For each submodule software can select between seven signal sources for the FORCE\_OUT signal: the local FORCE bit, the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, or the EXT\_FORCE signal from on or off chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master signals or EXT\_FORCE signal should be selected.

The following figure illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the EXTA or EXTB alternate external control signals. The selection can be determined ahead of time and, when a FORCE\_OUT event occurs, these values are presented to the signal selection mux which immediately switches the requested signal to the output of the mux for further processing downstream.

**Figure 40-17. Force Out Logic**

The local FORCE signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the local FORCE bit of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT\_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

#### 40.4.2.7 Independent or Complementary Channel Operation

Writing a logic one to the INDEP bit of the CNFG register configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to the INDEP bit configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in the following figure in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by the IPOL bit.

**Figure 40-18. Complementary Channel Pair**

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in the following figure.

**Figure 40-19. Typical 3 Phase AC Motor Drive**

Complementary operation allows the use of the deadtime insertion feature.

#### 40.4.2.8 Deadtime Insertion Logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

**Figure 40-20. Deadtime Insertion and Fine Control Logic**

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure above. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

### Note

To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. However, the transistor's characteristics may cause its switching-off time to be longer than its switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in the following figure.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of peripheral clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

Figure 40-21. Deadtime Insertion

#### 40.4.2.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See the following figure. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

**Figure 40-22. Deadtime Distortion**

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths were shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the motor current waveform. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor current for that pair. See the figure above. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the SUB $n$ \_VAL $x$  registers. Either the SUB $n$ \_VAL2/SUB $n$ \_VAL3 or the SUB $n$ \_VAL4/SUB $n$ \_VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the SUB $n$ \_VAL2/SUB $n$ \_VAL3 or SUB $n$ \_VAL4/SUB $n$ \_VAL5 pair is active depends on either:

- The state of the current status pin, PWMx, for that driver
- The state of the odd/even correction bit, IPOL, for that driver

To correct deadtime distortion, software can decrease or increase the value in the appropriate SUB $n$ \_VAL $x$  register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

#### 40.4.2.8.2 Manual Correction

To detect the current status, the voltage on each PWMx pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in the DTx bits in the CTRL1 register. The DTx bits are a timing marker especially indicating when to toggle between PWM value registers. Software can then set the IPOL bit to switch between SUB $n$ \_VAL2/SUB $n$ \_VAL3 and SUB $n$ \_VAL4/SUB $n$ \_VAL5 register pairs according to DTx values.

**Figure 40-23. Current-status Sense Scheme for Deadtime Correction**

Both D flip-flops latch low, DT0 = 0, DT1 = 0, during deadtime periods if current is large and flowing out of the complementary circuit. See the figure above. Both D flip-flops latch the high, DT0 = 1, DT1 = 1, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results will be  $DT0 = 0$  and  $DT1 = 1$ . Thus, the best time to change one PWM value register to another is just before the current zero crossing.

**Figure 40-24. Output Voltage Waveforms**

## 40.4.2.9 Output Logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic in the figure are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program the

POLA and POLB bits before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the PWMxFS fields.

**Figure 40-25. Output Logic Section**

#### 40.4.2.10 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure illustrates the block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8-bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8-bit value that is specified by the user (EDGCMPlx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. this

feature is useful for dividing down high frequency signals for capture processing so that capture interrupts don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt after "n" events have been counted.

**Figure 40-26. Enhanced Capture (E-Capture) Logic**

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by the EDGx1 and EDGx0 bits whose functionality is listed in the figure above. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

### 40.4.2.11 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via the FLVL bits. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of the PWMxFS bits.

The fault decoder disables PWM pins selected by the fault logic and the disable mapping register (DISMAP). See the following figure for an example of the fault disable logic. Each bank of bits in DISMAP control the mapping for a single PWM pin. Refer to following table.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.

**Figure 40-27. Fault decoder for PWMA**

**Table 40-2. Fault Mapping**

| PWM Pin | Controlling Register Bits |
|---------|---------------------------|
| PWMA    | DISA[3:0]                 |
| PWMB    | DISB[3:0]                 |
| PWMX    | DISX[3:0]                 |

#### 40.4.2.11.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with the `FILT_PER` field of the `FFILTx` register. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using the `FILT_CNT` field of the same register. Setting `FILT_PER` to all 0 disables the input filter for a given `FAULTx` pin.

Upon detecting a logic 0 on the filtered `FAULTx` pin (or a logic 1 if `FLVLx` is set), the corresponding `FFPINx` and fault flag, `FFLAGx`, bits are set. The `FFPINx` bit remains set as long as the filtered `FAULTx` pin is zero. Clear `FFLAGx` by writing a logic 1 to `FFLAGx`.

If the `FIEx`, `FAULTx` pin interrupt enable bit is set, the `FFLAGx` flag generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears the `FFLAGx` flag by writing a logic one to the bit
- Software clears the `FIEx` bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the `FAULTx` inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

#### 40.4.2.11.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, `FAUTOx`, configures faults from the `FAULTx` pin for automatic clearing.

When `FAUTOx` is set, disabled PWM pins are enabled when the `FAULTx` pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If `FFULLx` is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle. Clearing the `FFLAGx` flag does not affect disabled PWM pins when `FAUTOx` is set.

Figure 40-28. Automatic Fault Clearing

#### 40.4.2.11.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for manual clearing:

- If the fail safe mode bits, FSAFEx, are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See the following figure. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.
- If the fail safe mode bits, FSAFEx, are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag
  - The filter detects a logic one on the FAULTx pin at the start of the next PWM full or half cycle boundary. See [Figure 40-30](#). If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.

Figure 40-29. Manual Fault Clearing (FSAFE=0)

**Figure 40-30. Manual Fault Clearing (FSAFE=1)**

### Note

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or EXTA and EXT B. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, RUN equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, RUN equals zero. Thus, fault clearing occurs at peripheral cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

#### 40.4.2.11.4 Fault Testing

The FTEST bit is used to simulate a fault condition on each of the fault inputs.

### 40.4.3 PWM Generator Loading

This section describes load enabling, load frequency, the reload flag, reload errors, and initialization of the PWM generator.

#### 40.4.3.1 Load Enable

The LDOK bit enables loading of the following PWM generator parameters:

- The prescaler divisor—from SUB $n$ \_CTRL1[PRSC]
- The PWM period and pulse width—from the SUB $n$ \_INIT and SUB $n$ \_VALx registers

LDOK allows software to finish calculating all of these PWM parameters so they can be synchronously updated.  $SUBn\_CTRL1[PRSC]$ ,  $SUBn\_INIT$  and  $SUBn\_VALx$  are loaded by software into a set of outer buffers. When LDOK is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transferred to the inner set of registers immediately upon setting LDOK if LDMOD is set. Set LDOK by reading it when it is a logic zero and then writing a logic one to it. After loading, LDOK is automatically cleared.

### 40.4.3.2 Load Frequency

The LDFQ bits in the CTRL1 register select an integral loading frequency of one to 16 PWM reload opportunities. The LDFQ bits take effect at every PWM reload opportunity, regardless the state of the LDOK bit. The HALF and FULL bits in the CTRL1 register control reload timing. If FULL is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If HALF is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both HALF and FULL are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

Figure 40-31. Full Cycle Reload Frequency Change

Figure 40-32. Half Cycle Reload Frequency Change

Figure 40-33. Full and Half Cycle Reload Frequency Change

### 40.4.3.3 Reload Flag

At every reload opportunity the PWM Reload Flag (RF) in the FlexPWM\_SUBn\_STS register is set. Setting RF happens even if an actual reload is prevented by the LDOK bit. If the PWM reload interrupt enable bit, RIE is set, the RF flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When RIE is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

Figure 40-34. PWMF Reload Interrupt Request

### 40.4.3.4 Reload Errors

Whenever either SUBn\_VALx or SUBn\_CTRL1[PSRC] is updated, the RUF flag is set to indicate that the data is not coherent. RUF will be cleared by a successful reload which consists of the reload signal while LDOK is set. If RUF is set and LDOK is clear when the reload signal occurs, a reload error has taken place and the REF bit is set. If RUF is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

### 40.4.3.5 Initialization

Initialize all registers and set the LDOK bit before setting the RUN bit.

## Note

Even if LDOK is not set, setting RUN also sets the RF flag. To prevent a CPU interrupt request, clear the RIE bit before setting RUN.

The PWM generator uses the last values loaded if RUN is cleared and then set while LDOK equals zero.

When the RUN bit is cleared:

- The RF flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

## 40.5 Resets

A reset will force all registers to their reset states and tri-state the PWM outputs.

## 40.6 Interrupts

Each of the submodules within the FlexPWM can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

**Table 40-3. Interrupt Summary**

| Core Interrupt  | Interrupt Flag    | Interrupt Enable      | Name                                | Description                      |
|-----------------|-------------------|-----------------------|-------------------------------------|----------------------------------|
| ipi_int_comp0   | CMPF_0            | CMPIE_0               | Submodule 0 compare interrupt       | Compare event has occurred       |
| ipi_int_capt0   | CFX1_0,<br>CFX0_0 | CFX1IE_0,<br>CFX0IE_0 | Submodule 0 input capture interrupt | Input capture event has occurred |
| ipi_int_reload0 | RF_0              | RIE_0                 | Submodule 0 reload interrupt        | Reload event has occurred        |
| ipi_int_comp1   | CMPF_1            | CMPIE_1               | Submodule 1 compare interrupt       | Compare event has occurred       |
| ipi_int_capt1   | CFX1_1,<br>CFX0_1 | CFX1IE_1,<br>CFX0IE_1 | Submodule 1 input capture interrupt | Input capture event has occurred |

*Table continues on the next page...*

**Table 40-3. Interrupt Summary (continued)**

| Core Interrupt  | Interrupt Flag    | Interrupt Enable      | Name                                | Description                       |
|-----------------|-------------------|-----------------------|-------------------------------------|-----------------------------------|
| ipi_int_reload1 | RF_1              | RIE_1                 | Submodule 1 reload interrupt        | Reload event has occurred         |
| ipi_int_comp2   | CMPF_2            | CMPIE_2               | Submodule 2 compare interrupt       | Compare event has occurred        |
| ipi_int_capt2   | CFX1_2,<br>CFX0_2 | CFX1IE_2,<br>CFX0IE_2 | Submodule 2 input capture interrupt | Input capture event has occurred  |
| ipi_int_reload2 | RF_2              | RIE_2                 | Submodule 2 reload interrupt        | Reload event has occurred         |
| ipi_int_comp3   | CMPF_3            | CMPIE_3               | Submodule 3 compare interrupt       | Compare event has occurred        |
| ipi_int_capt3   | CFX1_3,<br>CFX0_3 | CFX1IE_3,<br>CFX0IE_3 | Submodule 3 input capture interrupt | Input capture event has occurred  |
| ipi_int_reload3 | RF_3              | RIE_3                 | Submodule 3 reload interrupt        | Reload event has occurred         |
| ipi_int_rerr    | REF_0             | REIE_0                | Submodule 0 reload error interrupt  | Reload error has occurred         |
|                 | REF_1             | REIE_1                | Submodule 1 reload error interrupt  |                                   |
|                 | REF_2             | REIE_2                | Submodule 2 reload error interrupt  |                                   |
|                 | REF_3             | REIE_3                | Submodule 3 reload error interrupt  |                                   |
| ipi_int_fault   | FFLAG             | FIE                   | Fault input interrupt               | Fault condition has been detected |

## 40.7 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered SUB $n$ \_VALx registers.

**Table 40-4. DMA Summary**

| DMA Request               | DMA Enable | Name                                    | Description                                |
|---------------------------|------------|-----------------------------------------|--------------------------------------------|
| Submodule 0 read request  | CX0DE_0    | Capture FIFO X0 read request            | CVAL0 contains a value to be read          |
|                           | CX1DE_0    | Capture FIFO X1 read request            | CVAL1 contains a value to be read          |
|                           | CAPTDE_0   | Capture FIFO read request source select | Selects source of read DMA request         |
| Submodule 0 write request | VALDE_0    | SUB $n$ _VALx write request             | SUB $n$ _VALx registers need to be updated |
| Submodule 1 read request  | CX0DE_1    | Capture FIFO X0 read request            | CVAL0 contains a value to be read          |

*Table continues on the next page...*

**Table 40-4. DMA Summary (continued)**

| DMA Request               | DMA Enable | Name                                    | Description                                |
|---------------------------|------------|-----------------------------------------|--------------------------------------------|
|                           | CX1DE_1    | Capture FIFO X1 read request            | CVAL1 contains a value to be read          |
|                           | CAPTDE_1   | Capture FIFO read request source select | Selects source of read DMA request         |
| Submodule 1 write request | VALDE_1    | SUB $n$ _VALx write request             | SUB $n$ _VALx registers need to be updated |
| Submodule 2 read request  | CX0DE_2    | Capture FIFO X0 read request            | CVAL0 contains a value to be read          |
|                           | CX1DE_2    | Capture FIFO X1 read request            | CVAL1 contains a value to be read          |
|                           | CAPTDE_2   | Capture FIFO read request source select | Selects source of read DMA request         |
| Submodule 2 write request | VALDE_2    | SUB $n$ _VALx write request             | SUB $n$ _VALx registers need to be updated |
| Submodule 3 read request  | CX0DE_3    | Capture FIFO X0 read request            | CVAL0 contains a value to be read          |
|                           | CX1DE_3    | Capture FIFO X1 read request            | CVAL1 contains a value to be read          |
|                           | CAPTDE_3   | Capture FIFO read request source select | Selects source of read DMA request         |
| Submodule 3 write request | VALDE_3    | SUB $n$ _VALx write request             | SUB $n$ _VALx registers need to be updated |

# Chapter 41

## Cross-Triggering Unit (CTU)

### 41.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

In PWM driven systems it is important to schedule the acquisition of the state variables with respect to the PWM cycle. State variables are obtained through the following peripherals: ADC, position counter (for example, quadrature decoder, resolver, and sine-cos sensor), and PWM duty cycle decoder.

The Cross-Triggering Unit (CTU) is intended to completely avoid CPU involvement in the acquisition of state variables during a control cycle defined by the PWM cycle, the half PWM cycle, or a multiple number of PWM cycles. Several CTU registers are double-buffered, thus allowing coherent update during the transition from one control cycle to the next. Thus double-buffered registers updated at control cycle N will be updated during the transition from control cycle N to control cycle N+1.

