**21.5.2 INTC Current Priority Register for Processor 0 (INTC\_CPR0)**

The INTC\_CPR<sub>n</sub> masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC\_CPR<sub>n</sub>[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC\_IACKR<sub>n</sub>) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC\_EOIR<sub>n</sub>) is written, the LIFO is popped into the INTC\_CPR<sub>n</sub> PRI field. An exception case in hardware vector mode to this behavior is described in [Hardware vector mode](#).

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See [Priority ceiling protocol](#).

**NOTE**

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See [Ensuring coherency](#) for example code to ensure coherency.

| 27–31<br>PRI     | Priority of the currently executing ISR, according to the field values 31 (highest priority) down to 0 (lowest priority). |

## 21.5.3 INTC Interrupt Acknowledge Register for Processor 0 (INTC\_IACKR0)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC\_IACKR<sub>*n*</sub> has side effects from reads. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC\_IACKR<sub>*n*</sub> does not have side effects in hardware vector mode.

### NOTE

When the corresponding INTC\_BCR[HVEN<sub>*n*</sub>] = 1, a read of the INTC\_IACKR has no side effects.

Address: 0h base + 20h offset = 20h

### INTC\_IACKR0 field descriptions

| Field             | Description                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–19<br>VTBA      | Vector table base address. Can be the base address of a vector table of addresses of ISRs.                                                                                                                                                                                 |
| 20–29<br>INTVEC   | Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode. |
| 30–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                    |

### 21.5.4 INTC End Of Interrupt Register for Processor 0 (INTC\_EOIR0)

Writing to the INTC\_EOIR $n$  signals the end of the servicing of the interrupt request. When the INTC\_EOIR $n$  is written, the priority last pushed on the LIFO is popped into INTC\_CPR $n$ . The values and size of data written to the INTC\_EOIR $n$  are ignored. Those values and sizes written to this register neither update the INTC\_EOIR $n$  contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

Address: 0h base + 30h offset = 30h

**INTC\_EOIR0 field descriptions**

| Field       | Description                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------|
| 0–31<br>EOI | End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request. |

### 21.5.5 INTC Software Set/Clear Interrupt Register (INTC\_SSCIR $n$ )

The INTC\_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC\_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

See [Figure 21-2](#) for limitations on writing to this register.

## Memory map and register definition

Address: 0h base + 40h offset + (1d × i), where i=0d to 15d

| Bit   | 0 | 1 | 2 | 3 | 4 | 5 | 6   | 7   |
|-------|---|---|---|---|---|---|-----|-----|
| Read  | 0 |   |   |   |   |   | 0   | CLR |
| Write |   |   |   |   |   |   | SET | w1c |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0   | 0   |

### INTC\_SSICIR<sub>n</sub> field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                      |
| 6<br>SET        | Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.                                                                                                                                                                     |
| 7<br>CLR        | Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect.<br><br>0 Interrupt request not pending within INTC.<br>1 Interrupt request pending within INTC. |

## 21.5.6 INTC Priority Select Register (INTC\_PSR<sub>n</sub>)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC\_PSR<sub>n</sub> is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC\_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC\_PSR registers. The peripheral interrupt requests are assigned vectors 32-1023, and their priorities are configured in INTC\_PSR32-1023, respectively.

See [Figure 21-2](#) for limitations on writing to this register.

### NOTE

Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

### NOTE

Interrupts are not detected while the PSRs are being written.

Address: 0h base + 60h offset + (2d × i), where i=0d to 1023d

| 4–6<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 7<br>SWTN        | This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWTN sets the bit. On the interrupt acknowledge cycle, the SWTN bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SELN field of the PSR. |
| 8–10<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 11–15<br>PRIN    | Priority select. Selects the priority for the interrupt requests. PRI has values 31 (highest priority) down to 0 (lowest priority).                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 21.5.7 INTC Monitor Mode Register 0 (INTC\_MMRC0)

The Monitor Mode Register is used to configure measurement options of the INTC.

| 30–31<br>MM      | Monitor Mode. Controls whether the INTC monitors the latency or interrupt handler time <ul style="list-style-type: none"> <li>00 Disabled</li> <li>01 IACK - Interrupt Acknowledge - timer is active from assertion of IRQ until interrupt acknowledge. An error is signaled if timer exceeds the programmed interrupt latency and the programmed interrupt latency is non-zero.</li> <li>10 EOI - End Of Interrupt - timer is active from assertion of IRQ until the end of the interrupt handler. The timer will continue to run even if interrupt handler is preempted. An error is signaled if timer exceeds the programmed interrupt latency and the programmed interrupt latency is non-zero.</li> <li>11 SW - Software - timer is active from assertion of IRQ until the end of the interrupt handler unless it is preempted. A return from interrupt will start the timer if it is the timer associated with the active IRQ. No error is signaled; rather software can read the timer at any time.</li> </ul> |

**21.5.8 INTC HIPRI Register (INTC\_HIPRI $n$ C0)**

The HIPRI log2(SOURCES)-bit registers are used to indicate which IRQ is to be monitored or checked. The mnemonic is of the form HIPRI $m$ C $n$ , where the 'n' is the corresponding Processor and the 'm' is the monitor instance for that Processor.

Address: 0h base + 1004h offset + (4d × i), where i=0d to 2d

## 21.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

### 21.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose  $PRI_n$  value in  $INTC\_PSR_n$  is higher than the  $PRI$  value in  $INTC\_CPR_n$ , negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the  $PRI$  value in the associated  $INTC\_CPR_n$  is updated with the corresponding  $PRI_n$  value in  $INTC\_PSR_n$ .

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

#### 21.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

#### 21.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers ( $INTC\_SSCIR_n$ ) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by

software by writing a 1 to a SET bit in INTC\_SSCIR $n$ . This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor  $n$  will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor  $n$  which has been assigned to handle that interrupt request, as determined by the setting of the INTC\_PSR $n$ [PRC\_SEL $n$ ] bits.

### 21.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–15 are assigned vectors 0–15, respectively. The peripheral interrupt requests are assigned vectors from 16 to a number as high as needed to cover all peripheral interrupt requests.

### 21.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI $n$  and PRC\_SEL $n$  values set in INTC\_PSR $n$ . The result of that comparison also is compared to PRI in the associated INTC\_CPR $n$ . The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

### 21.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in [Figure 21-1](#) are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated `INTC_IACKRn`, and if in hardware vector mode, for the interrupt vector provided to the processor.

#### 21.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

#### 21.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

#### 21.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

#### 21.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with `PRI` in the associated `INTC_CPRn`. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of `PRI` in the associated `INTC_CPRn`, or the `PRI` value in the associated `INTC_CPRn` is lowered below this highest priority. This highest priority then becomes the new priority which is written to `PRI` in the associated

INTC\_CPR $n$  when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI $n$  in INTC\_PSR $n$  are zero will not cause a preemption because their PRI $n$  will not be higher than PRI in the associated INTC\_CPR $n$ .

Another function of the comparator is to signal an update of the INTC\_IACKR $n$  with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC\_CPR $n$  occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

### 21.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC\_CPR $n$ . Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC\_CPR $n$  does not need to be loaded from the associated INTC\_CPR $n$  and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC\_CPR $n$ .

The PRI value in the associated INTC\_CPR $n$  is pushed onto the LIFO when the associated INTC\_IACKR $n$  is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC\_CPR $n$  whenever the associated INTC\_EOIR $n$  is written. An exception case in hardware vector mode to this behavior is described in [Hardware vector mode](#).

Although the INTC supports up to 32 priorities, an ISR executing with PRI in the INTC\_CPR $n$  equal to 31 will not be preempted. Therefore, the LIFO supports the stacking of 31 priorities. However, the LIFO is only 30 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 31 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

## 21.6.3 Handshaking with processor

This section describes handshaking with the processor.

### 21.6.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

#### 21.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to [Figure 21-3](#).

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 21-3](#). The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC\_CPR $n$ , it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC\_IACKR $n$  is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in [Software vector mode](#).

#### 21.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC\_EOIR $n$  must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC\_CPR $n$ . Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC\_CPR $n$  is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction

address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

### Figure 21-3. Timing diagram of software vector mode handshaking

### 21.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 21-4](#). As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC\_CPR<sub>n</sub>, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC\_IACKR<sub>n</sub> is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC\_IACKR<sub>n</sub>. The rest of the handshaking is described in [Hardware vector mode](#).

The handshaking near the end of the interrupt exception handler, that is the writing to the associated `INTC_EOIRn`, is the same as in software vector mode. See [End of interrupt exception handler](#).

**Figure 21-4. Timing diagram for hardware vector mode handshaking**

## 21.6.4 Interrupt Controller Monitor (INTCM)

Isolated in its own hierarchy, the interrupt latency monitor logic is used to monitor or check interrupt latency for reliability, safety, and interrupt software requirements.

### 21.6.4.1 Operation

The following section lists the operation of the INTCM.

#### 21.6.4.1.1 TIMERn

A clear of TIMERn will clear the corresponding error.

The TIMERn will not run if there is a corresponding error.

If the INTC\_MMRn[MM] is enabled and an error is signaled, disable TIMERn.

If the INTC\_MMRn[MM] is enabled, for a transition from 0 to 1 of SOURCE input that is being monitored by INTC\_HIPRn registers, clear and enable TIMERn. Once the timer reaches the maximum count, it will stop and not roll over. Software can read the TIMERn value at any time.

If the INTC\_MMRn[MM] is enabled and if the TIMERN is enabled, then it should increment each cycle.

If the INTC\_MMRn[MM] is enabled and if INTC\_LATn is non-zero, an error will be signaled if the timer exceeds INTC\_LATn or if the TIMERN reaches the maximum count.

If the INTC\_MMRn[MM] is IACK and an interrupt acknowledge asserts for the monitored source, INTC\_HIPRIn[IRQ], then the enabled TIMERN should stop. As an extra check, the IRQ is used to ensure that the acknowledged interrupt matches the monitored interrupt INTC\_HIPRIn[IRQ].

If the INTC\_MMRn[MM] is SW and an interrupt acknowledge occurs where a monitored interrupt is preempted, the enabled TIMERN should stop.

If the INTC\_MMRn[MM] is EOI or SW for a monitored interrupt which has an INTC\_EOIRn, the enabled TIMERN should stop.

If the INTC\_MMRn[MM] is SW and if INTC\_EOIRn, and if the previous one is monitored, it will be re-enabled.

## 21.7 Initialization/application information

This section contains initialization/application information.

### 21.7.1 Initialization flow

After exiting reset, all of the PRIn and PRC\_SELn fields in INTC\_PSRn are zero, and PRI in the INTC\_CPRn registers is 31. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt\_request\_initialization:
  - Configure HVENn in INTC\_BCR.
  - Configure VTBA<sub>n</sub> in INTC\_IACKR<sub>n</sub>.
  - Raise the PRIn fields and set the PRC\_SELn fields to the desired processor in INTC\_PSRn.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
  - Lower PRI in INTC\_CPRn to zero.
  - Enable processor(s) recognition of interrupts.

## 21.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

### 21.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

```

interrupt_exception_handler:

blr         # branch to epilog

```

## 21.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC\_CPR<sub>n</sub> having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC\_CPR<sub>n</sub> priority 0 and outside the control of the RTOS, the RTOS executes at INTC\_CPR<sub>n</sub> priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC\_CPR<sub>n</sub> priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC\_CPR<sub>n</sub> while the shared resource is being accessed.

An ISR whose  $PRI_n$  in  $INTC\_PSR_n$  has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

## 21.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

**Table 21-1. Order of ISR execution example**

| Step # | Step Description                                                                                        | Code executing at end of step |                     |        |        |        |                             | PRI in INTC_CPR at end of step |
|--------|---------------------------------------------------------------------------------------------------------|-------------------------------|---------------------|--------|--------|--------|-----------------------------|--------------------------------|
|        |                                                                                                         | RTOS                          | ISR108 <sub>1</sub> | ISR208 | ISR308 | ISR408 | interrupt exception handler |                                |
| 1      | RTOS at priority 0 is executing.                                                                        | X                             |                     |        |        |        |                             | 0                              |
| 2      | Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.                                |                               | X                   |        |        |        |                             | 1                              |
| 3      | Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.                                |                               |                     |        |        | X      |                             | 4                              |
| 4      | Peripheral interrupt request 300 at priority 3 asserts.                                                 |                               |                     |        |        | X      |                             | 4                              |
| 5      | Peripheral interrupt request 200 at priority 3 asserts.                                                 |                               |                     |        |        | X      |                             | 4                              |
| 6      | ISR408 completes. Interrupt exception handler writes to INTC_EOIR <sub>n</sub> .                        |                               |                     |        |        |        | X                           | 1                              |
| 7      | Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first. |                               |                     | X      |        |        |                             | 3                              |
| 8      | ISR208 completes. Interrupt exception handler writes to INTC_EOIR <sub>n</sub> .                        |                               |                     |        |        |        | X                           | 1                              |
| 9      | Interrupt taken. ISR308 starts to execute.                                                              |                               |                     |        | X      |        |                             | 3                              |

**Table 21-1. Order of ISR execution example (continued)**

| Step # | Step Description                                                                 | Code executing at end of step |                     |        |        |        |                             | PRI in INTC_CPR at end of step |
|--------|----------------------------------------------------------------------------------|-------------------------------|---------------------|--------|--------|--------|-----------------------------|--------------------------------|
|        |                                                                                  | RTOS                          | ISR108 <sup>1</sup> | ISR208 | ISR308 | ISR408 | interrupt exception handler |                                |
| 10     | ISR308 completes. Interrupt exception handler writes to INTC_EOIR <sub>n</sub> . |                               |                     |        |        |        | X                           | 1                              |
| 11     | ISR108 completes. Interrupt exception handler writes to INTC_EOIR <sub>n</sub> . |                               |                     |        |        |        | X                           | 0                              |
| 12     | RTOS continues execution.                                                        | X                             |                     |        |        |        |                             | 0                              |

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

## 21.7.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

### 21.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC\_CPR<sub>n</sub>) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC\_CPR<sub>n</sub> to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC\_CPR<sub>n</sub> to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

## 21.7.5.2 Ensuring coherency

This section discusses how to ensure coherency.

### 21.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC\_CPR $n$ . The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC\_CPR $n$  can be made by those system services with the code sequence:

```
GetResource:
    wrteei 0           # disable external interrupts to the Processor
    raise PRI         # Write to CPR, cache inhibit, guarded
    mbar              # flush out writes from store buffer
    wrteei 1           # enable external interrupts to the Processor
    isync              # re-fetch Processor pipeline

ReleaseResource:
    mbar              # flush out writes from store buffer
    wrteei 0           # disable external interrupts to the Processor
    lower PRI         # Write to CPR, cache inhibit, guarded
    wrteei 1           # enable external interrupts to the Processor
```

#### 21.7.5.2.1.1 Interrupt request to processor

Referencing [Figure 21-1](#), the interrupt request logic to the processor is shown in the following figure.

**Figure 21-5. Interrupt Request Block Diagram**

Assuming that there are no  $IRQ_n$  deasserted (no pending interrupt requests to processor  $n$ ), if one of the external interrupt sources ( $INT\_SOURCES$ ) has a priority higher than the  $INTC\_CPR_n$ , then interrupt request to the processor ( $IRQ_n$ ) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge ( $IACK$ ) is asserted
- If the  $EEn$  bit has been cleared by the `wrtiei` instruction (see the code sequence in [Interrupt with blocked priority](#)),  $IRQ_n$  will be re-evaluated when processor  $n$  writes to the  $INTC\_CPR_n$  while processor  $n$  ignores  $IRQ_n$

This provides a safe way to guarantee that no interrupts will be recognized by processor  $n$  while updating the  $INTC\_CPR_n$ .

#### 21.7.5.2.2 Raised priority preserved

Before the instruction after the `GetResource` system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. The following figure shows the timing diagram for this scenario, and the following table explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 21-6. Timing diagram of raised priority preserved

Table 21-2. Raised priority preserved events

| Event | Description                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A     | Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.                                                                |
| B     | Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.                                                |
| C     | Write to msree bit to disable external interrupts                                                                                                                       |
| D     | ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.                                                                          |
| E     | PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted. |
| F     | Write to msree bit to enable external interrupts                                                                                                                        |

### 21.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100  $\mu$ s, ISR2 executes every 200  $\mu$ s, and ISR3 executes every 300  $\mu$ s. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150  $\mu$ s, then it has a higher priority than ISR2.

The INTC supports 32 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500  $\mu$ s would share a priority, ISRs with request rates around 250  $\mu$ s would share a priority, and so on. With this approach, a range of ISR request rates of  $2^{16}$  could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

## 21.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

### 21.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRIn value in INTC\_PSR $_n$ , which becomes the PRI value in INTC\_CPR $_n$  with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit

in `INTC_SSCIR $n$` . Writing a '1' to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower `PRI $n$`  value in the `INTC_PSR $n$` , therefore will not cause preemptive scheduling inefficiencies.

### 21.7.7.2 Scheduling an ISR on another processor

Since the SET bits in the `INTC_SSCIR $n$`  are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in `INTC_SSCIR $n$`  is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

### 21.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in `INTC_SSCIR $n$` , one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in [Scheduling a lower priority portion of an ISR](#)) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

#### Note

Lowering the `PRI` value in `INTC_CPR $n$`  within an ISR to below the ISR's corresponding `PRI` value in `INTC_PSR $n$`  allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

## 21.7.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

### 21.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

### 21.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

### 21.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their `PRIn` values in `INTC_PSRn` must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to `INTC_SSCIRn` as the clearing of the flag bit that caused the present ISR to be executed. Refer to [End of interrupt exception handler](#) for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's `PRIn` value in `INTC_PSRn`.

## 21.7.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC\_CPR<sub>n</sub>). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC\_CPR<sub>n</sub>, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
wrtteei 0                # disable processor recognition of external interrupts
oldCPRn = INTC_CPRn;     # save INTC_CPRn
(branch to the pop_lifo)

pop_lifo:
  store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI, etc...
  examine INTC_CPRn[PRI], and store onto stack
  if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
  branch to push_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
  load stacked PRI value and store to INTC_CPRn
  load INTC_IACKn         # IACK; push INTC_CPRn into LIFO
  if stacked PRI values are not depleted, branch to push_lifo

