectional signals (EOUT[1:0])</i>.</li> <li>Changed <i>These signals need to be mapped to appropriate pins for external visibility</i> to <i>For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information</i>.</li> <li>In the list that begins with <i>These resets influence the state of the failure indication pins</i>, changed <i>Pin reset (RESET_b)</i> to <i>Chip pin reset (RESET_B)</i>.</li> </ul> </li> <li>In the FCCU_CFG register description, edited the following field names and descriptions for clarity: <ul style="list-style-type: none"> <li>FOPE</li> <li>SM</li> </ul> </li> </ul> |

- PS
- FOM
- FOP

- Rewrote the FCCU\_EOUT\_SIG\_EN register description for clarity.
- Added the following note to the FCCU\_EOUT\_SIG\_EN[EOUTENx] field description: *To ensure that the FOSU module is aware that fault-output signaling is enabled as a reaction for the associated noncritical fault channel (so that FOSU doesn't mistakenly generate a destructive chip reset), you must set this field to enabled when FCCU is configured for any mode other than Bistable fault-output mode.*
- In [FSM description](#), in the list item *Configuration*, added the following: *The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration by writing either to TRANS\_LOCK or PERMT\_LOCK, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.*

## B.70 STCU2 changes

- In [Startup self-test mode selection](#), added Note: "During startup self-tests, once the STCU2 registers are configured they cannot be overridden."
- In [Shutdown self-test initiation procedure](#), added Note: "During shutdown self-tests, once the STCU2 registers are configured they cannot be overridden via IPS until the self-testing is complete."
- Added modules for Partition C0 in [Table 70-6](#).
- Added a note "Make sure that the flash is in IDLE state before starting LBIST (Self Test) operation." in [Use cases and limitations](#).
- In [Table 70-6](#), added RCCU module in Partition C1 and ENET module in Partition P0.
- Updated STCU online configuration in [Table 70-4](#).

## B.71 REG\_PROT module changes

- In [Memory map and register definition](#), made editorial changes.
- In [Overview](#), added AIPS\_LITE as an option to use the term PBRIDGE (PBRIDGE/ AIPS\_LITE).
- In [General](#), modified the sentence "For all addresses that are protected ..." to "For all addresses (peripheral registers) that are protected ....".
- Removed topic "Initialization/application information".

## B.72 WKPU module changes

- Editorial changes.
- In [NMI Configuration Register \(WKPU\\_NCR\)](#), changed the field name in NCR[NDSS0] note from HID0[MCP\_EN] to HID0[EMCP].
- In [WKPU memory map and register definition](#), modified the note "Reserved registers will read...".
- In [NMI management](#), added a sentence "Please see chip specific section for details on NMI implementation".
- Added register access level information.
- In [Non-maskable interrupts](#), changed "The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event" to "The WKPU supports the capturing of a

## Protected Registers changes

second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, though it creates an overrun condition."

- Changed [NMI Status Flag Register \(WKPU\\_NSR\)](#) access type from read/write to W1C.
- In [External signal description](#), deleted a paragraph.

## B.73 Protected Registers changes

- No substantial content changes