The CTU provides four FIFO memory blocks to temporarily store ADC results for CPU access.

## 41.2 Block diagram

**Figure 41-1. CTU block diagram**

## 41.3 CTU overview

The CTU receives several signals from different sources such as PWM, timers, position decoder, and/or external pins. These signals are then processed to generate up to eight trigger events. An input event can be a rising edge, a falling edge, or both edges of the incoming signal. The output can be a pulse, an ADC command, or a stream of consecutive ADC commands for oversampling support. The outputs are targeted to one or more peripherals such as ADCs and timers.

The CTU implements the following features:

- Cross triggering between ADC, PWM timers, on-chip general purpose timers, and external pins
- Double-buffered trigger unit that generates up to 8 triggers
- Trigger generation unit configurable in sequential or triggered modes
- Trigger delay functionality to compensate for the delay of external low pass filters
- Double-buffered ADC command list pointers
- Double-buffered ADC conversion command list
- Each trigger has the capability to generate consecutive conversion commands

- ADC conversion commands allow two ADCs to be controlled synchronously with queue selection to store conversion results
- DMA support

In a typical application, the CTU interfaces with the following peripherals:

- PWM generators for motor control
- Timers
- External signals

The inputs are 16 digital signals. The CTU detects the rising and/or falling edges for each one of them.

[Figure 41-1](#) shows a high level CTU block diagram. The CTU hardware architecture consists of two subunits:

- Trigger generator subunit
- Scheduler subunit

The Trigger generator subunit receives CTU input signals and selects the active edges in order to generate the Master Reload signal. The Master Reload is used to load several CTU double buffered registers. See sections [TGS in triggered mode](#) and [TGS in sequential mode](#) for more details about the Master Reload signal. The Trigger generator subunit also generates up to eight trigger event signals which are used by the Scheduler subunit.

The Scheduler subunit generates the trigger event output according to the trigger event signals from the Trigger generator subunit. The trigger event output starts an ADC conversion or generates output signals to trigger events for IPs in the SoC. See section [Scheduler subunit \(SU\)](#) for more detail about the Scheduler subunit.

### 41.3.1 Interaction with other peripherals

The following figure shows an example of how the CTU interacts with on chip peripherals.

**Figure 41-2. CTU application example: interaction with other peripherals**

### NOTE

For the specific manner in which the CTU interacts with other peripherals on your particular device, see the device configuration details.

## 41.3.2 Modes of operation

The CTU has two main modes of operation:

1. Triggered mode: the input event from the CTU interface is used to generate a sequence of up to 8 triggers to several outputs such as the ADCs, timers, and external triggers. Internal sequencer logic is used to schedule the triggers based upon the input event occurrence.
2. Sequential mode: each input event generates only one trigger for the selected output, such as ADCs, timers, and external triggers.

## 41.4 Signal description

The following table shows the chip-level signals for the CTU module.

**Table 41-1. Signal properties**

| Name    | Function                         |
|---------|----------------------------------|
| EXT_IN  | Input pin for external triggers  |
| EXT_TRG | Output pin for external triggers |

## 41.5 Memory Map and Registers

CTU registers are implemented in two sizes:

- 32-bit registers: byte access for write operations and 32-bit access for read operation
- 16-bit registers: byte access for write operations and 32-bit access for read operations

If a 32-bit write operation is performed over a 16-bit register, the write operation is performed on the 4 aligned bytes. Read operation should be performed only at 32-bit boundary.

### NOTE

Reserved bit registers, when available for write operations, should be written always with logic 0. Read access does not return meaningful data from reserved bit registers. This module does not issue transfer errors when trying to access its reserved locations.

### NOTE

If the system attempts to access an invalid address within the CTU memory map, such as a non-existent register, it does not assert a slave bus error signal to the system. So the user should not rely on such an error when accessing the CTU.

The following tables describe the CTU memory mapped registers.

## CTU memory map

| Address offset (hex) | Register name                                                                  | Width (in bits) | Access | Reset value | Section/ page                |
|----------------------|--------------------------------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 0                    | Trigger Generator Subunit Input Selection Register (CTU_TGSISR)                | 32              | R/W    | 0000_0000h  | <a href="#">41.5.1/1214</a>  |
| 4                    | Trigger Generator Subunit Control Register (CTU_TGSCR)                         | 16              | R/W    | 0000h       | <a href="#">41.5.2/1218</a>  |
| 6                    | Trigger Compare Register (CTU_T0CR)                                            | 16              | R/W    | 0000h       | <a href="#">41.5.3/1219</a>  |

### 41.5.1 Trigger Generator Subunit Input Selection Register (CTU\_TGSISR)

The TGSISR register is double buffered. The load from the corresponding buffer to the register is controlled by the TGSISR\_RE bit in the CTU\_CR register. The TGSISR\_RE bit is self negated. Once set, this bit remains set until the TGSISR register is updated from the corresponding buffer register. Reads to the TGSISR register actually return the content of the buffer and not the content of the register. Thus, a read will return the most recent data written to the register address even though the buffer data is not synchronized with the register data.

**NOTE**

For the particular input connection assigned to each field in this register, see the CTU's chip-specific configuration details.

Address: 0h base + 0h offset = 0h

| 27–31<br>T4_INDEX | Trigger 4 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23. |

## 41.5.8 Trigger Handler Control Register 1 (CTU\_THCR1)

The THCR1 register is double buffered. The update from the corresponding buffer register is controlled by the MRS signal. The THCR1 and THCR2 registers are together organized into 8 groups of 7 enable bits. Each group is associated with one trigger from the Trigger subunit. Each group of enable bits has 7 enables corresponding to a master trigger enable, External Trigger output enable, 4 eTimer outputs, and the ADC command list enable, respectively. If the master trigger enable  $Tn\_E$  is cleared, the trigger is disabled and the other trigger enable bits in the group have no effect.

Address: 0h base + 24h offset = 24h

|       |   |      |        |        |        |        |        |         |   |      |        |        |        |        |        |         |

### 41.5.9 Trigger Handler Control Register 2 (CTU\_THCR2)

The THCR2 register is double buffered. The update from the corresponding buffer register is controlled by the MRS signal. The THCR1 and THCR2 registers are together organized into 8 groups of 7 enable bits. Each group is associated with one trigger from the Trigger subunit. Each group of enable bits has 7 enables corresponding to a master trigger enable, External Trigger output enable, 4 eTimer outputs, and the ADC command list enable, respectively. If the master trigger enable Tn\_E is cleared, the trigger is disabled and the other trigger enable bits in the group have no effect.

Address: 0h base + 28h offset = 28h

**41.5.10 Commands List Register A for ADC single-conversion mode commands (CTU\_CLR\_A\_n)**

The Command List Register (CLR\_x\_n), where n = 1,.....,24, has one of three formats (CLR\_A\_n, CLR\_B\_n, CLR\_C\_n) depending on the setting of its CMS and ST0 bits. If CMS=0 and ST0=0, the single conversion mode is selected and the CLR register assumes the CLR\_A\_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where i=0d to 23d

|       |     |    |     |      |   |   |     |   |   |   |    |    |    |    |    |    |

**41.5.11 Command List Register B for ADC dual-conversion mode commands (CTU\_CLR\_B\_n)**

The Command List Register (CLR\_x\_n), where  $n = 1, \dots, 24$ , has one of three formats (CLR\_A\_n, CLR\_B\_n, CLR\_C\_n) depending on the setting of its CMS and ST0 bits. If CMS=1 and ST0=0, the dual conversion mode is selected and the CLR register assumes the CLR\_B\_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where  $i=0d$  to 23d

|       |     |    |     |      |   |   |     |      |   |   |    |    |      |    |    |    |

## 41.5.12 Command List Register C for self-test commands (CTU\_CLR\_C\_n)

The Command List Register (CLR\_x\_n), where  $n = 1, \dots, 24$ , has one of three formats (CLR\_A\_n, CLR\_B\_n, CLR\_C\_n) depending on the setting of its ST0 bit. You must first set ST0 to 1 to set the CLR register in the self-test mode register format. In this case, the CLR register assumes the CLR\_C\_n format described in the following figure.

Address: 0h base + 2Ch offset +  $(2d \times i)$ , where  $i=0d$  to 23d

|       |     |       |     |        |       |    |     |     |

**41.5.13 FIFO DMA Control Register (CTU\_FDCR)**

The FDCR register enables the DMA requests issued by the CTU FIFOs. The DMA request occurs when it is enabled and the corresponding FIFO had reached a threshold defined in register FTH.

**NOTE**

Interrupt and DMA are controlled independently, thus FIFO DMA operation and interrupts can be enabled at the same time.

**41.5.14 FIFO Control Register (CTU\_FCR)**

This register implements interrupt enable bits to signal FIFO behavior. FIFO overrun, overflow, empty, and full indication from one of the FIFOs are OR-ed together to indicate through one interrupt line that one or more flags are active. After receiving an interrupt the FST register should be checked to evaluate what caused that interrupt. There is one interrupt line per FIFO module.

Address: 0h base + 70h offset = 70h

**41.5.15 FIFO Threshold Register (CTU\_FTH)**

This register defines the threshold value for four FIFO modules. The threshold is used for comparison against the FIFO pointer and to evaluate if an overflow condition occurred for that FIFO. The overflow flag indicates that a certain amount of data, defined by the threshold value, is available in the FIFO for read. The overflow condition is set if the number of elements in the FIFO is greater than the threshold value. Thus, out of reset this register is set to detect one element in the respective FIFO since the initial value is zero.

**NOTE**

The threshold value should not exceed the FIFO size

Address: 0h base + 74h offset = 74h

| 16–23<br>TH1 | FIFO 1 Threshold. |
| 24–31<br>TH0 | FIFO 0 Threshold. |

41.5.16 FIFO Status Register (CTU\_FST)

This register has the flags that indicate the status of the FIFO modules. Up to four FIFOs are supported. FIFO overrun, overflow, empty, and full flags are available. If enabled by the FCR register bits, these flags can generate an interrupt to the CPU. There is one interrupt signal per FIFO which combines overrun, overflow, empty, and full flags.

NOTE

The only actual error indication corresponds to the overrun flags which stay asserted once the overrun condition occurs. They are cleared by writing 1 to the respective flag. The overflow, empty, and full flags correspond to the current state of the FIFOs.

NOTE

Bits OR3, OR2, OR1, and OR0 can be read and cleared by software

### 41.5.19 Error Flag Register (CTU\_EFR)

The EFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

#### NOTE

The ERRCMP field reads 0 at reset. When reset is released, this field remains cleared until the CTU timer clock is enabled.

After the CTU timer clock is enabled, ERRCMP reads 1. This field must be cleared before enabling the interrupt requests.

Address: 0h base + C0h offset = C0h

#### CTU\_EFR field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–1<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                      |
| 2<br>LIST_BE    | List Busy Error. Indicates that a list of commands is trying to send commands to a busy ADC or to the same ADC at the same time. It also indicates a conflict in the self-test algorithm execution by the ADCs, see Self-Test Execution Errors section. Cleared if 1 is written to this bit location.<br><br>0 No error<br>1 Error                                                                                                                           |
| 3<br>CS         | Self test Counter Status. This bit indicates if a self-test algorithm is in progress. If 1 is written to this bit, a reset to the self test counter will occur, thus terminating the self-test algorithm execution. As a status bit it indicates:<br><br>0 All the counters are at reset value, thus none of the self-test algorithm are executing<br>1 One of the counters used in self test mode is not in the reset state, thus self-test is in progress. |
| 4<br>ET_OE      | External Trigger generation Overrun Error. This bit is set when an external trigger occurs while a trigger input is being processed by the TGS. It is cleared if 1 is written to this bit location.<br><br>0 No error<br>1 Error                                                                                                                                                                                                                             |
| 5<br>ERRCMP     | Error Compare. When a match occurs, the TGS Counter has reached the TGSCCR value. Cleared if 1 is written to this bit location.                                                                                                                                                                                                                                                                                                                              |

| Field        | Description                                                                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15<br>MRS_RE | Master Reload Signal Reload Error. If an MRS occurs while the user is updating a double-buffered register, the MRS_RE is set indicating an error condition. Cleared if 1 is written to this bit location.<br><br>0 No error<br>1 Error |

## 41.5.20 Interrupt Flag Register (CTU\_IFR)

The IFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

**NOTE**

The Tn\_I fields read 0 at reset. When reset is released, these fields remain cleared until the CTU timer clock is enabled. After the CTU timer clock is enabled, the Tn\_I fields read 1. These flags must be cleared before enabling the interrupt requests.

Address: 0h base + C2h offset = C2h

| 8–15<br>COTGT   | Control ON-Time and Guard Time for external trigger. See <a href="#">Scheduler subunit (SU)</a> for a more detailed description. |

### 41.5.23 Control Register (CTU\_CR)

#### NOTE

The CTU\_ADC\_R bit resets all lists in execution. If CTU list execution is in parallel mode, this bit resets both lists even if they issued commands to different ADCs. Also, the self-test algorithm counters go to reset state.

#### NOTE

Bits Tn\_SG, CTU\_ADC\_R, CGRE, and MRS\_SG can be set by software. Bits CTU\_ODIS, DFE, GRE, and TGSISR\_RE can be read and set by software.

Address: 0h base + C8h offset = C8h

| Bit   | 0     | 1     | 2     | 3     | 4     | 5     | 6     | 7     |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Read  |       |       |       |       |       |       |       |       |
| Write | T7_SG | T6_SG | T5_SG | T4_SG | T3_SG | T2_SG | T1_SG | T0_SG |
| Reset | 0     | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

41.5.25 Expected Value A Register (CTU\_EXPAR)

The EXPAR register has the expected number of system clock cycles (the slave bus clock) for an AD conversion to be completed by the ADC connected to Port A. If SAF\_CNT\_A\_EN is set in the IR register and a conversion takes a number of cycles out of the interval defined by EXPA and CNTRNG to complete, then the SERR\_A error bit is set in the IFR register. Please see the CNTRNGR for more details.

41.5.26 Expected Value B Register (CTU\_EXPBR)

The EXPBR register has the expected number of system clock cycles (the slave bus clock) for an AD conversion to be completed by the ADC connected to Port B. If SAF\_CNT\_B\_EN is set in the IR register and a conversion takes a number of cycles out of the interval defined by EXPB and CNTRNG to complete, then the SERR\_B error bit is set in the IFR register. Please see the CNTRNGR for more details.