  INTC_CPRn = oldCPRn; # restore original INTC_CPRn and re-evaluate pending external
interrupts
  wrteei 1              # enable processor recognition of interrupts
```

### NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

## 21.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.

# Chapter 22

## Enhanced Direct Memory Access (eDMA)

### 22.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

#### 22.1.1 eDMA system block diagram

[Figure 22-1](#) illustrates the components of the eDMA system, including the eDMA module ("engine").

Figure 22-1. eDMA system block diagram

22.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 22-1. eDMA engine submodules

| Submodule    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address path | <p>This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI<sub>n</sub>[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.</p> <p>When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes</p> |

Table continues on the next page...

**Table 22-1. eDMA engine submodules (continued)**

| Submodule                         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | the new values for the TCDn_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCDn_CITER field, and a possible fetch of the next TCDn from memory as part of a scatter/gather operation.                                                                                                                                                                                                                                                                 |
| Data path                         | <p>This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.</p> <p>The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).</p>                                           |
| Program model/channel arbitration | This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).                                                                                                                                                                                                                                                                         |
| Control                           | This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write. |

The transfer-control descriptor local memory is further partitioned into:

**Table 22-2. Transfer control descriptor memory**

| Submodule         | Description                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Memory controller | This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled. |
| Memory array      | TCD storage for each channel's transfer profile.                                                                                                                                                                                                                                                |

### 22.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures
- Error detection and error correction

In the discussion of this module,  $n$  is used to reference the channel number.

## **22.2 Modes of operation**

The eDMA operates in the following modes:

**Table 22-3. Modes of operation**

| Mode   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Normal | <p>In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.</p> <p>A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.</p> |
| Debug  | <p>DMA operation is configurable in Debug mode via the control register:</p> <ul style="list-style-type: none"> <li>• If CR[EDBG] is cleared, the DMA continues to operate.</li> <li>• If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.</li> </ul>                                                                                                                                                                         |
| Wait   | Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.                                                                                                                                                                                                                                                                                                                                                                                                    |

## 22.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

### 22.3.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD<sub>n</sub> definition is presented as 11 registers of 16 or 32 bits.

### 22.3.2 TCD initialization

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

## 22.3.3 TCD structure

### DMA Basics: TCD Structure

- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD

| Word<br>Offset | 0                   | 1                     | 2                            | 3 | 4     | 5 | 6 | 7     | 8    | 9 | 10 | 11 | 12    | 13 | 14 | 15   | 16   | 17           | 18 | 19 | 20 | 21 | 22                  | 23   | 24     | 25           | 26   | 27    | 28       | 29      | 30    | 31 |
|----------------|---------------------|-----------------------|------------------------------|---|-------|---|---|-------|------|---|----|----|-------|----|----|------|------|--------------|----|----|----|----|---------------------|------|--------|--------------|------|-------|----------|---------|-------|----|

<sup>1</sup> The fields implemented in Word 2 depend on whether EDMA\_CR[EMLM] bit is set to 0 or 1.

## 22.3.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

### DMA memory map

| Address offset (hex) | Register name             | Width (in bits) | Access | Reset value | Section/ page              |
|----------------------|---------------------------|-----------------|--------|-------------|----------------------------|
| 0                    | Control Register (DMA_CR) | 32              | R/W    | 0000_0400h  | <a href="#">22.3.1/663</a> |

**22.3.1 Control Register (DMA\_CR)**

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

### NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn\_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn\_SADDR) or destination address (TCDn\_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn\_SADDR), to the final destination address (TCDn\_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn\_SLAST and TCDn\_DLAST\_SGA) are used to compute the next TCDn\_SADDR and TCDn\_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn\_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn\_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

Address: 0h base + 0h offset = 0h

**DMA\_CR field descriptions**

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–13<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 14<br>CX          | Cancel Transfer<br><br>0 Normal operation<br>1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.                                                                                                                                          |
| 15<br>ECX         | Error Cancel Transfer<br><br>0 Normal operation<br>1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt. |

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25<br>CLM      | <p>Continuous Link Mode</p> <p><b>NOTE:</b> Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing.</p> <p>0 A minor loop channel link made to itself goes through channel arbitration before being activated again.</p> <p>1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.</p> |
| 26<br>HALT     | <p>Halt DMA Operations</p> <p>0 Normal operation</p> <p>1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 27<br>HOE      | <p>Halt On Error</p> <p>0 Normal operation</p> <p>1 Any error causes the HALT bit to set. **22.3.2 Error Status Register (DMA\_ES)**

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle

- A bit in the ES shows an uncorrectable error occurred while the device has ECC protection on the TCD SRAM
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See the Error Reporting and Handling section for more details.

Address: 0h base + 4h offset = 4h

| Field     | Description                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| 31<br>DBE | Destination Bus Error<br><br>0 No destination bus error<br>1 The last recorded error was a bus error on a destination write |

**22.3.3 Enable Request Register (DMA\_ERQ)**

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

Address: 0h base + Ch offset = Ch

**22.3.4 Enable Error Interrupt Register (DMA\_EEI)**

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

Address: 0h base + 14h offset = 14h

22.3.5 Set Enable Request Register (DMA\_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 18h offset = 18h

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | SAER | 0 |   |   | SERQ |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

### 22.3.6 Clear Enable Request Register (DMA\_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 19h offset = 19h

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAER | 0 |   |   | CERQ |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**DMA\_CERQ field descriptions**

| Field         | Description                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------|
| 0<br>NOP      | No Op enable<br><br>0 Normal operation<br>1 No operation, ignore the other bits in this register                 |

### 22.3.7 Set Enable Error Interrupt Register (DMA\_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ah offset = 1Ah

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | SAEE | 0 |   |   | SEEI |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

DMA\_SEEI field descriptions

| Field         | Description                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------|
| 0<br>NOP      | No Op enable<br><br>0 Normal operation<br>1 No operation, ignore the other bits in this register                      |

| 3–7<br>SEEI   | Set Enable Error Interrupt<br><br>Sets the corresponding bit in EEI                                                   |

### 22.3.8 Clear Enable Error Interrupt Register (DMA\_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Bh offset = 1Bh

| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAEE | 0 |   |   | CEEI |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**DMA\_CEEI field descriptions**

| Field         | Description                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------|

| 3–7<br>CEEI   | Clear Enable Error Interrupt<br><br>Clears the corresponding bit in EEI                                                  |

### 22.3.9 Clear Interrupt Request Register (DMA\_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ch offset = 1Ch

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAIR | 0 |   |   | CINT |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

DMA\_CINT field descriptions

| Field         | Description                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------|
| 0<br>NOP      | No Op enable<br><br>0 Normal operation<br>1 No operation, ignore the other bits in this register                    |

| 2<br>Reserved | This field is reserved.                                                                                             |
| 3–7<br>CINT   | Clear Interrupt Request<br><br>Clears the corresponding bit in INT                                                  |

### 22.3.10 Clear Error Register (DMA\_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Dh offset = 1Dh

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CAEI | 0 |   |   | CERR |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

DMA\_CERR field descriptions

| Field         | Description                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| 0<br>NOP      | No Op enable<br><br>0 Normal operation<br>1 No operation, ignore the other bits in this register                  |

| 2<br>Reserved | This field is reserved.                                                                                           |
| 3–7<br>CERR   | Clear Error Indicator<br><br>Clears the corresponding bit in ERR                                                  |

22.3.11 Set START Bit Register (DMA\_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Eh offset = 1Eh

|       |     |      |   |   |   |      |   |   |
|-------|-----|------|---|---|---|------|---|---|
| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | SAST | 0 |   |   | SSRT |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

DMA\_SSRT field descriptions

| Field         | Description                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>NOP      | No Op enable<br><br>0 Normal operation<br>1 No operation, ignore the other bits in this register                                                       |
| 1<br>SAST     | Set All START Bits (activates all channels)<br><br>0 Set only the TCDn_CSR[START] bit specified in the SSRT field<br>1 Set all bits in TCDn_CSR[START] |

### 22.3.12 Clear DONE Status Bit Register (DMA\_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Fh offset = 1Fh

| Bit   | 0   | 1    | 2 | 3 | 4 | 5    | 6 | 7 |
|-------|-----|------|---|---|---|------|---|---|
| Read  | 0   | 0    |   |   |   | 0    |   |   |
| Write | NOP | CADN | 0 |   |   | CDNE |   |   |
| Reset | 0   | 0    | 0 | 0 | 0 | 0    | 0 | 0 |

**DMA\_CDNE field descriptions**

| Field         | Description                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|

| 3–7<br>CDNE   | Clear DONE Bit<br><br>Clears the corresponding bit in TCDn_CSR[DONE]                                                                |

### 22.3.13 Interrupt Request Register (DMA\_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

Address: 0h base + 24h offset = 24h

|       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

**22.3.14 Error Register (DMA\_ERR)**

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

## Memory map/register definition

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEL. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

Address: 0h base + 2Ch offset = 2Ch

**22.3.15 Hardware Request Status Register (DMA\_HRS)**

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

**NOTE**

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Address: 0h base + 34h offset = 34h

| Bit   | 0     | 1     | 2     | 3     | 4     | 5     | 6     | 7     | 8     | 9     | 10    | 11    | 12    | 13    | 14    | 15    |

**22.3.16 Channel n Priority Register (DMA\_DCHPRIn)**

When fixed-priority channel arbitration is enabled ( $CR[ERCA] = 0$ ), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address:  $0h \text{ base} + 100h \text{ offset} + (1d \times i)$ , where  $i=0d$  to  $31d$

**22.3.17 Channel  $n$  Master ID Register (DMA\_DCHMID $n$ )**

The DMA master ID replication registers allow the DMA to use the same protection level and system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master, for example, a core, programs a TCD, its master ID and protection level are captured when the TCD $n$ .CSR control attributes are written. Although the scatter/gather operation can change the contents of TCD $n$ \_CSR, that operation does not affect the DCHMID  $n$  registers.

Address: 0h base + 140h offset + (1d  $\times$  i), where i=0d to 31d

| 0–4<br>SMOD    | <p>Source Address Modulo</p> <p>0 Source address modulo feature is disabled</p> <p>≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.</p> |

### 22.3.21 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA\_TCDn\_NBYTES\_MLNO)

This register, or one of the next two registers (TCD\_NBYTES\_MLOFFNO, TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD\_NBYTES\_MLOFFNO and TCD\_NBYTES\_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

#### DMA\_TCDn\_NBYTES\_MLNO field descriptions

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>NBYTES | <p>Minor Byte Transfer Count</p> <p>Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.</p> <p><b>NOTE:</b> An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.</p> |

### 22.3.22 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA\_TCDn\_NBYTES\_MLOFFNO)

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

## Memory map/register definition

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD\_NBYTES\_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

### 22.3.23 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA\_TCDn\_NBYTES\_MLOFFYES)

One of three registers (this register, TCD\_NBYTES\_MLNO, or TCD\_NBYTES\_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD\_NBYTES\_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD\_NBYTES\_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

### DMA\_TCDn\_CSR field descriptions

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–1<br>BWC         | <p>Bandwidth Control</p> <p>Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch.</p> <p><b>NOTE:</b> If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.</p> <p>00 No eDMA engine stalls.<br/> 01 Reserved<br/> 10 eDMA engine stalls for 4 cycles after each R/W.<br/> 11 eDMA engine stalls for 8 cycles after each R/W.</p> |
| 2<br>Reserved      | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 3–7<br>MAJORLINKCH | <p>Major Loop Link Channel Number</p> <p>If (MAJORELINK = 0) then:</p> <ul style="list-style-type: none"> <li>No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted.</li> </ul> <p>Otherwise:</p> <ul style="list-style-type: none"> <li>After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.</li> </ul>                                                                                                                                                                                                                                                                                                              |
| 8<br>DONE          | <p>Channel Done</p> <p>This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated.</p> <p><b>NOTE:</b> This bit must be cleared to write the MAJORELINK or ESG bits.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9<br>ACTIVE        | <p>Channel Active</p> <p>This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## DMA\_TCDn\_CSR field descriptions (continued)

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10<br>MAJORELINK | <p>Enable channel-to-channel linking on major loop complete</p> <p>As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel.</p> <p><b>NOTE:</b> To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</p> <p>0 The channel-to-channel linking is disabled.<br/>1 The channel-to-channel linking is enabled.</p>                                                                                                                                                                                |
| 11<br>ESG        | <p>Enable Scatter/Gather Processing</p> <p>As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory.</p> <p><b>NOTE:</b> To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</p> <p>0 The current channel's TCD is normal format.<br/>1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.</p> |
| 12<br>DREQ       | <p>Disable Request</p> <p>If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero.</p> <p>0 The channel's ERQ bit is not affected.<br/>1 The channel's ERQ bit is cleared when the major loop is complete.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 13<br>INTHALF    | <p>Enable an interrupt when major counter is half complete.</p> <p>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER &gt;&gt; 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress.</p> <p><b>NOTE:</b> If BITER = 1, do not use INTHALF. Use INTMAJOR instead.</p> <p>0 The half-point interrupt is disabled.<br/>1 The half-point interrupt is enabled.</p>                                  |
| 14<br>INTMAJOR   | <p>Enable an interrupt when major iteration count completes.</p> <p>If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero.</p> <p>0 The end-of-major loop interrupt is disabled.<br/>1 The end-of-major loop interrupt is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 15<br>START      | <p>Channel Start</p> <p>If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

*Table continues on the next page...*

**DMA\_TCDn\_CSR field descriptions (continued)**

| Field | Description                                                                 |
|-------|-----------------------------------------------------------------------------|
| 0     | The channel is not explicitly started.                                      |
| 1     | The channel is explicitly started via a software initiated service request. |

## 22.4 Functional description

The operation of the eDMA is described in the following subsections.

### 22.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

**Figure 22-2. eDMA operation, part 1**

This example uses the assertion of the eDMA peripheral request signal to request service for channel  $n$ . Channel activation via software and the  $TCDn\_CSR[START]$  bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for  $TCDn$ . Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel  $x$  or  $y$  registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel  $x$  or  $y$  registers.

The following diagram illustrates the second part of the basic data flow:

**Figure 22-3. eDMA operation, part 2**

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

Figure 22-4. eDMA operation, part 3

### 22.4.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx\_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.

- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

### **NOTE**

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST\_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn\_CITER[E\_LINK] bit does not equal the TCDn\_BITER[E\_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error

occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx\_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA\_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

### NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx\_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request,

are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

### 22.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

### 22.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

### 22.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

#### NOTE

All architectures will not meet the assumptions listed above.  
See the SRAM configuration section for more information.

This table compares peak transfer rates based on different possible system speeds. Specific chips/devices may not support all system speeds listed.

**Table 22-4. eDMA peak transfer rates (Mbytes/sec)**

| System Speed, Width | Internal SRAM-to-<br>Internal SRAM | 32 bit internal peripheral<br>bus-to-Internal SRAM | Internal SRAM-to-32 bit<br>internal peripheral bus |
|---------------------|------------------------------------|----------------------------------------------------|----------------------------------------------------|
| 66.7 MHz, 64 bit    | 266.7                              | 66.6                                               | 53.3                                               |
| 83.3 MHz, 64 bit    | 333.3                              | 83.3                                               | 66.7                                               |
| 100.0 MHz, 64 bit   | 400.0                              | 100.0                                              | 80.0                                               |
| 133.3 MHz, 64 bit   | 533.3                              | 133.3                                              | 106.7                                              |
| 150.0 MHz, 64 bit   | 600.0                              | 150.0                                              | 120.0                                              |

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

### 22.4.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

**Table 22-5. Hardware service request process**

| Cycle                                                     |                                                  | Description                                                                                                                                                                                                                                            |
|-----------------------------------------------------------|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| With internal peripheral bus read and internal SRAM write | With SRAM read and internal peripheral bus write |                                                                                                                                                                                                                                                        |
| 1                                                         |                                                  | eDMA peripheral request is asserted.                                                                                                                                                                                                                   |
| 2                                                         |                                                  | The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD <sub>n</sub> _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD <sub>n</sub> word 7.                         |
| 3                                                         |                                                  | Channel arbitration begins.                                                                                                                                                                                                                            |
| 4                                                         |                                                  | Channel arbitration completes. The transfer control descriptor local memory read is initiated.                                                                                                                                                         |
| 5–6                                                       |                                                  | The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles                                                              |
| 7                                                         |                                                  | The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.         |
| 8–11                                                      | 8–12                                             | The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.                                                                                                         |
| 12                                                        | 13                                               | This cycle represents the data phase of the last destination write.                                                                                                                                                                                    |
| 13                                                        | 14                                               | The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD <sub>n</sub> fields into the local memory. The TCD <sub>n</sub> word 7 is read and checked for channel linking or scatter/gather requests. |
| 14                                                        | 15                                               | The appropriate fields in the first part of the TCD <sub>n</sub> are written back into the local memory.                                                                                                                                               |
| 15                                                        | 16                                               | The fields in the second part of the TCD <sub>n</sub> are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.                                                                                      |
| 16                                                        | 17                                               | The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.                                                                          |

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can

be processed every 11.5 cycles ( $4 + (4+5)/2 + 3$ ). This is the time from Cycle 4 to Cycle  $x + 5$ . The resulting peak request rate, as a function of the system frequency, is shown in the following table.

**Table 22-6. eDMA peak request rate (MReq/sec)**

| System frequency (MHz) | Request rate<br>with zero wait states | Request rate<br>with wait states |
|------------------------|---------------------------------------|----------------------------------|
| 66.6                   | 7.4                                   | 5.8                              |
| 83.3                   | 9.2                                   | 7.2                              |
| 100.0                  | 11.1                                  | 8.7                              |
| 133.3                  | 14.8                                  | 11.6                             |
| 150.0                  | 16.6                                  | 13.0                             |

A general formula to compute the peak request rate with overlapping requests is:

$$\text{PEAKreq} = \text{freq} / [ \text{entry} + (1 + \text{read\_ws}) + (1 + \text{write\_ws}) + \text{exit} ]$$

where:

**Table 22-7. Peak request formula operands**

| Operand  | Description                                             |
|----------|---------------------------------------------------------|
| PEAKreq  | Peak request rate                                       |
| freq     | System frequency                                        |
| entry    | Channel startup (4 cycles)                              |
| read_ws  | Wait states seen during the system bus read data phase  |
| write_ws | Wait states seen during the system bus write data phase |
| exit     | Channel shutdown (3 cycles)                             |

### 22.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 1) + (1 + 3) + 3 ] \text{ cycles} = 11.5 \text{ Mreq/sec}$$

For an internal peripheral bus to SRAM transfer,

$$\text{PEAKreq} = 150 \text{ MHz} / [ 4 + (1 + 2) + (1 + 1) + 3 ] \text{ cycles} = 12.5 \text{ Mreq/sec}$$

Assuming an even distribution of the two transfer types, the average peak request rate would be:

$$\text{PEAKreq} = (11.5 \text{ Mreq/sec} + 12.5 \text{ Mreq/sec}) / 2 = 12.0 \text{ Mreq/sec}$$

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD $n$ \_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

### Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

## 22.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

### 22.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI $n$  registers if a configuration other than the default is desired.

3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQH and ERQL registers.
6. Request channel service via either:
  - Software: setting the TCDn\_CSR[START]
  - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCDn\_SADDR, to the destination, as defined by TCDn\_DADDR, continue until the number of bytes specified by TCDn\_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn\_SADDR, TCDn\_DADDR, and TCDn\_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

**Table 22-8. TCD Control and Status fields**

| TCDn_CSR field name | Description                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| START               | Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware) |
| ACTIVE              | Status bit indicating the channel is currently in execution                                                             |
| DONE                | Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)           |
| D_REQ               | Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service          |
| BWC                 | Control bits for throttling bandwidth control of a channel                                                              |
| E_SG                | Control bit to enable scatter-gather feature                                                                            |
| INT_HALF            | Control bit to enable interrupt when major loop is half complete                                                        |
| INT_MAJ             | Control bit to enable interrupt when major loop completes                                                               |

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 22-5. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

Figure 22-6. Memory array terms

### 22.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx\_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

### 22.5.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

### 22.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

### 22.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Fixed group arbitration, Fixed channel arbitration](#), but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

## 22.5.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

### 22.5.4.1 Single request

To perform a simple transfer of  $n$  bytes of data with one activation, set the major loop to one ( $\text{TCDn\_CITER} = \text{TCDn\_BITER} = 1$ ). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the  $\text{TCDn\_CSR}[\text{DONE}]$  bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCDn\_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn\_CSR[DONE] = 0, TCDn\_CSR[START] = 0, TCDn\_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
  - a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
  - b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
  - c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
  - d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
  - e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
  - f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
  - g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
  - h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes:  $\text{TCDn\_SADDR} = 0\text{x}1000$ ,  $\text{TCDn\_DADDR} = 0\text{x}2000$ ,  $\text{TCDn\_CITER} = 1$  ( $\text{TCDn\_BITER}$ ).
7. The eDMA engine writes:  $\text{TCDn\_CSR}[\text{ACTIVE}] = 0$ ,  $\text{TCDn\_CSR}[\text{DONE}] = 1$ ,  $\text{INT}[n] = 1$ .
8. The channel retires and the eDMA goes idle or services the next channel.

### 22.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:  $\text{TCDn\_CSR}[\text{DONE}] = 0$ ,  $\text{TCDn\_CSR}[\text{START}] = 0$ ,  $\text{TCDn\_CSR}[\text{ACTIVE}] = 1$ .
4. eDMA engine reads: channel  $\text{TCDn}$  data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
  - a. Read byte from location  $0\text{x}1000$ , read byte from location  $0\text{x}1001$ , read byte from  $0\text{x}1002$ , read byte from  $0\text{x}1003$ .
  - b. Write 32-bits to location  $0\text{x}2000 \rightarrow$  first iteration of the minor loop.
  - c. Read byte from location  $0\text{x}1004$ , read byte from location  $0\text{x}1005$ , read byte from  $0\text{x}1006$ , read byte from  $0\text{x}1007$ .
  - d. Write 32-bits to location  $0\text{x}2004 \rightarrow$  second iteration of the minor loop.
  - e. Read byte from location  $0\text{x}1008$ , read byte from location  $0\text{x}1009$ , read byte from  $0\text{x}100\text{A}$ , read byte from  $0\text{x}100\text{B}$ .
  - f. Write 32-bits to location  $0\text{x}2008 \rightarrow$  third iteration of the minor loop.

- g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
- h. Write 32-bits to location 0x200C → last iteration of the minor loop.
- 6. eDMA engine writes:  $TCDn\_SADDR = 0x1010$ ,  $TCDn\_DADDR = 0x2010$ ,  $TCDn\_CITER = 1$ .
- 7. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ .
- 8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
- 9. Second hardware, that is, eDMA peripheral, requests channel service.
- 10. The channel is selected by arbitration for servicing.
- 11. eDMA engine writes:  $TCDn\_CSR[DONE] = 0$ ,  $TCDn\_CSR[START] = 0$ ,  $TCDn\_CSR[ACTIVE] = 1$ .
- 12. eDMA engine reads: channel TCD data from local memory to internal register file.
- 13. The source to destination transfers are executed as follows:
  - a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
  - b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
  - c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
  - d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
  - e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
  - f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
  - g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
  - h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
- 14. eDMA engine writes:  $TCDn\_SADDR = 0x1000$ ,  $TCDn\_DADDR = 0x2000$ ,  $TCDn\_CITER = 2$  ( $TCDn\_BITER$ ).
- 15. eDMA engine writes:  $TCDn\_CSR[ACTIVE] = 0$ ,  $TCDn\_CSR[DONE] = 1$ ,  $INT[n] = 1$ .

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

### 22.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2<sup>4</sup> byte (16-byte) size queue.

**Table 22-9. Modulo example**

| Transfer Number | Address    |
|-----------------|------------|
| 1               | 0x12345670 |
| 2               | 0x12345674 |
| 3               | 0x12345678 |
| 4               | 0x1234567C |
| 5               | 0x12345670 |
| 6               | 0x12345674 |

## 22.5.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

### 22.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD<sub>n</sub>\_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD<sub>n</sub>\_CSR[START] bit and the TCD<sub>n</sub>\_CSR[ACTIVE] bit. The minor-loop-

complete condition is indicated by both bits reading zero after the `TCDn_CSR[START]` was set. Polling the `TCDn_CSR[ACTIVE]` bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

| Stage | TCDn_CSR bits |        |      | State                                            |
|-------|---------------|--------|------|--------------------------------------------------|
|       | START         | ACTIVE | DONE |                                                  |
| 1     | 1             | 0      | 0    | Channel service request via software             |
| 2     | 0             | 1      | 0    | Channel is executing                             |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle |

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the `TCDn_CITER` field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

| Stage | TCDn_CSR bits |        |      | State                                                              |
|-------|---------------|--------|------|--------------------------------------------------------------------|
|       | START         | ACTIVE | DONE |                                                                    |
| 1     | 0             | 0      | 0    | Channel service request via hardware (peripheral request asserted) |
| 2     | 0             | 1      | 0    | Channel is executing                                               |
| 3a    | 0             | 0      | 0    | Channel has completed the minor loop and is idle                   |
| 3b    | 0             | 0      | 1    | Channel has completed the major loop and is idle                   |

For both activation types, the major-loop-complete status is explicitly indicated via the `TCDn_CSR[DONE]` bit.

The `TCDn_CSR[START]` bit is cleared automatically when the channel begins execution regardless of how the channel activates.

### 22.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true `TCDn_SADDR`, `TCDn_DADDR`, and `TCDn_NBYTES` values if read while a channel executes. The true values of the `SADDR`, `DADDR`, and `NBYTES` are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, `SADDR` and

DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

### 22.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The `TCDn_CSR[ACTIVE]` bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two `TCDn_CSR[ACTIVE]` bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

## 22.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the `TCDn_CSR[START]` bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The `TCDn_CITER[E_LINK]` field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set `TCD12_CSR[START]` bit

2. Minor loop done → set TCD12\_CSR[START] bit
3. Minor loop done → set TCD12\_CSR[START] bit
4. Minor loop done, major loop done → set TCD7\_CSR[START] bit

When minor loop linking is enabled ( $\text{TCDn\_CITER[E\_LINK]} = 1$ ), the  $\text{TCDn\_CITER[CITER]}$  field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled ( $\text{TCDn\_CITER[E\_LINK]} = 0$ ), the  $\text{TCDn\_CITER[CITER]}$  field uses a 15-bit vector to form the current iteration count. The bits associated with the  $\text{TCDn\_CITER[LINKCH]}$  field are concatenated onto the CITER value to increase the range of the CITER.

### Note

The  $\text{TCDn\_CITER[E\_LINK]}$  bit and the  $\text{TCDn\_BITER[E\_LINK]}$  bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e., use another channel's TCD, at the end of a loop.

**Table 22-10. Channel Linking Parameters**

| Desired Link Behavior     | TCD Control Field Name | Description                                                                    |
|---------------------------|------------------------|--------------------------------------------------------------------------------|
| Link at end of Minor Loop | CITER[E_LINK]          | Enable channel-to-channel linking on minor loop completion (current iteration) |
|                           | CITER[LINKCH]          | Link channel number when linking at end of minor loop (current iteration)      |
| Link at end of Major Loop | CSR[MAJOR_E_LINK]      | Enable channel-to-channel linking on major loop completion                     |
|                           | CSR[MAJOR_LINKCH]      | Link channel number when linking at end of major loop                          |

## 22.5.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

### 22.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

### 22.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e\_link bit during channel execution (see the diagram in [TCD structure](#)). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e\_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e\_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e\_link bit.
2. Read back the TCD.major.e\_link bit.
3. Test the TCD.major.e\_link request status:
  - If TCD.major.e\_link = 1, the dynamic link attempt was successful.
  - If TCD.major.e\_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e\_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

### 22.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e\_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e\_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e\_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e\_link and TCD.e\_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

#### NOTE

The user must clear the TCD.done bit before writing the TCD.major.e\_link or TCD.e\_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

#### 22.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e\_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the TCD.d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

3. Write the TCD.dlast\_sga field with the scatter/gather address.
4. Write 1b to the TCD.e\_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e\_sg request status and TCD.major.linkch value:

If e\_sg = 1b, the dynamic link attempt was successful.

If e\_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e\_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e\_sg value cleared the e\_sg bit).

### 22.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast\_sga field as a TCD identification (ID).

1. Write 1b to the TCD.d\_req bit.

Should a dynamic scatter/gather attempt fail, setting the d\_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.

2. Write the TCD.dlast\_sga field with the scatter/gather address.
3. Write 1b to the TCD.e\_sg bit.
4. Read back the TCD.e\_sg bit.
5. Test the TCD.e\_sg request status:

If e\_sg = 1b, the dynamic link attempt was successful.

If e\_sg = 0b, read the 32 bit TCD dlast\_sga field.

If e\_sg = 0b and the dlast\_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If  $e\_sg = 0b$  and the  $dlast\_sga$  changed, the dynamic link attempt was successful (the new TCD's  $e\_sg$  value cleared the  $e\_sg$  bit).

## Chapter 23

# Direct Memory Access Multiplexer (DMAMUX)

## 23.1 Introduction

### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

### 23.1.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

**Figure 23-1. DMAMUX block diagram**

## 23.1.2 Features

The DMAMUX module provides these features:

- Up to 27 peripheral slots and up to six always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

## 23.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

## 23.2 External signal description

The DMAMUX has no external pins.

## 23.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

**DMAMUX memory map**

| Address offset (hex) | Register name                                  | Width (in bits) | Access | Reset value | Section/page               |
|----------------------|------------------------------------------------|-----------------|--------|-------------|----------------------------|
| 0                    | Channel Configuration register (DMAMUX_CHCFG0) | 8               | R/W    | 00h         | <a href="#">23.3.1/742</a> |
| 1                    | Channel Configuration register (DMAMUX_CHCFG1) | 8               | R/W    | 00h         | <a href="#">23.3.1/742</a> |
| 2                    | Channel Configuration register (DMAMUX_CHCFG2) | 8               | R/W    | 00h         | <a href="#">23.3.1/742</a> |

**23.3.1 Channel Configuration register (DMAMUX\_CHCFGn)**

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

**NOTE**

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

## 23.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Enabling and configuring sources](#) is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

### 23.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

### Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

**Figure 23-2. DMAMUX triggered channels**

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

**Figure 23-3. DMAMUX channel triggering: normal operation**

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

**Figure 23-4. DMAMUX channel triggering: ignored trigger**

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5  $\mu$ s (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

### 23.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in [Modes of operation](#).

### 23.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are six additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

## 23.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

### 23.5.1 Reset

The reset state of each individual bit is shown in [Memory map/register definition](#). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

### 23.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

#### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

### NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR    0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
```

```
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);

```

## Initialization/application information

```
In File main.c:  
#include "registers.h"  
:  
:  
*CHCFG8 = 0x00;  
*CHCFG8 = 0x87;
```

# Chapter 24

## Error Injection Module (EIM)

### 24.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Error Injection module is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of the peripheral memories. See the chip-specific EIM information to determine which peripheral memories are supported by this method.

#### 24.1.1 Overview

The Error Injection Module (EIM) provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

#### NOTE

The following diagram shows an example EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

**Figure 24-1. EIM functional block diagram (64-bit read data bus and 8-bit checkbit bus)**

## 24.1.2 Features

The EIM includes these features:

- Supports 1 error injection channel
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

## 24.2 Memory map and register definition

The EIM provides an IPS programming model mapped to an on-platform peripheral slot.

### Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation will result in non-deterministic behavior.

### Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model.
  - Each descriptor consists of Error Injection Channel Descriptor Word0-1 (EICHD $n$ \_WORD0-1) and, depending on the implementation, Word2 (EICHD $n$ \_WORD2).
  - When Word2 is unused, the corresponding word in the 16-byte structure is unused.
  - The fourth word in the 16-byte structure is always unused.

## EIM memory map

| Address offset (hex) | Register name                                                | Width (in bits) | Access | Reset value | Section/ page              |
|----------------------|--------------------------------------------------------------|-----------------|--------|-------------|----------------------------|
| 0                    | Error Injection Module Configuration Register (EIM_EIMCR)    | 32              | R/W    | 0000_0000h  | <a href="#">24.2.1/754</a> |
| 4                    | Error Injection Channel Enable register (EIM_EICHEN)         | 32              | R/W    | 0000_0000h  | <a href="#">24.2.2/755</a> |

24.2.3 Error Injection Channel Descriptor, Word0  
(EIM\_EICHDn\_WORD0)

The first word of the Error Injection Channel Descriptor defines a left-justified mask field (CHKBIT\_MASK) whose width is up to 8 bits. Each bit of CHKBIT\_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid bit, EICHEN[EICHnEN].

Address: 0h base + 100h offset + (256d × i), where i=0d to 0d

## 24.2.4 Error Injection Channel Descriptor, Word1 (EIM\_EICH $D_n$ \_WORD1)

The second word of the Error Injection Channel Descriptor defines the bits in the mask corresponding to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH $n$ EN].

## 24.2.5 Error Injection Channel Descriptor, Word2 (EIM\_EICH $D_n$ \_WORD2)

The third word of the Error Injection Channel Descriptor, when present, defines the bits in the mask corresponding to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH $n$ EN].

Address: 0h base + 108h offset + (256d × i), where i=0d to 0d

24.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel, execute both of the following:

- Assert the EICHEN[EICHnEN] field, where *n* denotes the channel number.
- Assert EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHDn\_WORD register, write the EICHDn\_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHDn\_WORD register clears the corresponding EICHEN[EICHnEN] field.

The EIM supports 1 error injection channel. Each channel:

- is assigned to a single memory array interface.
- intercepts the assigned memory read data bus and checkbit bus and injects errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHDn\_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 24-1 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

# Chapter 25

## Dual PLL Digital Interface (PLLDIG)

### 25.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Dual PLL system composed of PLL0 and PLL1 analog blocks and the digital interface (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

A key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1.

### 25.2 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

### 25.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.

- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
  - The loss of lock indication is sent to the FCCU via the system glue logic.

## 25.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL $n$ CR[CLKCFG]. PLLDIG operates in normal mode with a reference clock and PLL enabled.

### NOTE

Mode changes are controlled by configuring the MC\_ME Mode Configuration registers (MC\_ME\_<mode>\_MC).

Normal mode is defined as the mode where the clocks are driven by the PLLs. When using a crystal for the reference clock, reset should remain asserted until the oscillator has stabilized.

### 25.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In normal mode, PLL0 receives an input clock from the reference which can be prescaled by the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0 PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, and modulation enable are programmed by configuring the PLLFM register.

### NOTE

While powering down the PLLs and if PLL0:PHI1 is used as the source for PLL1, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Configuring the appropriate MC\_ME\_<mode>\_MC register to start PLL1 should only be done after PLL0 has achieved lock.

## 25.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

**PLLDIG memory map**

| Address offset (hex) | Register name                                             | Width (in bits) | Access | Reset value                 | Section/ page              |
|----------------------|-----------------------------------------------------------|-----------------|--------|-----------------------------|----------------------------|

25.5.3 PLLDIG PLL0 Divider Register (PLLDIG\_PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. PLL0DV can be modified at anytime, but the changes become effective only after the PLL is disabled, then reenabled. If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or interrupt based on which is enabled. The reduced frequency divider bitfields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective when PLL0 is disabled, then reenabled.

Address: 0h base + 8h offset = 8h

- \* Notes:
- MFD field: See Clocking chapter for reset value
  - PREDIV field: See Clocking chapter for reset value
  - RFDPHI field: See Clocking chapter for reset value

- RFDPHI1 field: See Clocking chapter for reset value

### PLLDIG\_PLL0DV field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 10–15<br>RFDPHI   | <p>PHI reduced frequency divider.</p> <p>This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.</p>                                                                                                                                                                                                                                 |
| 16<br>Reserved    | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 17–19<br>PREDIV   | <p>Input clock predivider.</p> <p>This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. The PREDIV value 000b causes the input clock to be inhibited.</p> <p>000 Clock inhibit<br/> 001 Divide by 1<br/> 010 Divide by 2<br/> 011 Divide by 3<br/> 100 Divide by 4<br/> 101 Divide by 5<br/> 110 Divide by 6<br/> 111 Divide by 7</p> |
| 20–24<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 25–31<br>MFD      | <p>Loop multiplication factor divider.</p> <p>This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 8...127 (8h...7Fh). All other values are reserved (see <a href="#">Clock configuration</a> for details).</p>                                                    |

25.5.4 PLLDIG PLL1 Control Register (PLLDIG\_PLL1CR)

The PLL1CR is shown in the following table. It contains the operational state of PLL1, and is used to enable/disable PLL specific interrupts.

Address: 0h base + 20h offset = 20h

**25.5.6 PLLDIG\_PLL1 Divider Register (PLLDIG\_PLL1DV)**

The values of the reduced frequency divider (RFDPHI) and loop multiplication factor divider (MFD) can be modified at anytime, but the new values only become effective after the PLL is disabled, then reenabled.

Address: 0h base + 28h offset = 28h

25.5.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG\_PLL1FM)

The PLL1FM register controls enables frequency modulation, and provides controls for modulation mode selection, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). The PLL would then be required to be power cycled to regain normal functionality.

Address: 0h base + 2Ch offset = 2Ch

### 25.5.8 PLLDIG PLL1 Fractional Divide Register (PLLDIG\_PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (PLL $n$ CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 30h offset = 30h

## PLLDIG\_PLL1FD field descriptions (continued)

| Field             | Description                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | 0 Fractional divide disabled.<br>1 Fractional divide enabled.                                                                                                                                                                                                                                              |
| 2–13<br>Reserved  | This field is reserved.                                                                                                                                                                                                                                                                                    |
| 14–15<br>Reserved | Reserved.<br>This field is reserved.<br><b>Important:</b> This field must be written 00b.                                                                                                                                                                                                                  |
| 16–19<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                    |
| 20–31<br>FRCDIV   | Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by the equation in the section <a href="#">Clock configuration</a> . |

## 25.6 Register classification for safety requirements

This module is classified as ViMo (Vital Modules) for functional safety. Hence, the registers of this module have been classified as shown in the Functional Safety chapter.

## 25.7 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

### 25.7.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for the PLL s are discussed in detail in the *Data Sheet*.

### 25.7.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{pll0\_phi} = f_{pll0\_ref} \times \left( \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]} \right)$$

**Equation 1. PLL0 PHI Output Frequency**

$$f_{pll0\_phi1} = f_{pll0\_ref} \times \left( \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

**Equation 2. PLL0 PHI1 Output Frequency**

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left( \frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}}{2 \times PLL1DV[RFDPHI]} \right)$$

**Equation 3. PLL1 PHI Output Frequency**

The relationship between the VCO frequency ( $f_{VCO}$ ) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{pll0\_VCO} = \frac{f_{pll0\_ref} \times PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]}$$

**Equation 4. PLL0 VCO Frequency**

$$f_{pll1\_VCO} = f_{pll1\_ref} \times \left( PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}} \right)$$

**Equation 5. PLL1 VCO Frequency****NOTE**

$f_{pll0\_phi1}$  is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL $n$ SR[LOCK] flag are immediately negated if the fields of the PLL $n$ DV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL $n$ SR[LOCK] flag is held negated. After the timer expires, the PLL $n$ SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL $n$ CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

### Note

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC\_ME\_<mode>\_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in [Initialization information](#).

## 25.7.3 Loss of lock

The PLL digital interface registers provide the flexibility to select whether to generate an interrupt, assert system reset, or do nothing in the event that the PLL loses lock according to the available PLL $n$ CR options.

Loss of lock indication is only generated when the PLL is operating in normal mode.

The lock indication from the analog PLL is synchronized and stored in the status register. When the analog PLL loses lock or regains lock, it will be immediately indicated in the status register (after a synchronization time).

A pair of counters monitor the reference and feedback clocks to determine when the system has acquired frequency lock. Once the PLL has locked, the counters continue to monitor the reference and feedback clocks and report whether the PLL has lost lock. The lock status is indicated in the status register.

## 25.7.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in [Figure 25-1](#). The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Figure 25-1. Triangular frequency modulation

**NOTE**

The device maximum operating frequency includes the frequency modulation. If center modulation is used, the  $f_{\text{sys}}$  must be below  $f_{\text{max}}$  by MD percentage such that

$$f_{\text{max}} = f_{\text{sys}} \times (1 + (\text{MD}\% / 100)).$$

The following equations define how to calculate PLL1FM[MODPRD] and PLL1FM[INCSTP] based on the output frequency of the feedback divider ( $f_{\text{ref}}$ ), the modulation frequency ( $f_{\text{mod}}$ ) and the modulation depth percentage (MD).

$$\text{PLL1FM}[\text{MODPRD}] = \text{round}\left(\frac{f_{\text{pll1\_ref}}}{4 \times f_{\text{mod}}}\right)$$

**Equation 6. PLL1FM[MODPRD] Calculation**

The equation to determine PLL1FM[INCSTP] is shown in [Equation 7 on page 779](#).

$$\text{PLL1FM}[\text{INCSTP}] = \text{round}\left(\frac{(2^{15} - 1) \times \text{MD} \times \text{PLL1DV}[\text{MFD}]}{100 \times 5 \times \text{PLL1FM}[\text{MODPRD}]}\right)$$

**Equation 7. PLL1FM[INCSTP] Calculation**

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

$$(\text{PLL1FM}[\text{MODPRD}] \times \text{PLL1FM}[\text{INCSTP}]) < 2^{15}$$

**Equation 8. PLL1FM[MODPRD] and PLL1FM[INCSTP] Restriction**

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is shown in [Equation 9 on page 779](#).

$$\text{ModulationDepth} = \text{round}\left(\frac{\text{PLL1FM}[\text{MODPRD}] \times \text{PLL1FM}[\text{INCSTP}] \times 100 \times 5}{(2^{15} - 1) \times \text{PLL1DV}[\text{MFD}]}\right)$$

### Equation 9. Modulation Depth

FM parameters should only be changed, and FM enabled, after PLL0 has obtained lock. The sequence for reprogramming the FM is:

1. Power down PLL1 by writing MC\_ME\_<mode>\_MC[PLL1ON] = 0, followed by a mode change.
2. Write a mode change to MC\_ME\_<mode>\_MC[PLL1ON].
3. Program the PLL1FM while PLL1 is powered down.
4. Power up the PLL1 by writing MC\_ME\_<mode>\_MC[PLL1ON] = 1, followed by a mode change.
5. Write a mode change to MC\_ME\_<mode>\_MC[PLL1ON].

## 25.8 Initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC\_ME\_DRUN\_MC. The Dual PLLDIG initialization procedure is described in the "Clocking" chapter.

### NOTE

See the "Mode Entry Module (MC\_ME)" chapter in this *Reference Manual* more details.

## Chapter 26

# Clock Monitor Unit (CMU)

### 26.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0\_RMN with CLKMN0\_RMT as the reference clock
- Monitors CLKMN0\_RMT frequency with CLKMT0\_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0\_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

#### NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0\_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which can take the necessary corrective actions as its configuration dictates.

The CMU can monitor CLKMN0\_RMT, which must have a frequency higher than that of CLKMT0\_RMN divided by the factor shown in CMU\_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper

and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU\_HFREFR) and CMU Low Frequency Reference Register (CMU\_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0\_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

**NOTE**

See the "Clocking" chapter for the number of CMU instances on this chip.

**26.1.1 Main features**

- CLKMT0\_RMN frequency measurement with CLKMN0\_RMT as reference clock.
- CLKMN0\_RMT monitoring with respect to  $\text{CLKMT0\_RMN} \div 2^{\text{CSR}[\text{RCDIV}]}$  clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to  $\text{CLKMT0\_RMN} \div 4$ .
- Event generation for various failures detected inside monitoring unit.

**26.2 Block diagram**

The block diagram of the CMU module(s) is shown in the “Clocking” chapter of this Reference Manual.

**26.3 Signals**

The table below describes the signals on the boundary of the CMU (in alphabetical order).

**Table 26-1. Signal description**

| Signal     | I/O | Description                                                                                                                                                                                                                                                                                                  |
|------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLKMN0_RMT | I   | Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals. |
| CLKMN1     | I   | Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.                                                                                           |

*Table continues on the next page...*

**Table 26-1. Signal description (continued)**

| Signal     | I/O | Description                                                                                                                                                                                                          |
|------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLKMT0_RMN | I   | Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals. |

**NOTE**

See the "Clocking" chapter for device specific clock sources of each CMU.

## 26.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

**NOTE**

See "Clocking" chapter for register and field availability details.

**CMU memory map**

| Address offset (hex) | Register name                                             | Width (in bits) | Access | Reset value                 | Section/ page              |
|----------------------|-----------------------------------------------------------|-----------------|--------|-----------------------------|----------------------------|
| 0                    | CMU Control Status Register (CMU_CSR)                     | 32              | R/W    | <a href="#">See section</a> | <a href="#">26.4.1/784</a> |

| 12–31<br>FD      | Measured frequency bits.<br><br>This register displays the measured frequency ( $f_{\text{sel}}$ ) with respect to the reference clock ( $f_{\text{CLKMN0\_RMT}}$ ). The measured value is given by the following formula:<br><br>$f_{\text{sel}} = (f_{\text{CLKMN0\_RMT}} \times \text{CMU\_MDR[MD]}) \div \text{CMU\_FDR[FD]}$ |

### 26.4.3 CMU High Frequency Reference Register CLKMN1 (CMU\_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU\_HFREFR register.

Address: 0h base + 8h offset = 8h

CMU\_HFREFR field descriptions

| Field            | Description                                                                                                                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                       |
| 20–31<br>HFREF   | High Frequency reference value.<br>These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: $(\text{HFREF} \div 16) \times (f_{\text{CLKMT0\_RMN}} \div 4)$ . |

### 26.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU\_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU\_LFREFR register.

Address: 0h base + Ch offset = Ch

CMU\_LFREFR field descriptions

| Field            | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 0–19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

Table continues on the next page...

CMU\_LFREFR field descriptions (continued)

| Field          | Description                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20–31<br>LFREF | Low Frequency reference value.<br><br>These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by:<br>$(\text{LFREF} \div 16) \times (f_{\text{CLKMTO\_RMN}} \div 4)$ . |

26.4.5 CMU Interrupt Status Register (CMU\_ISR)

NOTE

All flags in the CMU\_ISR are set asynchronously. This register must be read only after an interrupt(safe mode entry) is triggered by the CMU. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

NOTE

Before entering low-power stop modes, all clock frequency measurements in the CMU should be disabled. Failing to do so may result in spurious interrupts.

Address: 0h base + 10h offset = 10h

## Register description and memory map

| Bit   | 16       | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28       | 29   | 30   | 31   |
|-------|----------|----|----|----|----|----|----|----|----|----|----|----|----------|------|------|------|
| R     | Reserved |    |    |    |    |    |    |    |    |    |    |    | Reserved | FHHI | FLLI | OLRI |
| W     |          |    |    |    |    |    |    |    |    |    |    |    |          | w1c  | w1c  | w1c  |
| Reset | 0        | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0        | 0    | 0    | 0*   |

\* Notes:

- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

## CMU\_ISR field descriptions

| 12–31<br>MD      | Measurement duration bits<br><br>This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR[SFM] = 1. |

## 26.5 Functional description

### 26.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0\_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU\_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0\_RMT signal. The measurement starts when CMU\_CSR[SFM] = 1. The measurement duration is given by the contents of CMU\_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU\_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU\_FDR[FD]. The frequency of the selected clock ( $f_{\text{sel}}$ ) can be derived from the value loaded in the CMU\_FDR[FD] as shown in the following equation:

$$f_{\text{sel}} = f_{\text{CLKMN0\_RMT}} \times \frac{\text{CMU\_MDR[MD]}}{\text{CMU\_FDR[FD]}}$$

### 26.5.2 CLKMN0\_RMT supervisor

If frequency of CLKMN0\_RMT is smaller than the frequency of  $\text{CLKMT0\_RMN} \div 2^{\text{CMU\_CSR[RCDIV]}}$  and CLKMN0\_RMT is 'ON' as signaled by the MC\_ME, then:

- The CMU writes 1 to CMU\_ISR[OLRI].
- The CMU asserts the OLR signal.

#### Note

$f_{\text{CLKMN0\_RMT}}$  must be greater than  $f_{\text{CLKMT0\_RMN}} \div 2^{\text{CMU\_CSR[RCDIV]}}$  by at least 0.5 MHz in order to guarantee correct  $f_{\text{CLKMN0\_RMT}}$  monitoring.

### 26.5.3 CLKMN1 supervisor

The frequency of CLKMN1 ( $f_{\text{CLKMN1}}$ ) can be monitored by programming  $\text{CMU\_CSR[CME]} = 1$ . CLKMN1 monitoring starts as soon as  $\text{CMU\_CSR[CME]} = 1$ . This monitor can be disabled at any time by programming  $\text{CMU\_CSR[CME]} = 0$ .

If  $f_{\text{CLKMN1}}$  is greater than the reference value determined by fields  $\text{CMU\_HFREFR[HFREF]}$  and CLKMN1 is 'ON' as signaled by the MC\_ME, then:

- The CMU writes 1 to CMU\_ISR[FHHI].
- The CMU asserts the FHH signal.

If  $f_{\text{CLKMN1}}$  is less than a reference value determined by the bits  $\text{CMU\_LFREFR[LFREF]}$  and the CLKMN1 is 'ON' as signaled by the MC\_ME, then:

- The CMU writes 1 to CMU\_ISR[FLLI].
- The CMU asserts the FLL signal.

#### Note

An example of determining the  $\text{HFREF}_{\text{Actual}}$  is as follows. Assume a  $f_{\text{CLKMT0\_RMN}} = 16$  MHz with a accuracy of  $\pm 5\%$ . In order to monitor a  $f_{\text{CLKMN1}} = 200$  MHz, the ideal  $\text{HFREF}_{\text{Ideal}} = 800$ . The actual HFREF value will be 842 when the accuracy is taken into consideration ( $\text{HFREF}_{\text{Actual}} = (\text{HFREF}_{\text{Ideal}} \div 0.95)$ ).

The actual LFREF value will be 762 when accuracy is taken into consideration ( $\text{LFREF}_{\text{Actual}} = \text{LFREF}_{\text{Ideal}} \div 1.05$ ).

## Chapter 27

# Clock Generation Module (MC\_CGM)

### 27.1 Introduction

#### 27.1.1 Overview

The clock generation module (MC\_CGM) generates reference clocks for all the chip blocks. The MC\_CGM selects one of the system clock sources to supply the system clock. The MC\_ME controls the system clock selection (see the MC\_ME chapter for details). A set of MC\_CGM registers controls the clock dividers that are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources that have addressable memory spaces are accessed through the MC\_CGM memory space.

The following figure is the MC\_CGM block diagram.

**Figure 27-1. MC\_CGM Block Diagram**

### 27.1.2 Features

The MC\_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC\_ME control

- performs progressive system clock frequency change depending on MC\_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

## 27.2 External Signal Description

The MC\_CGM delivers output clocks to the CLKOUT pin for off-chip use and/or observation.

The LFAST-SysClk pin can be either driven by the MC\_CGM or used as an input to source the LFAST PLL clock.

## 27.3 Memory Map and Register Definition

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM\_PCS\_DIVC1 register RATE bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

**MC\_CGM memory map**

|-------------|-------------------------------------------------------------------------------------------------------------------|
| 0–7<br>SDUR | Switch Duration<br>This value defines the duration of one PCS clock switch step in terms of 16 MHz IRCOSC cycles. |

**27.3.2 PCS Divider Change Register 1 (MC\_CGM\_PCS\_DIVC1)**

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the 8-40 MHz XOSC on ramp-up and ramp-down, respectively. See [Progressive System Clock Switching](#) for details on how to set these values.

This register is reset only on a power-on reset.

### NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

## 27.3.3 PCS Divider End Register 1 (MC\_CGM\_PCS\_DIVE1)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the 8-40 MHz XOSC on ramp-down. See [Progressive System Clock Switching](#) for details on how to set this value.

This register is reset only on a power-on reset.

### NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

| 0–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                      |
| 12–31<br>DIVE    | Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the 8-40 MHz XOSC. |

### 27.3.4 PCS Divider Start Register 1 (MC\_CGM\_PCS\_DIVS1)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the 8-40 MHz XOSC on ramp-up. Register *n* corresponds to system clock source *n*. See [Progressive System Clock Switching](#) for details on how to set these values.

This register is reset only on a power-on reset.

#### NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 70Ch offset = 70Ch

27.3.5 PCS Divider Change Register 2 (MC\_CGM\_PCS\_DIVC2)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the PLL0 PHI on ramp-up and ramp-down, respectively. See [Progressive System Clock Switching](#) for details on how to set these values.

This register is reset only on a power-on reset.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

**MC\_CGM\_PCS\_DIVC4 field descriptions**

| Field             | Description                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>INIT      | Divider Change Initial Value - This is initial change value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.                   |
| 16–23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                        |
| 24–31<br>RATE     | Divider Change Rate - This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the PLL1 PHI. |

### 27.3.9 PCS Divider End Register 4 (MC\_CGM\_PCS\_DIVE4)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the PLL1 PHI on ramp-down. See [Progressive System Clock Switching](#) for details on how to set this value.

This register is reset only on a power-on reset.

#### NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 72Ch offset = 72Ch

#### MC\_CGM\_PCS\_DIVE4 field descriptions

| Field            | Description                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------|
| 0–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                 |
| 12–31<br>DIVE    | Divider End Value - This is the clock divider end value for the clock ramp-down phase when switching from the PLL1 PHI. |

### 27.3.10 PCS Divider Start Register 4 (MC\_CGM\_PCS\_DIVS4)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the PLL1 PHI on ramp-up. See [Progressive System Clock Switching](#) for details on how to set this value.

This register is reset only on a power-on reset.

#### NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

### MC\_CGM\_PCS\_DIVS4 field descriptions

| Field            | Description                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                        |
| 12–31<br>DIVS    | Divider Start Value - This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI. |

## 27.3.11 System Clock Select Status Register (MC\_CGM\_SC\_SS)

This register provides the current system clock source selection.

Address: 0h base + 7E4h offset = 7E4h

| Bit   | 0 | 1 | 2 | 3 | 4       | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12    | 13 | 14 | 15   |
|-------|---|---|---|---|---------|---|---|---|---|---|----|----|-------|----|----|------|
| R     | 0 |   |   |   | SELSTAT |   |   |   | 0 |   |    |    | SWTRG |    |    | SWIP |
| W     |   |   |   |   |         |   |   |   |   |   |    |    |       |    |    |      |
| Reset | 0 | 0 | 0 | 0 | 0       | 0 | 0 | 0 | 0 | 0 | 0  | 0  | *     | *  | *  | 0    |

| Bit   | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| R     | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

\* Notes:

- SWTRG field: The value of the SWTRG field is “000” after a power-on reset and “100” after all other resets.

### MC\_CGM\_SC\_SS field descriptions

| Field           | Description                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------|
| 0–3<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.              |
| 4–7<br>SELSTAT  | System Clock Source Selection Status - This value indicates the current source for the system clock. |

## 27.3.12 System Clock Divider 0 Configuration Register (MC\_CGM\_SC\_DC0)

This register controls system clock divider 0.

### NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

### WARNING

Use only odd DIV values (i.e., division factor of 2, 4, 6, 8, etc.). Even values will cause incorrect device behavior.

Address: 0h base + 7E8h offset = 7E8h

## 27.3.13 Auxiliary Clock 0 Select Control Register (MC\_CGM\_AC0\_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 0 divider 0: motor control clock
- divided by auxiliary clock 0 divider 1: SGEN clock
- divided by auxiliary clock 0 divider 2: ADC clock

**NOTE**

PLL1 is routed on N15P devices into the AUX Clock Selector 0. It is recommended not to enable Frequency modulation on PLL1 when it is being used as a clock source for AUX Clock Selector 0.

See [Figure 27-5](#) for details.

### 27.3.15 Auxiliary Clock 0 Divider 0 Configuration Register (MC\_CGM\_AC0\_DC0)

This register controls auxiliary clock 0 divider 0.

**NOTE**

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 808h offset = 808h

### 27.3.20 Auxiliary Clock 2 Divider 0 Configuration Register (MC\_CGM\_AC2\_DC0)

This register controls auxiliary clock 2 divider 0.

#### NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 848h offset = 848h

### 27.3.27 Auxiliary Clock 5 Divider 0 Configuration Register (MC\_CGM\_AC5\_DC0)

This register controls auxiliary clock 5 divider 0.

**NOTE**

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 8A8h offset = 8A8h

### 27.3.28 Auxiliary Clock 6 Select Control Register (MC\_CGM\_AC6\_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 6 divider 0: CLKOUT pin clock

See [Figure 27-11](#) for details.

Address: 0h base + 8C0h offset = 8C0h

### 27.3.31 Auxiliary Clock 10 Select Control Register (MC\_CGM\_AC10\_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 10 divider 0: ENET\_CLK

See [Figure 27-12](#) for details.

Address: 0h base + 940h offset = 940h

27.3.33 Auxiliary Clock 10 Divider 0 Configuration Register (MC\_CGM\_AC10\_DC0)

This register controls auxiliary clock 10 divider 0.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 948h offset = 948h

## 27.4 Functional Description

### 27.4.1 System Clock Generation

The following figure shows the block diagram of the system clock generation logic. The MC\_ME provides the system clock select and switch mask (see MC\_ME chapter for more details), and the MC\_RGM provides the safe clock request (see MC\_RGM chapter for more details). The safe clock request forces the selector to select the 16 MHz IRCOSC as the system clock and to ignore the system clock select.

Figure 27-2. MC\_CGM System Clock Generation Overview

#### 27.4.1.1 System Clock Source Selection

During normal operation, the system clock selection is controlled

- on a SAFE mode or reset event, by the MC\_RGM
- otherwise, by the MC\_ME

## 27.4.1.2 Progressive System Clock Switching

Based on the power level values of the current and target modes, the MC\_ME requests the MC\_CGM to ramp the system clock frequency down and/or up. During ramp-down, the rate of the frequency change is based on the CGM\_PCS\_SDUR, CGM\_PCS\_DIVCn, and CGM\_PCS\_DIVEN registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the CGM\_PCS\_SDUR, CGM\_PCS\_DIVCn, and CGM\_PCS\_DIVSn registers, where n corresponds to the target system clock source selection.

### 27.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency ( $f_{chg}$ ) and for a given source clock frequency  $f_{src}$  (current or target clock source), the maximum allowed frequency change rate  $a_{max}$  is given in the following equation.

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

**Equation 10**

### 27.4.1.2.2 Configuration of CGM\_PCS\_SDUR

The switch duration field CGM\_PCS\_SDUR[SDUR] defines the duration of one system clock switch step in terms of the 16 MHz internal RC oscillator. After the expiration of this time, the module changes the clock divider value, which changes the frequency of the system clock.

### 27.4.1.2.3 Configuration of CGM\_PCS\_DIVCn[RATE]

For a given maximum allowed frequency change rate  $a_{max}$  the value d to be programmed into the PCS\_DIVCn[RATE] register is given in the following table.

**Table 27-1. MC\_CGM CGM\_PCS\_DIVCn[RATE] values**

| $a_{max}$ | d     | CGM_PCS_DIVCn[RATE] |
|-----------|-------|---------------------|
| 0.05      | 0.012 | 12                  |
| 0.10      | 0.048 | 48                  |
| 0.15      | 0.112 | 112                 |
| 0.20      | 0.184 | 184                 |

### 27.4.1.2.4 Generic Clock Change Properties

The number  $k$  of required steps to reach or leave the divided system clock with frequency  $f_{div}$  from the source clock with frequency  $f_{src}$  is given in the following equation.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2 \left( 1 - \frac{f_{src}}{16\text{MHz}} \right)}{d}} \right\rceil$$

**Equation 11**

### 27.4.1.2.5 Clock Ramp-Down

The clock ramp-down starts with the divider value 1 and with the given divider increment value  $\text{PCD\_DIVCn}[\text{RATE}]$  and ends with the given divider value  $\text{PCS\_DIVE}[\text{DIVE}]$ .

The divider end value for clock ramp-down is given in the following equation.

$$\text{PCS\_DIVE}[\text{DIVE}] = \frac{f_{src}}{16\text{MHz}} \times 1000 - 1$$

**Equation 12**

Where  $f_{curr}$  is the frequency of the currently selected system clock source.

**Figure 27-3. MC\_CGM System Clock Ramp-Down Timing ( $k = 6$  example)**

### 27.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value  $\text{PCS\_DIVS}[\text{DIVS}]$  and with the given divider decrement value  $\text{PCD\_DIVCn}[\text{INIT}]$  and ends with the divider value 1.

The initial divider change start value  $\text{PCS\_DIVCn}[\text{INIT}]$  for system clock ramp-up is given in [Equation 13 on page 829](#).

$$\text{PCS\_DIVCn[INIT]} = d \times k \times 1000$$

### Equation 13

Where  $k$  is calculated from [Equation 11 on page 828](#) using the target system clock source frequency  $f_{\text{targ}}$ . The divider start value for clock ramp-up is given in [Equation 14 on page 829](#).

$$\text{PCS\_DIVSn[DIVS]} = \left(1 + d \frac{k(k+1)}{2}\right) \times 1000 - 1$$

### Equation 14

Figure 27-4. MC\_CGM System Clock Ramp-Up Timing ( $k = 6$  example)

#### 27.4.1.3 System Clock Disable

During the TEST mode, the system clock can be disabled by the MC\_ME.

#### 27.4.1.4 System Clock Dividers

The MC\_CGM generates the following derived clock from the system clock:

- AIPS clock - controlled by the CGM\_SC\_DC0 register

### 27.4.2 Auxiliary Clock Generation

[Figure 27-5](#) through [Figure 27-11](#) show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

## Functional Description

- Auxiliary Clock 0 Select Control Register (MC\_CGM\_AC0\_SC)
- Auxiliary Clock 3 Select Control Register (MC\_CGM\_AC3\_SC)
- Auxiliary Clock 4 Select Control Control Register (MC\_CGM\_AC4\_SC)
- Auxiliary Clock 5 Select Control Register (MC\_CGM\_AC5\_SC)

**Figure 27-5. MC\_CGM Auxiliary Clock 0 Generation Overview**

Figure 27-6. MC\_CGM Auxiliary Clock 1 Generation Overview

Figure 27-7. MC\_CGM Auxiliary Clock 2 Generation Overview

## Functional Description

**Figure 27-8. MC\_CGM Auxiliary Clock 3 Generation Overview**

**Figure 27-9. MC\_CGM Auxiliary Clock 4 Generation Overview**

**Figure 27-10. MC\_CGM Auxiliary Clock 5 Generation Overview**

**Figure 27-12. MC\_CGM Auxiliary Clock 10 Generation Overview**

**Figure 27-13. MC\_CGM Auxiliary Clock 11 Generation Overview**

### 27.4.2.1 Auxiliary Clock Dividers

The MC\_CGM generates the following derived clocks:

- Motor Control clock - controlled by the **CGM\_AC0\_DC0** register
- SGEN clock - controlled by the **CGM\_AC0\_DC1** register
- ADC clock - controlled by the **CGM\_AC0\_DC2** register
- FlexRay clock - controlled by the **CGM\_AC1\_DC0** register
- SENT clock - controlled by the **CGM\_AC1\_DC1** register
- CAN clock - controlled by the **CGM\_AC2\_DC0** register
- LFAST PLL clock - controlled by the **CGM\_AC5\_DC0** register
- CLKOUT pin clock - controlled by the **CGM\_AC6\_DC0** register
- ENET clock - controlled by the **CGM\_AC10\_DC0** register
- ENET TIME clock - controlled by the **CGM\_AC11\_DC0** clock register

### 27.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The MC\_CGM has the following control registers for built-in dividers:

- [System Clock Divider 0 Configuration Register \(MC\\_CGM\\_SC\\_DC0\)](#)
- [Auxiliary Clock 0 Divider 0 Configuration Register \(MC\\_CGM\\_AC0\\_DC0\)](#)
- [Auxiliary Clock 0 Divider 1 Configuration Register \(MC\\_CGM\\_AC0\\_DC1\)](#)
- [Auxiliary Clock 0 Divider 2 Configuration Register \(MC\\_CGM\\_AC0\\_DC2\)](#)
- [Auxiliary Clock 1 Divider 0 Configuration Register \(MC\\_CGM\\_AC1\\_DC0\)](#)
- [Auxiliary Clock 1 Divider 1 Configuration Register \(MC\\_CGM\\_AC1\\_DC1\)](#)
- [Auxiliary Clock 2 Divider 0 Configuration Register \(MC\\_CGM\\_AC2\\_DC0\)](#)
- [Auxiliary Clock 5 Divider 0 Configuration Register \(MC\\_CGM\\_AC5\\_DC0\)](#)
- [Auxiliary Clock 6 Divider 0 Configuration Register \(MC\\_CGM\\_AC6\\_DC0\)](#)
- [Auxiliary Clock 10 Divider 0 Configuration Register \(MC\\_CGM\\_AC10\\_DC0\)](#)
- [Auxiliary Clock 11 Divider 0 Configuration Register \(MC\\_CGM\\_AC11\\_DC0\)](#)

## Functional Description

The reset value of all counters is '1'. If a divider has its DE bit in the respective configuration register set to '0' (the divider is disabled), any value in its DIV field is ignored.

## Chapter 28

# OSC Digital Interface (XOSC)

### 28.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provide the register interface for the programmable features. Selection of the XOSC as a source clock is controlled by the Clock Generation Module (MC\_CGM). The XOSC is enabled and disabled by configuring the Mode Entry Module (MC\_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control
- Crystal oscillator mode selection
  - Loop Controlled Pierce Mode (LCP)
  - Full Swing Pierce Mode (FSP)

### 28.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that is used as an input to the PLLs and can be selected as the reference clock for many of the peripherals on the device.

The table below shows the possible configurations of the XOSC.

**Table 28-1. XOSC configurations**

| OSC EN<br>(from<br>MC_ME) | XOSC_CTL[OSCBYP] | XTAL                       | EXTAL                      | XOSC Output | XOSC MODE              |
|---------------------------|------------------|----------------------------|----------------------------|-------------|------------------------|
| 0                         | 0                | Crystal, or left<br>opened | Crystal, or left<br>opened | 0           | Power down, IDDQ       |
| 0                         | 1                | x                          | external clock             | Undefined   | Reserved, OSC Disabled |
| 1                         | 1                | x                          | external clock             | XTALOUT     | Bypass, OSC Enabled    |
| 1                         | 0                | crystal                    | crystal                    | XTALOUT     | Normal, OSC Enabled    |

### 28.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC\_ME) module (see “Mode Entry Module (MC\_ME)” chapter). The ME\_<mode>\_MC[XOSCON] controls the power down of oscillator based on the current device mode (see “MC\_ME Memory Map” table for available *modes*). The status of the XOSC is shown in the MC\_ME\_GS[S\_XOSC].

### 28.2.2 Oscillator startup delay

A bit in the UTEST flash memory determines whether the analog portion of the oscillator is enabled at powerup. If enabled, the analog portion of the oscillator is powered-up during Phase3 of the device reset sequence (pre-self-test sequence). In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches  $XOSC\_CTL[EOCV] \times 512$ , a signal is sent to the MC\_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL0).

The default value for this field after reset depends on implementation and can be found in the XOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

#### Note

It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

### 28.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached ( $\text{OSCCNT} = \text{XOSC\_CTL}[\text{EOCV}] \times 512$ ). The  $\text{XOSC\_CTL}[\text{I\_OSC}]$  will be set and an interrupt will be generated if the interrupt mask is set ( $\text{XOSC\_CTL}[\text{M\_OSC}] = 1$ ).

### 28.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting  $\text{XOSC\_CTL}[\text{OSCBYP}]$ . This field can only be set by software and is only cleared by a system reset. In bypass mode, the oscillator is disabled and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

#### NOTE

The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

#### NOTE

Power down from the MC\_ME will have no effect on the oscillator. The bypass clock will continue running in the device. It is ensured that mode transitions from the MC\_ME complete successfully by providing bypass information to the MC\_ME.

### 28.2.5 Crystal oscillator mode selection

There are two oscillator mode selections possible, Full Swing Pierce mode and Loop Controlled Pierce mode. The operating mode is selected by configuring the  $\text{XOSC\_CTL}[\text{OSCM}]$ .

#### 28.2.5.1 Loop Controlled Pierce mode

Loop Controlled Pierce mode (LCP) is the default oscillator mode. LCP has the following attributes:

- Provides a smaller frequency range

- Limits the amplitude of the crystal oscillation utilizing Amplitude Loop Control (ALC)
- Reduced EMI
- Reduced power consumption
- Shorter settling time
- Crystal is exposed to reduced stress since the amplitude is reduced
- Reduced number of external components, feedback resistor already integrated

### 28.2.5.2 Full Swing Pierce mode

Full Swing Pierce mode (FSP) has the following attributes when compared with LCP:

- Provides a wider frequency range
- Less susceptible to noise
- The crystal amplitude is rail-to-rail
  - Distorted oscillation with several harmonics
  - Increased EMI
- Slower settling time
- Feedback resistor and 300 ohms of current limitation are already integrated.

#### NOTE

Consult with crystal supplier to determine the need of extra resistance in XTAL to avoid crystal overdrive.

## 28.3 Memory map and register definition

### XOSC memory map

| Address offset (hex) | Register name                    | Width (in bits) | Access | Reset value                 | Section/ page              |
|----------------------|----------------------------------|-----------------|--------|-----------------------------|----------------------------|
| 0                    | XOSC Control Register (XOSC_CTL) | 32              | R/W    | <a href="#">See section</a> | <a href="#">28.3.1/841</a> |

### 28.3.1 XOSC Control Register (XOSC\_CTL)

#### NOTE

The XOSC\_CTL is only writable in supervisor mode.

## Chapter 29

# IRCOSC Digital Interface

### 29.1 Introduction

The Internal RC Oscillator Digital Interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

### 29.2 Functional description

The IRCOSC provides a high frequency ( $f_{MRC}$ ) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see the Data Sheet for timing details) which is required for stabilization. The IRCOSC status is updated in the MC\_ME\_GS[S\_IRC] field (see the "Mode Entry Module MC\_ME" chapter).

The IRCOSC output frequency can be trimmed by configuring IRCOSC\_CTL[USER\_TRIM[4:0]]. The USER\_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with  $\delta f_{var\_SW}$ , as defined in the Data Sheet.

## 29.3 Memory map and register definition

### IRCOSC memory map

| Address offset (hex) | Register name                        | Width (in bits) | Access | Reset value                 | Section/ page              |
|----------------------|--------------------------------------|-----------------|--------|-----------------------------|----------------------------|
| 0                    | IRCOSC Control Register (IRCOSC_CTL) | 32              | R/W    | <a href="#">See section</a> | <a href="#">29.3.1/844</a> |

### 29.3.1 IRCOSC Control Register (IRCOSC\_CTL)

The IRCOSC\_CTL contains user programmable parameters.

IRCOSC\_CTL is writable only in supervisor mode.

Address: 0h base + 0h offset = 0h

## IRCOSC\_CTL field descriptions (continued)

| Field             | Description                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19–23<br>Reserved | This field is reserved.<br>This field can be written at any time, but writes have no effect. Reads return the previously written value.                                                   |
| 24–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                   |
| 26<br>Reserved    | This field is reserved.<br>This field may sometimes have the value of 1, and can be cleared by writing a 1 to this bit. However, this field has no effect on the IRCOSC or chip behavior. |
| 27–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                   |

## 29.3.2 Frequency trimming calculation

Table 29-1. IRCOSC\_CTL[USER\_TRIM] frequency trimming calculation

| USER_TRIM[4:0] value | Frequency                               |
|----------------------|-----------------------------------------|
| ....                 | ....                                    |
| 10011                | $f + (3 \times \delta f_{\text{TRIM}})$ |
| 10010                | $f + (2 \times \delta f_{\text{TRIM}})$ |
| 10001                | $f + \delta f_{\text{TRIM}}$            |
| 10000                | $f$                                     |
| 00000                | $f$                                     |
| 00001                | $f - \delta f_{\text{TRIM}}$            |
| 00010                | $f - (2 \times \delta f_{\text{TRIM}})$ |
| 00011                | $f - (3 \times \delta f_{\text{TRIM}})$ |
| ....                 | ....                                    |

**NOTE**

See the data sheet for  $\delta f_{\text{TRIM}}$  value and min/max frequency variations.

# Chapter 30

## RAM Controller (PRAMC)

### 30.1 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. Shown below in [Figure 30-1](#) is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture.

**Figure 30-1. Simplified platform block diagram**

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

## 30.2 SRAM controller memory map and register definition

The RAM controller module provides an IPS programming model mapped to a standard on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

**NOTE**

Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

**PRAMC memory map**

| Address offset (hex) | Register name                                       | Width (in bits) | Access | Reset value | Section/ page              |
|----------------------|-----------------------------------------------------|-----------------|--------|-------------|----------------------------|
| 0                    | Platform RAM Configuration Register 1 (PRAMC_PRCR1) | 32              | R/W    | 0000_0200h  | <a href="#">30.2.1/849</a> |

**30.2.1 Platform RAM Configuration Register 1 (PRAMC\_PRCR1)**

The Platform RAM Configuration Register 1 (PRCR1) is used to specify operation of the RAM controller.

**NOTE**

This register is accessible only in supervisor mode. Accesses in user mode return a transfer error.

Address: 0h base + 0h offset = 0h

## 30.3 Functional description

This section describes the functions of the RAM controller.

### 30.3.1 Read and Write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

#### NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

#### 30.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

#### 30.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the `PRCRx[FT_DIS]` field inserts a register in the read data path for use when operating the controller at high frequencies. The state of `PRCRx[FT_DIS]` field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if `PRCRx[FT_DIS]=0`, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if `PRCRx[FT_DIS]=1`, and a WRAP4 burst will have an access time of 3-2-2-2.

#### NOTE

The number of cycles taken for a RAM access can vary  $\pm 1$  clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles

depending on RAM speed relative to the PRAMC controller clock frequency.

## **30.3.2 Writes**

This section discusses various write operations of the RAM controller.

### **30.3.2.1 64-bit writes**

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

### **30.3.2.2 Less than 64-bit writes**

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. [Figure 30-2](#) provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to [Reliability considerations](#).

**Figure 30-2. Read-modify-write datapath**

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

### 30.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

#### NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

## 30.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (`e_stmw`) in Power Architecture VLE.

## 30.5 Reliability considerations

This section discusses reliability considerations of the RAM controller.

### 30.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field).

---

[illegible]

### 30.5.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:

- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

Consider the following example whereby the master presents a 16-bit write request at address 0x4000\_0000:

- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x4000\_0000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

### 30.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions:

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor also verifies the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

**Figure 30-3. RAM controller transaction monitor block diagram**

# Chapter 31

## Flash Memory Controller (PFLASH)

### 31.1 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to on-chip System RAM that can be used as overlay RAM.

The flash memory controller supports one 64-bit AHB bus and a 256-bit read data interface from each flash memory array. The AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. The mini-cache entry is 256 bits in size, matching the flash array page size and providing 256 bytes of total buffered storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

### 31.2 Features

The following list summarizes the key features of the flash memory controller:

- One 64-bit AHB interface port (p0) allowing access to dedicated prefetch mini-cache.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.

- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip system RAM

### 31.3 Block diagrams

Figure 31-1 illustrates the connections of the flash memory controller and flash memory array within the chip.

Figure 31-1. Platform-centric simple block diagram with flash memory controller

### 31.4 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration and overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario. There is no idle indicator for the flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the flash, code execution must be temporarily moved to system RAM.

**PFLASH\_PFCR3 field descriptions**

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–1<br>P0_WCFG | Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers.<br><br>In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit.<br><br>This field is initialized by hardware reset.<br><br>00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type.<br>01 Reserved |

**31.4.3 Platform Flash Access Protection Register (PFLASH\_PFAPR)**

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

**NOTE**

See the chip-specific platform flash controller information for details about the actual masters available on the device.

**31.4.4 Platform Flash Remap Control Register (PFLASH\_PFCRCR)**

The PFCRCR is used to globally enable/disable the calibration remap function.

**CAUTION**

Overlay remap functions, when used with line read buffers enabled (PFLASH\_PFCRx[BFy\_EN] field(s)='1') have a potential to cause data coherency issues, i.e., prefetched data in a line read buffer can become out-of-sync with data contained at the associated flash address range. To prevent this issue, always clear the flash controller line read buffers prior to enabling any remap region.

To clear the flash controller line read buffers, issue an interlock write command to a valid flash memory address. There will not be an actual flash program operation performed, but the flash controller mini-cache will be cleared as a side effect of executing the command. The interlock write must be issued from a core having appropriate access to flash. The sequence is as follows:

1. Set the C55FMC\_MCR[PGM] field to '1'
2. Issue a 64-bit write to a valid flash address on a 64-bit boundary, i.e., the least significant 5 bits of the address are '0'
3. Clear C55FMC\_MCR[PGM]

Address: 0h base + 10h offset = 10h

31.4.5 Platform Flash Remap Descriptor Enable Register (PFLASH\_PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 8 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Address: 0h base + 14h offset = 14h

| 8–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

31.4.6 Platform Flash Calibration Region Descriptor n Word0 (PFLASH\_PFCRDn\_Word0)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 100h offset + (16d × i), where i=0d to 7d

PFLASH\_PFCRDn\_Word0 field descriptions

| Field              | Description                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–27<br>LSTARTADDR | Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. |
| 28–31<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                       |

31.4.7 Platform Flash Calibration Region Descriptor n Word1 (PFLASH\_PFCRDn\_Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region.

The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 104h offset + (16d × i), where i=0d to 7d

PFLASH\_PFCRDn\_Word1 field descriptions

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–27<br>PSTARTADDR | Calibration Remap Descriptor <i>n</i> Physical Start Address - This field defines the most significant bits of the 0-modulo-size physical start byte address of the calibration remap descriptor. This address corresponds to the physical address which maps to the destination calibration overlay memory. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. |
| 28–31<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                     |

### 31.4.8 Platform Flash Calibration Region Descriptor n Word2 (PFLASH\_PFCRDn\_Word2)

The third word of the calibration region descriptor defines a per-master calibration remap enable and the remap region size. For cacheable spaces being remapped, the minimum region size is 32 bytes to match the flash page and cache line sizes. Writes to this word clear the calibration remap descriptor's valid bit.

Address: 0h base + 108h offset + (16d × i), where i=0d to 7d

### 31.5 Functional description

The flash memory controller interfaces between:

- The AHB system bus port
- Flash memory array
- System RAM

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

### 31.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

### 31.5.2 Access protections

On-chip Flash memory accesses are subject to restrictions based on chip security implementation and/or requirements based on functional restrictions of the flash memory, e.g., a read access to a flash block while it is currently being written is not allowed. When a prohibited access is attempted, a system bus error termination results.

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding read access control or write access control settings do not allow the access, thus causing a protection violation. See [Platform Flash Access Protection Register \(PFLASH\\_PFAPR\)](#) for more detail. In this case the flash memory controller does not initiate the requested flash array access.
- Attempted access by an AHB master to a flash region where the corresponding censorship control is asserted.
- The flash returns an error response on an attempted access to a partition that is unavailable. (see [Flash error response operation](#) or [Embedded Flash Memory](#)).
- Attempted access by an AHB master to a reserved region in the flash memory map.

The flash array may also signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

### 31.5.2.1 Censorship

The flash space is defined by regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- UTEST flash

Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

### 31.5.2.2 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in [Platform Flash Access Protection Register \(PFLASH\\_PFAPR\)](#). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

### 31.5.3 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

#### NOTE

Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

### 31.5.4 Line read buffers and prefetch operation

The AHB ports of the flash memory controller contains a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see [Platform Flash Configuration Register 1 \(PFLASH\\_PFCR1\)](#)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

**Figure 31-2. Flash memory controller 4-entry, 2-way mini-cache organization**

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in [Platform Flash Configuration Register 1 \(PFLASH\\_PFCR1\)](#). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR1[P0\_BFEN] must be set to '1',

2. PFCR1[P0\_PFLIM] must be non-zero, and
3. Either PFCR1[P0\_IPFEN] or PFCR1[P0\_DPFEN] must be asserted.

Refer to [Platform Flash Configuration Register 1 \(PFLASH\\_PFCR1\)](#) for a description of these controls.

### 31.5.5 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to [Platform Flash Configuration Register 1 \(PFLASH\\_PFCR1\)](#) for a description of these controls. Prefetches are never triggered by write cycles.

### 31.5.6 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to [Platform Flash Configuration Register 1 \(PFLASH\\_PFCR1\)](#) for a description of these controls.

### 31.5.7 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration (P0\_WCFG) field. Refer to [Platform Flash Configuration Register 3 \(PFLASH\\_PFCR3\)](#). The buffers can be organized as a "pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

### 31.5.8 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to on-chip System RAM that can be used as overlay RAM.

The overlay function supports the following features:

- Can be mapped over internal flash memory
  - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces

- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash
  - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function :
  - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
  - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay targets:

- A portion of the system RAM can be used for overlay.

### 31.5.8.1 PFlash calibration remap to RAM

The overlay RAM is selected based on the translated physical address.

The translated physical address defines the destination memory. [Table 31-1](#) shows the base addresses for the calibration data memories as defined by the system memory map.

**Table 31-1. Calibration data memory base addresses**

| Calibration Memory | Base Address      | Possible Access Sources |
|--------------------|-------------------|-------------------------|
| Flash Arrays       | 0x0{8,9,A}--_---- | P0, P1                  |
| System RAM         | 0x40{0,1}-_----   | P0, P1                  |

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address.