### 41.5.27 Counter Range Register (CTU\_CNTRNGR)

The CNTRNGR register provides a way to mask out the less significant bits in the EXP\_A and EXP\_B fields of EXPAR and EXPBR registers, respectively. If set, bits in CNTRNG mask out related bits in EXP\_A and EXP\_B fields, thus providing a range in which a conversion should occur. The expression used for the conversion range check is: set SERR\_A bit if (conversion counter & ~CNTRNG > EXP\_A & ~CNTRNG) or (conversion counter & ~CNTRNG < EXP\_A & ~CNTRNG), where the conversion counter increments at system clock rate (slave bus clock rate). This equation also applies to SERR\_B and EXP\_B.

#### NOTE

The 1s in the CNTRNG must be set from the right to the left (less significant bits) without gap with 0.

#### NOTE

The safety counter allowed range is obtained by taking the EXP\_A/B value and exchanging to "X" the corresponding positions where the CNTRNG bit is 1.

|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 8–15<br>CNTRNG  | If set, the bits in this field mask out the equivalent bits of the expected values EXP_A and EXP_B. In this way, a range of system clock (slave bus clock) cycles is defined for a conversion to occur. This means the bit positions with 1s in the CNTRNG change the corresponding bits on EXP_A/EXP_B and safety counters A/B to "X". For example, with EXP_A = 1b0010_1101 and CNTRNG = 0b0111, the safety counter can end with values of the format 0b0010_1XXX to avoid SERR_A error flag. |

## 41.6 Functional description

The CTU is comprised by two subunits: the Trigger Generator subunit, or TGS, and the Scheduler subunit, or SU. The TGS is responsible for generating triggers based on the module input signals connected to timer modules. The trigger signal from TGS is then connected to the scheduler subunit, which is responsible for the generation of ADC commands or triggers to on-chip logic such as timers. The following sections describe the TGS and SU in more detail.

### 41.6.1 Trigger Generator subunit (TGS)

The Trigger Generator subunit, TGS, generates up to eight trigger events. The main sub-blocks in the TGS are:

- Counter: generates sequential trigger events
- Trigger List: with 8 x 16-bit double-buffered registers for timing comparison

The TGS has two modes of operation:

- **Triggered mode:** each event source generates up to eight trigger event outputs.
- **Sequential mode:** each event source generates only one trigger event output.

## Note

An *event* means a pulse generated from the selected CTU trigger inputs. It is represented in Figure 41-5 by the ES signal (event signal).

External signals, represented by EXT\_IN in Figure 41-5, may be asynchronous related to the CTU clock. For this reason the external trigger inputs are filtered by a CTU programmable digital filter. The external signal is considered at 1 if it is stable at 1 during FILTER\_N CTU clock cycles and it is considered to be at 0 if it is stable at 0 during FILTER\_N CTU clock cycles, where FILTER\_N is defined in the digital filter register (DFR).

Trigger events can be initiated by hardware or by software. A software trigger is generated by writing to the CTU Control Register, CR. The CR register Tx\_SG bits are automatically cleared by the CTU hardware when the respective trigger event is generated.

### 41.6.2 TGS in triggered mode

Figure 41-3 shows the TGS configuration in Triggered mode.

Figure 41-3. Trigger Generator subunit in triggered mode

## Note

The CTU clock should be connected to the same clock source used by the CTU inputs clock. In [Figure 41-3](#) these inputs are from the PWM generator, eTimers, and EXT\_IN.

The TGS has 16 input signals selected from the input selection register (TGSISR). The available selections are:

- Inactive, no selection
- Rising edge
- Falling edge
- Both edges

Up to 32 input events corresponding to 16 input signals are selected through the TGSISR register and OR-ed in order to generate the Master Reload Signal (MRS), which defines a *control cycle*.

The MRS can also be generated by software. The software operation is done by writing to the MRS\_SG bit in the CTU Control Register. The MRS\_SG bit is self cleared; thus, it reads always as 0. The MRS is used to re-load the TGS Counter Register with the values from the double-buffered TGSCRR register. The MRS is also used to re-load all double-buffered registers, such as the trigger compare registers, TGSCR and TGSCRR, with the corresponding buffered values.

The triggers list registers consist of 8 compare registers (T0CR through T7CR). Each register is associated with a comparator, where a match generates an output trigger. On the occurrence of a re-load triggered by MRS, the comparison for trigger events generation starts from the first cycle of counting. However, the comparison with the TGS Counter Compare Register (TGSCCR) is always disabled during one TGS clock cycle and then re-enabled. A match between TGSCCR and the TGS counter stops the TGS counter. Therefore, this one cycle disable allows the user to configure the TGSCCR and TGSCRR with the same value.

The prescaler for TGS and SU is defined by the PRES bits in the TGS Control Register and divides the CTU clock. The available selections for the prescaler values are 1, 2, 3, and 4.

[Figure 41-4](#) shows a timing diagram for the TGS operation in triggered mode. The MRS and the trigger event occurrences are indicated along with the delay relative to the MRS occurrence.

**Figure 41-4. Example timing diagram for TGS in triggered mode**

### 41.6.3 TGS in sequential mode

Figure 41-5 shows the blocks and signals related to the TGS in sequential mode.

In sequential mode only one of the 32 input signals is selected by the 5-bit MRS\_SM (master reload selection). The selected signal re-loads the trigger list and resets the 3-bit ES counter which selects the trigger event. Sequences of up to eight trigger events are generated in one control cycle.

The 32 input events corresponding to 16 input signals with 2 edges detection per signal are individually enabled through the register TGSISR and OR-ed in order to generate the event signal ES. The ES signal is used to re-load the TGS counter register and to increment the 3-bit ES counter.

Figure 41-6 is a timing diagram for TGS in sequential mode showing the MRS and ES. The trigger events are indicated with the delay with respect to the ES. Note that initially ES and MRS are aligned. The TGS counter is re-loaded on each ES and starts counting up until the next ES or until it matches the value in TGSCCR register and stops.

## 41.6.4 TGS counter

The TGS counter counts from negative to positive values as defined by the re-load and stop values defined in register TGSCRR and TGSCCR, respectively. The maximum counter value is 0x7FFF; after that, a counter wrap occurs and the counter value transitions from 0x7FFF to 0x8000. The following figure shows TGS counting examples.

TGS starts from TGSCRR and is reloaded before reaching TGSCCR

TGS starts from TGSCRR up to TGSCCR and is reloaded at MRS

TGS starts from TGSCRR and is reloaded at MRS, note that TGSCRR=TGSCCR

TGS starts from TGSCRR and wraps to 0x8000 and then stops at TGSCC

**Figure 41-7. TGS counter behavior**

### Note

The TGS counter starts counting after an MRS and only stops if a counter wrap occurs and TGSCCR value is reached before the next MRS occurs.

### 41.6.5 Scheduler subunit (SU)

The following figure shows the block diagram of the Scheduler subunit. The SU trigger event outputs are:

1. ADC command or ADC stream of commands
2. eTimer1 pulse
3. eTimer2 pulse
4. External trigger pulse

**Figure 41-8. Scheduler subunit**

The SU receives 8 trigger signals from the Trigger Generator subunit, TGS, and starts a command list to the selected ADC or generates the trigger event outputs. This module has the same functionality in both TGS modes: triggered and sequential. Each of the 4 SU outputs can be linked to any of the 8 trigger events from TGS. This is implemented by the Trigger Handler block. Each trigger event can be linked to one or more SU outputs.

If two events are linked at the same time to the same output (either ADC commands or output triggers) an error is generated and flagged in the EFR register's TnOE bits. In this case, only the trigger with the lowest index is used. For example, if trigger 0 and trigger 1 are linked to the same ADC output and they occur at the same time, an error is generated and the ADC command corresponding to trigger 0 is generated.

When a trigger is linked to an ADC, an associated ADC stream of commands is generated. The ADC Commands List Control Register CLCR1/2 defines the list entry point that is the first command to be executed. Subsequent list pointers are generated in an incremental way as the commands in the list are executed. When a trigger is linked to an eTimer or an EXT\_TRG shown in the above figure, an event is generated on the corresponding output. The external trigger output has two modes of operation configured by TGSCR register bit ET\_M:

- Pulse mode: a pulse with one system clock width is generated at the output pin
- Toggle mode: the output pin toggles its state as a result of each trigger event

An *ON-Time* and *Guard-Time* are defined for both Pulse and Toggle modes. The COTR register, Control *On-Time* Register, defines the (*ON-Time* + *Guard-Time*) duration. After a trigger has occurred a new trigger will be generated only after (*ON-time* + *Guard-Time*). The COTR register only applies to external triggers; it does not affect ADC commands.

## 41.6.6 ADC commands list

The SU implements a command list that stores the ADC commands. The command list stores up to 24 x 16-bit commands (see [ADC command list format](#)) in a double-buffered implementation. The command list buffer registers may be updated at any time between two consecutive MRS, but the changes are transferred from the buffers to the actual registers only after an MRS occurs, so a correct reload procedure is performed (see [Reload mechanism](#)). The first command in a list is pointed by the 5-bit CLCRx register. Once a command list is triggered, it executes until the last command is found. The last command (n) is defined by the LC bit of the next command (n+1) in the list. Note that the command with LC=1 does not belong to the list and thus it is not executed. Note also that the LC bit is ignored in the first command of a list. See the command list registers, CLR\_A\_n, CLR\_B\_n, or CLR\_C\_n, where n = 1,...,24. The figure below describes the state diagram for the Commands List execution. A sequence of commands on the list is executed until the last command is found. See [ADC command list format](#) for more details.

**Figure 41-9. ADC command list scanning state diagram**

### Note

The CTU reads the next command line (the LC bit) to determine if the present command is the last one to be executed.

## 41.6.7 ADC command list format

The ADC command can be configured for single or dual conversion. In single conversion mode, the command targets one ADC only. In dual conversion mode, the conversion command is sent to both ADCs at the same time. Due to the clock domain crossing between CTU and ADCs, there could be a misalignment of up to one ADC clock cycle between the two commands.

The result of each conversion, in both modes, is stored in one of the four available FIFOs. In dual conversion mode, both ADCs store the result of their conversion in the same FIFO. If both ADCs access the FIFO in the same clock cycle, ADC unit A has higher priority, otherwise the first available conversion result is stored first.

The CTU supports up to 32 channels for both ADCs. The same physical channel cannot be assigned for both ADCs in a dual conversion mode. If there is an attempt to do so, an error is flagged in the EFR register's ICE bit, but the CTU sends the command to both ADCs.

In general, an ADC command is composed by the following fields depending upon the conversion format used (see [Commands List Register A for ADC single-conversion mode commands \(CTU\\_CLR\\_A\\_n\)](#)):

- Channel A: ADC A channel number (4 bits)
- Channel B: ADC B channel number (4 bits)
- Target ADC selection: ADC A or ADC B used in single conversion mode only (1 bit)
- FIFO selection bits for the selected ADC unit: up to four FIFOs (2 bits)
- Conversion mode selection: single or dual conversion mode (1 bit)
- Last command (LC): defines the last command in a list (1 bit)
- Interrupt request: enable interrupt request on command execution (1 bit)

The first command of a list is indicated by the CLCR1/2 registers' Tx\_INDEX field. The last command is indicated by the LC (Last Command bit) of the following command in the command list. The first command is always executed. The execution of the following commands is controlled by the LC bit.

The figure below describes several scenarios for the command sequencing. If the first command indicated by the CLCR1/2 register is one of the lines identified as "Last command," then the list is a single command list. Note also that the list pointer wraps back to the first command in the list after command 24 is executed and if it is not the last command. If no command is defined as the last command, then the list will be executed continuously in a loop of 24 commands.

- Command List A: two command queues are available with elements 4 and 24 being last commands
- Command List B: sub-list 1 with one single command at address 1, and sub-list 2 with a queue of commands with last command at address 24
- Command List C: sub-list 2 with one single command at address 24, and sub-list 1 with a command queue with last command at address 23
- Command List D: two command queues with a wrap at address 24

**Figure 41-10. Command list sequencing**

### Note

The addresses shown in the above figure do not represent addresses in the memory map. Please refer to the Memory Map section to check for the actual addresses.

## 41.6.8 ADC command list operation modes

There are two modes of operation regarding the ADC command list execution: **streaming** mode and **parallel** mode. In streaming mode, the command lists should behave as a stream of commands, meaning that two or more lists cannot be executed at the same time, but only in a sequence. Thus if list 1 is triggered, it should finish the execution of its last command before list 2 can be triggered. If there is an attempt to trigger more than one list at the same time, then an error occurs.

In parallel mode, up to two lists can be executed at the same time. In order to avoid errors during the execution of two parallel lists, they should not have commands for both ADCs. Therefore, if list 1 has commands for ADC A, then list 2 should only have commands for ADC B. Note also that if a shared analog input is used by one of the lists, it should not be used by the other list in order to avoid a contention and therefore an error. ADC dual conversion commands should also not be used in parallel mode.

Figure 41-11 shows the execution of two lists in streaming mode. While a list is being executed, any attempt to trigger the execution of another list while in this mode will cause an error. Note that both lists may have commands for ADC A or B with no restriction. Also, dual commands may be used.

## Functional description

**Figure 41-11. List execution in Streaming Mode**

Figure 41-12 shows the execution of two lists in parallel mode. There are no restrictions for the triggers of both lists. After the two lists are triggered, no other triggers are allowed. If there is an attempt to trigger a third list while lists 1 and 2 are executing, then an error will be issued by setting ADC\_OE bit in EFR register. Note that list 1 only has commands for ADC A and list 2 only has commands for ADC B. Having ADC A and ADC B commands in the same list may cause an error since two commands for the same ADC could be executed from different lists at the same time.

### Note

The mixing of commands for both ADCs in the same list in parallel mode must not be used since the correct execution of commands in this case is not guaranteed by the CTU hardware.

**Figure 41-12. List execution in parallel mode**

The list mode is controlled by the PAR\_LIST bit in the LISTCSR register.