The read data interface of system RAM is 64 bits wide, whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(RWSC + 2) \geq \left( \frac{\text{IntrinsicFlashAccessTime}}{\text{OperatingFrequencyClockPeriod}} + 2 \right) \geq (\text{OverlayRAMTransferBurstLatency})$$

### Equation 15. Access time

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150 °C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD $n$ ) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries.

The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to determine the region "hit". The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region "hit" data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRD<sub>x</sub> and CRD<sub>y</sub>, the translated address from CRD<sub>y</sub> is used, given  $y > x$ .

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

## 31.5.9 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

### 31.5.9.1 e2eECC End-to-End ECC

#### 31.5.9.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns `fl_rdata = 0xFFFFFFFF_FFFFFFFF`, `fl_cdata = 0xFF`. The flash memory controller calculates the `addr_chkbit = 0xC4` using the H-matrix; it inverts the `fl_cdata` vector to 0x00 and factors in the `addr_chkbit = 0xC4` to produce the following valid e2eECC codeword:

`addr = 0x00345678`, `rdata = 0xFFFFFFFF_FFFFFFFF`, `rchkbit = 0xC4` ( $0x00 \wedge 0xC4$ )

2. Program address 0x00345678 with data = 0xBABEFACE\_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

`addr = 0x00345678`, `wdata = 0xBABEFACE_DEADBEEF`, `wchkbit = 0xE3`

Before performing the interlock write to the flash array, the flash memory controller adjusts the `chkbit` value as `fl_wchkbit = 0xD8` ( $0xE3 \wedge 0xFF \wedge 0xC4$ ) by toggling the original write checkbits and then factoring in the `addr_ecc`. Accordingly, the codeword stored in the flash array is:

`fl_data = 0xBABEFACE_DEADBEEF`, `fl_checkbit = 0xD8`

3. Read address 0x00345678. The flash array returns the stored codeword, `fl_rdata = 0xBABEFACE_DEADBEEF`, `fl_rchkbit = 0xD8`. The flash memory controller inverts the checkbit vector and factors in the address checkbits ( $0xD8 \wedge 0xFF \wedge 0xC4$ ) to produce:

`addr = 0x00345678`, `rdata = 0xBABEFACE_DEADBEEF`, `rchkbit = 0xE3`

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

### **31.5.9.2 Flash address generation check**

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

#### **31.5.9.2.1 Overlay RAM feedback check**

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

### 31.5.9.2.2 Reliability considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming `PFCRCR[SAFE_CAL]=1`, the flash memory controller treats the set of available calibration region descriptors as a replicated pair, with each set containing half the total number of available calibration region descriptors.

If there are 32 calibration region descriptors, `CRD0 – CRD31`, and `PFCRCR[SAFE_CAL]=1`, the flash memory controller treats `CRD0 – CRD15` and `CRD16 – 32` as replicated sets of 16 calibration region descriptors, where:

- `CRD0` and `CRD16` are configured identically
- `CRD1` and `CRD17` are configured identically
- `CRD2` and `CRD18` are configured identically
- ...
- and `CRD15` and `CRD31` are configured identically

Expressed more generally, the contents of `CRD[n]` must be identical to the contents of `CRD[(N/2) + n]`, where `N` is the total number of region descriptors and  $0 \leq n \leq (N/2) - 1$ .

#### Note

It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in `CRD0` to `CRD[(N/2) – 1]` and the calibration regions defined in `CRD[N/2]` to `CRD[N – 1]`. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

Figure 31-3. Safety-critical calibration remap datapath with redundancy

### 31.5.10 ECC on data flash accesses

ECC events detected on accesses to data flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU. For non-correctable error detection, the flash memory controller returns a value of FFFF\_FFFFh to the requesting master.

#### **NOTE**

EEPROM should be avoided for storage of executable code.

### **31.5.11 Array integrity considerations**

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

## Chapter 32

# Embedded Flash Memory (c55fmc)

### 32.1 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

Figure 32-1. c55fmc block diagram

### 32.1.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see [Functional Description](#).

### 32.1.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

### 32.1.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *Low power mode* turns off all DC current sources within the embedded flash memory on the Vflash domain, and enables VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in low power mode.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

## 32.2 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

## 32.3 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks..

### 32.3.1 Module Configuration Register (C55FMC\_MCR)

#### NOTE

1. A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in [Functional Description](#).
2. See [Functional Description](#) for information about simultaneous MCR writes, and priority levels.

Address: 0h base + 0h offset = 0h

|                  | <p>corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring without voltage issues<br/>1 A previous read may have been corrupted due to read voltage being out of range</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1<br>RRE         | <p>Read Reference Error</p> <p>RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring without reference issues<br/>1 A previous read may have been corrupted due to read reference being out of range</p>                                                                                                                                                                                                                                                                                                                                                     |
| 2<br>AEE         | <p>Address Encode Error</p> <p>AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring without address encode mismatches<br/>1 A previous read may be corrupted based on address encode mismatch</p> |
| 3<br>EEE         | <p>ECC after ECC Error</p> <p>EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring without ECC after ECC mismatches<br/>1 A previous read may be corrupted based on ECC calculation errors</p>                                                                                                                                                          |
| 4–15<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 16<br>EER        | <p>ECC Event Error</p> <p>This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring normally.<br/>1 An ECC Error occurred during a previous read.</p>                                                                                                                                                                        |
| 17<br>RWE        | <p>Read-While-Write Event Error</p> <p>This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                | <p>reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring normally.<br/>1 A read-while-write error occurred during a previous read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 18<br>SBC      | <p>Single Bit Correction</p> <p>SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect.</p> <p>0 Reads are occurring without corrections.<br/>1 A Single Bit Correction occurred during a previous read.</p>                                                                                                                                                                                                                                                                                                                                                                                        |
| 19<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 20<br>PEAS     | <p>Program Access Space</p> <p>PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations. The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only.</p> <p>0 UTest NVM address space is disabled for program/erase and main address space enabled.<br/>1 UTest NVM address space is enabled for program/erase and main address space disabled.</p>    |
| 21<br>DONE     | <p>State Machine Status</p> <p>DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences.</p> <p><b>NOTE:</b> This bit transitions from a 0 to 1 during reset and remains at 1 after reset.</p> <p>0 Flash memory is executing a high voltage operation.<br/>1 Flash memory is not executing a high voltage operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 22<br>PEG      | <p>Program/Erase Good</p> <p>The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only.</p> <p>The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.</p> |

|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <p>PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase.</p> <p>PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program.</p> <p><b>NOTE:</b></p> <ol style="list-style-type: none"> <li>1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block.</li> <li>2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation.</li> </ol> <p>0 Program or erase operation failed.<br/>1 Program or erase operation successful.</p> |
| 23<br>PECIE       | <p>Program/Erase Complete Interrupt Enable</p> <p>PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed.</p> <p>0 An interrupt request will not be generated when the DONE flag is set.<br/>1 An interrupt request will be generated when the DONE flag is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 24–26<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 27<br>PGM         | <p>Program</p> <p>PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions:</p> <ul style="list-style-type: none"> <li>• User mode read (ERS is low and UTE is low)</li> <li>• Erase suspend (ERS and ESUS are 1) with EHV low</li> </ul> <p>PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset.</p> <p>0 Flash memory is not executing a program sequence.<br/>1 Flash memory is executing a program sequence.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 28<br>PSUS        | <p>Program Suspend</p> <p>PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition.</p> <p>PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset.</p> <p>0 Program sequence is not suspended.<br/>1 Program sequence is suspended.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 29<br>ERS  | <p>Erase</p> <p>ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset.</p> <p>0 Flash memory is not executing an erase sequence.<br/>1 Flash memory is executing an erase sequence.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 30<br>ESUS | <p>Erase Suspend</p> <p>ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within T<sub>es</sub> of this transition.</p> <p>ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset.</p> <p>0 Erase sequence is not suspended.<br/>1 Erase sequence is suspended.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 31<br>EHV  | <p>Enable High Voltage</p> <p>The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions:</p> <ul style="list-style-type: none"> <li>• Erase (ERS = 1, ESUS = 0)</li> <li>• Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0)</li> <li>• Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0)</li> </ul> <p>If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM.</p> <p>In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation.</p> <p>When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high.</p> <p>A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low.</p> <p><b>NOTE:</b> Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.</p> <p>0 Flash memory is not enabled to perform a high voltage operation.<br/>1 Flash memory is enabled to perform a high voltage operation.</p> |

### 32.3.2 Extended Module Configuration Register (C55FMC\_MCRE)

#### NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

Address: 0h base + 8h offset = 8h

| 0<br>TSLOCK | <p>UTest NVM Lock.</p> <p>This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses.</p> <p>The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended.</p> |

A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for.<br>Mid Blocks exist in partitions 2 and 3.<br>The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended.<br>The default value of the LOCK bits is locked.<br>In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect.<br>0 Block is available for program and erase operations.<br>1 Block is locked and unavailable for program and erase operations |

### 32.3.4 Lock 1 register (C55FMC\_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h

### 32.3.10 Select 3 register (C55FMC\_SEL3)

The Select 3 (SEL3) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 44h offset = 44h

### 32.3.11 Address register (C55FMC\_ADR)

The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h

| 8–28<br>ADDR      | Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits.<br><br>ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field. |
| 29–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 32.3.12 UTest 0 register (C55FMC\_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h

**C55FMC\_UT0 field descriptions**

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>UTE  | <p>U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register.</p> <p>0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked<br/> 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked</p> |
| 1<br>SBCE | <p>Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | 0 Single Bit Corrections observation is disabled.<br>1 Single Bit Correction observation is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2–12<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 13<br>CPR         | Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written.<br><br>0 Customer Programmable Read Voltage and Reference Detection Error is not enabled<br>1 Customer Programmable Read Voltage and Reference Detection Error is enabled |
| 14<br>CPA         | Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written.<br><br>0 Customer Programmable Address Encode Detection Error is not enabled<br>1 Customer Programmable Address Encode Detection Error is enabled                                                 |
| 15<br>CPE         | Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written.<br><br>0 Customer Programmable EDC after ECC Detection Error is not enabled<br>1 Customer Programmable EDC after ECC Detection Error is enabled                                                      |
| 16–21<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 22<br>NAIBP       | Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0.<br><br>1 Array Integrity state machine is at a break point.<br>0 Array Integrity state machine is not currently at a break point.                                                                        |
| 23<br>AIBPE       | Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints.<br><br>1 Array Integrity breakpoints are enabled during Array Integrity Checks.<br>0 Array Integrity breakpoints are not enabled.                                                                                                                                                                                                                                                                                                                                                                    |
| 24<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25<br>AISUS       | Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.                                                                                                                                                                                                                                                                                                                                                    |

**C55FMC\_UT0 field descriptions (continued)**

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p>1 Array integrity sequence is suspended.</p> <p>0 Array integrity sequence not suspended.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 26<br>MRE      | <p>Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high.</p> <p>1 Margin reads are enabled.</p> <p>0 Margin reads are not enabled.</p>                                                                                                                                                                                                                                                                                                  |
| 27<br>MRV      | <p>Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high.</p> <p>1 One's margin reads are requested.</p> <p>0 Zero's margin reads are requested.</p>                                                                                                                                                                                                                                                                             |
| 28<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 29<br>AIS      | <p>Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential.</p> <p>It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high.</p> <p>1 Array integrity sequence is sequential.</p> <p>0 Array integrity sequence is proprietary sequence.</p>                                    |
| 30<br>AIE      | <p>Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0.</p> <p>0 Array integrity checks are not enabled.</p> <p>1 Array integrity checks are enabled.</p> |
| 31<br>AID      | <p>Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only.</p> <p>0 Array integrity check is ongoing.</p> <p>1 Array integrity check is done.</p>                                                                                                                                                       |

### 32.3.13 UMISR register (C55FMC\_UMn)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

#### C55FMC\_UMn field descriptions

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>MISR | <p>MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required).</p> <p>The MISR can be seeded to any value by writing the MISR registers.</p> <p><b>NOTE:</b> Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way.</p> <p>The MISR register provides a means to calculate a MISR during array integrity operations.</p> <p>The MISR can be represented by the following polynomial:</p> $x^{289} + x^7 + x^6 + x^5 + x^4 + x^2 + 1$ <p>The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read.</p> <p>The MISR register is used in array integrity operations.</p> <p>If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.</p> |

### 32.3.14 UMISR register (C55FMC\_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

| 31<br>MISR       | <p>MISR[288].</p> <p>The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required).</p> <p>The MISR can be seeded to any value by writing the MISR registers.</p> <p><b>NOTE:</b> Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way.</p> <p>The MISR register provides a means to calculate a MISR during array integrity operations.</p> <p>The MISR can be represented by the following polynomial:</p> $x^{289} + x^7 + x^6 + x^5 + x^4 + x^2 + 1$ <p>The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read.</p> <p>The MISR register is used in array integrity operations.</p> <p>If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained</p> |

### 32.3.15 Over-Program Protection 0 register (C55FMC\_OPP0)

The Over-Program Protection 0 (OPP0) register provides a means to protect blocks from being over-programmed. This register shows the over-program protection status.

#### NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

**32.3.16 Over-Program Protection 1 register (C55FMC\_OPP1)**

The Over-Program Protection 1 (OPP1) register provides a means to protect blocks from being over programmed. This register shows the over-program protection status.

**NOTE**

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

## 32.4 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in [Module Configuration Register \(C55FMC\\_MCR\)](#). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

**Table 32-1. MCR bit set/clear priority levels**

| Priority level | MCR Bit(s) |
|----------------|------------|
| 1              | ERS        |
| 2              | PGM        |
| 3              | EHV        |
| 4              | ESUS, PSUS |

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- Low Power mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

### **32.4.1 User Mode**

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

#### **32.4.1.1 Read and write**

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read, except when the embedded flash memory is in low power mode. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

#### **NOTE**

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

**NOTE**

Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation ( $MCR[EHV] = 1$  or  $MCR[DONE] = 0$ ) will result in the interlock write being ignored, and address and data will not be updated.

**NOTE**

Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be  $MCR[PEG] = 0$ . See the Module Configuration Register (MCR) section for more information.

**32.4.1.2 Program**

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

### Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

### NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail ( $\text{MCR}[\text{PEG}] = 0$ ), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the  $\text{MCR}[\text{PGM}]$  bit from a 0 to a 1.

### NOTE

Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.
3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to  $0\text{x}\text{FFFF\_FFFF}$ .
4. Write a logic 1 to the  $\text{MCR}[\text{EHV}]$  bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the  $\text{MCR}[\text{DONE}]$  bit goes high.

**NOTE**

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF\_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

**Warning**

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

**32.4.1.2.1 Program software locking**

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

#### 32.4.1.2.2 Program hardware locking

Hardware locking which only affects the program operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

#### 32.4.1.2.3 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

#### NOTE

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency is not limited, enabling at least 20µs between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation.

#### 32.4.1.2.4 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

#### 32.4.1.2.5 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset.

#### 32.4.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.
2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

**NOTE**

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed.
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

**NOTE**

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored. The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

#### **32.4.1.3.1 Erase software locking**

Software Locking affect erase operation. For details on this see [Program software locking](#).

#### **32.4.1.3.2 Erase hardware locking**

Hardware locking which only affects the erase operation is also available for UTest, 16 KB, 32 KB, 64 KB, and 256 KB blocks.

### 32.4.1.3.3 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

#### Warning

In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.

#### Warning

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory will respond by completing the operation with a fail code (MCR[PEG] = 0). Although suspend frequency is not limited, enabling at least 5mS between suspend resume and future

suspend requests improve the opportunity for the flash to complete the operation.

## **32.4.2 Low Power mode**

In Low Power mode, the embedded flash memory enables VDDF power gating, and disables circuits on the VFLASH domain. No reads from or writes to the embedded flash memory are possible when in Low Power mode.

Prior to entering Low Power Mode, it is required that all program, erase, and UTest operations be stopped prior to entering the mode. If Low Power mode is entered while an operation is suspended, entering Low Power mode will have the same effect as a reset during suspend.

When in Low Power mode, register access is prevented. Flash core accesses are also prevented until power mode is exited. Flash core reads and writes may occur after power mode is exited.

The embedded flash memory returns to a post-reset state in all cases.

## **32.4.3 UTest mode**

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

### **32.4.3.1 Array integrity self check**

Array integrity is checked using a predefined address sequence (based on UT0[AIS]), and this operation is executed on selected blocks. The data to be read is customer-specific - user code may be programmed into the flash memory and the correct MISR signature is calculated based on that code. Any random or nonrandom code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value, to determine if an incorrect read or ECC detection was noted. Array integrity MISR value is calculated after ECC detection and correction. Array integrity requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the system frequency being used. The array integrity check consists of the following sequence of events:

1. Enable UTest mode.

2. Select the block or blocks to be receive the array integrity check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for array integrity check do not need to be unlocked.

#### NOTE

Unselected blocks are still read as part of the array integrity sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

#### NOTE

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

#### NOTE

For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that AIS be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, ensure that UT0[SBCE] is set.
6. Set the UT0[AIE] bit.
  - a. If desired, the array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and then continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers will contain a signature for the portion of the operation that was completed prior to the abort, and will not be deterministic. Prior to doing another array integrity operation, the UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8, and UM9 registers may need to be initialized to the desired seed value by doing register writes.
  - b. If desired, the array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the

flash may be done. Once [AID] goes high, UT0[AISUS] may be cleared to resume the array integrity sequence.

### NOTE

User mode array reads requested during the array integrity test will be ignored, to ensure that the array integrity operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

7. Wait until the UT0[AID] bit goes high.
8. If breakpoints were enabled, check UT0[NAIBP], and if this is set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear MCR[SBC] or MCR[EER] bits. Then the operation may be resumed by clearing UT0[NAIBP]. Continue to wait until the UT0[AID] bit goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

### NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit.

## 32.4.3.2 User margin read

User margin read may be done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin reads are done at a read margin level checking for erased bits or programmed bits encroaching on the nominal read level. User margin read is a self-timed event, and is independent of system clocks or wait states selected. Margin ECC corrections and detections are noted during the user margin read test. Margin read MISR value is calculated after ECC detection and correction.

The data to be read is customer-specific, and user code may be programmed into the flash memory. Any random or non-random code is valid. Once the operation is completed, the margin read results can be checked by reading the MCR[EER] bit and the MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, as well as checking the MISR.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode.
2. Select the block or blocks to receive margin read check by writing 1's to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers. Blocks selected for margin read do not need to be unlocked.

#### **NOTE**

Unselected blocks are still read as part of the margin read sequence, to enable full transition coverage. The result read on unselected blocks will not be captured in the MISR. Selecting fewer blocks will not result in a faster margin read execution time.

#### **NOTE**

It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

#### **NOTE**

For margin read checks of the flash memory, sequential addressing is recommended. Setting AIS to 0 is possible for Margin Reads, but using the sequence takes more time, and is not recommended.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. Ensure that the MCR[EER] and MCR[SBC] bits are cleared.
6. If you want to detect single bits during margin read, set UT0[SBCE] to 1.
7. Set the UT0[MRE] bit.
8. Set the UT0[MRV] bit to the desired value depending on if it is desired to do one's margin or zero's margin.
9. Set the UT0[AIE] bit.

**NOTE**

User mode array reads requested during the margin read test will be ignored, to ensure that the margin read operation is not corrupted. The memory array will not respond to array read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

**NOTE**

During Margin Read operations, with AID low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

10. Wait until the UT0[AID] bit goes high.
  - a. If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See [Array integrity self check](#) for more information.
11. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

**NOTE**

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

12. Write a logic 0 to the UT0[AIE] bit.

## 32.5 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

### **Warning**

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

# Chapter 33

## Flash OTP Control

### 33.1 Introduction

The chapter describes access permissions for flash memory blocks.

### 33.2 One Time Programmable (OTP) Blocks

The flash memory is divided into several blocks, which can be used as one time programmable (OTP) blocks. If a block is designated to be OTP, it cannot be erased, and already written locations in the flash memory cannot be overwritten (overwrite protection). This applies even if the overwriting would solely clear bits that were still 1.

DCF records control which blocks are set to be OTP. Note that DCF records are applied only during device reset, so appending a record only takes affect after the next reset.

### 33.3 OTP DCF Records

#### 33.3.1 OTP Record - Low and Mid Blocks

Each flash memory block can be set to be OTP (one time programmable). This record controls the OTP functionality of the low and middle blocks.

|              |              |           |           |
|--------------|--------------|-----------|-----------|
| 0            | 1            | 2:15      | 16:31     |
| <i>rsrvd</i> | <i>rsrvd</i> | LOWBLOCKS | MIDBLOCKS |

|            |
|------------|
| 0:31       |
| 0100_0010h |

Figure 33-1. OTP Record - Low and Mid Blocks

Programming a '1' via a DCF record means the block will be OTP and erase-locked.

33.3.2 OTP Record - High Blocks

Each flash memory block can be set to be OTP (one time programmable). This record controls the OTP functionality of the high blocks.

|              |           |
|--------------|-----------|
| 0:15         | 16:31     |
| <i>rsrvd</i> | HIGHBLOCK |

|            |
|------------|
| 0:31       |
| 0100_0014h |

Figure 33-2. OTP Record - High Blocks

The initial value of each OTP control bit is '0'. Programming a '1' via DCF record means the block will be OTP.

33.3.3 OTP Record - Lower 256k Blocks

Each flash memory block can be set to be OTP (one time programmable). This record controls the OTP functionality of the lower 256k blocks.

|           |
|-----------|
| 0:31      |
| 256BLCK_L |

|            |
|------------|
| 0:31       |
| 0100_0018h |

Figure 33-3. OTP Record - Lower 256k Blocks

The initial value of each OTP control bit is '0'. Programming a '1' via DCF record means the block will be OTP.

## Chapter 34

# Decorated Storage Memory Controller (DSMC)

### 34.1 Introduction

This section details the hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called "*decorated storage*". It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A "decoration" is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l [b,h,w] d{cb}x rT, rB, rA` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st [b,h,w] d{cb}x rS, rB, rA` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the `rB` register (hence the "`x`" mnemonic suffix, signaling an "indexed" addressing mode) and the decoration is specified by the `rA` register. The core transmits the contents of the `rA` register as the decoration value along with the access address (register `rB`) to the DSMC.

The decorated load and store instruction formats are shown in the following figure.

**Table 34-1. Power Architecture decorated load and store instruction formats**

|         | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8  | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|---------|---|---|---|---|---|---|---|---|----|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| lbdx    | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rT |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | /  |
| lhdx    | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rT |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 1  | /  |
| lwdx    | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rT |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | /  |
| lbdcbx  | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rT |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | /  |
| lhdcbx  | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rT |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | /  |
| lwdcbx  | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rT |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | /  |
|         | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8  | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |

| sthdx   | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rS |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 1  | /  |
| stwdx   | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rS |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 1  | /  |
| stbdcbx | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rS |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | /  |
| sthdcbx | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rS |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 1  | 0  | 1  | 0  | 0  | 0  | 0  | 1  | 0  | /  |
| stwdcbx | 0 | 1 | 1 | 1 | 1 | 1 |   |   | rS |   |    |    | rA |    |    |    | rB |    |    |    | 1  | 0  | 1  | 1  | 0  | 0  | 0  | 0  | 0  | 1  | 0  | /  |

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit "decoration". The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.

The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

## 34.2 DSMC block diagram

The following block diagram, [Figure 34-1](#), shows the basic datapaths for the ECC logic in the DSMC. On both the read data path (hrdata) and the write data path (hwdata) there is logic to detect an ECC error and correct the data. The circle with X inside represents an XOR operation. The ecc\_hmatrix and ecc\_detect blocks are coefficient matrixes based on the Hsiao ECC algorithm. Notice in the recalculation of the s\_hwchckbit[7:0] that there is a read chckbit from the slave (hrchckbit), a zero padded result contribution, and a contribution from the hwchckbit from the master. The details of the DSMC bit field and other operations are not shown (represented by the DSMC Operation box).

Figure 34-1. DSMC Block diagram

### 34.3 Decorated stores: `st [b,h,w] d{cb}x rS, rA, rB`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>.<size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

### 34.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit memory container

Table 34-2. Decoration format: BFINS

|         | 0 | 1 | 2 | 3 | 4 | 5      | 6      | 7      | 8 | 9 | 10 | 11  | 12  | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|---------|---|---|---|---|---|--------|--------|--------|---|---|----|-----|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| bfins.b | 0 | 0 | 0 | 0 | 0 | 0      | 0      | SRTBIT |   | 0 | 0  | 0   | BFW |    | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |
| bfins.h | 0 | 0 | 0 | 0 | 0 | 0      | SRTBIT |        |   |   | 0  | 0   | BFW |    |    | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |
| bfins.w | 0 | 0 | 0 | 0 | 0 | SRTBIT |        |        |   |   | 0  | BFW |     |    |    | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |

This command inserts a bit field defined by SRTBIT and BFW into the memory "container" defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read
if bfw == 0
    then bfw = container

if ((srtbit + bfw) <= container) // generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp & ~mask // modify
      | wdata & mask

mem[accessAddress, size] = tmp // memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS), that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.*

To illustrate, consider the following example of the insertion of the 3-bit field "xyz" into an 8-bit memory container, initially set to "abcd\_efgh". For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz_----,
    then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
    then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
    then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
    then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
    then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_xyz,
    then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
    then destination is "abcd_efxy"
```

```
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
    then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

### 34.3.1.1 Compare-and-Store (CAST)

**Table 34-3. Decoration format: CAST**

|        | 0 | 1 | 2 | 3 | 4    | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16   | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24  | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|--------|---|---|---|---|------|---|---|---|---|---|----|----|----|----|----|----|------|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|
| cast.b | 1 | 0 | 0 | 1 | -    | - | - | - | - | - | -  | -  | -  | -  | -  | -  | -    | -  | -  | -  | -  | -  | -  | -  | CD8 |    |    |    |    |    |    |    |
| cast.h | 1 | 0 | 0 | 1 | -    | - | - | - | - | - | -  | -  | -  | -  | -  | -  | CD16 |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |
| cast.w | 1 | 0 | 0 | 1 | CD28 |   |   |   |   |   |    |    |    |    |    |    |      |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size] // memory read

if (size == 8) // define compare_operand
    compare_operand = CD8
else if (size == 16)
    compare_operand = CD16
    else compare_operand = {0x0, CD28} // zero-filled data

if (tmp == compare_operand) // compare - "modify"
    mem[accessAddress, size] = wdata // memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

#### 34.3.1.1.1 Logical AND (AND)

**Table 34-4. Decoration format: AND**

|                 |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| and.<br>{b,h,w} | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|                 | 1 | 0 | 1 | 0 | - | - | - | - | - | - | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata              // modify
mem[accessAddress, size] = tmp // memory write
```

### 34.3.1.1.2 Logical OR (OR)

Table 34-5. Decoration format: OR

|            | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|------------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| or.{b,h,w} | 1 | 1 | 0 | 0 | - | - | - | - | - | - | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata              // modify
mem[accessAddress, size] = tmp // memory write
```

### 34.3.1.1.3 Logical Exclusive-OR (XOR)

Table 34-6. Decoration format: XOR

|                 | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|-----------------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| xor.<br>{b,h,w} | 1 | 1 | 1 | 1 | - | - | - | - | - | - | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata              // modify
mem[accessAddress, size] = tmp // memory write
```

### 34.3.1.2 Decorated Loads: $1[b,h,w]d\{cb\}x\ rT, rA, rB$

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an "extract") operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

#### 34.3.1.2.1 Simple Load (SLD)

Table 34-7. Decoration format: SLD

|                 | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|-----------------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| sld.<br>{b,h,w} | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

#### 34.3.1.2.2 Registers-and-memory exchange (SWAP)

Table 34-8. Decoration format: SWAP

|        | 0 | 1 | 2 | 3 | 4    | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16   | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24  | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|--------|---|---|---|---|------|---|---|---|---|---|----|----|----|----|----|----|------|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|
| swap.b | 0 | 1 | 0 | 1 | -    | - | - | - | - | - | -  | -  | -  | -  | -  | -  | -    | -  | -  | -  | -  | -  | -  | -  | WD8 |    |    |    |    |    |    |    |
| swap.h | 0 | 1 | 0 | 1 | -    | - | - | - | - | - | -  | -  | -  | -  | -  | -  | WD16 |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |
| swap.w | 0 | 1 | 0 | 1 | WD28 |   |   |   |   |   |    |    |    |    |    |    |      |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp    = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)                // store_operand - "modify"
    store_operand = WD8
else if (size == 16)
    store_operand = WD16
    else store_operand = {0x0, WD28} // zero-filled write data

mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

### 34.3.1.2.3 Load-and-Set-1(Bit) (LAS1)

Table 34-9. Decoration format: LAS1

|        | 0 | 1 | 2 | 3 | 4 | 5   | 6   | 7   | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|--------|---|---|---|---|---|-----|-----|-----|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| las1.b | 0 | 1 | 1 | 0 | 0 | 0   | 0   | BIT |   | - | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |
| las1.h | 0 | 1 | 1 | 0 | 0 | 0   | BIT |     |   | - | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |
| las1.w | 0 | 1 | 1 | 0 | 0 | BIT |     |     |   | - | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  | -  |    |

This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp    = mem[accessAddress, size] // memory read
rdata = tmp // rT = rdata = tmp
mask   = 1 << (container - bit - 1) // generate bit mask
tmp    = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

## 34.4 DSMC timing diagram

The following timing diagram, shown below, shows a decorated load followed by a decorated store instruction which is then followed by a normal load instruction. Both decorated instructions are read-modify-write instructions and thus they take at least two cycles to execute. In the first cycle an ECC calculation is performed on the read data as

well as the write data. Then in the second cycle of the decorated instruction the decorated operation is performed and if it is a decorated store, the result is merged with the read data and sent to the write data bus along with the recalculated ECC write chkbits.

Figure 34-2. DSMC timing diagram

## 34.5 DSMC instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated).

Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

# Chapter 35

## ADC Configuration

### 35.1 Overview

There are four Analog to Digital Converter (ADC) modules located on the MPC5744P microcontroller. Each ADC consists of 16 channels. The particular ADC set has been chosen with 12-bit Successive Approximation Register (SAR) architecture to allow for precision conversion and sampling in less than 1  $\mu$ s compounded.

To allow temperature readings while running your application, ADC0 has one channel for temperature sensor TSENS0, and ADC1 has one channel for temperature sensor TSENS1. In addition, all four ADCs have watchdog functionality that compares ADC results against predefined levels before results are stored in the appropriate ADC result location.

The ADCs operate on two different modes: Regular mode and Motor Control mode.

Regular mode features:

- Register based interface with the CPU: one result register per channel
- ADC state machine managing three request flows: regular command, hardware injected command, software injected command
- Selectable priority between software and hardware injected commands
- 16 analog watchdogs comparing ADC results against predefined levels (low, high, range)
- DMA compatible interface

Motor Control mode features:

- Triggered mode only
- Four independent result queues (1x16 entries, 2x8 entries, 1x4 entries)
- Result alignment circuitry (left justified, right justified)
- 32-bit read mode that allows channel ID on one of the 16-bit parts
- DMA compatible interfaces

Integrated with the four ADCs are two Cross Triggering Units (CTUs). Each CTU allows automatic generation of ADC conversion requests on user-selected conditions with minimal CPU intervention. These conversion requests, which occur in what is called CTU Control mode, take place during the PWM period for dynamic configuration.

## **35.2 ADC configuration**

### **35.2.1 Block diagram**

The diagram below shows the four different ADCs and their interaction with the other modules on the device. The appropriate pin muxing is also highlighted in the diagram and is described in [ADC pin muxing](#).

#### **NOTE**

All four ADCs have only two possible ADC supplies: ADC0 and ADC1. These two supplies must be enabled to use the ADC functionality.

### 35.2.2 CTU interface

Each ADC is controlled by the CTU (in CTU Control Mode). In this mode, the CTU can control each ADC by sending an ADC command. During the CTU Control Mode, the CPU is able to write in the ADC registers but it can not start a new conversion. For the MPC5744P device the CTU0 is the controller for ADC0 and ADC1 whilst the CTU1 controls the ADC2 and ADC3 modules.

#### NOTE

CTU Clock (MC\_CLK) and ADC\_CLK should either be same and synchronous or CTU can also operate with ADC\_CLK being an integer plus half (1.5, 2.5, 3.5, ...) of MC\_CLK clock.

### 35.2.3 eTimer interface

All four ADCs allow an external trigger source to start a conversion. This feature is enabled through the injection external trigger enable (JTRGEN) bit in the Main Configuration Register (MCR) of the ADC. For the MPC5744P this external trigger feature is connected to timer channel 5 of an eTimer module, through which the eTimer sends an external trigger event. The eTimer1 is connected to ADC0 and ADC1, and the eTimer2 is connected to the ADC2 and ADC3 modules.

### 35.2.4 DMA interface

For each ADC a DMA request can be performed after the conversion of every channel.

#### NOTE

For 1N65H, the ADC\_DMAE[DCLR] bit is RESERVED and should not be programmed by software.

### 35.2.5 FCCU interface

Each ADC on the MPC5744P device is connected to the Fault Collection and Control Unit (FCCU) and has the ability to create both critical and non-critical faults. For more on what these faults mean, please refer to the FCCU chapter.

## 35.3 ADC pin muxing

The following table provides ADC pin multiplexing details.

**Table 35-1. ADC pin muxing**

| ADC                               |            | INT/EXT | Signal source    |         | Package Availability |
|-----------------------------------|------------|---------|------------------|---------|----------------------|
| ADC Instance                      | Channel No |         | Source           | Ext Pin |                      |
| Shared external channels - ADC0/1 |            |         |                  |         |                      |
| ADC0                              | 11         | EXT     | ADC0_ADC1_AN[11] | PAD[25] | 144LQFP              |
| ADC1                              | 11         |         |                  |         | 257BGA               |
| ADC0                              | 12         | EXT     | ADC0_ADC1_AN[12] | PAD[26] | 144LQFP              |
| ADC1                              | 12         |         |                  |         | 257BGA               |
| ADC0                              | 13         | EXT     | ADC0_ADC1_AN[13] | PAD[27] | 144LQFP              |

### 35.3.1 ADC channel conversion

For ADC channel conversion:

- Both Vref VDD\_HV\_ADRE0 and VDD\_HV\_ADRE1 must be powered up.
- Both must be at the same level

# Chapter 36

## Analog-to-Digital Converter (ADC)

### 36.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The analog-to-digital converter (ADC) uses Successive Approximation Register (SAR) architecture and provides accurate and fast conversions for a wide range of applications.

### 36.2 Overview

#### 36.2.1 Parts of the ADC

Figure 36-1. ADC high-level block diagram

The ADC is comprised of:

- An ADC digital interface (ADCD). The ADCD holds the configuration, control, and status registers accessible to software via the host bus. The converted value is stored in a register and then transferred through the DMA or host access.
- An ADC analog hard macrocell (ADCA). The analog channel inputs are fed to the inputs of the ADCA. Each channel is sampled for a specific duration and compared with an analog voltage generated with digital code via a digital-to-analog converter (DAC) in the ADCA. The comparison result is given to the ADCD to generate the converted digital value.

### 36.2.2 ADC clock signals

The ADC uses the following clock signals:

- Bus clock—bus clock at ADCD. Used to access the registers and the operating clock of inter-module interfaces.
- AD\_clk—derived from *bus clock*, this signal serves as the operating clock for the ADCA and the SAR controller inside the ADCD.

The relation between the two clocks is determined by the setting of the ADC\_MCR[ADCLKSEL] field.

- If ADC\_MCR[ADCLKSEL] is 1, the clock signals are the same
- If ADC\_MCR[ADCLKSEL] is 0, AD\_clk is half of the bus clock.

#### NOTE

1. Regardless of the setting of the ADC\_MCR[ADCLKSEL] field, the maximum clock speed for the ADC clock (AD\_clk) is 80 MHz.
2. Depending on your chip's configuration and timing needs, MCR[ADCLKSEL] may always need to be 1.

If the bus clock for the microcontroller is 80 MHz and ADC\_MCR[ADCLKSEL] is 1, the ADC clock (AD\_clk) is 80 MHz.

If the bus clock for the microcontroller is 80 MHz and ADC\_MCR[ADCLKSEL] is 0, the ADC clock (AD\_clk) is 40 MHz.

See [ADCLKSEL](#) for details on the ADC\_MCR register fields.

### 36.2.3 About ADC channels

#### 36.2.3.1 Channel configuration

ADC channels can be configured in the following ways:

- The sampling duration is controlled independently, through programming the Conversion Timing Register (CTR).
- Separate mask registers can be programmed to configure the channels to be converted (each bit in these registers represents one channel).
- Temperature Sensor (TSENS) and other special channels (band gap, supply etc.) are available on specific channels. (See the chip-specific configuration for availability.)
- Analog watchdogs allow continuous hardware monitoring of the converted value from input channels. (See the chip-specific configuration for availability.)
- Capacitive self test
- Presampling

#### 36.2.3.2 Initiating conversions

Conversions can be initiated by either software or hardware.

The ADCD has an on-chip Cross-Triggering Unit (CTU) interface that can also initiate conversions. The CTU interface supports CTU Control mode.

An example of an application for which CTU triggering is suitable is a current control loop for lamps or LEDs. Using an on-chip timer module as trigger source, a CTU can initiate periodic conversions.

#### 36.2.3.3 Interrupt/DMA support

The ADCD provides interrupt/DMA support for each type of channel for various end-of-channel conversion conditions. Data can be transferred via DMA.

### 36.2.3.4 Self-test

The ADCD can be configured to periodically check the health of the ADCA through various self-tests and communicate any critical/non-critical faults to an on-chip Fault Collection and Control Unit (FCCU) if available (See the chip-specific section for availability). The severity (critical/noncritical) of the different tests is programmable.

## 36.3 Features

The following general features are implemented in the ADC. (See the chip-specific section for availability of features, as each instance of an ADC within a chip may support different features.)

- Resolution: 12-bit
- Maximum speed: 1 Mega samples/second at 80 MHz
- 16 channels
- Sampling time register
  - *precision* channels:
    - 0 - 15 (ADC0)
    - 0 - 15 (ADC1)
    - 0 - 4, 10, 14 (ADC2)
    - 0 - 7, 10 - 14 (ADC3)

### NOTE

The Temperature Sensor uses the value in the CTR1 register

- Modes of operation:
  - Normal
  - Injected
  - CTU
- Normal mode supports One-Shot/Scan (continuous)
- Injected mode supports One-Shot
- Presampling
- Power-Down mode
- Two abort features that allow you to abort either a single channel in a chain or the full chain in normal and injected mode
- Each channel has a dedicated register for conversion results and mode of operation (normal, injected, or CTU)
- Analog watchdog support:
  - Up to 16 analog watchdogs
  - Configurable for different channels

- Auto clock-off feature
- Programmable clock prescaler (bus clock divided by 2)
- CTU Control mode
- DMA support for each channel
- Interrupts for the following conditions:
  - End of conversion for a single channel for both normal and injected conversions
  - End of conversion for a chain for both normal and injected conversions
  - End of CTU conversion
  - Watchdog thresholds crossover
- Software-initiated calibration
- Self-testing feature

## 36.4 Memory Map/Register Definition

The following tables describe the registers and bit meanings for this module.

### NOTE

There will be an Access Error for Reserved and out-of-range addresses. Special exceptions are the Reserved spaces at 039Ch and 03A4h: Do not write or change any value in these locations, or the ADC might malfunction.

### NOTE

See the chip-specific configuration information because not all registers are available in all ADC instances.

#### Control logic registers:

- [Main Configuration Register \(ADC\\_MCR\)](#)
- [Main Status register \(ADC\\_MSR\)](#)
- [Interrupt Status Register \(ADC\\_ISR\)](#)
- [Channel Pending register 0 \(ADC\\_CEOCFR0\)](#)
- [Interrupt Mask Register \(ADC\\_IMR\)](#)
- [Channel Interrupt Mask Register 0 \(ADC\\_CIMR0\)](#)
- [Watchdog Threshold Interrupt Status Register \(ADC\\_WTISR\)](#)
- [Watchdog Threshold Interrupt Mask Register \(ADC\\_WTIMR\)](#)
- [Analog Watchdog Out of Range Register 0 \(ADC\\_AWORR0\)](#)

#### DMA registers:

- [DMA Enable register \(ADC\\_DMAE\)](#)
- [DMA Channel Select Register 0 \(ADC\\_DMAR0\)](#)

**Threshold registers:**

These registers are used to store the user programmable lower and upper thresholds 12-bit values. These registers include:

- [Threshold Register \(ADC\\_THRHLR<sub>n</sub>\)](#)

**Presampling registers:**

- [Presampling Control Register \(ADC\\_PSCR\)](#)
- [Presampling register 0 \(ADC\\_PSR0\)](#)

**Conversion timing registers:**

- [Conversion Timing Register 0 \(ADC\\_CTR0\)](#)
- [Conversion Timing Register 1 \(ADC\\_CTR1\)](#)

**Mask register:** These registers are used to program which input channels must be converted during Normal and Injected conversion. These registers include:

- [Normal Conversion Mask Register 0 \(ADC\\_NCMR0\)](#)
- [Injected Conversion Mask Register 0 \(ADC\\_JCMR0\)](#)

**Delay registers:**

- [Power Down Exit Delay Register \(ADC\\_PDEDR\)](#)

**Data registers:**

The conversion results for the internal channels are loaded into data registers. Each data register also gives information regarding the corresponding result. These registers start with CDR0:

- [Channel Data Register \*n\* \(Precision Channels\) \(ADC\\_CDR<sub>n</sub>\)](#)

**Self test registers:**

- [Self Test Configuration Register 1 \(ADC\\_STCR1\)](#)
- [Self Test Configuration Register 2 \(ADC\\_STCR2\)](#)
- [Self Test Configuration Register 3 \(ADC\\_STCR3\)](#)
- [Self Test Status Register 1 \(ADC\\_STSR1\)](#)
- [Self Test Status Register 2 \(ADC\\_STSR2\)](#)
- [Self Test Status Register 3 \(ADC\\_STSR3\)](#)
- [Self Test Status Register 4 \(ADC\\_STSR4\)](#)
- [Self Test Baud Rate Register \(ADC\\_STBRR\)](#)
- [Self Test Analog Watchdog Register 0 \(ADC\\_STAW0R\)](#)
- [Self Test Analog Watchdog Register 4 \(ADC\\_STAW4R\)](#)
- [Self Test Analog Watchdog Register 1A \(ADC\\_STAW1AR\)](#)
- [Self Test Analog Watchdog Register 1B \(ADC\\_STAW1BR\)](#)
- [Self Test Analog Watchdog Register 2 \(ADC\\_STAW2R\)](#)
- [Self Test Analog Watchdog Register 5 \(ADC\\_STAW5R\)](#)

- Self Test Data Register 1 (ADC\_STDR1)
- Self Test Data Register 2 (ADC\_STDR2)

**Other registers include:**

- Calibration, BIST Control and status Register (ADC\_CALBISTREG)
- Offset and Gain User Register (ADC\_OFSGNUSR)

**ADC memory map**

| Address offset (hex) | Register name                                            | Width (in bits) | Access | Reset value | Section/ page                |

**ADC\_MSR field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | 0   Uncalibrated or calibration unsuccessful<br>1   Calibration was run and it was successful                                                                                                                                                            |
| 1–6<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                  |
| 7<br>NSTART        | This status bit is used to signal that a Normal conversion is ongoing.                                                                                                                                                                                   |
| 8<br>JABORT        | This status bit is used to signal that an Injected conversion has been aborted by CTU. That bit is reset when a new injected conversion starts.                                                                                                          |
| 9–10<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                  |
| 11<br>JSTART       | This status bit is used to signal that an Injected conversion is ongoing.                                                                                                                                                                                |
| 12<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                  |
| 13<br>SELF_TEST_S  | This status bit signals that self test conversion is ongoing.                                                                                                                                                                                            |
| 14<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                  |
| 15<br>CTUSTART     | This status bit is used to signal that a CTU conversion is ongoing.<br><br>This bit is set when a CTU trigger pulse is received and the CTU conversion starts. When Control Mode is enabled this bit is reset when the CTU is disabled (CTUEN set to 0). |
| 16–22<br>CHADDR    | Channel under measure address.<br><br>Status bits are used to signal which channel is under measure.                                                                                                                                                     |
| 23–25<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                  |
| 26<br>ACKO         | Auto clock off enable.<br><br>This status bit is used to signal if the Auto clock off feature is on.                                                                                                                                                     |
| 27–28<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                  |
| 29–31<br>ADCSTATUS | Status of the ADC.<br><br>000   Idle<br>001   Power Down<br>100   Sample<br>110   Conversion<br>010   Wait state (waiting to start conversion [external trigger])<br>011   Busy in Calibration                                                           |

### 36.4.3 Interrupt Status Register (ADC\_ISR)

Address: 0h base + 10h offset = 10h

|       |    |    |    |    |    |    |    |    |    |    |    |    |       |      |      |     |     |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|-------|------|------|-----|-----|
| Bit   | 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12    | 13   | 14   | 15  |     |

**ADC\_ISR field descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–26<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 27<br>EOCTU      | End of CTU conversion.<br>This bit is set for a digital end of conversion on a the CTU Channel; active when set.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 28<br>JEOC       | End of injected channel conversion.<br>This bit is set for a digital end of conversion on an injected channel; active when set.                                                                                                                                                                                                                                                                                                                                                                                                  |
| 29<br>JECH       | End of injected chain conversion.<br>This bit is set for a digital end of chain conversion on an injected channel; active when set.<br><b>NOTE:</b> If there is no channel selected in the ADC_JCMRn register(s) and there is a start of conversion trigger, then ADC_ISR[JECH] is set and a JECH interrupt is immediately issued (if enabled). Similarly, if no channel is selected in the ADC_NCMRn register and a normal conversion is triggered, ADC_ISR[ECH] is set and an ECH interrupt is immediately issued, if enabled. |
| 30<br>EOC        | End of channel conversion.<br>This bit is set for a digital end of conversion on a Normal Channel; active when set.                                                                                                                                                                                                                                                                                                                                                                                                              |
| 31<br>ECH        | End of chain conversion.<br>This bit is set for a digital end of chain conversion on a Normal Channel; active when set.<br><b>NOTE:</b> If there is no channel selected in the ADC_NCMRn register(s) and there is a start of conversion trigger, then ADC_ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).                                                                                                                                                                                               |

*Table continues on the next page...*

## ADC\_ISR field descriptions (continued)

| Field | Description                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | Similarly, if no channel is selected in the ADC_JCMRn register and an injected conversion is triggered, ADC_ISR[JECH] is set and a JECH interrupt is immediately issued, if enabled. |

## 36.4.4 Channel Pending register 0 (ADC\_CEOCFR0)

## NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 14h offset = 14h

| 29<br>MSKJECH     | Mask bit for JECH.<br>When set, the interrupt is enabled.                               |
| 30<br>MSKEOC      | Mask bit for EOC.<br>When set, the interrupt is enabled.                                |
| 31<br>MSKECH      | Mask bit for ECH.<br>When set, the interrupt is enabled.                                |

### 36.4.6 Channel Interrupt Mask Register 0 (ADC\_CIMR0)

The fields in this register globally enable or disable end of conversion interrupts by channels within the range of Channel 0 through 31.

**NOTE**

This register may contain fields for channels that have not been implemented. See the chip-specific details to find which channels are applicable.

Address: 0h base + 24h offset = 24h

|       |       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|-------|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|

ADC\_PSCR field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–24<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                           |
| 25–26<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                           |
| 27–28<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                           |
| 29–30<br>PREVAL0  | Internal voltage selection for Presampling.<br><br>These two bits select analog input voltage for presampling from the available four internal voltages for Internal precision channels (Channel 0 to 31). Refer to <a href="#">Presampling channel enable</a> .                                                                                                  |
| 31<br>PRECONV     | Convert Presampled value<br><br>If bit PRECONV is set, presampling is followed by the conversion. Sampling will be bypassed and conversion of presampled data will be done. This bit has no effect on conversion of a channel when presampling on that channel is disabled (for example $PSRx[PRESy] = 0$ , where $x$ = register index and $y$ = channel number). |

### 36.4.13 Presampling register 0 (ADC\_PSR0)

See the chip configuration details for the availability of this register.

Address: 0h base + 84h offset = 84h

**36.4.14 Conversion Timing Register 0 (ADC\_CTR0)**

Conversion timing register. CTR0 is associated with channels 0 to 31.

**NOTE**

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 94h offset = 94h

| 24–31<br>INPSAMP  | <p>Configuration of sampling phase duration.</p> <p>This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles.</p> <p><b>NOTE:</b> The Bandgap voltage sampling time is controlled by CTR0[INPSAMP]. CTR0[INPSAMP] is also used for the external channel sample time. When the user software needs to sample the Bandgap voltage, it must change the CTR0[INPSAMP] value to allow for a longer time while the Bandgap is being sampled, then change its value back to the normal value for sampling external channels.</p> |

### 36.4.15 Conversion Timing Register 1 (ADC\_CTR1)

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 98h offset = 98h

**36.4.17 Injected Conversion Mask Register 0 (ADC\_JCMR0)**

Enable bits of Injected Sampling for channel 0 to 31.

**NOTE**

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

| 0–23<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                   |
| 24–31<br>PDED    | The delay between the power down bit reset and the start of conversion. The power down delay is calculated as $(PDED \times 1/[ADC\_clock\_frequency])$ . |

36.4.19 Channel Data Register *n* (Precision Channels) (ADC\_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC\_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC\_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC\_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 100h offset + (4d × i), where i=0d to 15d

ADC\_CDR*n* field descriptions

| Field            | Description                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------|
| 0–11<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                              |
| 12<br>VALID      | Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read. |

Table continues on the next page...

**ADC\_CDR<sub>n</sub> field descriptions (continued)**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**36.4.22 Channel Watchdog Select Register 1 (ADC\_CWSELR1)**

WSEL\_CHn[3:0] bit field: Selects the threshold register which provides the values to be used for upper and lower thresholds for channel n.

**NOTE**

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 2B4h offset = 2B4h

**ADC\_STSR1 field descriptions (continued)**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6<br>WDTERR      | <p>Watchdog timer error of the ADC sub-system (algorithm check for completion within safe time). The WDTERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDTERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDTERR] mapping.</p> <p>0 No failure<br/>1 Failure occurred</p>                                                                                                                                                                                                        |
| 7<br>OVERWR      | <p>Overwrite error.</p> <p>Used to notify when the STSR1[ERRx] bit is overwritten by a newer one. The OVERWR status bit is cleared writing 1. A 0 write is an invariant operation. The new error status is written or discarded according to the MCR[OWREN] bit value. To avoid OVERWR indication, the ERRx status bit must be cleared (via software).</p>                                                                                                                                                                                                                                                                                                                      |
| 8<br>ST_EOC      | <p>Self Test EOC Bit.</p> <p>This bit is set along with EOC bit when end_of_conversion signal is received from ADC analog for self test channel. The ST_EOC status bit is cleared by writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled by STCR2[MSKST_EOC]. (Also, IMR[MSKEOC] has to be enabled.)</p>                                                                                                                                                                                                                                                                                                                                     |
| 9–12<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 13<br>WDG_EOA_C  | <p>This bit indicates that Algorithm C has been completed. This bit is generated after the last STEP of algorithm C is executed. The WDG_EOA_C status bit is cleared by writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_C] = 1). This bit is set only if STAW4R[WDTE] = 1. For CTU conversions, this bit is significant only for Burst mode of operation.</p>                                                                                                                                                                                                                                                            |
| 14<br>Reserved   | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 15<br>WDG_EOA_S  | <p>This bit indicates that Algorithm S has been completed. This bit is generated after the last STEP of algorithm S is executed. The WDG_EOA_S status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_S] = 1). This bit is set only if STAW0R[WDTE] = '1'. For CTU conversions, this bit is significant only for Burst mode of operation.</p>                                                                                                                                                                                                                                                             |
| 16<br>ERR_C      | <p>Indicates an error on the self testing channel (algorithm C). The ERR_C status bit is cleared writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_C] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_C bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical type or Non-Critical type lines are asserted according to the STCR2[FMAx] mapping.</p> <p>0 No C-algorithm ERROR<br/>1 C-algorithm ERROR occurred</p>                                                           |
| 17<br>Reserved   | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 18<br>ERR_S2     | <p>Indicates an error on the self testing channel (algorithm SUPPLY, step2). The ERR_S2 status bit is cleared by writing a 1b. A 0b write is an invariant operation. It generates an interrupt ("ipi_int_er" line) if enabled (STCR2[MSKERR_S2] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S2 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping.</p> <p>0 No ERROR occurred on the sampled signal<br/>1 ERROR occurred on the sampled signal</p> |

**ADC\_STSR1 field descriptions (continued)**

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19<br>ERR_S1      | <p>Indicates an error on the self testing channel (algorithm SUPPLY, step1). The ERR_S1 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S1] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S1 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping.</p> <p>0 No VDD ERROR<br/>1 VDD ERROR occurred</p>              |
| 20<br>ERR_S0      | <p>Indicates an error on the self testing channel (algorithm SUPPLY, step0). The ERR_S0 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S0] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S0 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical type fault lines are asserted according to the STCR2[FMAx] mapping.</p> <p>0 No VREF ERROR<br/>1 VREF ERROR occurred</p> |
| 21<br>Reserved    | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 22–26<br>STEP_C   | <p>Step of the algorithm C when an ERR_C has occurred.</p> <p>0.. (NUM_C_STEPS-1) =&gt; algorithm C</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 27–31<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

36.4.30 Self Test Status Register 2 (ADC\_STSR2)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 354h offset = 354h

ADC\_STSR2 field descriptions

| Field             | Description                                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

**36.4.33 Self Test Data Register 1 (ADC\_STDR1)**

The ADC\_STDR1 register contains the most current result data for conversions executed during ADC self test. Additionally, the register contains status bits to indicate whether result data has been read and whether existing conversion data has been overwritten by a newer result.

**NOTE**

1. For Algorithm S step 1, the result data contained in this register is not the final step 1 result. The step 1 data is the conversion of the analog supply (VDDA). This VDDA conversion result is divided by the Algorithm S step 0 conversion data and the result is written to the ADC\_STDR2 register.
2. The least significant 3 bits of the analog supply (VDDA) conversion executed during Algorithm S step 1 processing are always '0'. The conversion performed in Algorithm S Step 1 is not on the full scale analog supply. Instead, the voltage sampled is  $VDDA / 8$ . The prescaling is done to avoid issues that can arise in the analog portion of the ADC when  $VREFH = VDDA = 3.3\text{ V}$ , or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 before being written to this register to scale the result to the expected level, which results in the 3 least significant bits having a value of '0'.

Address: 0h base + 370h offset = 370h

### 36.4.36 Self Test Analog Watchdog Register 1A (ADC\_STAW1AR)

This register contains values associated with the ADC's supply self test step 1, in which the analog supply (VDDA) is sampled and a fixed point division is performed, dividing the conversion result by the result from step 0 (bandgap voltage). The integer portion of the result is handled separately from the fractional part, i.e., they have separate data registers and threshold fields. Thresholds in this register are applied to the integer portion of the result. Thresholds in the ADC\_STAW1BR register are applied to the fractional portion of the result.

### 36.4.38 Self Test Analog Watchdog Register 2 (ADC\_STAW2R)

This register contains control values associated with the ADC's supply self test step 2, in which the ADC's high reference voltage is sampled and converted. Note that there is no upper threshold value in this register since the conversion result should ideally be FFFh (12-bit) or 3FF (10-bit).

The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments. |

### 36.4.39 Self Test Analog Watchdog Register 4 (ADC\_STAW4R)

This register contains ADC self test configuration controls associated with the ADC's capacitive self test (also referred to as "Algorithm C") sequence, which samples voltages from the ADC's internal capacitor matrix. The watchdog enable fields (AWDE and WDTE) affect all Algorithm C steps; the threshold fields (THRH and THRL) fields are specific to Algorithm C Step 0.

The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.</p> |

**36.4.40 Self Test Analog Watchdog Register 5 (ADC\_STAW5R)**

This register contains ADC self test threshold values associated with all capacitive self test (also referred to as "Algorithm C") steps other than Step 0, which is controlled by fields in the ADC\_STAW4R register.

Note that the threshold values in this register are distinctly different than those in the ADC\_STAW4R register. The threshold values in this register do not represent a voltage conversion value relative to the ADC high reference voltage, but instead represent the upper and lower thresholds for the absolute difference between the voltage sampled and converted in an Algorithm C step and the voltage sampled and converted in Algorithm C Step 0. Ideally, the difference will be zero.

| 4–15<br>THRH      | High threshold value for step N of C algorithm (N = 1 to CS-1).<br><br>This value is read by the ADC as twos-complement, but should be written positive. If the watchdog is enabled (STAW4R[AWDE] = 1) and (STDR1[TCDATA] (step-N) – STDR1[TCDATA] (step-0)) > STAW5R[THRH], then STSR1[ERR_C] is set.<br><br><b>NOTE:</b> The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments. |
| 16–19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 20–31<br>THRL     | Low threshold value for step 0 of C algorithm.<br><br>This value is read by the ADC as twos-complement, and it should be the negative of STAW5R[THRH]. If the watchdog is enabled (STAW4R[AWDE] = 1) and (STDR1[TCDATA] (step-N) – STDR1[TCDATA] (step-0)) < STAW5R[THRL], then STSR1[ERR_C] is set.<br><br><b>NOTE:</b> The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.   |

### 36.4.41 Calibration, BIST Control and status Register (ADC\_CALBISTREG)

This register controls the Offset calculation, Calibration and BIST functionality with Averaging option. The averaging function has no effect in other conversion modes.

Address: 0h base + 3A0h offset = 3A0h

**36.4.42 Offset and Gain User Register (ADC\_OFSGNUSR)**

This register contains the user configured offset and Gain values used by ADC for data processing and have all the bits valid (MSB through LSB).

OFFSET and Gain Calibration values can be either positive or negative, so they need to be in 2's complement format with MSB as sign bit.

Address: 0h base + 3A8h offset = 3A8h

**36.5 Functional description**

The following sections detail the ADCD interfaces as well as the functionality of this module.

### 36.5.1 Conversion

After power-up or reset, the ADC is in power-down mode until the MCR[PWDN] field is written. There are some configurations, listed below, available only in power-down mode, that must be handled before exiting power down.

- Clock selection for SAR Controller (AD\_clk): MCR [ADCLKSEL]

After the above configurations, ADC need to be taken out from power-down mode by writing '0' into MCR [PWDN], Conversions can be initiated now in the following modes:

- Normal
- Injected
- CTU Triggered

#### 36.5.1.1 Normal conversion

The conversion mode generally used to convert channels is called normal conversion. Programming the available Normal Conversion Mask Register(s) (ADC\_NCMR $n$ ) selects the channel(s). Each channel can be individually enabled by setting a bit in the corresponding field of the NCMR $n$  register.

- NCMR0 serves *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)
  - 0 - 4, 10, 14 (ADC2)
  - 0 - 7, 10 - 14 (ADC3)

The mask register(s) must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends. Conversion always starts from the lowest channel number selected and sequentially goes to the highest number.

##### 36.5.1.1.1 Starting a normal conversion

After programming the MCR and NCMR0 $n$  register(s), a normal conversion is started via *software* by setting the MCR[NSTART] bit.

To start a normal conversion via *external trigger*, enable external trigger by setting the (MCR[TRGEN] bit. A programmed event (rising/falling edge depending on MCR[EDGE] bit) on the normal trigger input starts the conversion.

Detection of an active edge defined by MCR[EDGE] bit (rising=1, falling=0) on the external trigger will start the normal conversion.

### 36.5.1.2 Normal conversion operating modes

Two operating modes are available for normal conversion:

- One-Shot mode
- Scan mode

The MCR[MODE] bit determines which mode is used during a normal conversion. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, during which the sampled analog value is converted to digital as shown in the figure below.

**Figure 36-2. Normal conversion flow**

#### 36.5.1.2.1 One shot mode

In one shot mode (MCR[MODE] = 0) a sequential conversion specified in the following mask register(s) is performed only once:

- NCMR0

At the end of each conversion, the digital result of the conversion is stored into the corresponding data register(CDRx, x = channel number).

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in One-Shot mode. Conversion starts with channel B, followed by the conversion of channels D and E. At the end of conversion of channel E, the scanning of channels will stop.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time, MCR[NSTART] is reset by hardware, allowing the software to program a new start of conversion in advance. In this case, the newly requested conversion starts after completing the running/current conversion. However, for the sake of simplicity and straightforwardness, it is advisable to program the NSTART bit for the new conversion only after the completion of the running conversion. To know the end of conversion of running chain, application will either wait for an End of Chain (ECH) Interrupt or check the status of MSR[NSTART] prior to setting MCR[NSTART] again.

If the conversion chain is started by the external trigger, the trigger input will not be observed by the ADC block until the current conversion chain is finished. After the chain is over, the next chain can be invoked/triggered by another hardware trigger edge.

### 36.5.1.2.2 Scan mode

In scan mode ( $\text{MCR}[\text{MODE}] = 1$ ), a sequential conversion of  $n$  channels specified in the  $\text{NCMR}_n$  register(s) is continuously performed. At the end of each conversion, the converted result is stored into the corresponding data registers, as in One-Shot mode.

The  $\text{MSR}[\text{NSTART}]$  status bit is automatically set when the normal conversion starts. Unlike One-Shot mode, the  $\text{MCR}[\text{NSTART}]$  bit is not reset automatically in Scan mode. It can be reset by software when you need to stop Scan mode. In that case, the ADC completes the current chain and, after the last conversion, resets  $\text{MSR}[\text{NSTART}]$ .