### 41.6.9 ADC results FIFOs

ADC results are stored in one of the four FIFOs. The FIFOs allow the storage of ADC results according to the type of data acquisition (phase currents, rotor position, ground-noise, and so on) so the software can distinguish data from several ADC channels. Each FIFO has its own interrupt line, DMA request signal, and a status register. The target FIFO for a conversion result is specified in the ADC command. Each FIFO element is 32 bits wide. The following figure shows the FIFO selection for ADC A and ADC B results.

**Figure 41-13. FIFO selection for ADC results storage**

The CTU FIFOs are fixed depth. For example:

- FIFO0 and FIFO1: 16 entries each, dimensioned for full PWM period current acquisitions
- FIFO2 and FIFO3: 4 entries each, dimensioned for low rate acquisitions

FIFO access can be done by 16-bit or 32-bit read transaction. In 32-bit reads the conversion result, the target ADC, and the channel number are accessed. 8-bit access must not be used; otherwise, the FIFO pointer increments and the complete data is not retrieved. The FIFO result register can be read in a right- or left-aligned format using two different addresses:

- Unsigned right-justified, read from register FLx (for FIFO x)  
(Conversion result is unsigned right-justified data, i.e. bits [11:0] are used for 12-bit resolution and bits [15:12] always return zero)
- Signed left-justified, read from register FLx (for FIFO x)

(Conversion result is signed left-justified data, i.e. bit [15] is reserved for sign and is always read as zero, bits [14:3] are used for 12-bit resolution and bits [2:0] always return zero)

The FIFO access should be based on the status bits in the FCR register. Empty and full indication are provided. If data is read from an empty FIFO, then the read data should not be considered as valid data. Note that there is no indication of an underflow condition. If the FIFO is full and there is an attempt to write more data, then the new data is not written to the FIFO and an overrun flag is set.

### 41.6.10 Reload mechanism

In order to assure coherent programming, several CTU registers are double-buffered, thus allowing the programming of new data on the buffers while not affecting data being used. All registers are uploaded with buffer data at the same time. For the majority of the CTU registers the re-load is controlled by the Master Reload Signal, MRS.

Since the Master Reload Signal is generated by the hardware, it may occur while the software is still updating the buffer registers. In this case, noncoherent values are written to the registers because the CPU did not finish the programming of all registers. In order to avoid this situation, a General Reload Enable, GRE, control bit is provided. If GRE is cleared then no reload occurs. If this bit is set, then the reload is done when MRS occurs. The GRE bit is automatically cleared by MRS or is cleared by software using the CGRE bit in the same register. The CGRE bit is self-cleared and thus always read as zero.

The software should be able to program all registers buffers within a control cycle. In order to help the software to evaluate that a flawless register programming was executed, the MRS\_RE flag is provided in the EFR register. If cleared, this flag indicates that all register buffers were programmed before MRS occurred, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programming cycle has initiated.
- Set GRE to indicate that all updates to the buffer registers were performed.
- The reload of all registers is executed when the MRS occurs. Since GRE is set then MRS\_RE will not be set.
- GRE and FGRE are cleared when MRS occurs.

See [Figure 41-14](#) for more details.

An error is flagged by MRS\_RE when MRS occurs, GRE is cleared, and FGRE is set. This scenario indicates that the software has initiated a register programming but has not finished it before the MRS, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programming cycle has initiated.
- MRS occurs and GRE is not set. In this case MRS\_RE is set and, if enabled, an interrupt is generated.
- FGRE is not cleared when MRS occurs and no register is updated, since GRE is cleared.

Note that the software does not need to update all double-buffered registers during a *control cycle*. In order to avoid the error indication it is sufficient to set GRE before a MRS occurs.

A race condition occurs when GRE is being cleared by CGRE at the same time that an MRS occurs. In this case, GRE is considered to be cleared and no reload occurs. Another race condition may occur between CGRE and GRE being set. Since these two bits are in the same register they could eventually be set at the same time. In this case, CGRE has precedence; thus, GRE is cleared.

### Note

MRS has priority over the TGSISR\_RE bit in the CR register, which is the re-synchronization bit of the TGSISR.

The following figure describes two scenarios for the register re-load. Scenario (a) is a normal re-load where the buffers of the double-buffered registers are programmed and the GRE bit is set before the next MRS occurs. The scenario presented in (b) describes an error condition where the software did not signal the hardware that all registers are ready for re-load before the next MRS. This is indicated by GRE being at zero when MRS occurs. In this case, MRS\_RE flag is set indicating the fault condition.

**Figure 41-14. Reload scenarios**

## 41.7 Interrupts and DMA Requests

### 41.7.1 DMA support

The DMA interface can be used to configure the CTU registers. A DMA request is issued if MRS occurs and the GRE bit is set. In this case, the previously transferred data is loaded from the buffers into the registers and a new transfer cycle is initiated with the DMA request. The DMA done signal from the DMA controller is used to set GRE bit which allows the reload to be performed. The following figure describes this operation.

**Figure 41-15. Register reload using DMA**

DMA support can also be provided for reading FIFO stored data. Each FIFO can be configured to perform a DMA request when the number of stored words reaches a threshold value defined in the FTH register. See the FIFO Threshold, FTH, register for more information. After a DMA\_DONE and the remaining data in the FIFO is below the watermark, then the DMA request is removed. Thus for an efficient operation, the DMA should be configured to execute a loop reading all data in the FIFO considering the amount of data the same as defined by the watermark.

### 41.7.2 CTU faults and errors

The CTU detects and signals the following error conditions:

- MRS reload error: MRS occurs while user is updating the double-buffered registers.
- Sequential mode trigger overrun SM\_TO: more than 8 event signals occur before the next MRS in TGS sequential mode.

- Trigger event overrun indicated by 4 interrupt signals ADC\_OE, T0\_OE, T1\_OE and ET\_OE: a trigger event occurs during the time frame when the previous trigger was not completed.
- The CTU allows the user to pre-set a trigger to the eTimer1 in the middle of an ADC conversion. In parallel mode even two ADCs' commands can be issued at the same time. The error only occurs if the second trigger is targeting the same ADC.
- Invalid (unrecognized) ADC command occurs and the ICE bit is set.
- Master reload signal overrun MRS\_O: MRS occurs before all triggers selected by (Tn\_E and (TnETE or TnTmE or Tn\_ADCE)) bits in THCR1/2 registers have occurred.
- TGS\_OSM TGS overrun in sequential mode: a new event occurs before the trigger event selected by the previous event had occurred.

The faults/errors flags in the CTU error flag register and in the CTU interrupt flag register can be cleared by writing 1 to the respective bit. Writing 0 to these bits has no effect.

### Note

The CTU does not support write-protection mechanism for any register, meaning that all registers are accessible at any time.

The CTU does not generate a transfer error when its reserved address space is accessed.

#### 41.7.2.1 CTU parallel list errors

The command list operation in parallel mode may generate errors since two lists may be in execution at the same time. Below some error conditions are described.

Commands for the same ADC are issued at the same time by two lists. In this case:

- One of the commands is disregarded and an error is issued.
- The LIST\_BE bit in the EFR register is set.
- The address of the list commands are shown in the LISTCSR register.
- The address of the command that was not executed is indicated in the LISTCSR register.

A third list is triggered when two lists are already being executed. In this case:

- The third list is not executed and an error is indicated by the ADC\_OE bit in the EFR register.

One list is being executed and a second list is triggered; the first command of the second list is for the same ADC being used by the first list. In this case:

- The command of the second list is not executed.
- The address of the second list command is shown in the LISTCSR register.
- The LIST\_BE bit in the EFR register is set.

### 41.7.3 CTU interrupt/DMA requests

The CTU generates the following interrupt/DMA requests which are controlled by the IR register:

- Error interrupt request, see [CTU faults and errors](#) (1 interrupt line)
- ADC command interrupt request (1 interrupt line).
- MRS interrupt request (1 interrupt line)
- Trigger event interrupt request (1 interrupt line for each trigger event)
- FIFOs interrupt and/or DMA transfer request (1 interrupt line for each FIFO). See FIFO control register, FCR.
- DMA transfer request on the MRS occurrence if GRE bit is set

## 41.8 Self test mode

The CTU is capable of issuing a self test command to the ADC.

The CLR<sub>x</sub> register is used to set up a self test command. [Table 41-2](#) describes the ST0 and ST1 bits that control self-test functionality.

**Table 41-2. Self-test command**

| ST_CMS bit | ST1 bit  | ST0 bit | Command description            |
|------------|----------|---------|--------------------------------|
| 0          | Not Used | 0       | no self test single conversion |
| 1          | Not Used | 0       | no self test dual conversion   |
| Not Used   | 0        | 1       | self test command              |

*Table continues on the next page...*

**Table 41-2. Self-test command (continued)**

| ST_CMS bit | ST1 bit | ST0 bit | Command description                    |
|------------|---------|---------|----------------------------------------|
| 0          | 1       | 1       | no self test command single conversion |
| 1          | 1       | 1       | no self test command dual conversion   |

Two algorithms are available in self test mode, see [Table 41-3](#).

**Table 41-3. Self-test algorithm selection**

| ALG <sup>1</sup> | Number of steps | Executed Algorithm     |
|------------------|-----------------|------------------------|
| 00               | 3               | Algorithm S            |
| 01 <sup>2</sup>  | –               | Reserved               |
| 10               | 12              | Algorithm C            |
| 11               | 15              | Algorithm FULL (S + C) |

1. ALG refers to the CLR<sub>x</sub> register field.

2. The 01 selection causes a command execution error and the LIST\_BE flag is set in the Error Flag Register (EFR).

The self-test S algorithm is executed in an atomic burst of conversions independent of the BSIZE value in the CLR<sub>x</sub> register. Below are described the steps for this algorithm execution.

- Step 0: VBGAP/VREF test
- Step 1: VDD/VREF test
- Step 2: VREF/VREF test

When the FULL algorithm is selected, the CTU executes the S algorithm followed by the C algorithm.

The self-test execution follows the trigger scheme selected for the CTU, either triggered mode or sequential mode can be selected.

In order to completely execute one of the algorithms described in [Table 41-3](#) a certain number of steps need to be performed. Each step corresponds to the time for one ADC conversion to complete. These steps may be executed at once, by just one command, or they can be interleaved with other ADC commands. In order to executed self-test commands interleaved with other conversion commands it is sufficient to set the BSIZE field in the CLR<sub>x</sub> register for a value lower than the number of steps defined for the selected algorithm. The following figure shows the execution of the C algorithm interleaved with regular ADC commands.

**Figure 41-16. C Algorithm execution interleaved with others ADC commands**

In the figure above, the last C self-test sequence intentionally shows BSIZE set to a larger value than the remaining steps needed to complete the C algorithm. In this case, the number of executed self-test steps does not follow BSIZE but instead it follows the number of remaining steps for the selected self-test algorithm, which in this case is 3 steps.

### Note

The S algorithm steps do not interleave with other ADC commands even if BSIZE is smaller than 3. Independent of BSIZE value all the 3 steps of the S algorithm are executed in a contiguous sequence.

The number of steps needed to completely execute the selected self-test algorithm is as follows:

- S algorithm requires 3 steps
- C algorithm requires 12 steps
- FULL runs all algorithm and requires 15 steps

In the figure below, the FULL algorithm is executed interleaved with other ADC commands. The BSIZE = 3 in the first and second self-test commands produces different number of executed self-test steps.

**Figure 41-17. FULL algorithm execution interleaved with other ADC commands**

### 41.8.1 Self-test execution errors

When a self-test algorithm is initiated for an ADC, it should complete before any other self-test algorithm is started in the same ADC. In other words, one self-test algorithm should not be interleaved with another self-test algorithm. Any attempt to do so will cause the ongoing list execution to be halted and cause the LIST\_BE error flag (see [LIST\\_BE](#)) to be set. In order to evaluate if a self-test algorithm is running, the CS bit (see [CS](#)) can be checked. If set, this bit indicates a self-test has initiated in one of the ADCs. If a self-test algorithm conflict occurs, as described, the recovery procedure is to issue a software reset through the CTU\_ADC\_R bit in the CR register.

An error condition (see [LIST\\_BE](#)) is also caused when the reserved value 01 is selected for the self-test algorithm.

## 41.9 Power saving modes

In order to reduce power consumption, a STOP mode is provided.

### 41.9.1 STOP mode

The STOP signal is an input to the CTU that disables the clocks for all registers including memory mapped registers. Thus, writes have no effect and reads do not return valid data after STOP mode is entered.

The CTU enters STOP mode immediately after STOP signal is asserted, thus in order to avoid wrong module operation some housekeeping should be performed prior to entering low power mode:

- The triggers should be disabled thus no pending ADC commands exist.
- The CTU output need also be disabled through the CTU\_ODIS bit.
- The FIFOs should be empty with no pending data conversion for read.

# Chapter 42

## System Timer Module (STM)

### 42.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section provides an overview, list of features, and modes of operation for the STM.

#### 42.1.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the system clock divided by an 8-bit prescale value (1 to 256).

#### 42.1.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

### 42.1.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM\_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

## 42.2 External signal description

The STM does not have any external interface signals.

## 42.3 Memory map and registers

The STM programming model includes a group of 32-bit registers—a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

**STM memory map**

| Address offset (hex) | Register name                             | Width (in bits) | Access | Reset value | Section/page                |
|----------------------|-------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | STM Control Register (STM_CR)             | 32              | R/W    | 0000_0000h  | <a href="#">42.3.1/1275</a> |

STM\_CMPn field descriptions (continued)

| Field | Description |
|-------|-------------|
|-------|-------------|

42.4 Functional description

The STM has one 32-bit up counter (STM\_CNT) that is used as the time base for all channels. When enabled, the counter increments at the system clock frequency divided by a prescale value. The STM\_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM\_CR[TEN] bit. When enabled in normal mode, the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM\_CR[FRZ] bit. When the STM\_CR[FRZ] bit is set, the counter is stopped in debug mode; otherwise, it continues to run in debug mode. The counter rolls over at 0xFFFF\_FFFF to 0x0000\_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM\_CCRn), a channel interrupt register (STM\_CIRn), and a channel compare register (STM\_CMPn). The channel is enabled by setting the STM\_CCRn[CEN] bit. When enabled, the channel will set the STM\_CIRn[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing 1 to the STM\_CIRn[CIF] bit. A write of 0 to the STM\_CIRn[CIF] bit has no effect.

NOTE

The STM counter does not advance when the system clock is stopped.

# Chapter 43

## Software Watchdog Timer (SWT)

### 43.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section provides an overview, list of features, and modes of operation for the SWT.

#### 43.1.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires, the SWT generates an interrupt or hardware reset request. The SWT can be configured to generate a reset request or interrupt on an initial time-out. The SWT always generates a reset request on a second consecutive time-out.

#### 43.1.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode

- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

### 43.1.3 Modes of operation

The SWT supports three device modes of operation: normal, debug and stop. When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT\_CR. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT\_CR. If the STP bit is set, the counter is stopped in stop mode, otherwise it continues to run.

## 43.2 External signal description

The SWT module does not have any external interface signals.

## 43.3 Memory Map and Registers

The SWT programming model has seven 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. Other types of invalid accesses include: writes to read-only registers, incorrect values written to the service register when enabled, accesses to reserved addresses and accesses by masters without permission. If the RIA bit in the SWT\_CR is set then the SWT generates a system reset on an invalid access otherwise a bus error is generated. If either the HLK or SLK bits in the SWT\_CR are set, then the SWT\_CR, SWT\_TO, SWT\_WN, and SWT\_SK registers are read-only.

The SWT memory map is shown in the following table.

**SWT memory map**

| Address offset (hex) | Register name                   | Width (in bits) | Access | Reset value | Section/ page               |

### 43.3.3 SWT Time-out Register (SWT\_TO)

The SWT Time-out (SWT\_TO) register contains the 32-bit time-out period. This register is read-only if either the SWT\_CR[HLK] or SWT\_CR[SLK] bits are set.

Address: 0h base + 8h offset = 8h

**SWT\_TO field descriptions**

| Field       | Description                                                                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>WTO | Watchdog time-out period in clock cycles. An internal 32-bit down counter is loaded with 261600 cycles, when the service sequence is written or when the SWT is enabled. |

**43.3.4 SWT Window Register (SWT\_WN)**

The SWT Window (SWT\_WN) register contains the 32-bit window start value. This register is cleared on reset. This register is read-only if either the SWT\_CR[HLK] or SWT\_CR[SLK] bits are set.

Address: 0h base + Ch offset = Ch

|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 16–31<br>WSC     | Watchdog Service Code<br><br>This field is used to service the watchdog and to clear the soft lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] field is 01b, two pseudorandom key values are written to service the watchdog, see <a href="#">Functional description</a> for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the soft lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero. |

43.3.6 SWT Counter Output Register (SWT\_CO)

The SWT Counter Output (SWT\_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Address: 0h base + 14h offset = 14h

SWT\_CO field descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>CNT | Watchdog Count. When the watchdog is disabled (SWT_CR[WEN]=0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN]=1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to six system plus eight counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter. |

### 43.3.7 SWT Service Key Register (SWT\_SK)

The SWT Service Key (SWT\_SK) register holds the previous (or initial) service key value. This register is read-only if either the SWT\_CR[HLK] or SWT\_CR[SLK] bits are set.

Address: 0h base + 18h offset = 18h

|       |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |    |

**SWT\_SK field descriptions**

| Field            | Description                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                              |
| 16–31<br>SK      | Service Key<br><br>This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] is 01b, the next key value to be written to the SWT_SR is $(17 \cdot SK + 3) \bmod 2^{16}$ . |

## 43.4 Functional description

### 43.4.1 Introduction

The SWT is a 32-bit window watchdog timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- a control register (SWT\_CR),
- an interrupt register (SWT\_IR),
- a time-out register (SWT\_TO),
- a window register (SWT\_WN),
- a service register (SWT\_SR),
- a counter output register (SWT\_CO), and
- a service key register (SWT\_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

#### **43.4.1.1 SWT\_CR register**

The SWT\_CR register includes bits to enable the timer, set configuration options, and lock configuration of the module. The watchdog is enabled by setting the SWT\_CR[WEN] bit. The reset value of the SWT\_CR[WEN] bit is device specific.<sup>1</sup> If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

#### **43.4.1.2 SWT\_TO register**

The SWT\_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100, in which case the time-out period is set to 0x100. When the SWT is enabled, the time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. See the Configuration section to determine the source that is used to clock the down counter.

#### **43.4.1.3 SWT\_CO register**

The SWT\_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT\_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT\_CR[WEN] cleared) and the value of the SWT\_CO register read to determine if the internal down counter is working properly.

---

1. See the chip-specific SWT information.

## 43.4.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT\_CR, SWT\_TO, SWT\_WN and SWT\_SK registers are read-only.

### 43.4.2.1 Hard lock

The hard lock is enabled by setting the SWT\_CR[HLK] bit, which can only be cleared by a reset.

### 43.4.2.2 Soft lock

The soft lock is enabled by setting the SWT\_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

## 43.4.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT\_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT\_CR[WEN] bit to be set.

## 43.4.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation that is determined by the SWT\_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence

#### 43.4.4.1 Fixed service sequence mode

If the SWT\_CR[SMD] field is 00b, the fixed service sequence mode is selected, which requires writing 0xA602, then 0xB480 to the SWT\_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

#### 43.4.4.2 Keyed service sequence mode

If the SWT\_CR[SMD] field is 01b, then the keyed service sequence mode is selected, which requires writing two pseudorandom keys to the SWT\_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined by the equation in the following figure. This algorithm will generate a sequence of  $2^{16}$  different key values before repeating. The state of the key generator is held in the SWT\_SK register. For example, if SWT\_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT\_SR register, the SWT\_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT\_SR[WSC] field, SWT\_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

**Figure 43-1. Pseudorandom Key Generator**

#### 43.4.4.3 Window mode

If window mode is enabled (SWT\_CR[WND] bit is set), the service sequence must be performed in the last part of the time-out period defined by the window register. The window is open when the down counter is less than the value in the SWT\_WN register. Outside of this window, service sequence writes are invalid accesses and generate a bus error or reset depending on the value of the SWT\_CR[RIA] bit. For example, if the SWT\_TO register is set to 5000 and SWT\_WN register is set to 1000, then the service sequence must be performed in the last 20% of the time-out period. There is a short lag in the time it takes for the window to open due to synchronization logic in the watchdog design. This delay could be up to three system plus four counter clock cycles.

#### 43.4.5 Time-out

The Interrupt Then Reset bit (SWT\_CR[ITR]) controls the SWT's action taken when a time-out occurs.

- If the SWT\_CR[ITR] bit is 0, the SWT generates a reset request immediately on any time-out.
- If the SWT\_CR[ITR] bit is 1, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period.
  - The interrupt is indicated by the Time-out Interrupt Flag (SWT\_IR[TIF]).
  - Clear the interrupt by writing 1 to SWT\_IR[TIF].

If the service sequence is not written before the second consecutive time-out, the SWT generates a reset request.

### 43.4.6 Initialization

All registers should be initialized before setting the SWT\_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

## Chapter 44

# Periodic Interrupt Timer (PIT)

### 44.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

#### 44.1.1 Block diagram

The following figure shows the block diagram of the PIT module.

**Figure 44-1. Block diagram of the PIT**

### NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

## 44.1.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

## 44.2 Signal description

The PIT module has no external pins.

## 44.3 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.

**PIT memory map**

### 44.3.1 PIT Module Control Register (PIT\_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

## Memory map/register description

Address: 0h base + 0h offset = 0h

44.3.2 PIT Upper Lifetime Timer Register (PIT\_LTMR64H)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 0h base + E0h offset = E0h

PIT\_LTMR64H field descriptions

| Field       | Description                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>LTH | Life Timer value<br><br>Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1. |

44.3.3 PIT Lower Lifetime Timer Register (PIT\_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 0h base + E4h offset = E4h

**PIT\_LTMR64L field descriptions**

| Field       | Description                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>LTL | Life Timer value<br><br>Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read. |

**44.3.4 Timer Load Value Register (PIT\_LDVALn)**

These registers select the timeout period for the timer interrupts.

Access: User read/write

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

|       |     |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

## 44.4 Functional description

This section provides the functional description of the module.

### 44.4.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

### 44.4.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

**Figure 44-2. Stopping and starting a timer**

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

**Figure 44-3. Modifying running timer period**

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

**Figure 44-4. Dynamically setting a new load value**

### 44.4.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

### 44.4.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

### 44.4.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

## 44.5 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.

- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every  $5.12 \text{ ms} / 20 \text{ ns} = 256,000$  cycles and Timer 3 every  $30 \text{ ms} / 20 \text{ ns} = 1,500,000$  cycles. The value for the LDVAL register trigger is calculated as:

$\text{LDVAL trigger} = (\text{period} / \text{clock period}) - 1$

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

## 44.6 Example configuration for chained timers

### NOTE

Check if 100 MHz frequency for PIT timer is valid for your device in the clocking chapter.

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

## 44.7 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

# Chapter 45

## CAN (FlexCAN)

### 45.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0 B protocol specification. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive (Rx) Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

**Figure 45-1. FlexCAN block diagram**

### 45.1.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The CAN Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames

- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

## 45.1.2 FlexCAN module features

The FlexCAN module includes these distinctive legacy features:

- Full implementation of the CAN protocol specification, Version 2.0 B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused structures space can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation

- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes

New major features are also provided:

- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors).

### 45.1.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ\_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See [Stop mode](#) for more information.

## 45.2 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 45-1. FlexCAN signal descriptions

| Signal | Description      | I/O    |
|--------|------------------|--------|
| CAN Rx | CAN Receive Pin  | Input  |
| CAN Tx | CAN Transmit Pin | Output |

### 45.2.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 45.2.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 45.3 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

### 45.3.1 FlexCAN memory mapping

The complete memory map for a FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of [Table 45-2](#).

**Table 45-2. Register access and reset information**

| Register                                          | Access type | Affected by hard reset | Affected by soft reset |
|---------------------------------------------------|-------------|------------------------|------------------------|
| Module Configuration Register (MCR)               | S           | Yes                    | Yes                    |
| Control 1 register (CTRL1)                        | S/U         | Yes                    | No                     |
| Free Running Timer register (TIMER)               | S/U         | Yes                    | Yes                    |
| Rx Mailboxes Global Mask register (RXMGMASK)      | S/U         | No                     | No                     |
| Rx Buffer 14 Mask register (RX14MASK)             | S/U         | No                     | No                     |
| Rx Buffer 15 Mask register (RX15MASK)             | S/U         | No                     | No                     |
| Error Counter Register (ECR)                      | S/U         | Yes                    | Yes                    |
| Error and Status 1 Register (ESR1)                | S/U         | Yes                    | Yes                    |
| Interrupt Masks 2 register (IMASK2)               | S/U         | Yes                    | Yes                    |
| Interrupt Masks 1 register (IMASK1)               | S/U         | Yes                    | Yes                    |
| Interrupt Flags 2 register (IFLAG2)               | S/U         | Yes                    | Yes                    |
| Interrupt Flags 1 register (IFLAG1)               | S/U         | Yes                    | Yes                    |
| Control 2 Register (CTRL2)                        | S/U         | Yes                    | No                     |
| Error and Status 2 Register (ESR2)                | S/U         | Yes                    | Yes                    |
| CRC Register (CRCR)                               | S/U         | Yes                    | Yes                    |
| Rx FIFO Global Mask register (RXFGMASK)           | S/U         | No                     | No                     |
| Rx FIFO Information Register (RXFIR)              | S/U         | No                     | No                     |
| Message buffers                                   | S/U         | No                     | No                     |
| Rx Individual Mask Registers                      | S/U         | No                     | No                     |
| Memory Error Control Register (MECR)              | S/U         | Yes                    | Yes                    |
| Error Injection Address Register (ERRIAR)         | S/U         | Yes                    | Yes                    |

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

This module's memory map includes sixty-four 128-bit message buffers (MBs) that occupy the range from offset 0x80 to 0x47F .

**CAN memory map**

| Address offset (hex) | Register name                                    | Width (in bits) | Access | Reset value | Section/ page                |

## 45.3.2 Module Configuration Register (CAN\_MCR)

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Address: 0h base + 0h offset = 0h

| 1<br>FRZ      | Freeze Enable<br><br>The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR Register is set or when Debug mode is requested at chip level . When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.<br><br>0 Not enabled to enter Freeze mode.<br>1 Enabled to enter Freeze mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2<br>RFEN     | Rx FIFO Enable<br><br>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in section "Arbitration and Matching Timing"). This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br>0 Rx FIFO not enabled.<br>1 Rx FIFO enabled.                                                                                                                                                                                                                                                                                  |
| 3<br>HALT     | Halt FlexCAN<br><br>Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode.<br><br>0 No Freeze mode request.<br>1 Enters Freeze mode if the FRZ bit is asserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4<br>NOTRDY   | FlexCAN Not Ready<br><br>This read-only bit indicates that FlexCAN is either in Disable mode , Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes.<br><br>0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode.<br>1 FlexCAN module is either in Disable mode , Stop mode or Freeze mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 6<br>SOFTTRST | Soft Reset<br><br>When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER , ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, all RXIMR registers, RXMGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR, all Message Buffers .<br><br>The SOFTTRST bit can be asserted directly by the CPU when it writes to the MCR Register, but it is also asserted when global soft reset is requested at chip level . Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. |