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in Scan mode.  $\text{MCR}[\text{MODE}] = 1$  is set for Scan mode. Conversion starts from channel B, followed by the conversion of channels D and E. At the end of the conversion of channel E, the conversion of channel B starts again, followed by the conversion of channels D and E. This sequence repeats itself until  $\text{MCR}[\text{NSTART}]$  is reset by software.

This scan chain can be stopped by writing 0 to  $\text{MCR}[\text{NSTART}]$ . The conversion stops when the ongoing chain is finished.

#### NOTE

If the conversion is started by an external trigger,  $\text{MCR}[\text{NSTART}]$  is not set. As a consequence, once started, the only way to stop a Scan mode conversion started by an external trigger is to set the  $\text{MCR}[\text{MODE}]$  bit to 0.

### 36.5.1.2.3 End of conversion

In both modes, at the end of each conversion an end-of-conversion (EOC) interrupt is issued if enabled by the corresponding mask bit in the following register(s):

- $\text{CIMR0}$

Additionally, the EOC interrupt must be enabled in the  $\text{IMR}$  register. After the conversion of all the channels selected in the  $\text{NCMR}_n$  register(s) is completed and the conversion operation is considered finished,  $\text{ISR}[\text{ECH}]$  is set and an end-of-chain (ECH) interrupt is issued (if enabled in  $\text{IMR}[\text{MSKECH}]$ ). The corresponding channel bit within the appropriate  $\text{CEOCFR}_n$  register is updated to indicate that data is available on the data register ( $\text{CDR}_n$ ) of the respective channel. If there is no channel selected in the  $\text{NCMR}_n$  register(s) and there is a start of conversion trigger, then  $\text{ISR}[\text{ECH}]$  is set and an ECH interrupt is immediately issued (if enabled).

#### NOTE

To add or remove channels to/from the ongoing chain:

1. Clear the MCR[NSTART] bit
2. Set/clear mask bit for the needed channels in NCMR $n$
3. Set the MCR[NSTART] bit

### 36.5.1.3 Injected conversion

An injected conversion is a conversion chain that can be injected at any time, including into an ongoing normal conversion chain. To do so, configure the injected mask register(s):

- JCMR0

As in a normal conversion, each internal or external channel can be individually selected for injected conversion.

- JCMR0 controls *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)
  - 0 - 4, 10, 14 (ADC2)
  - 0 - 7, 10 - 14 (ADC3)

Injected conversion can only be run in One-Shot mode, and can only interrupt a normal conversion. Please note, that a CTU conversion cannot be interrupted by an injected conversion. In this case, the injected conversion is discarded. When an injected chain is inserted into an ongoing normal chain, the ongoing normal channel is suspended and the injected channel request is processed. After completing the last channel in the injected chain, normal conversion resumes from the channel at which it was suspended as shown in the following figure.

**Figure 36-3. Injected sample/conversion sequence**

### 36.5.1.3.1 Starting injected conversion

The injected conversion can be started via *software* by setting the MCR[JSTART] bit to start an injected conversion; the current normal conversion is suspended and the injected chain is converted.

To start an injected conversion via *external trigger*, enable external triggering by setting MCR[JTRGEN]=1. A programmed event (rising/falling edge depending on MCR[JEDGE] bit) on the injection trigger input starts the injected conversion.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time, the MCR[JSTART] bit is reset, allowing software to program a new start of conversion in advance. In that case, the new requested conversion starts after the running conversion is completed.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit in IMR) and at the end of the chain an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit in IMR). The status bit ISR[JECH] is also set.

If the content of all the injected conversion mask registers (JCMR<sub>n</sub>) is zero (i.e., no channel is selected) the interrupt JECH is immediately issued to resume normal operation or conversion mode.

The corresponding channel bit in the appropriate CEOCFR<sub>n</sub> register is updated to indicate that data is available in the data register (CDR) of the respective channel.

Once started, injected chain conversion cannot be interrupted by Normal or another Injected conversion. A CTU trigger has the higher priority; injected conversion has a lower priority. Therefore, only a CTU trigger can interrupt an ongoing injected conversion. In this case, the injected conversion will be discarded.

### 36.5.1.4 Aborting conversions

Two different abort functions are provided:

- A single channel abort
- A chain abort

You can abort the ongoing conversion by setting the MCR[ABORT] bit. The current conversion is aborted and the conversion of the next channel of the chain is immediately started. The abort action may take 1 to 4 cycles of the bus clock to abort the current conversion depending on the state of the conversion. At the start of any conversion and at the end of a particular conversion, when internal state counters are changing, then abort is delayed by a maximum of 3 cycles to take all states in stable condition. Abort also should

not be programmed along with and within 3 cycles of programming the MCR[NSTART] or MCR[JSTART]. This may not have a significant impact from software point of view since on any SoC the next write access comes only after a minimum of 3 clock cycles.

### NOTE

Programming Abort or Abort chain with NSTART or JSTART in idle condition has no effect.

For a Normal conversion chain having only one channel:

1. Abort re-runs the conversion again from the Abort point

If both Normal and Injected conversions are started by hardware trigger and they are coming in a particular cycle-dependent manner, e.g.,

1. When Abort is programmed one cycle after start of Injected conversion followed by a start of normal conversion in the next cycle of Abort, or
2. When Abort comes one cycle after the start of a normal conversion followed by the start of an Injected conversion in next cycle,

then Abort may or may not be detected and the Missing of Abort will consume maximum of 1  $\mu$ s (one conversion time) more time for the execution of to-be-aborted conversion.

In the case of an abort operation, the MSR[NSTART/JSTART] bit remains set, if not in last channel of chain, and the MCR[ABORT] bit is reset as soon as the channel is aborted. The EOC corresponding to the aborted channel is not generated. This behavior is true for Normal or Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is also possible to abort the current chain of conversions by setting the MCR[ABORTCHAIN] bit. In that case, the behavior of the ADC depends on the MCR[MODE] bit (One-Shot/Scan) for Normal conversion. In One-Shot mode, MSR[NSTART] is automatically reset together with the MCR[ABORTCHAIN]. Otherwise, in Scan mode, a new chain is started, and the current chain is aborted. The EOC of the current aborted conversion is not generated, but an ECH interrupt is generated to signal the end of the chain. For Injected conversion, the behavior of ABORTCHAIN is same as for One-shot Normal conversion. In this case, MSR[JSTART] is automatically reset together with the MCR[ABORTCHAIN].

When an ABORTCHAIN is requested while an injected chain is running over a suspended normal chain, both injected and normal chains are aborted; both MSR[NSTART] and MSR[JSTART] are reset. ABORT and ABORTCHAIN requests are ignored during CTU conversion. ABORT requests are also discarded during Self-Test conversion.

## 36.5.2 Crosstriggering Unit interface

The Crosstriggering Unit (CTU) interface enhances the injected conversion capability of the ADC. The CTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. The CTU/ADC interface is shown in the figure below. The CTU generates a trigger and a channel number to be converted. A single channel is converted for each request. After performing the conversion, the ADC returns the result.

The conversion result is also saved in the corresponding data register and it is compared with watchdog thresholds if requested. DMA and interrupt feature of ADC can also be used during CTU conversion.

**Figure 36-4. ADC Crosstriggering Unit**

The CTU interface has one mode of operation, Control.

The CTU interface is enabled by programming the MCR[CTUEN] bit.

### 36.5.2.1 CTU Control mode

In CTU Control mode, if enabled via MCR[CTUEN], the CPU is able to write in the ADC registers, but it cannot start a conversion. Conversion requests can be generated only by a CTU trigger. If a normal or injected conversion is requested when the CTU is enabled (MCR[CTUEN]), it will be automatically discarded.

Along with CTU trigger the ctu\_numchannel is taken as channel and CTU conversion starts. MSR[CTUSTART] is set automatically at this point and it remains set unless the CTU is disabled by resetting MCR[CTUEN].

CTU conversions must be requested when calibration is over. If a CTU trigger is received during calibration, the calibration stops immediately in order to satisfy the CTU request. Calibration will fail in this case.

If another CTU trigger is received before the `ctu_nextcmd` signal, the new request is discarded.

### 36.5.3 ADC clock prescaler and sample time settings

The clock (`AD_clk`) provided to the ADC's SAR controller, which controls the ADCA, must satisfy particular conditions of frequency and duty cycle. The maximum acceptable frequency is 80 MHz with a duty cycle equal to 50% ( $\pm 5\%$ ).

The `AD_clk` frequency can be scaled by programming the `MCR[ADCLKSEL]` bit. If this bit is set, `AD_clk` frequency is the same as the bus clock. Otherwise, `AD_clk` frequency is half of the bus clock. `MCR[ADCLKSEL]` can only be written in power-down, when `MCR[PWDN] = 1`.

Sampling times are controlled by settings in the Conversion Timing Register (`CTRn`).

- `CTR0` controls sampling time for *precision* channels:
  - 0 - 15 (`ADC0`)
  - 0 - 15 (`ADC1`)
  - 0 - 4, 10, 14 (`ADC2`)
  - 0 - 7, 10 - 14 (`ADC3`)

The exception is the Temperature Sensor channel, which always uses the `CTR1` value. See [Conversion Timing Register 1 \(`ADC\_CTR1`\)](#) for details.

### 36.5.4 Presampling

Presampling allows the ADC internal capacitor to precharge or discharge to a defined level before it starts the actual sampling/conversion of the analog input coming from the pads. This is useful for resetting information (history effect/offset) regarding the last converted data. During presampling, the ADC samples the internally generated voltage while, during sampling, the ADC samples the analog input coming from the pads.

Presampling can be enabled/disabled on an individual channel by setting the corresponding bit in the applicable `PSRn` register.

- `PSR0` controls precision channels

After enabling the presampling for a channel, the normal sequence of operation is presampling + sampling + evaluation for that channel. Sampling of the channel can be bypassed by setting `PSCR[PRECONV]`. When sampling of a channel is bypassed, the presampled voltage will be converted.

See [Conversion time](#) for the conversion's timing equation.

**Figure 36-5. Presampling sequence**

**Figure 36-6. Presampling sequence with PRECONV = 1**

### 36.5.4.1 Presampling channel enable

The presampling channels are selected by programming the presampling register ([Presampling Control Register \(ADC\\_PSCR\)](#)). These are used to enable analog switches that samples an internally generated voltage. It is possible to select presample voltage from four internally available voltages depending on the value of PREVAL<sub>x</sub> [*x* = 0,1,2] fields in the PSCR register as given in [Table 36-1](#).

**Table 36-1. Presample voltage selection**

| PREVAL <sub>n</sub> | Presampling voltage                                                                      |
|---------------------|------------------------------------------------------------------------------------------|
| 00b                 | Presample voltage 1: VSS_HV_ADV (High voltage ground for ADC)                            |
| 01b                 | Presample voltage 2: VDD_HV_ADV/8 (Power High voltage Supply for ADC, SGEN divided by 8) |
| 10b                 | Presample voltage 3: VSS_HV_ADRE1 (High voltage ground for ADC/TSENS)                    |
| 11b                 | Presample voltage 4: VDD_HV_ADRE1 (High voltage reference for ADC/TSENS)                 |

The PREVAL<sub>n</sub> fields are associated with specific channels, as shown in [Table 36-2](#).

**Table 36-2. PREVAL<sub>n</sub> channel association**

| Field   | Channels                                                                                                                                                    |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PREVAL0 | <ul style="list-style-type: none"> <li>• 0 - 15 (ADC0)</li> <li>• 0 - 15 (ADC1)</li> <li>• 0 - 4, 10, 14 (ADC2)</li> <li>• 0 - 7, 10 - 14 (ADC3)</li> </ul> |

The temperature sensor channel is an exception. It can be mapped with any of the channels, but it uses the PREVAL1 value to select the presample voltage because its physical properties may be different than the other internal precision channels.

### 36.5.5 Programmable analog watchdog

#### NOTE

The number of analog watchdogs and channels may vary depending on the ADC instance on your chip. Please see the chip-specific section for how many are available on each instance.

The analog watchdogs are used for determining whether the result of a conversion lies within a given guard area (as shown in [Figure 36-7](#)) specified by an upper and a lower threshold value named THRH and THRL, respectively.

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside the guard area, then the corresponding threshold violation interrupt is generated.

The comparison result is stored as WTISR[WDGxH] and WTISR[WDGxL], as explained in the following table. Depending on the WTIMR[MSKWDGxL] and WTIMR[MSKWDGxH] mask bits, an interrupt is generated upon threshold violation.

**Table 36-3. Values of WDGxH and WDGxL fields**

| WDGxH | WDGxL | Converted data                                            |
|-------|-------|-----------------------------------------------------------|
| 1     | 0     | converted data > THRH                                     |
| 0     | 1     | converted data < THRL                                     |
| 0     | 0     | $\text{THRH} \leq \text{converted data} \leq \text{THRL}$ |

**Figure 36-7. Guarded Area**

#### 36.5.5.1 Analog watchdog setting

For each watchdog there is one Threshold value (Low and High) Register (THRHLR).

The analog watchdog for each channel can be enabled independently by programming CWENR $n$  register bits.

- CWENR0 controls *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)
  - 0 - 4, 10, 14 (ADC2)
  - 0 - 7, 10 - 14 (ADC3)

The availability of these registers depends on device configuration.

Threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLR $x$ , ( $x=0..15$ )) by the WSEL\_CH $x$  field of CWSELR $x$  ( $x=0..11$ ) register.

Each CWSELR $x$  register holds selection for 8 consecutive channels. CWSELR0 holds 8 WSEL\_CH fields for channel 0 to 7. Likewise CWSELR1 is for channel 8 to 15 and so on. The availability of fields and registers depends on device configuration.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in the Analog Watchdog Out of Range Register (AWORR).

For example, if channel number 12 is to be monitored with the threshold values in register THRHLR3, then CWSELR1[WSEL\_CH4] needs to be programmed with 3. The enabling will be done by setting the bit corresponding to channel 12 in the CWENR0 register.

A set of threshold values (THRHLR $x$ ) can be linked to several ADC channels. The threshold values to be selected for a channel needs be programmed only once in the CWSELR $x$  register.

### 36.5.6 DMA functionality

A Direct Memory Access (DMA) request can be programmed after the conversion of every channel by setting the respective masking bit in the following register(s):

- DMAR0

The DMA masking registers must be programmed before starting any conversion.

The DMA transfers can be enabled using the ADC\_DMAE[DMAEN] bit. When the DMAE[DCLR] bit is set, the DMA request is cleared on the reading of the register for which DMA transfer has been enabled.

### 36.5.7 Interrupts

ADC generates the following maskable interrupt signals:

- End-of-conversion interrupt (EOC) request
- End-of-chain interrupt (ECH) request
- End-of-injected conversion interrupt (JEOC) request
- End-of-injected chain interrupt (JECH) request
- End-of-CTU conversion interrupt (EOCTU) request
- Watchdog threshold interrupt (WDGxL and WDGxH) requests

Interrupts are generated during the conversion process to signal events, like the end of a conversion, as explained in the register description for the Interrupt Status Register (ISR). The ISR and the Interrupt Mask Register (IMR) allow you to check and enable the interrupt request.

Interrupts can be individually enabled on a channel-by-channel basis by programming the Channel Interrupt Mask Register (CIMR).

A Channel Pending Register (CEOCFR<sub>n</sub>) is also provided in order to signal which of the channels' measurement has been completed.

Analog Watchdog interrupts are enabled by Watchdog Threshold Interrupt Mask Register (WTIMR) and the status can be checked at Watchdog Threshold Interrupt Status Register (WTISR). The watchdog interrupt source sets two fields, WDGxH and WDGxL, for each channel monitored in the WTISR.

In particular, the EOC, ECH, EOCTU, JEOC, and JECH interrupt lines are combined (OR-ed) on the same line. The EOC interrupt request is cleared by clearing either ISR[EOC] or all bits of CEOCFR. The JEOC interrupt request is cleared by clearing either ISR[JEOC] or all bits of CEOCFR. The EOCTU interrupt request is cleared by clearing either ISR[EOCTU] or all bits of CEOCFR. Also, the self-test end of algorithm interrupts STSR1[WDG\_EOA\_S] and STSR1[WDG\_EOA\_C] are combined.

All WDGxH and WDGxL requests are combined on the second line.

Another interrupt on the third line is a combination of WDSERR, WDTERR, ERR\_S0, ERR\_S1, ERR\_S2, and ERR\_C in STSR1.

The ISR register contains the interrupt pending request status. If you want to clear a particular interrupt event status, then writing a 1 to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all the other bits of the ISR register must be programmed to 0.)

### **36.5.8 Power-Down mode**

The analog part of the ADC can be put in Power-Down mode by setting the MCR[PWDN] bit, which shuts off the ADCA and stops the clock in the SAR controller. After power-on or device reset, the ADCA is kept in Power-Down mode by default, so this state must be exited before starting any operation by resetting the MCR[PWDN] bit. In Power-Down mode, no conversion and calibration can be started. Trigger from CTU during power down is discarded. In the ADC power-down mode, the CTU must not start any conversion.

The MCR[PWDN] bit may be programmed high at any time. However, if a conversion is ongoing, then the ADCA cannot be sent immediately into Power-down mode. In fact, the ADC enters Power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN function.

The ADC status in MSR[ADCSTATUS] field shows Power-down status only when ADC enters in Power-down mode.

If CTU is enabled and MSR[CTUSTART] is 1, then the MCR[PWDN] bit cannot be set. When CTU Control mode enabled, the application needs to reset the CTUEN bit before entering Power-Down mode.

After the power-down phase is complete, the process ongoing before the power-down phase must be restarted manually .

#### **NOTE**

Resetting the MCR[PWDN] bit and setting the MCR[NSTART] or MCR[JSTART] bit during the same cycle is forbidden.

### **36.5.9 Auto-Clock-Off mode**

To reduce power consumption in Idle mode (without going into Power-Down mode), an auto-clock-off feature can be enabled by setting MCR[ACKO]. When enabled, the analog clock is automatically switched off when no operation is ongoing (that is, when no conversion has been programmed).

**NOTE**

This feature must remain off during calibration.

### 36.5.10 Calibration and Self Test

The ADC is calibrated and tested runtime through the same set of test conversions. The test result is used for computation and stored during the calibration process and only checked in self test. The two modes of running tests are as follows:

1. High-Accuracy mode/Calibration. Needs to be run after power-on reset and whenever required in runtime operation. Calibrates the ADC and updates calibration-related registers.
2. Quick-Check mode/Self-Test. Used for runtime functional self-tests to improve reliability. Catches any runtime fault or accuracy shift from previously calibrated values. Please see the chip-specific configuration information as self-test may not be available in all ADC instances.

The following sections describe both and the steps for executing them.

#### 36.5.10.1 Calibration (High Accuracy mode)

The functioning of the analog block of ADC depends on the accuracy of values of its various parts and parameters, such as the value of capacitors, the gain of the amplifier, and so on. Due to variations in manufacturing and various runtime environmental effects, the actual values may differ from the ideal values for which the ADC is targeted.

Because of these deviations, the ADC's converted values contain errors. To eliminate these errors, the ADC must be calibrated prior to any conversion.

In the calibration process, a fixed known reference voltage ( $V_{refH}$ ) is sampled many times and converted under various controlled conditions to check for deviations between these converted values and predefined values.

The deviations, known as offsets or modified values, are used to eliminate errors during the data processing of normal conversions.

Calibration needs to be performed after every power-up/destructive reset and whenever required in runtime operation. The applicability of destructive reset depends on device configuration. Please check the ADC configuration for the device.

**Note**

The ADC must be recalibrated if the operating conditions (particularly VrefH) change significantly. Calibration should also be performed again if the Self-Test indicates that a recalibration is needed.

Recommended settings:

- Clock frequency = 40 MHz
- Averging – Maximum (512)

The calibration process will take ~12ms of time with the above recommended settings.

**NOTE**

If the ADC clock frequency is > 40MHz during calibration, the accuracy of the calibration process will be compromised, hence the performance of the ADC. Thus, it is strongly recommended to run the calibration with 40 MHz clock.

As calibration is a time consuming process, it can be performed after a long interval – probably several hours of operation – but it is not necessary to recalibrate frequently. The goal is to maximize the possible accuracy delivered from conversion and to catch any structural fault to flag the error.

The calibration routine sets the fail flag (CALBISTREG[TEST\_FAIL]) to indicate:

- A fault in ADC
- A premature abort of the calibration

Calibration is aborted if a normal conversion is initiated during calibration; this is called *premature termination*. The terminating conversion and the immediate next one to it will have invalid result in this case.

CALBISTREG[TEST\_FAIL] = 1 indicates that the ADC health is not good and that it will not meet specifications.

To execute this routine, follow these steps:

1. Configure the ADC to 40 MHz.
  - Put the ADC in power down mode: set MCR[PWDN]
  - Configure clock divider selection: reset MCR[ADCLKSEL]
  - Power-up the ADC: reset MCR[PWDN]
2. Configure the Calibration, BIST Control, and Status Register (CALBISTREG). The default values are set for maximum accuracy (recommended).
3. Start calibration: set CALBISTREG[TEST\_EN].

4. Wait for calibration to complete. Check MSR[ADCSTATUS] or till CALBISTREG[C\_T\_BUSY] becomes 0.
5. Check the value of MSR[CALIBRTD] to determine whether calibration was successful.
6. If MSR[CALIBRTD] = 1, calibration was successful; otherwise, it failed, and CALBISTREG[TEST\_FAIL] = 1.
7. If required, reconfigure the ADC clock frequency for normal operation.

### 36.5.10.2 Self test (Quick-Check/Safety mode)

For devices used for very critical applications requiring high reliability it is important to check at regular intervals if the ADC is functioning correctly. For this purpose, Self Testing feature (Quick Check) has been incorporated inside ADC.

The following testing algorithms are available for checking:

- Supply Self test: algorithm S. It includes the conversion of the bandgap, supply and VREF voltages. It includes a sequence of three test conversions (steps). The supply test conversions must be an atomic operation (no functional conversions interleaved).
- Capacitive Self test: algorithm C. It includes a sequence of 12 test conversions (steps) to check the capacitive array.

The capacitive test of ADC requires only 12 steps to test itself.

The capacitive array is used as DA converter to generate from  $V_{REFH}$  12 different voltages by distributing and partially discharging portions of the capacity array. These 12 voltages are sampled using some redundant capacities. C algorithm may be compared to providing 12 different voltages to ADC and validate the conversion result.

Two kinds of tests are performed in this mode, as shown in the following table.

**Table 36-4. Quick-Check mode tests**

| STCR3<br>[ALG]    | STCR3<br>[MSTEP] | Description                            | Outcome                                                                                                                                                                                                                                                                                        | Comment                                                                                                                                                                                                                                                                                                                    |

| 10<br>capacitive<br>test | 0–11                                                                    | One of the ADC-BIST steps is being run       | The difference or error of individual value from the previously calibrated value is being returned (unsigned) as an ADC result that is compared with a programmed value in the analog watchdog register(s) to detect any fault. The difference or error may be caused by any runtime fault, runtime accuracy shift, or device noise. | Ideally, the result value is expected to be 0. If the returned value is higher, this indicates runtime fault or accuracy shift. This indicates that ADC should be recalibrated in High-Accuracy mode to check whether the reported error can be handled by recalibrating or whether permanent damage to ADC has occurred.                                |
| 11                       | Supply test followed by Capacitive test in same sequence as shown above | —                                            | —                                                                                                                                                                                                                                                                                                                                    | —                                                                                                                                                                                                                                                                                                                                                        |

This mode is described in the following sections.

#### 36.5.10.2.1 Self test initialization and application information

ADC samples the internal  $V_{REFH}$  for the C algorithm and samples different supplies (bandgap,  $V_{DD}$  and  $V_{REFH}$ ) for the supply algorithm. It also provides signals for the following:

- Scheduling self-testing algorithms using configuration registers
- Monitoring the converted data using analog watchdog registers
- Flagging the error to FCCU in case a failure occurs in any of the algorithms

| ADC mode                      | TEST channel (ADCdig) | TEST channel (CTU) |
|-------------------------------|-----------------------|--------------------|
| CPU mode ( $MCR[CTUEN] = 0$ ) | Yes                   | No                 |

*Table continues on the next page...*

| ADC mode         | TEST channel (ADCdig)                                                              | TEST channel (CTU) |
|------------------|------------------------------------------------------------------------------------|--------------------|
|                  | <ul style="list-style-type: none"> <li>One-Shot mode</li> <li>Scan mode</li> </ul> |                    |
| CTU Control mode | No                                                                                 | Yes                |

### 36.5.10.2.2 CPU mode

In this case, the test channel works similarly to a normal conversion. The test channel is enabled by setting STCR2[EN].

Self-test conversions are executed by interleaving the Normal conversions. The sequencing of steps of the selected algorithm for test channel depends on the operating mode of normal conversion, selected by MCR[MODE].

In One-Shot mode, if the test channel is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in the STCR3 register. So, in One-Shot mode, the sequence is as follows:

1. Program NCMR $n$  register(s) to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC\_CTR $x$ [INPSAMP] = 20 d (for 1 MSPS operation )
3. Program MCR[MODE] = 0 to select One-Shot mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMP $x$ ].
5. Select the self-testing algorithm in STCR3[ALG]. The default is algorithm S.
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions, the step number programmed in STCR3[MSTEP] of the self-testing algorithm selected by STCR3[ALG] is executed similar to a normal functional channel.
10. On receiving an end-of-conversion for the test channel, the digital result is written in STDR1[TCDATA] and STDR1[VALID] is set. Also, ISR[EOC], ISR[ECH], and STSR1[ST\_EOC] are set. See the register descriptions ([Self Test Data Register 1 \(ADC\\_STDR1\)](#), [Interrupt Status Register \(ADC\\_ISR\)](#), and [Self Test Status Register 1 \(ADC\\_STSR1\)](#)) for details of settings for each test.
11. The state machine returns to the Idle state.

For example: in a device with channels A-B-C-D-E-F-G-H, channels B-D-E are to be converted in One-Shot mode. MODE = 0 is set for One-Shot mode. Refer to [Conversion](#). Conversion for channels B-D-E are done. After channel E test channel conversion is done and ISR[ECH] and ISR[EOC] are set.

MSR[NSTART] is automatically set when the normal conversion starts; it is reset at the end of conversion for the test channel.

In Scan mode, the consecutive steps of the selected self test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed at once without any functional conversion interleaved). So, in Scan mode the sequence is as follows:

1. Program the NCMR<sub>n</sub> registers to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC\_CTR<sub>x</sub>[INPSAMP] = 20 d (for 1 MSPS operation )
3. Program MCR[MODE] = 1 to select Scan mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMP<sub>x</sub>].
5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected (that is, all algorithms are executed step-by-step one after the other).
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of chain for the normal conversions (assuming a default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF\_TEST\_S] is set.
10. At the end of conversion of test channel for the last step of algorithm S, the digital result is written in STDR1[TCDATA] and STDR1[VALID] is set. At the same time, MSR[SELF\_TEST\_S] is reset. For step 1, the integral part and fractional part are written in STDR2[IDATA] and STDR2[FDATA]. Also, ISR[EOC], ISR[ECH], and STSR2[ST\_EOC] are set.
11. The next normal conversion chain starts.
12. At the end of the normal conversion chain, Step0 of the C algorithm is executed.
13. At the end of conversion of test channel for Step0 of the C algorithm, the digital result is stored in STDR1[TCDATA] and STDR1[VALID] is set (if MCR[OVERWR] is set). Also, ISR[EOC], ISR[ECH], and STSR2[ST\_EOC] are set.
14. The next normal conversion chain starts.
15. At the end of the normal conversion chain, step1 of C algorithm is executed.
16. This process continues for all steps of all algorithms.
17. The state machine returns to the Idle state when MCR[NSTART] is written to 0.

### NOTE

- Instead of starting a normal conversion with software (by setting MCR[NSTART]), if it is started by external trigger, the test channel behavior remains the same.

- Test channel conversion is not performed during injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, injection conversion arrives, then the test channel is aborted (just as a normal functional channel) and injected conversions are done. After injected conversions are completed, the test channel resumes from the step at which it was aborted. In this case, MSR.SELF\_TEST\_S remains high during the injected conversion.
- For self testing, MCR[MODE] should be programmed at least one cycle *before* setting MCR[NSTART]. It should not be changed thereafter until a conversion is ongoing.

### 36.5.10.2.3 CTU mode

For this chip, the operating mode is CTU Control mode.

When MCR[CTUEN] is set, the test channel conversion can be started only by the CTU interface; software cannot start it. STCR2[EN] does not have any effect in CTU mode. The CTUEN bit should not be changed while normal conversion is ongoing. The interface between the CTU and ADCD (for self test) is shown here:

For self testing conversions in CTU mode, the CTU asserts an indication that enables self test along with the CTU trigger that starts the self test conversion. The algorithm and the step number to be executed is put on the interface respectively.

#### NOTE

As already mentioned for algorithm S, the three steps must be atomic. In CTU mode, this is managed by the CTU itself; that is, the CTU has to send three triggers (one for each step) asserting the indication that enables self test and updating the step number for each step.

### 36.5.10.2.4 Abort and Abort Chain for self-test channel

Setting MCR[ABORT] during self-test channel has no effect.

In One-Shot mode, if MCR[ABORTCHAIN] is set when the test channel conversion is ongoing, the test channel is aborted and ECH is set. In this case, EOC for the test channel is not generated.

In Scan mode, if MCR[ABORTCHAIN] is set when test channel STEP N is ongoing, then the test channel STEP N is aborted and the next chain conversion starts. At the end of this chain, STEP N conversion is performed again. (If algorithm S is ongoing, the full algorithm is executed again.)

### 36.5.10.2.5 Self-test analog watchdog

ADCD also provides a monitor for the values returned by the ADC analog macro for self-test algorithms. The analog watchdogs are used to determine whether the result of conversion for self-test algorithms lie in a particular guard area. For this purpose, separate Self-Test Analog Watchdog Registers are provided for each algorithm.

If the analog watchdog feature is enabled (STAWxR[AWDE] = 1), a comparison is performed between the converted value and the threshold values after the conversion of each step of an algorithm. If the converted value does not lie between the upper and lower threshold values specified by the Analog Watchdog Register of the particular algorithm, the corresponding error bit (STSR1[ERR\_x]) is set and the step number during which the error occurred is updated in STSR1[STEP\_x] (in case of the C algorithm) and erroneous data is written in STSR4[DATAx]. STSR1[ERR\_x] generates an interrupt if enabled by the corresponding mask bit in STCR2. The fault indication is also given to the FCCU via the Critical and Non-Critical fault lines, so that necessary action can be taken at chip level.

The analog watchdog feature works differently in the case of algorithm S. As already mentioned, algorithm S is always an atomic operation. So, separate error bits are provided in STSR1 for each step of algorithm S to avoid an overwrite in case an error occurs in more than one step. Hence, there are separate mask bits for each step in STCR1. For the same reason, separate fields in the status registers (STSR2 and STSR3) exist to store erroneous data for each step.

In step 0 of supply algorithm, ADC measures the band gap voltage (+1.2V), which is assumed to be stable with very little variation (up to +/- 1.5%). The converted data of step 0 is measured with high (THR<sub>H</sub>) and low (THR<sub>L</sub>) threshold defined in STAW0R if enabled (STAW0R[AWDE]). The STSR1[ERR\_S0] is set to '1' if threshold is violated; once set, it is cleared to '0' by writing '1' to it.

In step 1 of supply algorithm, ADC measures the Analog supply (V<sub>dda</sub>) for the ADC, and then a fixed point division is performed with the result of step 1 (ADC supply voltage) and step 0 (band gap voltage). It takes around 26 cycles after EOC for step 1 to get a divided value, and it is the divided value on which analog watchdog checks are applied. So, the value to be compared for step 1 contains the integer as well as fractional part; two registers (STAW1AR and STAW1BR) are provided for this. The comparison is done first for the integer part using the threshold values programmed in STAW1AR. If the integer part lies in the range, the fractional part comparison is skipped; otherwise, it is compared with the values programmed in STAW1BR. The following table summarizes this feature for step 1.

**Table 36-5. Algorithm S (step 1) threshold comparison**

| STDR2[IDATA] (integer part)   | STDR2[FDATA] (fractional part) | STSR1[ERR_S1] |
|-------------------------------|--------------------------------|---------------|
| > STAW1AR[THR <sub>H</sub> ]  | Any value                      | Set           |
| < STAW1AR[THR <sub>L</sub> ]  | Any value                      | Set           |
| == STAW1AR[THR <sub>H</sub> ] | > STAW1BR.THR <sub>H</sub>     | Set           |
| == STAW1AR[THR <sub>L</sub> ] | < STAW1BR.THR <sub>L</sub>     | Set           |

In step 2 of supply algorithm, ADC measures the High Reference voltage (V<sub>rh</sub>); (V<sub>REF</sub>/V<sub>REF</sub>) is measured in order to check the integrity of sampling signal. For this particular conversion, no higher threshold value is required as the ideal value is 0xFFFF. Only the lower threshold value is programmed in STAW2R.

In the supply self-test algorithm, the band gap is measured with regard to the reference voltage (V<sub>rh</sub>) in step 0. The result is capable of catching mismatches between them. Step 1 measures the supply with regard to reference (V<sub>rh</sub>), and the result is taken to do a ratio (V<sub>dda</sub>/V<sub>bg</sub>). If the band gap voltage remains within +/-1.25% of its ideal value of 1.2 V, then by setting appropriate values of THR<sub>H</sub> and THR<sub>L</sub> in watchdog registers, the ADC self-test can catch more than 4% variation in supply and reference faithfully.

Algorithm C has total 12 steps. Output data of step 0 is compared with the threshold values stored in STAW4R, if enabled in the same register. The result of step 0 is used as an offset for rest of the steps (step 1 to 11). The absolute difference between the converted data of each of the steps (1 to 11) with the data of step 0 are compared with the threshold values of STAW5R, if enabled in STAW4R. Error in any step is indicated by STSR1[ERR\_C] and the data in error case is captured in STSR4.

Calculation of Threshold values:

S1 Algorithm: Calculated voltage comparison method:

The user software can implement a method of calculating S1 algorithm IDATA, FDATA, the THRH values, and the THRL values to voltages and then perform a comparison of the calculated voltage to the calculated THRH voltage and calculated THRL voltage.

The steps involved in this method are as follows:

1. Calculate the high threshold voltage:

$$(\text{STAW1AR} [\text{THRH}] + (\text{STAW1BR} [\text{THRH}] / 4096)) * \text{Vbandgap}$$

2. Calculate the low threshold voltage:

$$(\text{STAW1AR} [\text{THRL}] + (\text{STAW1BR} [\text{THRL}] / 4096)) * \text{Vbandgap}$$

3. Calculate the converted results to voltage:

$$(\text{STDR2} [\text{IDATA}] + (\text{STDR2} [\text{FDATA}] / 4096)) * \text{Vbandgap}$$

4. Compare result from step 3 to THRH and THRL. S1 algorithm passes

If (low threshold voltage <= converted voltage <= high threshold voltage).

### 36.5.10.2.6 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm implemented and checks that the algorithm completes within a safe time period. Watchdog timers can be enabled for CPU as well as CTU conversions. Each algorithm has a different watchdog timer that runs independently of the other. The watchdog timer for a particular algorithm can be enabled by setting STAWxR[WDTE]. The safe time value can be programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point at which step 0 of the same algorithm starts again.

The sequence is as follows:

1. Program NCMR0 to select channels to be converted for normal conversion in Scan mode (MODE = 1).
2. Modify the Sample period of normal conversion to 20 d cycles, write  $\text{ADC\_CTR}_x[\text{INPSAMP}] = 20 \text{ d (14 h)}$  (for 1 MSPS operation )

3. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected; that is, all algorithms will be executed step-by-step, one after the other.
4. Enable the self-testing channel by setting STCR2[EN].
5. Program the safe period value in STBRR[WDT].
6. Enable the watchdog timer by setting STAWxR[WDTE]. Assume the setting of WDTE to be  $t_0$ . (It is important to do all the programming first and to then enable WDTE as the safe time check is also performed between the setting of WDTE and the start of step 0 to check that algorithm has started within the safe time).
7. Start the normal conversion by setting MCR[NSTART].
8. After first chain conversion ends, step 0 of algorithm S is executed. Let's assume the start of STEP0 to be  $t_1$ .
9. Step 1 and step 2 of algorithm S are executed.
10. The next chain conversions are performed.
11. When chain conversion completes, step 0 of C algorithm is performed.
12. After each chain conversion, a consecutive step of the C algorithm is performed. A similar sequence follows for algorithm C.
13. After the last step of the C algorithm is performed, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S starts, repeating the whole sequence. Let's assume this time (starting of step 0) to be  $t_2$ .
14. For algorithm S, if  $(t_1 - t_0) > \text{Safe Period}$ , or if  $(t_2 - t_1) > \text{Safe Period}$ , then the watchdog timer flags an error and STSR1[WDTERR] is set. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDTERR]. Otherwise, the watchdog timer counter is reset and starts again to monitor the same for the next sequence.