## CAN\_MCR field descriptions (continued)

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p>Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied.</p> <p>0 No reset request.<br/>1 Resets the registers affected by soft reset.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 7<br>FRZACK   | <p>Freeze Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode".</p> <p><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN not in Freeze mode, prescaler running.<br/>1 FlexCAN in Freeze mode, prescaler stopped.</p> |
| 8<br>SUPV     | <p>Supervisor Mode</p> <p>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses.<br/>1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.</p>                                                                                                                                                                                                                                        |
| 9<br>Reserved | <p>This field is reserved.<br/>Always write 0 to this field.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 10<br>WRNEN   | <p>Warning Interrupt Enable</p> <p>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.<br/>1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.</p>                                                                                                                                                                                                                                                                                   |
| 11<br>LPMACK  | <p>Low-Power Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode.</p> <p><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN is not in a low-power mode.<br/>1 FlexCAN is in a low-power mode.</p>                                                                                                                                                                                                                                                                                                       |

| 14<br>SRXDIS   | Self Reception Disable<br><br>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br>0 Self reception enabled.<br>1 Self reception disabled.                                                                                                                                                                                                              |
| 15<br>IRMQ     | Individual Rx Masking And Queue Enable<br><br>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br>0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.<br>1 Individual Rx masking and queue feature are enabled.                                                                                                                                                                                                   |
| 16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 17<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 18<br>LPRIOEN  | Local Priority Enable<br><br>This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br>0 Local Priority disabled.<br>1 Local Priority enabled.                                                                                                                                                       |
| 19<br>AEN      | Abort Enable<br><br>This bit is supplied for backwards compatibility with legacy applications. When asserted, it enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br><b>NOTE:</b> When MCR[AEN] is asserted, only the abort mechanism (see Section "Transmission Abort Mechanism") must be used for updating Mailboxes configured for transmission.<br><br><b>CAUTION:</b> Writing the Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted.<br><br>0 Abort disabled.<br>1 Abort enabled. |

| 22–23<br>IDAM     | <p>ID Acceptance Mode</p> <p>This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>00    Format A: One full ID (standard and extended) per ID Filter Table element.</p> <p>01    Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element.</p> <p>10    Format C: Four partial 8-bit Standard IDs per ID Filter Table element.</p> <p>11    Format D: All frames rejected.</p>                                                                                                                                                                                     |
| 24<br>Reserved    | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 25–31<br>MAXMB    | <p>Number Of The Last Message Buffer</p> <p>This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Number of the last MB = MAXMB</p> <p><b>NOTE:</b> MAXMB must be programmed with a value smaller than the parameter NUMBER_OF_MB, otherwise the number of the last effective Message Buffer will be: (NUMBER_OF_MB - 1)</p> <p>Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in Section "Arbitration and Matching Timing").</p> |

### 45.3.3 Control 1 register (CAN\_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: 0h base + 4h offset = 4h

**CAN\_CTRL1 field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>PRES DIV | <p>Prescaler Division Factor</p> <p>This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Sclock frequency = PE clock frequency / (PRES DIV + 1)</p> |
| 8–9<br>RJW      | <p>Resync Jump Width</p> <p>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Resync Jump Width = RJW + 1.</p>                                                                                                                                                                                                                                              |
| 10–12<br>PSEG1  | <p>Phase Segment 1</p> <p>This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.</p>                                                                                                                                                                                                                                                                                                               |
| 13–15<br>PSEG2  | <p>Phase Segment 2</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 17<br>ERRMSK  | <p>Error Mask</p> <p>This bit provides a mask for the Error Interrupt.</p> <p>0 Error interrupt disabled.<br/>1 Error interrupt enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 18<br>CLKSRC  | <p>CAN Engine Clock Source</p> <p>This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock (driven by the PLL) or the crystal oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclck). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Section "Protocol Timing".</p> <p>0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock.<br/>1 The CAN engine clock source is the peripheral clock.</p>                                                                                                                                                                                                                                                                                                                                                                               |
| 19<br>LPB     | <p>Loop Back Mode</p> <p>This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> In this mode, the MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message.</p> <p>0 Loop Back disabled.<br/>1 Loop Back enabled.</p> |
| 20<br>TWRNMSK | <p>Tx Warning Interrupt Mask</p> <p>This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.</p> <p>0 Tx Warning Interrupt disabled.<br/>1 Tx Warning Interrupt enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 24<br>SMP         | <p>CAN Bit Sampling</p> <p>This bit defines the sampling mode of CAN bits at the Rx input. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Just one sample is used to determine the bit value.<br/>1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25<br>BOFFREC     | <p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p>0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B.<br/>1 Automatic recovering from Bus Off state disabled.</p> |
| 26<br>TSYN        | <p>Timer Sync</p> <p>This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special "SYNC" message, that is, global network time. If the RFEN bit in MCR is set (Rx FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Timer Sync feature disabled<br/>1 Timer Sync feature enabled</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 27<br>LBUF        | <p>Lowest Buffer Transmitted First</p> <p>This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIEN bit does not affect the priority arbitration. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Buffer with highest priority is transmitted first.<br/>1 Lowest number buffer is transmitted first.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 28<br>LOM         | <p>Listen-Only Mode</p> <p>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                  | <p>acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the REC, as if it was trying to acknowledge the message.</p> <p>Listen-Only mode acknowledgement can be obtained by the state of ESR1[FLTCNF] field which is Passive Error when Listen-Only mode is entered. There can be some delay between the Listen-Only mode request and acknowledge.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Listen-Only mode is deactivated.<br/>1 FlexCAN module operates in Listen-Only mode.</p> |
| 29–31<br>PROPSEG | <p>Propagation Segment</p> <p>This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Propagation Segment Time = (PROPSEG + 1) × Time-Quanta.</p> <p>Time-Quantum = one Sclock period.</p>                                                                                                                                                                                                                                                                                                  |

**45.3.4 Free Running Timer (CAN\_TIMER)**

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure; see Section "Mailbox Lock Mechanism".

## 45.3.5 Rx Mailboxes Global Mask Register (CAN\_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the MCR[IRMQ] bit is negated, RXMGMASK is always in effect.
- When the MCR[IRMQ] bit is asserted, RXMGMASK has no effect.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

**45.3.6 Rx 14 Mask register (CAN\_RX14MASK)**

This register is located in RAM.

RX14MASK is provided for legacy application support. When the MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 14h offset = 14h

**45.3.8 Error Counter (CAN\_ECR)**

This register has two 8-bit fields reflecting the value of two FlexCAN error counters: Transmit Error Counter (TXERRCNT field) and Receive Error Counter (RXERRCNT field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read-only except in Freeze mode, where they can be written by the CPU.

FlexCAN responds to any bus state as described in the protocol, for example, transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in Bus Off state.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FlexCAN state is 'Error Passive', and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in 'Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

**45.3.9 Error and Status 1 register (CAN\_ESR1)**

This register reflects various error conditions and some general status of the device. It is also the source of interrupts to the CPU.

A CPU read operation clears the following fields to 0, so these fields report error conditions that occurred after the last time the CPU read this register: BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, and STFERR. TXWRN, RXWRN, IDLE, TX, FLTCNF, and RX provide status information.

The following table shows the FlexCAN state variables and their meanings. Combinations not shown in the table are reserved.

| SYNCH | IDLE | TX | RX | FlexCAN state               |
|-------|------|----|----|-----------------------------|
| 0     | 0    | 0  | 0  | Not synchronized to CAN bus |
| 1     | 1    | x  | x  | Idle                        |
| 1     | 0    | 1  | 0  | Transmitting                |
| 1     | 0    | 0  | 1  | Receiving                   |

### CAN\_ESR1 field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–12<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 13<br>SYNCH      | CAN Synchronization Status<br><br>This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description.<br><br>0 FlexCAN is not synchronized to the CAN bus.<br>1 FlexCAN is synchronized to the CAN bus.                                                                                                                                                                                                                                                                                                                                                                   |
| 14<br>TWRNINT    | Tx Warning Interrupt Flag<br><br>If the WRNEN bit in MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode.<br><br>0 No such occurrence.<br>1 The Tx error counter transitioned from less than 96 to greater than or equal to 96. |
| 15<br>RWRNINT    | Rx Warning Interrupt Flag<br><br>If the WRNEN bit in MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRNMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode.<br><br>0 No such occurrence.<br>1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.                                                 |
| 16<br>BIT1ERR    | Bit1 Error<br><br>This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 45.3.10 Interrupt Masks 2 register (CAN\_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

**45.3.12 Interrupt Flags 2 register (CAN\_IFLAG2)**

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG2 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

### 45.3.13 Interrupt Flags 1 register (CAN\_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit MCR[RFEN] is set, the function of the 8 least significant interrupt flags BUF[7:0]I changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, and the BUF4TO0I field is reserved.

Before enabling the RFEN, the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when an RFFN value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

Before updating MCR[MAXMB] field, CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

## 45.3.14 Control 2 register (CAN\_CTRL2)

This register contains control bits for CAN errors, FIFO features, and mode selection.

Address: 0h base + 34h offset = 34h

|       |    |    |        |        |    |    |    |    |    |    |    |    |    |    |    |    |

| 4–7<br>RFFN | <p>Number Of Rx FIFO Filters</p> <p>This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by MCR[MAXMB].</p> <p><b>NOTE:</b> Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available.</p> <p>Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows:</p> <p><math>(\text{SETUP\_MB} - 6) \times 4</math></p> <p>where SETUP_MB is the least between NUMBER_OF_MB and MAXMB.</p> <p>The number of remaining Mailboxes available will be:</p> <p><math>(\text{SETUP\_MB} - 8) - (\text{RFFN} \times 2)</math></p> <p>If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional.</p> <table><tr><th>RFFN[3:0]</th><th>Number of Rx FIFO filters</th><th>Message Buffers occupied by Rx FIFO and ID Filter Table</th><th>Remaining Available Mailboxes<sup>1</sup></th><th>Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks</th><th>Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask<sup>2</sup></th></tr><tr><td>0x0</td><td>8</td><td>MB 0-7</td><td>MB 8-63</td><td>Elements 0-7</td><td>none</td></tr><tr><td>0x1</td><td>16</td><td>MB 0-9</td><td>MB 10-63</td><td>Elements 0-9</td><td>Elements 10-15</td></tr><tr><td>0x2</td><td>24</td><td>MB 0-11</td><td>MB 12-63</td><td>Elements 0-11</td><td>Elements 12-23</td></tr><tr><td>0x3</td><td>32</td><td>MB 0-13</td><td>MB 14-63</td><td>Elements 0-13</td><td>Elements 14-31</td></tr><tr><td>0x4</td><td>40</td><td>MB 0-15</td><td>MB 16-63</td><td>Elements 0-15</td><td>Elements 16-39</td></tr><tr><td>0x5</td><td>48</td><td>MB 0-17</td><td>MB 18-63</td><td>Elements 0-17</td><td>Elements 18-47</td></tr><tr><td>0x6</td><td>56</td><td>MB 0-19</td><td>MB 20-63</td><td>Elements 0-19</td><td>Elements 20-55</td></tr><tr><td>0x7</td><td>64</td><td>MB 0-21</td><td>MB 22-63</td><td>Elements 0-21</td><td>Elements 22-63</td></tr><tr><td>0x8</td><td>72</td><td>MB 0-23</td><td>MB 24-63</td><td>Elements 0-23</td><td>Elements 24-71</td></tr><tr><td>0x9</td><td>80</td><td>MB 0-25</td><td>MB 26-63</td><td>Elements 0-25</td><td>Elements 26-79</td></tr><tr><td>0xA</td><td>88</td><td>MB 0-27</td><td>MB 28-63</td><td>Elements 0-27</td><td>Elements 28-87</td></tr><tr><td>0xB</td><td>96</td><td>MB 0-29</td><td>MB 30-63</td><td>Elements 0-29</td><td>Elements 30-95</td></tr><tr><td>0xC</td><td>104</td><td>MB 0-31</td><td>MB 32-63</td><td>Elements 0-31</td><td>Elements 32-103</td></tr><tr><td>0xD</td><td>112</td><td>MB 0-33</td><td>MB 34-63</td><td>Elements 0-31</td><td>Elements 32-111</td></tr></table> | RFFN[3:0]                                               | Number of Rx FIFO filters                  | Message Buffers occupied by Rx FIFO and ID Filter Table          | Remaining Available Mailboxes <sup>1</sup>                                    | Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks | Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask <sup>2</sup> | 0x0 | 8 | MB 0-7 | MB 8-63 | Elements 0-7 | none | 0x1 | 16 | MB 0-9 | MB 10-63 | Elements 0-9 | Elements 10-15 | 0x2 | 24 | MB 0-11 | MB 12-63 | Elements 0-11 | Elements 12-23 | 0x3 | 32 | MB 0-13 | MB 14-63 | Elements 0-13 | Elements 14-31 | 0x4 | 40 | MB 0-15 | MB 16-63 | Elements 0-15 | Elements 16-39 | 0x5 | 48 | MB 0-17 | MB 18-63 | Elements 0-17 | Elements 18-47 | 0x6 | 56 | MB 0-19 | MB 20-63 | Elements 0-19 | Elements 20-55 | 0x7 | 64 | MB 0-21 | MB 22-63 | Elements 0-21 | Elements 22-63 | 0x8 | 72 | MB 0-23 | MB 24-63 | Elements 0-23 | Elements 24-71 | 0x9 | 80 | MB 0-25 | MB 26-63 | Elements 0-25 | Elements 26-79 | 0xA | 88 | MB 0-27 | MB 28-63 | Elements 0-27 | Elements 28-87 | 0xB | 96 | MB 0-29 | MB 30-63 | Elements 0-29 | Elements 30-95 | 0xC | 104 | MB 0-31 | MB 32-63 | Elements 0-31 | Elements 32-103 | 0xD | 112 | MB 0-33 | MB 34-63 | Elements 0-31 | Elements 32-111 |

| 8–12<br>TASD | <p><b>Tx Arbitration Start Delay</b></p> <p>This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency.</p> <p>The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa.</p> <p>If TASD is 0 then the arbitration start is not delayed, thus the CPU has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. On the other hand, if TASD is 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration.</p> <p>If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is not the best to be transmitted.</p> <p>The optimal configuration for TASD can be calculated as:</p> $TASD = 25 - \left\{ f_{CANCLK} \times [MAXMB + 3 - (RFEN \times 8) - (RFEN \times RFFN \times 2)] \times 2 \right\} / \left\{ f_{SYS} \times [1 + (PSEG1+1) + (PSEG2+1) + (PROPSEG+1)] \times (PRES DIV+1) \right\}$ <p>where:</p> <ul style="list-style-type: none"> <li>• <math>f_{CANCLK}</math> is the Protocol Engine (PE) Clock (see section "Protocol Timing"), in Hz</li> <li>• <math>f_{SYS}</math> is the peripheral clock, in Hz</li> <li>• MAXMB is the value in CTRL1[MAXMB] field</li> <li>• RFEN is the value in CTRL1[RFEN] bit</li> <li>• RFFN is the value in CTRL2[RFFN] field</li> <li>• PSEG1 is the value in CTRL1[PSEG1] field</li> <li>• PSEG2 is the value in CTRL1[PSEG2] field</li> <li>• PROPSEG is the value in CTRL1[PROPSEG] field</li> <li>• PRES DIV is the value in CTRL1[PRES DIV] field</li> </ul> |                           |                                                         |                                            |                                                                  |                                                                               |

No automatic Remote Response Frame will be generated.</p> <p>If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Remote Response Frame is generated.<br/>1 Remote Request Frame is stored.</p> |
| 15<br>EACEN       | <p>Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes</p> <p>This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits.<br/>1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.</p>                |
| 16–31<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER\_OF\_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

### 45.3.15 Error and Status 2 register (CAN\_ESR2)

This register reflects various interrupt flags and some general status.

Address: 0h base + 38h offset = 38h

| 0–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 9–15<br>LPTM    | Lowest Priority Tx Mailbox<br><br>If ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.                                                                                                                                                                                                                                                                                  |
| 16<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 17<br>VPS       | Valid Priority Status<br><br>This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox.<br><br><b>NOTE:</b> ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.<br><br>0    Contents of IMB and LPTM are invalid.<br>1    Contents of IMB and LPTM are valid. |
| 18<br>IMB       | Inactive Mailbox<br><br>If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 45.3.17 Rx FIFO Global Mask register (CAN\_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 48h offset = 48h

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

45.3.18 Rx FIFO Information Register (CAN\_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: 0h base + 4Ch offset = 4Ch

- \* Notes:
- x = Undefined at reset.

CAN\_RXFIR field descriptions

|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–22<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                 |
| 23–31<br>IDHIT   | Identifier Acceptance Filter Hit Indicator<br><br>This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted. |

45.3.19 Rx Individual Mask Registers (CAN\_RXIMRn)

These registers are located in RAM.

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on the setting of CTRL2[RFFN].

RXIMR can only be written by the CPU while the module is in Freeze mode; otherwise, they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: 0h base + 880h offset + (4d × i), where i=0d to 63d

- \* Notes:
- x = Undefined at reset.

45.3.20 Memory Error Control Register (CAN\_MECR)

This register contains control bits for memory error detection and correction (ECC).

NOTE

When bit CTRL2[ECRWRE] is 0, this register is read-only and writes to this register result in bus transfer errors.

Address: 0h base + AE0h offset = AE0h

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <b>NOTE:</b> When reading the report registers, this bit must be cleared to assure coherence on the consecutive register reads.<br><br>0 Enable updates of the error report registers.<br>1 Disable updates of the error report registers.                                                                                                                                                                                           |
| 23<br>ECDDIS      | Error Correction Disable<br><br>Disables completely the memory error detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions.<br><br>0 Enable memory error correction.<br>1 Disable memory error correction.            |
| 24<br>NCEFAFRZ    | Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode<br><br>Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes.<br><br>0 Keep normal operation.<br>1 Put FlexCAN in Freeze mode (according to the "Freeze mode" section). |
| 25–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                              |

**45.3.21 Error Injection Address Register (CAN\_ERRIAR)**

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM:

| RAM contents      | Injection address | Memory map |
|-------------------|-------------------|------------|
| FlexCAN Registers | Not mapped        | -          |
| MBs               | 0x0000            | 0x0080     |
| Reserved          | -                 | 0x0480     |
| RXIMRs            | 0x0400            | 0x0880     |
| Reserved          | -                 | 0x0980     |
| RXFIR_0           | 0x0500            | 0x0A80     |
| RXFIR_1           | 0x0504            | 0x0A84     |
| RXFIR_2           | 0x0508            | 0x0A88     |
| RXFIR_3           | 0x050C            | 0x0A8C     |
| RXFIR_4           | 0x0510            | 0x0A90     |
| RXFIR_5           | 0x0514            | 0x0A94     |
| Reserved          | -                 | 0x0A98     |

### CAN\_ERRIAR field descriptions

| Field            | Description                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------|
| 0–17<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                     |
| 18–31<br>INJADDR | Address Where Error Is To Be Injected<br><br>The two least significant bits of this field always read as 0. |

## 45.3.22 Error Injection Data Pattern Register (CAN\_ERRIDPR)

Holds the error pattern to be injected in the data word read from memory.

Address: 0h base + AE8h offset = AE8h

|       |       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|-------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit   | 0     | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
| R     |       |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     | DFLIP |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0     | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |    |

### CAN\_ERRIDPR field descriptions

| Field         | Description                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>DFLIP | Data flip pattern<br><br>Bits set to 1 in the flip pattern cause the corresponding data bit in the word read from memory to invert. |

### 45.3.23 Error Injection Parity Pattern Register (CAN\_ERRIPPR)

Holds the error pattern to be injected in parity bits read from memory along with data word.

Bits set to 1 in the flip pattern cause the corresponding parity bit in the word read from memory to invert.

Address: 0h base + AECh offset = AECh

| Bit   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|-------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

### 45.3.24 Error Report Address Register (CAN\_RERRAR)

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word in which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

## Memory map/register definition

Address: 0h base + AF0h offset = AF0h

**45.3.25 Error Report Data Register (CAN\_RERRDR)**

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see the “Message Buffer Code for Rx buffers” table) when reading a Message Buffer.

Address: 0h base + AF4h offset = AF4h

**CAN\_RERRDR field descriptions**

| Field         | Description                               |
|---------------|-------------------------------------------|
| 0–31<br>RDATA | Raw data word read from memory with error |

**45.3.26 Error Report Syndrome Register (CAN\_RERRSYNR)**

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND<sub>n</sub> field indicates the type of error and which bit in byte (n) is affected by the error. (SYND<sub>3</sub> corresponds to the most significant byte in the data word read from memory; SYND<sub>0</sub> corresponds to the least significant.)

**Table 45-4. Syndrome Definition**

| SYND <sub>n</sub> (hex) | Type | Bit affected    |
|-------------------------|------|-----------------|
| 00                      | -    | none (no error) |
| 01                      | Code | 0               |
| 02                      | Code | 1               |

*Table continues on the next page...*

**Table 45-4. Syndrome Definition (continued)**

| SYNDn (hex) | Type | Bit affected          |
|-------------|------|-----------------------|
| 04          | Code | 2                     |
| 07          | Data | 5                     |
| 08          | Code | 3                     |
| 0E          | Data | 7                     |
| 10          | Code | 4                     |
| 13          | Data | 2                     |
| 15          | Data | 6                     |
| 16          | Data | 1                     |
| 19          | Data | 3                     |
| 1A          | Data | 4                     |
| 1C          | Data | 0                     |
| All others  | -    | Non-correctable error |

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

45.3.27 Error Status Register (CAN\_ERRSR)

Holds the status bits of the error correction and detection operations. After raised, these flags must be cleared by writing 1 to them. Writing 0 has no effect.

### 45.3.28 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x47F is used by the mailboxes.

**Table 45-5. Message buffer structure**

**CODE** — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 45-6](#) and [Table 45-7](#). See [Functional description](#) for additional information.

**Table 45-6. Message buffer code for Rx buffers**

| CODE description                        | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------|----------------------------------|------------------|-------------------------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b0000: INACTIVE — MB is not active.    | INACTIVE                         | —                | —                                               | —                | MB does not participate in the matching process.                                                                                                                                                                                                                                                         |
| 0b0100: EMPTY — MB is active and empty. | EMPTY                            | —                | FULL                                            | —                | When a frame is received successfully (after the <a href="#">Move-in</a> process), the CODE field is automatically updated to FULL.                                                                                                                                                                      |
| 0b0010: FULL — MB is full.              | FULL                             | Yes              | FULL                                            | —                | The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL.<br>See <a href="#">Matching process</a> for matching details related to FULL code. |

|                                                                                                 |                                  | —                | —                                               | 1                | This code is ignored during matching and arbitration process. See <a href="#">Matching process</a> for details.     |
| CODE[0]=1b1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB. | BUSY <sup>5</sup>                | —                | FULL                                            | —                | Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE. |
|                                                                                                 |                                  | —                | OVERRUN                                         | —                |                                                                                                                     |

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.
3. Remote Request Stored bit from CTRL2 register. See section "Control 2 Register (CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 45-7. Message buffer code for Tx buffers**

| 0b1100: DATA — MB is a Tx Data Frame (MB RTR must be 0)             | DATA                    | 0      | INACTIVE                              | Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.                     |
| 0b1100: REMOTE — MB is a Tx Remote Request Frame (MB RTR must be 1) | REMOTE                  | 1      | EMPTY                                 | Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID. |
| 0b1110: TANSWER — MB is a Tx Response                               | TANSWER                 | —      | RANSWER                               | This is an intermediate code that is                                                                                                  |

**Table 45-7. Message buffer code for Tx buffers**

| CODE Description                            | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------|-------------------------|--------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame from an incoming Remote Request Frame |                         |        |                                       | automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details. |

**SRR** — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

**IDE** — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

**RTR** — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 45-6](#), [Table 45-7](#), and the description of the RRS bit in Control 2 Register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

### **DLC** — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see the [Table 45-5](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 45-8](#)).

### **TIME STAMP** — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

### **PRI0** — Local priority

This 3-bit field is used only when LPRI0\_EN bit is set in MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

### **ID** — Frame Identifier

In standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

### **DATA BYTE 0–7** — Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

**Table 45-8. DATA BYTEs validity**

| DLC | Valid DATA BYTEs |
|-----|------------------|
| 0   | none             |
| 1   | DATA BYTE 0      |
| 2   | DATA BYTE 0–1    |
| 3   | DATA BYTE 0–2    |
| 4   | DATA BYTE 0–3    |
| 5   | DATA BYTE 0–4    |
| 6   | DATA BYTE 0–5    |
| 7   | DATA BYTE 0–6    |
| 8   | DATA BYTE 0–7    |

### 45.3.29 Rx FIFO structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 45-9. Rx FIFO structure**

|      | 0           | 3 | 7           | 8 | 9           | 10  | 11  | 12  | 13 | 14 | 15          | 16         | 23          | 24 | 31          |  |
|------|-------------|---|-------------|---|-------------|-----|-----|-----|----|----|-------------|------------|-------------|----|-------------|--|
| 0x80 |             |   |             |   | SRR         | IDE | RTR | DLC |    |    |             | TIME STAMP |             |    |             |  |
| 0x84 |             |   | ID standard |   |             |     |     |     |    |    | ID extended |            |             |    |             |  |
| 0x88 | Data byte 0 |   |             |   | Data byte 1 |     |     |     |    |    |             |            | Data byte 2 |    | Data byte 3 |  |
| 0x8C | Data byte 4 |   |             |   | Data byte 5 |     |     |     |    |    |             |            | Data byte 6 |    | Data byte 7 |  |
| 0x90 | Reserved    |   |             |   |             |     |     |     |    |    |             |            |             |    |             |  |
| to   |             |   |             |   |             |     |     |     |    |    |             |            |             |    |             |  |
|      |             |   |             |   |             |     |     |     |    |    |             |            |             |    |             |  |
| 0xDC |             |   |             |   |             |     |     |     |    |    |             |            |             |    |             |  |

*Table continues on the next page...*

Table 45-9. Rx FIFO structure (continued)

|                     |                                   |
|---------------------|-----------------------------------|
| 0xE0                | ID filter table element 0         |
| 0xE4                | ID filter table element 1         |
| 0xE8<br>to<br>0x2D4 | ID filter table elements 2 to 125 |
| 0x2D8               | ID filter table element 126       |
| 0x2DC               | ID filter table element 127       |
|                     | = Unimplemented or reserved       |

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

Table 45-10. ID table structure

| Format | 0                           | 1   | 2                                             | 7 | 8                           | 15 | 16  | 17  | 18                                              | 23 | 24 | 30 | 31                           |
|--------|-----------------------------|-----|-----------------------------------------------|---|-----------------------------|----|-----|-----|-------------------------------------------------|----|----|----|------------------------------|
| A      | RTR                         | IDE | RXIDA<br>(standard = 2–12, extended = 2–30)   |   |                             |    |     |     |                                                 |    |    |    |                              |
| B      | RTR                         | IDE | RXIDB_0<br>(standard = 2–12, extended = 2–15) |   |                             |    | RTR | IDE | RXIDB_1<br>(standard = 18–28, extended = 18–31) |    |    |    |                              |
| C      | RXIDC_0<br>(std/ext = 0–7)  |     |                                               |   | RXIDC_1<br>(std/ext = 8–15) |    |     |     | RXIDC_2<br>(std/ext = 16–23)                    |    |    |    | RXIDC_3<br>(std/ext = 24–31) |
|        | = Unimplemented or Reserved |     |                                               |   |                             |    |     |     |                                                 |    |    |    |                              |

**RTR** — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

**IDE** — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

### **RXIDA** — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (2 to 12) are used for frame identification. In the extended frame format, all bits are used.

### **RXIDB\_0, RXIDB\_1** — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (2 to 12 and 18 to 28) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

### **RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

## **45.4 Functional description**

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 45-6](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 45-7](#)).

### 45.4.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)). If backwards compatibility is desired (MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 45-6](#) and [Table 45-7](#) in [Message buffer structure](#)).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

## 45.4.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIOEN] bits settings.

### 45.4.2.1 Lowest-number Mailbox first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIOEN] bit has no effect when CTRL1[LBUF] is asserted.

### 45.4.2.2 Highest-priority Mailbox first

If CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN] bit setting.