15. A similar sequence is followed for watchdog timers for algorithm C.

**Figure 36-8. Watchdog timer monitor for algorithm S**

**Notes:**

- As CTU does not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for CTU conversions.
- Take care not to enable the watchdog timer for an algorithm that is not to be executed.

### 36.5.10.2.6.1 Watchdog sequence checking

The watchdog timer also incorporates sequence checking features that check the order of a particular algorithm's steps. If the steps are not in order, then an error is flagged by setting the STSR1[WDSERR]. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDSERR].

A watchdog sequence error is flagged in the following cases:

- If the steps of any algorithm are not executed in the proper order.
  - If an abort chain occurs during a test channel conversion, that step has to be repeated at the end of the next chain. This will give a sequence error as soon as test channel conversion starts again.
    - Exception: If an abort chain occurs during the last step of algorithm S, then sequence errors are not flagged as the whole algorithm has to be repeated again.
  - If, for CTU conversions, the step numbers provided by the CTU are not in order.
- Watchdog sequence checking is significant for CTU burst mode only.

If injected conversion occurs during the test channel, watchdog sequence errors are *not* flagged although the ongoing step number is aborted and repeated again.

#### Note

The watchdog timer feature is applicable only for Scan mode, not for One-Shot mode.

### 36.5.10.2.7 Baud rate control for test channel

It defines the scheduling of the test channel between normal conversions. The scheduling rate is specified by STBRR[BR].

By default, if the test channel is enabled, one step of the selected algorithm is executed after every chain of normal conversion. The bandwidth consumed by the test channel depends on the number of channels in a normal chain. For example, if there are 100 normal conversions in a chain, then the test channel consumes only 1% of the total bandwidth, which is very small. However, if the number decreases to just four channels, then the bandwidth consumed by the test channel is 25%, which is significant (and may not be desirable as it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the test channel conversion to be performed, not at the end of every chain, but at the end of BR + 1 number of chains. For example, if BR = 5, a single step of the selected algorithm for the test channel is performed after six chain conversions, then the next step is performed at end of the next six chain conversions, and so on. By default, the value of BR is 0.

## Notes:

- This feature is applicable only for Scan mode, not for One-Shot mode. STBRR[BR] should be set to 0 for one shot mode.
- To use the baud rate feature in Scan mode, the NCMR register should have nonzero value.

### 36.5.10.2.7.1 Abort chain when baud rate is non-zero

As previously described, a nonzero value of STBRR[BR] means that the test channel conversion is performed at the end of BR + 1 number of chains. If an abort chain occurs during the chain in which the test channel is scheduled to be converted, then the test channel is converted after the next BR + 1 number of chains.

For example, if STBRR[BR] is programmed to 2, the sequence will be two normal chains (without any test channel conversion) followed by a chain with the test channel converted at the end. Now, if an abort chain occurs during first two chains it is treated as a normal chain abort and the test channel is converted at the end of the third chain only (as the case without any abort chain). But if the abort chain occurs during the third chain in which the test channel is scheduled to be converted, then the test channel is converted after next three chains (that is, at the end of sixth chain, counting from the beginning).

## 36.5.11 Conversion time

Total conversion time depends on ADC-SAR controller's operating clock. This clock can be prescaled to bus clock  $\div 2$ . The ADC-SAR operating clock (AD\_clk) is always synchronous with bus clock. The frequency of AD\_clk is dependent on settings of ADC\_MCR[ADCLKSEL].

If ADC\_MCR[ADCLKSEL] = 0, then  $AD\_clk = (\text{bus clock} \div 2)$

If ADC\_MCR[ADCLKSEL] = 1, then  $AD\_clk = \text{bus clock}$

The various components of conversion time and affecting configurations are shown and described in [Figure 36-9](#).

**Figure 36-9. Conversion time**

- **Trigger processing time (TPT):**  
To prepare the channel and start the operation, two clock cycles of bus clock is required by the ADC for the first conversion and for subsequent conversions in a chain, or for a continuous conversion, this time is not required as it is hidden in the pipeline operation. Triggers from Synchronous CTU interface requires two cycle of bus clock for first conversion and for back-to-back CTU conversions it takes only one cycle for trigger processing as the other cycle is hidden in pipeline operation. Triggers from Asynchronous CTU interface requires three cycles of bus clock for synchronization and processing.
- **Sample phase time (ST):**  
Sample time duration is controlled by the INPSAMP[7:0] field of Conversion timing Registers ADC\_CTRx ( $x = 0...2$ ) for different types of channels. Value in each register affects the sample time in similar way. The value in the register represents units of cycle of the AD\_clk. The minimum value of sample time is 8. If the value programmed is less than 8, then it has no effect on sample time duration and in this case sample time will be 8 AD\_clk cycles.
- **Compare phase time (CT):**  
The compare phase of the ADC is dependent on the resolution setting. It takes  $((n + 1) \times 4)$  cycles of AD\_clk, where  $n$  is the resolution setting configured in CALBISTREG[OPMODE].
- **Data processing time (DP):**

The ADC takes 2 cycles of AD\_clk to post process and load the data into registers.

- Total Conversion Time:

The total time required for single or first conversion is  $[TPT+ST+CT+DP]$  cycles of AD\_clk and for subsequent conversion is a chain or continuous conversion is  $[ST+CT+DP]$  cycles of AD\_clk.

Examples:

- CALBISTREG[OPMODE] = 110b; CTR<sub>x</sub>[INPSAMP] = 20d; software/hardware triggered (NSTART):
  - Single/First Conversion:  $2 + 20 + ((13 + 1) \times 4) + 2 = 2 + 20 + 56 + 2 = 80$  cycles of AD\_clk
  - Subsequent/continuous conversion:  $20 + ((13 + 1) \times 4) + 2 = 20 + 56 + 2 = 78$  cycles of AD\_clk
- CALBISTREG[OPMODE] = 001b; CTR<sub>x</sub>[INPSAMP] = 22d; software/hardware triggered (NSTART):
  - Single/First Conversion:  $2 + 22 + ((12 + 1) \times 4) + 2 = 2 + 22 + 52 + 2 = 78$  cycles of AD\_clk
  - Subsequent/continuous conversion:  $22 + ((12 + 1) \times 4) + 2 = 22 + 52 + 2 = 76$  cycles of AD\_clk
- CALBISTREG[OPMODE] = 110b; CTR<sub>x</sub>[INPSAMP] = 20d; CTU triggered:
  - Single/First Conversion:  $2 + 20 + ((13 + 1) \times 4) + 2 = 2 + 20 + 56 + 2 = 80$  cycles of AD\_clk
  - Subsequent/continuous conversion:  $1 + 20 + ((13 + 1) \times 4) + 2 = 1 + 20 + 56 + 2 = 79$  cycles of AD\_clk
- CALBISTREG[OPMODE] = 001b; CTR<sub>x</sub>[INPSAMP] = 22d; CTU triggered:
  - Single/First Conversion:  $2 + 22 + ((12 + 1) \times 4) + 2 = 2 + 22 + 52 + 2 = 78$  cycles of AD\_clk
  - Subsequent/continuous conversion:  $1 + 22 + ((12 + 1) \times 4) + 2 = 1 + 22 + 52 + 2 = 77$  cycles of AD\_clk
- Pre-Sampling:

When pre-sampling is enabled, the ADC does pre-sampling prior to starting the actual channel sampling as described in pre-sampling section. This phase takes CTR<sub>x</sub>[INPSAMP] cycles of AD\_clk. Additionally, to switch from pre-sample phase to actual channel sampling phase, it takes another two cycles of AD\_clk. So, total CTR<sub>x</sub>[INPSAMP] + 2 cycles additionally required for a conversion to be completed. Thus, in case of pre-sample, all the equations and examples above are valid with the addition of (CTR<sub>x</sub>[INPSAMP] + 2) cycles.

### 36.5.12 Conversion data processing

The raw converted ADC data contains many types of errors such as offset, gain, DC bias, and so on. Thus, to generate error-free results, raw converted data is processed before it is written to a result register. The process of error correction goes bit-by-bit during conversion with the values generated during the offset calculation and calibration process. This helps in reducing final data processing time as only one addition/addition (2's complement) is performed parallelly with conversion.

## 36.6 Clock frequency

The ADC internal blocks are designed to work with an 80 MHz clock. Thus, the specified speed can be met with this clock frequency. If the clock is faster than this, ADCA cannot work properly and the ADC may malfunction. If the clock is slower, then the ADC speed will be lower, but it will work properly. It should be noted that there is an absolute maximum value of the sampling time that the analog portion of the ADC can support. For slower clocks, the sampling clock count will need to be programmed accordingly.

# Chapter 37

## Temperature Sensor (TSENS)

### 37.1 Introduction

The device includes two on-chip temperature sensors. The temperature sensor module monitors device temperature and delivers one analog output signal and three digital output signals each (under- and over-temperature flags). The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device (see the ADC details for the channel number). The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage; sampled bandgap reference voltage, which comes from another module; and calibration parameter values stored in internal flash memory. The three digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions.

The digital outputs signal when the junction temperature drifts below the low temperature threshold or above one of the two high temperature thresholds. These signals notify the device to take action to appropriately adjust the device temperature in response to an out-of-specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

### 37.2 Functional Description

The temperature sensor generates one analog output voltage,  $V_{TSENS}(T)$ , which is proportional to the absolute current junction temperature of the device, and three digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or one of two pre-set high temperature thresholds.

An on-chip ADC module is used to convert the analog output voltage, as well as the bandgap reference voltage, into a digital representation. These values, along with parameter values stored in on-chip flash memory, are used by software to calculate the device junction temperature.

### **37.2.1 Temperature threshold detection (digital output generation)**

Temperature threshold trimming values are adjusted through calibration during factory test and stored in on-chip flash memory. While enabled, if a new trimming value is loaded into the Temperature Sensor module, it may take up to 1 microsecond for the digital outputs to be updated to reflect the new trimming condition.

When the temperature threshold detection feature is enabled, the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the following temperature thresholds are crossed.

- The low temperature digital output signals if the junction temperature falls below the low temperature threshold ( $-40^{\circ}\text{C}$ ).
- The high temperature digital output 1 signals if the junction temperature rises above the first high temperature threshold ( $150^{\circ}\text{C}$ ).
- The high temperature digital output 2 signals if the junction temperature rises above the second high temperature threshold ( $165^{\circ}\text{C}$ ).

#### **NOTE**

Some devices do not support  $165^{\circ}\text{C}$  operation.

The threshold detection circuit is calibrated with respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to  $-40^{\circ}\text{C}$ ), and the high temperature thresholds are trimmed such that one of them matches the hot insertion test temperature (nominally equal to  $150^{\circ}\text{C}$  or  $165^{\circ}\text{C}$ ). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated on [Figure 37-1](#).

Figure 37-1. Digital output behavior with temperature

### 37.2.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

## 37.3 Temperature formula

The system chain that translates device junction temperature into a digital variable is composed of the temperature sensor, a bandgap reference voltage source and the on-chip ADC. Both analog output voltages of the temperature sensor and the bandgap reference voltage source must be converted by the ADC into digital codes to obtain the device junction temperature. The temperature formula shown in [Figure 37-2](#) is used to calculate internal device junction temperature.

$$T \times 2^2 = \frac{(K_1 \times V_{BG\_CODE}(T)) \times 2^{-1} + (K_2 \times V_{TSENS\_CODE}(T)) \times 2^3}{[(K_3 \times V_{BG\_CODE}(T)) \times 2^2 + (K_4 \times V_{TSENS\_CODE}(T))] \times 2^{-10}} \quad [K]$$

$$V_{TSENS\_CODE}(T) = \frac{V_{TSENS}(T)}{V_{ref}} \times 2^{12} \qquad V_{BG\_CODE}(T) = \frac{V_{BG}(T)}{V_{ref}} \times 2^{12}$$

- T is the internal junction temperature in Kelvin
- $V_{TSENS}(T)$  is the temperature sensor output sampled by the ADC
- $V_{BG}(T)$  is the bandgap reference voltage sampled by the ADC
- $V_{ref}$  is the ADC reference voltage in normal usage of the device
- K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation stored in flash memory (obtained from factory calibration)

**Figure 37-2. Temperature formula**

Parameters K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation that are stored in flash memory during factory test and calibration. These constants must be used in the temperature formula to calculate device junction temperature.

## 37.4 Calculating device temperature

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap reference voltage using the on-chip ADC module and calculate  $V_{BG\_CODE}(T)$  according to the formula shown in [Figure 37-2](#).
2. Measure the temperature sensor output voltage using the on-chip ADC module and calculate  $V_{TSENS\_CODE}(T)$  according to the formula shown in [Figure 37-2](#)
3. Retrieve parameters K1, K2, K3, and K4 from flash memory.
4. Calculate T according to the formula shown in [Figure 37-2](#).

### Note

Temperature Formula may be calculated using signed 32-bit (integer) operations showing negligible precision loss.

# Chapter 38

## Sine Wave Generator (SGEN)

### 38.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Sine Wave Generator (SGEN) generates a high-quality sinusoidal voltage signal. It can be programmed with the desired oscillation frequency and amplitude voltage. A wide frequency range (1 kHz–50 kHz in 16 Hz steps) is easily programmable through a simple register interface. The linearity and noise performance is carefully optimized through digital processing.

**Figure 38-1. SGEN block diagram**

### 38.2 Features

- Input clock frequency range: 12 MHz–20 MHz
- Output sinusoidal signal:
  - Frequency range: 1 kHz–50 kHz
  - Peak-to-peak amplitude: user adjustable

## 38.3 Memory map and register description

The SGEN memory map is shown below followed by the description for each register and its fields.

**SGEN memory map**

| Address offset (hex) | Register name                | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Control Register (SGEN_CTRL) | 32              | R/W    | 0001_0000h  | <a href="#">38.3.1/1068</a> |
| 4                    | Status Register (SGEN_STAT)  | 32              | R/W    | 0000_0000h  | <a href="#">38.3.2/1070</a> |

### 38.3.1 Control Register (SGEN\_CTRL)

The SGEN\_CTRL register enables the following operations:

- Control and read the output sine wave frequency.
- Control and read the output sine wave amplitude.
- Enable and disable the input trigger to align the phase of the sine wave output.
- Select the active trigger input for phase alignment.

Address: 0h base + 0h offset = 0h

## 38.4 Functional description

### 38.4.1 Operation after a power-on reset

After a power-on reset, the SGEN produces a DC value (no sinusoidal fluctuations).

### 38.4.2 Output sine wave frequency

The output sine wave frequency  $f$  is controlled by SGEN\_CTRL[IOFREQ] according to [Equation 16 on page 1071](#) where frequencies  $f$  and InputFrequency are in Hz, and IOFREQ is in decimal format. IOFREQ must be chosen to ensure that  $f$  remains between 1 kHz and 50 kHz.

$$f = \frac{\text{InputFrequency}}{1048576} \times \text{IOFREQ}$$

**Equation 16. Output sine wave frequency**

### 38.4.3 Output sine wave amplitude

The amplitude of the output sine wave is controlled by SGEN\_CTRL[IOAMPL] as described in the following table.

**Table 38-1. Resulting sine wave amplitude for each IOAMPL value**

| IOAMPL value (decimal) | Sine wave amplitude (V) | Sine wave amplitude step (V) |
|------------------------|-------------------------|------------------------------|
| 0                      | 0.423                   |                              |
| 1                      | 0.487                   | 0.064                        |

*Table continues on the next page...*

## 38.5 Initialization and application information

### 38.5.1 Changing the output frequency

To change the output frequency:

1. Determine the required value of `SGEN_CTRL[IOFREQ]` using [Equation 16 on page 1071](#).
2. Ensure that `SGEN_CTRL[LDOS] = 0`.
3. Write the new value of the `SGEN_CTRL[IOFREQ]` field.
4. Set `SGEN_CTRL[LDOS]`.

The SGEN will begin producing the new sine wave frequency two input clock cycles after this procedure is completed.

### 38.5.2 Phase control of the sine wave output

The normal output of the sine wave generator is a free-running sine wave with the amplitude and frequency determined by the `SGEN_CTRL` register settings.

`SGEN_CTRL[TRIG_EN]` enables the user to phase align the sine wave output to one of the trigger inputs, which is selected by `SGEN_CTRL[TRIG_SEL]`. The trigger input is a periodic signal which has the same frequency as the sine wave output but might have a

different phase, either leading or lagging. The phase of the trigger input signal is compared to the phase the sine wave output. If a phase offset is detected, the sine wave output is realigned so that the phase difference becomes zero, beginning with the next sine wave cycle.

If the phase difference of the trigger input varies more than 1%, either leading or lagging, from sine wave output, no phase adjustment will take place. Instead, `SGEN_STAT[SERR]` will be set indicating that the phase offset has exceeded 1%. In this case, the sine wave output will not be re-generated.

#### NOTE

- Because the trigger input is an asynchronous signal, it must be held high for at least 2 SGEN clock cycles in order to capture the input trigger. This requirement must be guaranteed by the module generating the trigger input signal. If this requirement is not met, phase alignment will not function as expected.
- When `SGEN_CTRL[TRIG_EN]` is set, the sine wave output will not be generated until the first trigger occurs.
- If the actual trigger position falls in the  $\pm 1\%$  range, the sine wave output will be aligned to the trigger beginning with the next period.

### 38.5.3 Preserving the SGEN\_CTRL data

Changes made to the `SGEN_CTRL` register must be preserved for at least 50 clock cycles. Failure to do so might cause unexpected output from the SGEN.

# Chapter 39

## Enhanced Motor Control Timer (eTimer)

### 39.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section briefly describes the eTimer, its features and customization, and contains block diagrams.

#### 39.1.1 Overview

An eTimer module provides:

- Six identical counter/timer channels
- One watchdog timer function (might not be available on every eTimer module instance)

Each 16-bit counter/timer channel contains a prescaler, a counter, a load register, a hold register, two queued capture registers, two compare registers, two compare preload registers, and four control registers.

#### Note

This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The Load register provides the initialization value to the counter when the counter's terminal value has been reached. For true modulo counting the counter can also be initialized by the CMPLD1 or CMPLD2 registers.

The Hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters coherently.

The Capture registers enable an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG signal can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The Prescaler provides different time bases useful for clocking the counter/timer.

The Counter provides the ability to count internal or external events.

Within the eTimer module, the input pins are shareable.

### **39.1.2 Features**

The eTimer module design includes these distinctive features:

- 16-bit counters/timers: Six.
- Count up/down.
- Counters are cascadable.
- Enhanced programmable up/down modulo counting.
- Max count rate equals peripheral clock/2 for external clocks.
- Max count rate equals peripheral clock for internal clocks.
- Count once or repeatedly.
- Counters are preloadable.
- Compare registers are preloadable.
- Counters can share available input pins.
- Separate prescaler for each counter.
- Each counter has capture and compare capability.
- Continuous and single shot capture for enhanced speed measurement.
- DMA support of capture registers and compare registers.
- 32-bit watchdog capability to detect stalled quadrature counting (might not be available on every eTimer module instance).
- OFLAG comparison for safety critical applications.
- Programmable operation during debug mode and stop mode.
- Programmable input filter.
- Counting start can be synchronized across counters.

### 39.1.3 Module block diagram

The eTimer block diagram is shown in the following figure.

Figure 39-1. eTimer Block Diagram

### 39.1.4 Channel Block Diagram

Each of the timer/counter channels within the eTimer are shown in the following figure.

**Figure 39-2. eTimer Channel Block Diagram**

## 39.2 External Signal Descriptions

Each eTimer module has six external signals that can be used as either inputs or outputs. The number of auxilliary inputs per module is device-dependent. See the configuration section for more information. The eTimer also interfaces to the Peripheral Bus.

### 39.2.1 TIO[n:0] - Timer Input/Outputs

These pins can be independently configured to be either timer input sources or output flags. In [Figure 39-2](#), the TIO signals are shown as the Primary Inputs, and the Outputs from the OFLAG Control block.

### 39.2.2 TAI[n:0] - Timer Auxiliary Inputs

These pins act as alternate input choices for the timer channels. The TAI signals are shown as Aux Inp 1..n in .

### 39.3 Memory map and register definition

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. There are a set of registers for each timer channel, a set for the watchdog timer, and a set of configuration registers. Certain registers are labelled as not byte accessible. However, no error is generated if a byte access occurs.

The base address of the Watchdog Timer registers is equal to the base address of the eTimer plus an offset of 100h.

**ETIMER memory map**

| Address offset (hex) | Register name                                                      | Width (in bits) | Access | Reset value | Section/page                 |

### 39.3.1 Channel n Compare Register 1 (ETIMER\_CHn\_COMP1)

This read/write register stores the value used for comparison with the counter value. This register is not byte accessible. More explanation on the use of COMP1 can be found in [Usage of Compare Registers](#).

Address: 0h base + 0h offset + (32d × i), where i=0d to 5d

|       |       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |
|-------|-------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| Bit   | 0     | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| Read  | COMP1 |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |
| Write |       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |
| Reset | 0     | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |

| 0–15<br>COMP2 | Value used for comparison with the counter value |

39.3.3 Channel n Capture Register 1 (ETIMER\_CHn\_CAPT1)

This read-only register stores the value captured from the counter. It is actually a 2-deep FIFO and not a single register. This register is not byte accessible. CCCTRL[CPT1MODE] determines when a capture occurs.

Address: 0h base + 4h offset + (32d × i), where i=0d to 5d

39.3.4 Channel n Capture Register 2 (ETIMER\_CHn\_CAPT2)

This read-only register stores the value captured from the counter. It is actually a 2-deep FIFO and not a single register. This register is not byte accessible. CCCTRL[CPT2MODE] determines when a capture occurs.

Address: 0h base + 6h offset + (32d × i), where i=0d to 5d

### 39.3.5 Channel n Load Register (ETIMER\_CHn\_LOAD)

This read/write register stores the value used to initialize the counter. This register is not byte accessible.

Address: 0h base + 8h offset + (32d × i), where i=0d to 5d

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

### 39.3.6 Channel n Hold Register (ETIMER\_CHn\_HOLD)

This read-only register stores the counter's value whenever any of the counters within a module are read. This is used to support coherent reading of cascaded counters.

Address: 0h base + Ah offset + (32d × i), where i=0d to 5d

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

| 0–15<br>HOLD | Stores the counter's value whenever any of the counters within a module are read. |

### 39.3.7 Channel n Counter Register (ETIMER\_CHn\_CNTR)

This read/write register is the counter for this channel of the timer module. This register is not byte accessible.

Address: 0h base + Ch offset + (32d × i), where i=0d to 5d

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

|                 | 0 Count repeatedly.<br>1 Count until compare and then stop. When output mode 4h is used, the counter re-initializes after reaching the COMP1 value and continues to count to the COMP2 value then stops.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |                      |       |                      |       |                      |       |                      |       |                      |       |                      |       |          |       |          |       |                        |       |                        |       |                        |       |                        |       |                        |       |          |       |          |       |          |       |                   |       |                   |
| 9<br>LENGTH     | Count Length<br><br>This bit determines whether the counter counts to the compare value and then re-initializes itself to the value specified in the LOAD, CMPLD1, or CMPLD2 registers, or the counter continues counting past the compare value, to the binary roll over.<br><br>0 Continue counting to roll over.<br>1 Count until compare, then reinitialize. The value that the counter is reinitialized with depends on the settings of CLC1 and CLC2. If neither of these indicates the counter is to be loaded from one of the CMPLD registers, then the LOAD register is used to reinitialize the counter upon matching either COMP register. If one of CLC1 or CLC2 indicates that the counter is to be loaded from one of the CMPLD registers, then the counter will reinitialize to the value in the appropriate CMPLD register upon a match with the appropriate COMP register. If both of the CLC1 and CLC2 fields indicate that the counter is to be loaded from the CMPLD registers, then CMPLD1 will have priority if both compares happen at the same value. When output mode 4h is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until COMP1 value is reached, re-initializes, then counts until COMP2 value is reached, re-initializes, then counts until COMP1 value is reached, etc. |       |                      |       |                      |       |                      |       |                      |       |                      |       |                      |       |          |       |          |       |                        |       |                        |       |                        |       |                        |       |                        |       |          |       |          |       |          |       |                   |       |                   |
| 10<br>DIR       | Count Direction<br><br>This bit selects either the normal count direction up, or the reverse direction, down.<br><br>0 Count up<br>1 Count down                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |                      |       |                      |       |                      |       |                      |       |                      |       |                      |       |          |       |          |       |                        |       |                        |       |                        |       |                        |       |                        |       |          |       |          |       |          |       |                   |       |                   |
| 11–15<br>SECSRC | Secondary Count Source<br><br>These bits identify the source to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of the CNTR register. The selected input can also be used to specify the count direction. The polarity of the signal can be inverted by the SIPS bit of the CTRL2 register.<br><br><table> <tr><td>00000</td><td>Counter #0 input pin</td></tr> <tr><td>00001</td><td>Counter #1 input pin</td></tr> <tr><td>00010</td><td>Counter #2 input pin</td></tr> <tr><td>00011</td><td>Counter #3 input pin</td></tr> <tr><td>00100</td><td>Counter #4 input pin</td></tr> <tr><td>00101</td><td>Counter #5 input pin</td></tr> <tr><td>00110</td><td>Reserved</td></tr> <tr><td>00111</td><td>Reserved</td></tr> <tr><td>01000</td><td>Auxiliary input #0 pin</td></tr> <tr><td>01001</td><td>Auxiliary input #1 pin</td></tr> <tr><td>01010</td><td>Auxiliary input #2 pin</td></tr> <tr><td>01011</td><td>Auxiliary input #3 pin</td></tr> <tr><td>01100</td><td>Auxiliary input #4 pin</td></tr> <tr><td>01101</td><td>Reserved</td></tr> <tr><td>01110</td><td>Reserved</td></tr> <tr><td>01111</td><td>Reserved</td></tr> <tr><td>10000</td><td>Counter #0 output</td></tr> <tr><td>10001</td><td>Counter #1 output</td></tr> </table>                                                             | 00000 | Counter #0 input pin | 00001 | Counter #1 input pin | 00010 | Counter #2 input pin | 00011 | Counter #3 input pin | 00100 | Counter #4 input pin | 00101 | Counter #5 input pin | 00110 | Reserved | 00111 | Reserved | 01000 | Auxiliary input #0 pin | 01001 | Auxiliary input #1 pin | 01010 | Auxiliary input #2 pin | 01011 | Auxiliary input #3 pin | 01100 | Auxiliary input #4 pin | 01101 | Reserved | 01110 | Reserved | 01111 | Reserved | 10000 | Counter #0 output | 10001 | Counter #1 output |

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>OEN   | Output Enable<br><br>This bit determines the direction of the external pin.<br><br>0 The external pin is configured as an input.<br>1 OFLAG output signal will be driven on the external pin. Other timer channels using this external pin as their input will see the driven value. The polarity of the signal will be determined by the OPS bit.                                                                                                                                                                                                      |
| 1<br>RDNT  | Redundant Channel Enable<br><br>This bit enables redundant channel checking between adjacent channels (0 and 1, 2 and 3, 4 and 5 ). When this bit is clear, the RCF bit in this channel cannot be set. When this bit is set, the RCF bit will be set by a miscompare between the OFLAG of this channel and the OFLAG of its redundant adjacent channel which will cause the output of this channel to go inactive (logic 0 prior to consideration of the OPS bit).<br><br>0 Disable redundant channel checking.<br>1 Enable redundant channel checking. |
| 2<br>INPUT | External input signal<br><br>This read only bit reflects the current state of the signal selected via SECSRC after application of the SIPS bit and filtering.                                                                                                                                                                                                                                                                                                                                                                                           |
| 3<br>VAL   | Forced OFLAG Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**ETIMER\_CHn\_STS field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 6<br>WDF        | Watchdog Time-out Flag<br><br>This bit is set when the watchdog times out by counting down to zero. The watchdog must be enabled for time-out to occur and channel 0 must be in quadrature decode count mode (CNTMODE = 100). This bit is cleared by writing a 1 to this bit position after either writing a non-zero value to WDTOL and/or WDTOH or exiting quadrature decode counting mode. This bit is only in channel 0. If the watchdog timer is not implemented, then this bit is read-only zero. |
| 7<br>RCF        | Redundant Channel Flag                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**ETIMER\_CHn\_STS field descriptions (continued)**

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | <p>This field is set to 1 when there is a miscompare between this channel's OFLAG value and the OFLAG value of the corresponding redundant channel. Corresponding channels are grouped together in the following pairs: 0 and 1, 2 and 3, 4 and 5. This field can only be set to 1 if the RDNT bit is set. This field is cleared by writing a 1 to this field.</p> <p><b>NOTE:</b> This field is functional only in the even channels, i.e., 0, 2, 4. In the odd channels, this field cannot create an interrupt.</p> |
| 8<br>ICF2  | <p>Input Capture 2 Flag</p> <p>This bit is set when an input capture event (as defined by CPT2MODE) occurs and the word count of the CAPT2 FIFO exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF2DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF2DE is set (DMA).</p>                                                                                                                                                               |
| 9<br>ICF1  | <p>Input Capture 1 Flag</p> <p>This bit is set when an input capture event (as defined by CPT1MODE) occurs and the word count of the CAPT1 FIFO exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF1DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF1DE is set (DMA).</p>                                                                                                                                                               |
| 10<br>IEHF | <p>Input Edge High Flag</p> <p>This bit is set when a positive input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.</p>                                                                                                                                                                                                                                                                                                  |
| 11<br>IELF | <p>Input Edge Low Flag</p> <p>This bit is set when a negative input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.</p>                                                                                                                                                                                                                                                                                                   |
| 12<br>TOF  | <p>Timer Overflow Flag</p> <p>This bit is set when the counter rolls over its maximum value FFFFh or 0000h (depending on count direction). This bit is cleared by writing a one to this bit location.</p>                                                                                                                                                                                                                                                                                                             |
| 13<br>TCF2 | <p>Timer Compare 2 Flag</p> <p>This bit is set when a successful compare occurs with COMP2. This bit is cleared by writing a one to this bit location.</p>                                                                                                                                                                                                                                                                                                                                                            |
| 14<br>TCF1 | <p>Timer Compare 1 Flag</p> <p>This bit is set when a successful compare occurs with COMP1. This bit is cleared by writing a one to this bit location.</p>                                                                                                                                                                                                                                                                                                                                                            |
| 15<br>TCF  | <p>This bit is set when a successful compare occurs. This bit is cleared by writing a one to this bit location.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |

| 15<br>TCFIE  | Timer Compare Flag Interrupt Enable<br>Setting this bit enables interrupts when the TCF bit is set.    |

**39.3.13 Channel n Comparator Load Register 1  
(ETIMER\_CHn\_CMPLD1)**

This read/write register is the preload value for the COMP1 register. This register can also be used to load into the CNTR register. This register is not byte accessible. More information on the use of this register can be found in [Usage of Compare Load Registers](#).

Address: 0h base + 18h offset + (32d × i), where i=0d to 5d

|       |        |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>0 Free running mode is selected. If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and capture circuit 1 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.</p> <p>1 One shot mode is selected. If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and the ARM bit is cleared. No further captures will be performed until the ARM bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARM bit is then cleared.</p> |
| 15<br>ARM | <p>Arm Capture</p> <p>Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s).</p> <p>0 Input capture operation is disabled.</p> <p>1 Input capture operation as specified by the CPT1MODE and CPT2MODE bits is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**39.3.16 Channel n Input Filter Register (ETIMER\_CHn\_FILT)**

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any eTimer channel can use the input as a count source. The FILT register is also used to control the filtering of the corresponding auxilliary input if one exists.

The FILT\_PER value should be set such that the sampling period is larger the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT\_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the  $\text{FILT\_CNT} + 3$  power.

The values of FILT\_PER and FILT\_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT\_PER to a non-zero value) introduces a latency of:  $((\text{FILT\_CNT} + 3) \times \text{FILT\_PER}) + 2$  peripheral clock periods.

Address:  $0\text{h base} + 1\text{Eh offset} + (32\text{d} \times i)$ , where  $i=0\text{d}$  to  $5\text{d}$

| Field            | Description                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–4<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                        |
| 5–7<br>FILT_CNT  | Input Filter Sample Count<br><br>These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in this section.                                          |
| 8–15<br>FILT_PER | Input Filter Sample Period<br><br>These bits represent the sampling period (in peripheral clock cycles) of the eTimer input signal. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is \$00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in in this section. |

**39.3.17 Watchdog Time-out Low Word Register (ETIMER\_WDTOL)**

The fields in WDTOL and WDTOH are combined to form the 32 bit time-out count, WDTO, for the Timer watchdog function. This time-out count is used to monitor for inactivity on the inputs when channel 0 is in the quadrature decode count mode. The watchdog function is enabled whenever WDTO contains a non-zero value (although actual counting only occurs if channel 0 is in quadrature decode counting mode). The watchdog time-out down counter is loaded whenever WDTOH is written. This register is not byte accessible. See [Watchdog Timer](#) for more information on the use of the watchdog timer.

Address: 0h base + 100h offset = 100h

39.3.18 Watchdog Time-out High Word Register (ETIMER\_WDTH)

The fields in WDTOL and WDTH are combined to form the 32 bit time-out count, WDT, for the Timer watchdog function. This time-out count is used to monitor for inactivity on the inputs when channel 0 is in the quadrature decode count mode. The watchdog function is enabled whenever WDT contains a non-zero value (although actual counting only occurs if channel 0 is in quadrature decode counting mode). The watchdog time-out down counter is loaded whenever WDTH is written. This register is not byte accessible. See [Watchdog Timer](#) for more information on the use of the watchdog timer.

## 39.4 Functional Description

This section provides a functional description of eTimer.

### 39.4.1 General

Each channel has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.

## Functional Description

- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
  - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the channels within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be "captured"
- They can be used to generate interrupt requests

The polarity of the external inputs is selectable.

The primary output of each channel is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is programmable.

Any channel can be assigned as a "Master". A master's compare signal can be broadcasted to the other channels within the module. The other channels can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a Master channel's compare event occurs.

## 39.4.2 Counting Modes

The selected external signals are sampled at the eTimer's base clock rate and then run through a transition detector. The maximum count rate is one-half of the eTimer's base clock rate when using an external signal. Internal clock sources can be used to clock the counters at the eTimer's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CNTMODE field in the CTRL1 register is cleared when the count terminates.

### 39.4.2.1 STOP Mode

If the CNTMODE field is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

### 39.4.2.2 COUNT Mode

If the CNTMODE field is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting the PIPS bit, then the negative edge of the selected external input signal is counted.

See [CASCADE-COUNT Mode](#) through [VARIABLE-FREQUENCY PWM Mode](#) for additional capabilities of this operating mode.

### 39.4.2.3 EDGE-COUNT Mode

If the CNTMODE field is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment such as a simple encoder wheel.

### 39.4.2.4 GATED-COUNT Mode

If the CNTMODE field is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting the SIPS bit, then the counter will count while the selected secondary input is low.

### 39.4.2.5 QUADRATURE-COUNT Mode

If the CNTMODE field is set to 100, the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signals provides both count and direction information.

The following figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

### Figure 39-3. Quadrature Incremental Position Encoder

### 39.4.2.6 SIGNED-COUNT Mode

If the CNTMODE field is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

### 39.4.2.7 TRIGGERED-COUNT Mode

If the CNTMODE field is set to '110', the counter will begin counting the primary clock source after a positive transition (negative if SIPS = 1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. Subsequent secondary positive input transitions will continue to restart and stop the counting until a compare event occurs.

### Figure 39-4. Triggered Count Mode (Length=1)

### 39.4.2.8 ONE-SHOT Mode

If the CNTMODE field is set to '110', and the counter is set to reinitialize at a compare event (LENGTH = 1), and the OFLAG OUTMODE is set to '0101' (cleared on init, set on compare), the counter works in a "One-Shot Mode". An external events causes the counter to count, when terminal count is reached, the output is asserted. This "delayed" output can be used to provide timing delays.

**Figure 39-5. One-Shot Mode (Length=1)**

### 39.4.2.9 CASCADE-COUNT Mode

If the CNTMODE field is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This "Cascade" or "Daisy-Chained" mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to two counters may be cascaded to create a 32 bit wide synchronous counter.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective HOLD registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the HOLD registers of the other counters in the chain. The cascaded counter mode is synchronous.

### Note

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a "ripple" mode, where higher order counters will transition a clock later than a purely synchronous design.

### Note

A channel can be cascaded with any other channel, but you can't cascade more than 2 channels together. You can create separate cascades of pairs of channels. For example, you can cascade channels 0 and 1 and separately cascade channels 6 and 5. You can't cascade channels 0, 1, and 5.

## 39.4.2.10 PULSE-OUTPUT Mode

If the counter is setup for CNTMODE = 001, and the OFLAG OUTMODE is set to '1111' (gated clock output), and the ONCE bit is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

### Note

This does not work if the PRISRC is set to 11000 (IP\_bus/1).

Figure 39-6. Pulse Output Mode

## 39.4.2.11 FIXED-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count through roll-over (LENGTH = 0), continuous count (ONCE = 0) and the OFLAG OUTMODE is '0111' (set on compare, cleared on counter roll-over) then the counter output yields a Pulse Width Modulated

(PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

### 39.4.2.12 VARIABLE-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count till compare (LENGTH = 1), continuous count (ONCE = 0) and the OFLAG OUTMMODE is '0100' (toggle OFLAG and alternate compare registers) then the counter output yields a Pulse Width Modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

Figure 39-7. Variable PWM Waveform

CLC1=010, load COMP1 when CNTR=COMP1  
CLC2=101, load COMP2 when CNTR=COMP2

Figure 39-8. Variable Frequency PWM Mode Timing

39.4.2.13 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability.

The COMP1 register should be set to the desired maximum count value or FFFFh to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If the output mode is set to 0100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time. COMP1 is used when OFLAG=0 and COMP2 is used when OFLAG=1. OFLAG can be forced to a value using CTRL2[FORCE] and CTRL2[VAL].

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFh or 0000h, roll over, then begin counting toward the new value. The check is: CNTR = COMPx, *not* CNTR > COMP1 or CNTR < COMP2.

The use of the CMPLD1 and CMPLD2 registers to preload compare values will help to minimize this problem.

Figure 39-9. Compare Register and OFLAG Timing

### 39.4.2.14 Usage of Compare Load Registers

The CMPLD1, CMPLD2 and CCCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. A compare register can be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there is the possibility that the counter may have already counted past the new compare value by the time the compare register is updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are updated in hardware in the same way the counter register is re-initialized to the value stored in the LOAD register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See [Figure 39-8](#).

### 39.4.2.15 MODULO COUNTING Mode

To create a modulo counter using COMP1 and COMP2 as the counter boundaries (instead of \$0000 and \$FFFF), set the registers in the following manner. Set CNTMODE to either 100 (quadrature count mode) or 101 (count with direction mode). Use count through roll-over (LENGTH = 0) and continuous count (ONCE = 0). Set COMP1 and CMPLD1 to the upper boundary value. Set COMP2 and CMPLD2 to the lower boundary value. Set CMPMODE = 10 (COMP1 is used when counting up and COMP2 is used when counting down). Set CLC2 = 110 (load CNTR with value of CMPLD2 on COMP1 compare) and CLC1 = 111 (load CNTR with value of CMPLD1 on COMP2 compare).

### 39.4.2.16 Compare Register and OFLAG Operation

The compare flags and output flag are registered signals and can only change state after the counter reached the compare value. This means that, if the counter is continuously counting, then the compare flag is set on the count after the counter reaches the compare value. When counting is not continuous (such as when using a prescaler or when counting edges on the primary input), the compare flag or OFLAG are not updated until the counter is about to transition to the next count. This means that if the compare value is 4, then the flags will be changed on the same clock edge that transitions the counter from 4 to its next value.

Figure 39-10. OFLAG timing during non-continuous counting

Figure 39-11. OFLAG timing during continuous counting

### 39.4.3 Other Features

This section describes other features of eTimer.

#### 39.4.3.1 Redundant OFLAG Checking

This mode allows the user to bundle two timer functions generating any pattern to compare their resulting OFLAG behaviors (output signal).

The redundant mode is used to support online checks for reliability and functional safety reasons. Whenever a mismatch between the two adjacent channels occurs, it is reported via an interrupt to the core and the two outputs are put into their inactive states. An error is flagged via the RCF flag.

This feature can be tested by forcing a transition on one of the OFLAGs using the VAL and FORCE bits of the channel.

### 39.4.3.2 Loopback Checking

This mode is always available in that one channel can generate an OFLAG while another channel uses the first channel's OFLAG as its input to be measured and verified to be as expected.

### 39.4.3.3 Input Capture Mode

Input capture is used to measure pulse width (by capturing the counter value on two successive input edges) or waveform period (by capturing the counter value on two consecutive rising edges or two consecutive falling edges). The Capture Registers store a copy of the counter's value when an input edge (positive, negative, or both) is detected. The type of edge to be captured by each circuit is determined by the CPT1MODE and CPT2MODE bits whose functionality is listed in [CPT1MODE](#). Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

### 39.4.3.4 Master/Slave Mode

Any timer channel can be assigned as a Master (MSTR = 1). A Master's compare signal can be broadcasted to the other channels within the module. The other counters can be configured to reinitialize their counters (COINIT = 1) and/or force their OFLAG output signals (COFRC = 1) to predetermined values when a Master counter compare event occurs.

### 39.4.3.5 Watchdog Timer

#### NOTE

The watchdog timer may not be implemented on each eTimer module instance.

The watchdog timer is used to monitor for a stalled count when channel 0 is in quadrature count mode. When the watchdog is enabled, it loads the time-out value into a down counter. The down counter counts as long as channel 0 is in quadrature decode count mode. If this down counter reaches zero, an interrupt is asserted. The down counter is reloaded to the time-out value each time the counter value from channel 0 changes. If the channel 0 count value is toggling between two values (indicating a possibly stalled encoder), then the down counter is not reloaded.

## 39.5 Resets

The eTimer module can only be reset by a full system reset. This forces all registers to their reset state and clears the OFLAG signals if they are asserted. The counters will be turned off until the settings in the CTRL registers are changed.

## 39.6 Clocks

Each timer channel receives its own copy of the peripheral bus clock. This allows for better power management by turning off the clock to unused channels. The watchdog timer (if implemented) has its own version of this clock. Each bit of the ENBL register uses the clock for that corresponding channel. The DREQn registers use the clock for channel, 0 but this clock can be turned off after these registers have been programmed.

## 39.7 Interrupts

The following can generate interrupts within the eTimer.

- Watchdog timer (if implemented)
- Each channel can generate an interrupt from several sources

The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

**Table 39-1. Interrupt summary**

| Core interrupt             | Interrupt flag | Interrupt enable | Name                              | Description                                     |
|----------------------------|----------------|------------------|-----------------------------------|-------------------------------------------------|
| Channels 0-n               | TCF            | TCFIE            | Compare interrupt                 | Compare of counter and related compare register |
|                            | TCF1           | TCF1IE           | Compare 1 interrupt               | Compare of the counter and COMP1 register       |
|                            | TCF2           | TCF2IE           | Compare 2 interrupt               | Compare of the counter and COMP2 register       |
|                            | TOF            | TOFIE            | Overflow interrupt                | Generated on counter roll-over or roll-under    |
|                            | IELF           | IELFIE           | Input Low Edge interrupt          | Falling edge of the secondary input signal      |
|                            | IEHF           | IEHFIE           | Input High Edge interrupt         | Rising edge of the secondary input signal       |
|                            | ICF1           | ICF1IE           | Input Capture 1 interrupt         | Input capture event for CAPT1                   |
|                            | ICF2           | ICF2IE           | Input Capture 2 interrupt         | Input capture event for CAPT2                   |
| Watchdog <sup>1</sup>      | WDF            | WDFIE            | Watchdog time-out interrupt       | Watchdog has timed out                          |
| Redundant Channel Checking | RCF            | RCFIE            | Redundant Channel Fault interrupt | Miscompare with redundant channel               |

1. If applicable. Not all instantiations of eTimer implement a watchdog timer.

## 39.8 DMA

Each channel can request a DMA read access for each of the capture registers and a DMA write request for each of the compare preload registers. The DREQ registers select amongst these 32 DMA request sources to generate the 4 top level DMA request outputs.

**Table 39-2. DMA Summary**

| DMA Request  | DMA Enable | Name                 | Description            |
|--------------|------------|----------------------|------------------------|
| Channels 0-n | ICF1DE     | CAPT1 read request   | CAPT1 contains a value |
|              | ICF2DE     | CAPT2 read request   | CAPT2 contains a value |
|              | CMPLD1DE   | CMPLD1 write request | CMPLD1 needs an update |
|              | CMPLD2DE   | CMPLD2 write request | CMPLD2 needs an update |

# Chapter 40

## Motor Control Pulse Width Modulator Module (FlexPWM)

### 40.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section contains features, modes of operation, and block diagrams of the FlexPWM.

#### 40.1.1 Overview

The pulse width modulator module (FlexPWM) contains one or more PWM submodules, each capable of controlling a single half-bridge power stage. One or more fault channels may also be included.

This PWM is capable of controlling most motor types: AC induction motors (ACIM), Permanent Magnet AC motors (PMAC), both brushless (BLDC) and brush DC motors (BDC), switched (SRM) and variable reluctance motors (VRM), and stepper motors.

#### 40.1.2 Features

The FlexPWM module provides the following features:

- 16 bits of resolution for center, edge aligned, and asymmetrical PWMs
- PWM outputs capable of operating as complementary pairs or independent channels
- Can accept signed numbers for PWM generation
- Independent control of both edges of each PWM output

- Synchronization to external hardware or other PWM supported
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a "Force Out" event
- PWMX pin can optionally output a third PWM signal from each submodule
- PWMX channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions
- Capture is supported only for X channels not A and B channels
- Enhanced dual edge capture functionality
- The option to supply the source for each complementary PWM signal pair from any of the following:
  - External digital pin
  - Internal timer channel
  - External ADC input, taking into account values set in ADC high and low limit registers

### 40.1.3 Modes of operation

Care must be exercised when using this module in certain chip operating modes. Some motors (such 3-phase AC motors) require regular software updates for proper operation. Failure to do so could result in destroying the motor or inverter. Because of this, PWM outputs are placed in their inactive states in STOP mode, and optionally under debug mode. PWM outputs are reactivated (assuming they were active to begin with) when these modes are exited.

**Table 40-1. Modes when PWM operation is restricted**

| Mode  | Description                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| STOP  | Peripheral and CPU clocks are stopped. PWM outputs are driven inactive.                                                                               |
| DEBUG | CPU and peripheral clocks continue to run, but CPU maybe stalled for periods of time. PWM outputs are driven inactive as a function of the DBGEN bit. |

### 40.1.4 Block Diagrams

This section contains block diagrams of the FlexPWM.

### 40.1.4.1 Module level

Figure 40-1. PWM block diagram

### 40.1.4.2 PWM submodule

Figure 40-2. PWM submodule block diagram

## 40.2 External Signal Descriptions

The PWM module has external pins named PWMA[n], PWMB[n], PWMX[n], FAULT[n], EXT\_SYNC, EXT\_FORCE, EXTA[n], and EXTB[n]. The PWM module also has an on-chip input called EXT\_CLK and an on-chip output called OUT\_TRIG[n].

### 40.2.1 PWMA[n] and PWMB[n] - External PWM Pair

These pins are the output pins of the PWM channels. They can be independent PWM signals or a complementary pair.

### 40.2.2 PWMX[n] - Auxiliary PWM signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or they can be used to generate the IPOL bit during deadtime correction.

### 40.2.3 FAULT[n] - Fault inputs

These are input pins for disabling selected PWM outputs.

### 40.2.4 EXT\_SYNC - External Synchronization Signal

This input signal allows a source external to the PWM to initialize the PWM counter. In this manner the PWM can be synchronized to external circuitry.

### 40.2.5 EXT\_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner the PWM can be synchronized to external circuitry. An example would be to simultaneously switch all of the PWM outputs on a commutation boundary for trapezoidal control of a BLDC motor. The boundary can be established via external logic or an on-chip timer.

### 40.2.6 EXTA[n] and EXTB[n] - Alternate PWM Control Signals

These pins allow an alternate source to control the PWMA and PWMB outputs although typically, the EXTA input will be used for the generation of a complementary pair. Typical connections include ADC results registers, TMR outputs, GPIO inputs, and comparator outputs.

### 40.2.7 OUT\_TRIG0[n] and OUT\_TRIG1[n] - Output Triggers

These outputs allow the PWM submodules to control timing of the ADC conversions. See [Submodule n Output Trigger Control Register \(FlexPWM\\_SUBn\\_TCTRL\)](#) for a description of how to enable these outputs and how the compare registers match up to the output triggers.

### 40.2.8 EXT\_CLK - External Clock Signal

This on-chip input signal allows an on-chip source external to the PWM (typically a Timer) to control the PWM clocking. In this manner the PWM can be synchronized to the Timer. This signal must be generated synchronously to the PWM's clock since it is not resynchronized in the PWM.

### 40.2.9 EXT\_SWITCH - External Switch Signal

This input signal allows a source external to the PWM to control the PWM generation source within submodule1. This signal only functions on submodule1 and selects the source of the generated PWM signal to be either submodule1 or submodule0.

## 40.3 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level and the address offset is defined at the module level. There are a set of registers for each PWM submodule, for the configuration logic, and for each Fault channel.

Registers are only accessible using 16- or 32-bit accesses. Byte accesses are not allowed.

Submodule registers are repeated for each PWM submodule. The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is 50h. This is the base address of the PWM module plus an offset based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same offset.

The base address of the configuration registers is equal to the base address of the FlexPWM plus an offset of 140h.

The base address of the fault logic is equal to the base address of the FlexPWM plus an offset of 14Ch.

#### NOTE

A write access to the read-only Capture Value and Capture Value Cycle registers will result in a bus error.

## FlexPWM memory map

| Address offset (hex) | Register name                                                      | Width (in bits) | Access | Reset value                 | Section/ page                |

40.3.1 Submodule n Counter Register (FlexPWM\_SUBn\_CNT)

This read-only register displays the state of the signed 16-bit submodule counter. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 0h offset + (80d × i), where i=0d to 3d

|-------------|-------------------------------------------------------|
| 0–15<br>CNT | Count<br>State of the signed 16-bit submodule counter |

40.3.2 Submodule n Initial Count Register (FlexPWM\_SUBn\_INIT)

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of INIT\_SEL) or when FORCE is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

NOTE

The INIT register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. This register cannot be written when LDOK is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 2h offset + (80d × i), where i=0d to 3d

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>DBGEN    | Debug Enable<br><br>When set to one, the PWM will continue to run while the chip is in debug mode. If the device enters debug mode and this bit is zero, then the PWM outputs will be disabled until debug mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers.<br><br>For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in debug mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in debug mode. The key point is PWM parameter updates will not occur in debug mode. Any motors requiring such updates should be disabled during debug mode. If in doubt, leave this bit set to zero. |

**40.3.5 Submodule n Value Register 0 (FlexPWM\_SUBn\_VAL0)**

The 16-bit signed value in this buffered, read/write register defines the mid-cycle reload point for the PWM in PWM clock periods. This value also defines when the PWMX signal is set and the local sync signal is reset. This register is not byte accessible.

**NOTE**

The SUBn\_VAL0 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL0 cannot be written when LDOK is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 8h offset + (80d × i), where i=0d to 3d

FlexPWM\_SUBn\_VAL0 field descriptions

| Field        | Description                                                        |
|--------------|--------------------------------------------------------------------|
| 0–15<br>VAL0 | Value 0<br>Mid-cycle reload point for the PWM in PWM clock periods |

40.3.6 Submodule n Value Register 1 (FlexPWM\_SUBn\_VAL1)

The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter will reload itself with the contents of the INIT register and assert the local sync signal while resetting PWMX. This register is not byte accessible.

NOTE

The SUBn\_VAL1 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL1 cannot be written when LDOK is set. Reading VAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

NOTE

If SUBn\_VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. The PWMX output will be low for a minimum of one count every cycle after the count reaches VAL1. When the Master Sync signal (only originated by the Local Sync from sub-module 0) is used to control the timer period, the SUBn\_VAL1 register can be free for other functions such as PWM generation without duty cycle limitation.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Ah offset + (80d × i), where i=0d to 3d

| Field        | Description                                                             |
|--------------|-------------------------------------------------------------------------|
| 0–15<br>VAL1 | Value 1<br>Modulo count value (maximum count) for the submodule counter |

**40.3.7 Submodule n Value Register 2 (FlexPWM\_SUBn\_VAL2)**

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM23 high ( [PWM submodule](#) ). This register is not byte accessible.

**NOTE**

The SUBn\_VAL2 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL2 cannot be written when LDOK is set. Reading VAL2 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Ch offset + (80d × i), where i=0d to 3d

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

|--------------|------------------------------------------|
| 0–15<br>VAL2 | Value 2<br>Count value to set PWM23 high |

**40.3.8 Submodule n Value Register 3 (FlexPWM\_SUBn\_VAL3)**

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM23 low ( [PWM submodule](#) ). This register is not byte accessible.

**NOTE**

The SUBn\_VAL3 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL3 cannot be written when

LDOK is set. Reading VAL3 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Eh offset + (80d × i), where i=0d to 3d

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

40.3.9 Submodule n Value Register 4 (FlexPWM\_SUBn\_VAL4)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 high ( [PWM submodule](#) ). This register is not byte accessible.

NOTE

The SUBn\_VAL4 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL4 cannot be written when LDOK is set. Reading VAL4 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 10h offset + (80d × i), where i=0d to 3d

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

### 40.3.10 Submodule n Value Register 5 (FlexPWM\_SUBn\_VAL5)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 low ( [PWM submodule](#) ). This register is not byte accessible.

#### NOTE

The SUBn\_VAL5 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL5 cannot be written when LDOK is set. Reading VAL5 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 12h offset + (80d × i), where i=0d to 3d

**40.3.13 Submodule n Interrupt Enable Register (FlexPWM\_SUBn\_INTEN)**

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 1Ch offset + (80d × i), where i=0d to 3d

|                 | These bits enable the generation of OUT_TRIG0 and OUT_TRIG1 outputs based on the counter value matching the value in one or more of the SUBn_VALx registers. VAL0, VAL2, and VAL4 are used to generate OUT_TRIG0 and VAL1, VAL3, and VAL5 are used to generate OUT_TRIG1. The OUT_TRIGx signals are only asserted as long as the counter value matches the VALx value, therefore up to six triggers can be generated (three each on OUT_TRIG0 and OUT_TRIG1) per PWM cycle per submodule. |                 |                |   |           |   |           |   |           |   |           |   |           |   |           |

**40.3.16 Submodule n Fault Disable Mapping Register (FlexPWM\_SUBn\_DISMAP)**

This register determines which PWM pins are disabled by the fault protection inputs, illustrated in the table in [Fault Protection](#). Reset sets all of the bits in the fault disable mapping register.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 22h offset + (80d × i), where i=0d to 3d

### 40.3.17 Submodule n Deadtime Count Register 0 (FlexPWM\_SUBn\_DTCNT0)

Deadtime operation is only applicable to complementary channel operation. The 11-bit value written to this register is in terms of peripheral clock cycles regardless of the setting of PRSC and/or CLK\_SEL. Reset sets the deadtime count register to a default value of 0x07FF, selecting a deadtime of 2047 clock cycles. This register is not byte accessible.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 24h offset + (80d × i), where i=0d to 3d

| 14<br>ONESHOTX | <p>One Shot Mode Aux</p> <p>This bit selects between free running and one shot mode for the input capture circuitry.</p> <p>0 Free running mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.</p> <p>1 One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and the ARMX bit is cleared. No further captures will be performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARMX bit is then cleared.</p> |
| 15<br>ARMX     | <p>Arm X</p> <p>Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s).</p> <p>0 Input capture operation is disabled.<br/> 1 Input capture operation as specified by the EDGX bits is enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**40.3.20 Submodule n Capture Compare X Register (FlexPWM\_SUBn\_CAPTCMPX)**

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 32h offset + (80d × i), where i=0d to 3d

|       |         |   |   |   |   |   |   |   |          |   |    |    |    |    |    |    |

**FlexPWM\_SUBn\_CAPTCMPX field descriptions**

| Field            | Description                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>EDGCNTX   | Edge Counter X<br>This read only field contains the edge counter value for the PWMX input capture circuitry.                        |
| 8–15<br>EDGCOMPX | Edge Compare X<br>This read/write field is the compare value associated with the edge counter for the PWMX input capture circuitry. |

**40.3.21 Submodule n Capture Value 0 Register (FlexPWM\_SUBn\_CVAL0)**

This read only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by the EDGX0 bits. This is actually a 4-deep FIFO and not a single register. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 34h offset + (80d × i), where i=0d to 3d

|       |          |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

| Write |          |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |
| Reset | 0        | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |

**FlexPWM\_SUBn\_CVAL0 field descriptions**

| Field            | Description                               |
|------------------|-------------------------------------------|
| 0–15<br>CAPTVAL0 | Value captured from the submodule counter |

40.3.22 Submodule n Capture Value 0 Cycle Register (FlexPWM\_SUBn\_CVAL0CYC)

This read only register stores the cycle number corresponding to the value captured in CVAL0. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. This is actually a 4 deep FIFO and not a single register.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 36h offset + (80d × i), where i=0d to 3d

|       |   |   |   |   |   |   |   |   |   |   |    |    |          |    |    |    |
|-------|---|---|---|---|---|---|---|---|---|---|----|----|----------|----|----|----|
| Bit   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12       | 13 | 14 | 15 |

40.3.23 Submodule n Capture Value 1 Register (FlexPWM\_SUBn\_CVAL1)

This read only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by the EDGX1 bits. This is actually a 4 deep FIFO and not a single register. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 38h offset + (80d × i), where i=0d to 3d

|       |          |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

|------------------|-------------------------------------------|
| 0–15<br>CAPTVAL1 | Value captured from the submodule counter |

**40.3.24 Submodule n Capture Value 1 Cycle Register (FlexPWM\_SUBn\_CVAL1CYC)**

This read only register stores the cycle number corresponding to the value captured in CVAL1. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. This is actually a 4 deep FIFO and not a single register.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 3Ah offset + (80d × i), where i=0d to 3d

|       |   |   |   |   |   |   |   |   |   |   |    |    |          |    |    |    |

### 40.3.26 Mask Register (FlexPWM\_MASK)

#### NOTE

The MASKx bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Refer to the figure in [Force Out Logic](#) to see how FORCE\_OUT is generated. Reading the MASK bits reads the buffered value and not necessarily the value currently in effect. This double buffering can be overridden by setting the UPDATE\_MASK bits.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 142h offset = 142h

**40.3.27 Software Controlled Output Register (FlexPWM\_SWCOUT)****NOTE**

These bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Refer to the figure in [Force Out Logic](#) to see how FORCE\_OUT is generated. Reading these bits reads the buffered value and not necessarily the value currently in effect.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 144h offset = 144h

**40.3.28 Deadtime Source Select Register (FlexPWM\_DTsrcSEL)****NOTE**

The deadtime source select bits are double buffered and do not take effect until a FORCE\_OUT event occurs within the appropriate submodule. Refer to the figure in [Force Out Logic](#) to see how FORCE\_OUT is generated. Reading these bits reads the buffered value and not necessarily the value currently in effect.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 146h offset = 146h

| 8–11<br>CLDOK | <p>Clear Load Okay</p> <p>This write only bit is used to clear the LDOK bit. Write a 1 to this location to clear the corresponding LDOK. If a reload occurs with LDOK set at the same time that CLDOK is written, then the reload will not be performed and LDOK will be cleared. This bit is self clearing and always reads as a 0.</p> <table> <tr> <th>CLDOK bit</th><th>PWM submodule</th></tr> <tr> <td>0</td><td>0</td></tr> <tr> <td>1</td><td>1</td></tr> <tr> <td>2</td><td>2</td></tr> <tr> <td>3</td><td>3</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | CLDOK bit | PWM submodule | 0 | 0 | 1 | 1 | 2 | 2 | 3 | 3 |

| 12–15<br>LDOK | <p>Load Okay</p> <p>This field loads the PRSC bits of SUB<math>n</math>_CTRL1, SUB<math>n</math>_INIT, and SUB<math>n</math>_VALx registers into a set of buffers in each submodule. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if LDMOD is clear or immediately if LDMOD is set. Set LDOK by reading it when it is logic zero and then writing a logic one to it. SUB<math>n</math>_VALx, SUB<math>n</math>_INIT, and SUB<math>n</math>_CTRLx[PRSC] cannot be written while LDOK is set. LDOK is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic 1 to CLDOK. This bit cannot be written with a zero. LDOK can be set in DMA mode when the DMA indicates that it has completed the update of all SUB<math>n</math>_INIT, SUB<math>n</math>_VALx, or SUB<math>n</math>_CTRLx[PRSC]&gt; registers. Reset clears LDOK.</p> <table> <tr> <th>LDOK bit</th><th>PWM submodule</th></tr> <tr> <td>0</td><td>0</td></tr> <tr> <td>1</td><td>1</td></tr> <tr> <td>2</td><td>2</td></tr> </table> | LDOK bit  | PWM submodule | 0 | 0 | 1 | 1 | 2 | 2 |   |   |

| 5–7<br>FILT_CNT  | <p>Fault Filter Count</p> <p>These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in <a href="#">Input Filter Considerations</a>.</p>                                                                                                                                                                                                                                                              |
| 8–15<br>FILT_PER | <p>Fault Filter Period</p> <p>These bits represent the sampling period (in peripheral clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in <a href="#">Input Filter Considerations</a>.</p>                                                                                                                                                                                                                     |

### 40.3.33 Input Filter Considerations

The FILT\_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT\_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT\_CNT+3 power.

The values of FILT\_PER and FILT\_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT\_PER to a non-zero value) introduces a latency of ((FILT\_CNT+4) x FILT\_PER x peripheral clock period). Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This is to ensure rapid response to fault

conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set the FFLAG and FFPIN bits of the FSTS register.

## 40.4 Functional Description

This section describes the functionality of the FlexPWM.

### 40.4.1 PWM Capabilities

This section describes some capabilities of the PWM module.

#### 40.4.1.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in the following figure.

Figure 40-3. Center Aligned Example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

The figure above also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

#### **40.4.1.2 Edge Aligned PWMs**

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as illustrated in the following figure. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

**Figure 40-4. Edge Aligned Example (INIT=VAL2=VAL4)**

With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn off edge value and the motor voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

#### 40.4.1.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases ARE applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as illustrated in the following figure. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise

standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

**Figure 40-5. Phase Shifted Outputs Example**

An additional benefit of phase shifted PWMs can be seen in the following figure. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

**Figure 40-6. Phase Shifted PWMs Applied to a Transformer Primary**

#### 40.4.1.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method support two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWMA in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (see [Figure 40-17](#)) as shown in the following figure. The DBLPWM signal can be run through the deadtime insertion logic.

Figure 40-7. Double Switching Output Example

#### 40.4.1.5 ADC Triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. The following figure shows how this is accomplished. When specifying complimentary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators are free to perform other functions. In this example, the software doesn't have to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

**Figure 40-8. Multiple Output Trigger Generation in Hardware**

Since each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. The following figure shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In this figure, ALL submodule comparators are shown being used for ADC trigger generation.

**Figure 40-9. Multiple Output Triggers Over Several PWM Cycles**

#### 40.4.1.6 Enhanced Capture Capabilities (E-Capture)

When a PWMX pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

**Figure 40-10. Capture Capabilities of the E-Capture Circuit**

When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (e.g, PWMX) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. As an example, consider the following figure. In this application the output of a PWM power stage is connected to the PWMX pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVAL0 register value from the CVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays.

During deadtime, load inductance drives voltage with polarity that keeps inductive current flowing through diodes.

**Figure 40-11. Output Pulse Width Measurement Possible with the E-Capture Circuit**

#### 40.4.1.7 Synchronous Switching of Multiple Outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature can be extremely useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all submodule outputs, but they occur IMMEDIATELY after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called `FORCE_OUT`. This signal originates from the local `FORCE` bit within the submodule, from `submodule0`, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next `FORCE_OUT` event using the `SWCOUT` and `DTSRCSEL` registers. This selection lays dormant until the `FORCE_OUT` signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

The following figure shows a popular application that can benefit from this feature. On a brushless DC motor it is desirable on many cases to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of the following figure are a simplistic representation of these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE\_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

**Figure 40-12. Sensorless BLDC Commutation Using the Force Out Function**

### 40.4.1.8 Phase shifted full bridge for DC/DC converters

Use CTRL1[PHSSHFT] to allow the EXT\_SWITCH input to control the output of PWMA0/PWMB0. The EXT\_SWITCH input switches the source of the submodule0 output from the SUB0\_VALx registers to the SUB1\_VALx registers. This muxing can be seen in [Figure 40-16](#).

## 40.4.2 Functional Details

This section describes the implementation of various features of the PWM in greater detail.

### 40.4.2.1 PWM Clocking

The following figure shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the peripheral clock, EXT\_CLK, and AUX\_CLK. The EXT\_CLK is generated by an on-chip resource such as a Timer module and goes to all of the submodules. The AUX\_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8 bit prescaler and RUN bit from submodule0 can control all of the submodules. When AUX\_CLK is selected as the source for the submodule clock, the RUN bit from submodule0 is used instead of the local RUN bit from this submodule.

**Figure 40-13. Clocking Block Diagram for Each PWM Submodule**

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the peripheral clock frequency by 1-128. The prescaler bits, PRSC, in the control register (CTRL1), select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until the LDOK bit is set and a new PWM reload cycle begins or LDMOD is set.

### 40.4.2.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using the LDFQ bits and the FULL bit. A half cycle reload option is also supported (HALF) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the SUB<sub>n</sub>VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As illustrated in the following figure, the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

Figure 40-14. Register Reload Logic

### 40.4.2.3 Counter Synchronization

Referring to the following figure, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.

**Figure 40-15. Submodule Timer Synchronization**

The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0. The SUB $n$ \_VAL1 register and associated comparator of the other submodules can then be freed up for other functions such as PWM generation, input captures, output compares, or output triggers.

The EXT\_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE\_OUT signal assuming that the FORCE\_EN bit is set. As indicated by the figure above, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal. The FORCE\_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor

winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event with respect to the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result will be an oscillation caused by the beating between the PWM frequency and the commutation frequency.

#### 40.4.2.4 PWM Generation

The following figure illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated SUB $n$ \_VAL $x$  registers are utilized for each PWM output signal. One comparator and VAL $x$  register is used to control the turn on edge while a second comparator and SUB $n$ \_VAL $x$  register control the turn off edge.

Figure 40-16. PWM Generation Hardware

The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a rising edge of the Local Sync signal, comparator 1 generates a falling edge. Comparator 1 is also hardwired to the reload logic to generate the half cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the SUB $n$ \_VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the SUB $n$ \_VAL1 and SUB $n$ \_VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Sync signal effectively turning it into an auxiliary PWM signal (PWMX) assuming that the PWMX pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating 3 PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The muxes for PWM23 and PWM45, shown in the figure above, are only in submodule0.

If the comparators assert both the set and reset of the flip-flop at the same time, then the flop output goes to 0.

#### 40.4.2.5 Output Compare Capabilities

By using the SUB $n$ \_VAL $x$  registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

Referring again to [Figure 40-16](#), an output compare is initiated by programming a SUB $n$ \_VAL $x$  register for a timer compare which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWMA signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset

again after the compare has occurred, the SUB $n$ \_VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWMA signal that sets it low, the SUB $n$ \_VAL3 register is programmed with the appropriate count value and the SUB $n$ \_VAL2 register is programmed with a value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

#### 40.4.2.6 Force Out Logic