#### 45.4.2.2.1 Local Priority disabled

If MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

**Table 45-11. Composition of the arbitration value when Local Priority is disabled**

| Format             | Mailbox Arbitration Value (32 bits) |             |             |                             |             |
|--------------------|-------------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | Standard ID (11 bits)               | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | Extended ID[28:18] (11 bits)        | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

#### 45.4.2.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 45-12. Composition of the arbitration value when Local Priority is enabled**

| Format             | Mailbox Arbitration Value (35 bits) |                              |             |             |                             |             |
|--------------------|-------------------------------------|------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | PRIO (3 bits)                       | Standard ID (11 bits)        | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | PRIO (3 bits)                       | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 45.4.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the Data Length Code (DLC) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. T ASD value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX\_ERR\_CNT=124 to 128. T ASD value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
  - If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 45.4.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 45-6](#) and [Table 45-7](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 45-6](#) . If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

### CAUTION

*In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRXDIS] bit is not asserted. If the MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the IFLAG[BUF5I] "Frames available in Rx FIFO" bit in the IMASK1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional – needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional – needed only if a mask was used)
3. Read the Data field
4. Read the RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory – releases the MB and allows the CPU to read the next Rx FIFO entry)

#### 45.4.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame

- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

**Table 45-13. Matching architecture**

| Structure         | SMB[RTR] | CTRL2[RRS] | CTRL2[EAC EN] | MB[IDE]          | MB[RTR]             | MB[ID <sup>1</sup> ] | MB[CODE]                 |
|-------------------|----------|------------|---------------|------------------|---------------------|----------------------|--------------------------|
| Mailbox           | 0        | -          | 0             | cmp <sup>2</sup> | no_cmp <sup>3</sup> | cmp_msk <sup>4</sup> | EMPTY or FULL or OVERRUN |
| Mailbox           | 0        | -          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 0          | -             | cmp              | no_cmp              | cmp                  | RANSWER                  |
| Mailbox           | 1        | 1          | 0             | cmp              | no_cmp              | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 1          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| FIFO <sup>5</sup> | -        | -          | -             | cmp_msk          | cmp_msk             | cmp_msk              | -                        |

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no\_cmp: The SMB contents are not compared with the MB contents
4. cmp\_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY

- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - If MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox
  - If MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

**Table 45-14. Matching possibilities and resulting reception structures**

| RFEN                                                               | IRMQ | MRP            | Matched in MB     | Matched in FIFO      | Reception structure | Description                             |
|--------------------------------------------------------------------|------|----------------|-------------------|----------------------|---------------------|-----------------------------------------|
| <b>No FIFO, only MB, match is always MB first</b>                  |      |                |                   |                      |                     |                                         |
| 0                                                                  | 0    | X <sup>1</sup> | None <sup>2</sup> | - <sup>3</sup>       | None                | Frame lost by no match                  |

| 1                                                                  | 1    | 0              | X                 | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 0              | None              | Full                 | None                | Frame lost by FIFO full (FIFO Overflow) |
| 1                                                                  | 1    | 0              | Free              | Full                 | FirstMB             |                                         |
| 1                                                                  | 1    | 0              | NotFree           | Full                 | LastMb              | Overrun                                 |
| 1                                                                  | 1    | 1              | None              | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 1              | Free              | X                    | FirstMB             |                                         |
| 1                                                                  | 1    | 1              | NotFree           | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 1              | NotFree           | Full                 | LastMb              | Overrun                                 |

1. This is a don't care condition.

2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).

## Functional description

3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Refer to the description of the Rx Individual Mask Registers (RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXGMASK, RX14MASK, RX15MASK and RXFGMASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

### 45.4.5 Move process

There are two types of move process: move-in and move-out.

#### 45.4.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

#### **45.4.5.2 Move-out**

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

#### **45.4.6 Data coherence**

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

### 45.4.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters in BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.

- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

### 45.4.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instruction on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can lead to undesirable results:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without notice

In order to eliminate such risk and perform a *safe inactivation* the CPU must use the following mechanism along with the inactivation itself:

- For Tx Mailboxes, the Transmission Abort (see [Transmission abort mechanism](#))

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

#### **NOTE**

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by

FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

### 45.4.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking is done to prevent a new frame to be written into the MB while the CPU is reading it.

#### NOTE

The locking mechanism applies only to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

### Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)) and it will take place only when the module resumes to Normal or Freeze modes.

## 45.4.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

### Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the IRMQ bit is negated, then the FIFO filter table is affected by RXFGMASK.

## 45.4.8 CAN protocol related features

This section describes the CAN protocol related features.

### 45.4.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

### 45.4.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

### 45.4.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in the description of the Control 1 Register (CTRL1).

### 45.4.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (bit MDIS set in the Module Configuration Register).

**Figure 45-2. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The oscillator clock has better jitter performance.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See the description of the Control 1 Register (CTRL1).

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler Value})}$$

A bit time is subdivided into three segments<sup>1</sup> (see [Figure 45-3](#) and [Table 45-15](#)):

- SYNC\_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL1 Register (plus 1) to be 2 to 8 time quanta long

$$\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}$$

1. For further explanation of the underlying concepts, see ISO/DIS 11519-1, Section 10.3. See also the CAN 2.0A/B protocol specification for bit timing.

**Figure 45-3. Segments within the bit time**

Whenever CAN bit is used as a measure of duration (for example, MCR[FRZACK] and MCR[LPMACK]), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRES DIV + 1)}{f_{CANCLK}}$$

where:

- NCCP is the number of peripheral clocks in one CAN bit;
- $f_{CANCLK}$  is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- $f_{SYS}$  is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CTRL1[PSEG1] field;
- PSEG2 is the value in CTRL1[PSEG2] field;
- PROPSEG is the value in CTRL1[PROPSEG] field;
- PRES DIV is the value in CTRL1[PRES DIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

**Table 45-15. Time segment syntax**

| Syntax         | Description                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| SYNC_SEG       | System expects transitions to occur on the bus during this period.                                                                             |
| Transmit Point | A node in transmit mode transfers a new value to the CAN bus at this point.                                                                    |
| Sample Point   | A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample. |

The following table gives an overview of the CAN compliant segment settings and the related parameter values.

**Table 45-16. Bosch CAN 2.0B standard compliant bit time segment settings**

| Time segment 1 | Time segment 2 | Re-synchronization jump width |
|----------------|----------------|-------------------------------|
| 5 .. 10        | 2              | 1 .. 2                        |
| 4 .. 11        | 3              | 1 .. 3                        |
| 5 .. 12        | 4              | 1 .. 4                        |
| 6 .. 13        | 5              | 1 .. 4                        |
| 7 .. 14        | 6              | 1 .. 4                        |
| 8 .. 15        | 7              | 1 .. 4                        |
| 9 .. 16        | 8              | 1 .. 4                        |

### Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1). For bit time calculations, use an IPT (Information Processing Time) of 2, which is the value implemented in the FlexCAN module.

#### 45.4.8.5 Arbitration and matching timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

**Figure 45-4. Matching and move-in time windows**

Figure 45-5. Arbitration and move-out time windows

Figure 45-6. Arbitration at the end of bus off and move-out time windows

**NOTE**

The matching and arbitration timing shown in the preceding figures do not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in [Table 45-16](#)
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, see [Clock domains and restrictions](#)
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table:

**Table 45-17. Minimum ratio between peripheral clock frequency and CAN bit rate**

| Number of Message Buffers | RFEN | Minimum number of peripheral clocks per CAN bit |
|---------------------------|------|-------------------------------------------------|
| 16 and 32                 | 0    | 16                                              |
| 64                        | 0    | 25                                              |
| 16                        | 1    | 16                                              |
| 32                        | 1    | 17                                              |
| 64                        | 1    | 30                                              |

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, therefore the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in the preceding table can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRES DIV, PROPSEG, PSEG1, PSEG2) contained in the Control 1 Register (CTRL1).

In case of synchronous operation (when the peripheral clock frequency is equal to the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by selecting an adequate value for PRES DIV in order to meet the requirement in the preceding table. In case of asynchronous operation (the peripheral clock frequency greater than the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by both PRES DIV and/or the frequency ratio.

As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRES DIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

## 45.4.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator domain clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

### NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

### 45.4.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

#### CAUTION

“Permanent Dominant” failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a “Permanent Dominant”, the corresponding acknowledge can never be asserted.

#### 45.4.10.1 Freeze mode

This mode is requested by the CPU through the assertion of the HALT bit in the MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in a low-power mode. The acknowledgement is obtained through the assertion by the FlexCAN of FRZ\_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT\_RDY and FRZ\_ACK bits in MCR

After requesting Freeze mode, the user must wait for the FRZ\_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK\_SRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ\_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

### **45.4.10.2 Module Disable mode**

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM\_ACK bit in the same register. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM\_ACK bit and negates the FRZ\_ACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPM\_ACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

### 45.4.10.3 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

### 45.4.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, ECC Host Access Non-correctable Error, ECC FlexCAN Access Non-correctable Error, ECC Correctable Error, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception.

Each of the buffers has assigned a flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

### **Note**

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled ( $\text{MCR}[\text{RFEN}] = 1$ ), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag," and bits 4-0 are unused. See the description of IFLAG1 for more information.

For a combined interrupt where multiple MB interrupt sources are ORed together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Tx Warning, and Rx Warning generate interrupts like the MB interrupt sources, and they can be read from ESR1 and ESR2. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in CTRL1.

The interrupt sources for ECC errors—Host Access with Non-correctable Interrupt Flag, FlexCAN Access with Non-correctable Interrupt Flag, and Correctable Error Interrupt Flag—can be read in ERRSR and the corresponding interrupts masks bits are located in MECCR.

## **45.4.12 Bus interface**

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.

- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN is configured with 16 MBs, RFFN is 0x0, and MAXMB is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

### 45.4.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors). Errors in more than 2 bits may not be detected. When read, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

Memory errors are indicated to Host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by ECCDIS bit in Memory Error Control Register (MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations. It assures that memory has consistent parity bits associated to data.

**NOTE**

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CTRL2) grants write access to all memory positions from 0x080 to 0xADF.

To avoid that critical error correction configuration be accidentally changed, this protocol must be followed to enable the update of the Memory Error Control Register (MECR):

1. By default, ECRWRE bit in Control 2 Register (CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CTRL2).
3. Clear ECRWRDIS bit.
4. All writes to Memory Error Control Register (MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (MECR) by either setting ECRWRDIS or clearing ECRWRE.

**45.4.13.1 Sources of the Memory Access**

The FlexCAN memory can be accessed by 2 major sources (or requestors):

- by Host (CPU): largest word accessed is 32-bit wide
- by FlexCAN internals processes (Match, Arbitration, RxMove on reception, TxMove on transmission): largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

**45.4.13.2 Error Indication**

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separately than the ones detected in requests by FlexCAN internal processes. Corrected errors indication makes no distinction of the source of the access. There are 3 independent flags for these 3 cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both non-corrected and corrected errors are found in different bytes in the same read operation both flags are set.

The non-corrected error detected in Host accesses are also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit HANCEIF is not masked, the same non-corrected error will raise a bus transfer error and an interrupt request.

Each indication flag has one Overrun flag in Error Status Register (ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the Interrupt flag
4. If the Overrun flag is active:
  - a. Alert application that at least one error could not be handled
  - b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

### 45.4.13.3 Error Reporting

Report registers Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in the “Error Indication” section. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules.

1. If any of the 2 non-corrected error flags is currently set, does not update the registers (preserve the old non-corrected error reporting)
2. Else (no error flag is currently set or only the corrected error flag is currently set), update the report registers according to the new error; or according to the most severe of new errors if non-corrected and corrected errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the semantic described in the “Error Indication” section and in the Error Report Address Register (RERRAR) description.

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. How the reported addresses correspond to locations in the module memory map is shown in the Error Injection Address Register (ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the element accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by clearing the MECR[RERRDIS] bit before reading the report registers.

#### **45.4.13.4 Response to Errors**

Correctable errors have no consequence on FlexCAN operation, once the corrected data is used by Host or FlexCAN internal processes. For host-initiated reads, a non-corrected error detected does not affect FlexCAN operation.

Non-corrected errors detected on memory reads requested by FlexCAN do not stop the FlexCAN processing and this may result in incorrect operation.

If a non-corrected error occurs during a reception process (Match or RxMove), an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If a non-corrected error occurs during either an Arbitration or a TxMove process, either a non-highest priority frame may be mistakenly selected to be transmitted or no frame may be transmitted at all, when  $\text{MECR}[\text{NCEFAFRZ}] = 1$ .

The error report registers can provide information to the application for a customized handling of these situations. If the delay of this handling is not accepted and  $\text{MECR}[\text{NCEFAFRZ}] = 1$ , the FlexCAN stops operation automatically and enters Freeze mode when these errors are detected. See the Memory Error Control Register (MECR) description for more details.

#### **45.4.13.5 Error Injection**

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. How the error injection addresses correspond to locations in the module memory map is shown in the ERRIAR description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control Register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

### NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the HAERRIE and FAERRIE bits in Memory Error Control Register (MECR) must be cleared while configuring the memory injection registers.

## 45.5 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

### 45.5.1 FlexCAN initialization sequence

The FlexCAN module may be reset as follows:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See [Table 45-2](#) to see what registers are affected by soft reset.
- Chip level soft reset, which has the same effect as the SOFTRST bit in MCR

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLKSRC bit) should be selected while the module is in Disable mode. After the clock source is selected and the module is enabled (MDIS bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is unsynchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any

transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode; see [Freeze mode](#). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control Register
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Determine the bit rate by programming the PRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- When ECC is enabled, follow the initialization note in [Detection and Correction of Memory Errors](#)
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts) and in CTRL Register (for Bus Off and Error interrupts)
- Negate the HALT bit in MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

# Chapter 46

## Zipwire

### 46.1 Overview

The SIPI and LFAST modules work together as a single unit called Zipwire. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules.

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

### 46.2 Introduction

Zipwire is a group of modules that allow one MCU to have a fast, low pin count, serial communication link directly into the memory mapped peripherals and/or memories of another MCU or smart ASIC. Zipwire is implemented in hardware so there is no CPU load for the initiator or target node. Zipwire supports 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address at the target node.

Zipwire architecture is fully pipelined and support multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at 320 Mbaud using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate 20 MHz reference clock for a total of five pins.

Zipwire also supports a streaming mode for the transfer of large blocks of data.

In streaming mode Zipwire has a high transfer rate. For single random access, 32-bit read, from any 32-bit address location, the latency is approximately 1  $\mu$ s.

## 46.3 Zipwire Block Diagram

Figure 46-1 shows two MCUs with Zipwire connected using a five wire interface. Both MCUs support Target and Initiator modes of Zipwire. The SIPI Bus Master Interface is used for all Target mode transactions. The SIPI Register Interface is used for all Initiator Transactions and initial setup. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST reference clock coming from MCU B clock system. The Ref\_Clock can come from either MCU. It is user configurable, but it must be the same clock that drives both LFAST modules.

Figure 46-1. Zipwire connection diagram

## 46.4 Architecture

Zipwire is composed of several modules and system resources. The physical layer is LVDS with 1.2 V common mode voltage and 200mV swing.

The transport layer is a protocol called LFAST. LFAST is an asynchronous protocol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.

- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). SIPI runs on top of LFAST and is fully encapsulated within the LFAST payload. SIPI uses four fixed sizes of LFAST payload in Zipwire:

- 32-bit
- 64-bit
- 96-bit
- 288-bit

The SIPI protocol implements a suite of commands initiated by one MCU, for reading and writing any 32-bit address location in another connected MCU. The SIPI protocol allows either or both MCUs to initiate commands. The protocol also supports interrupt requests from one MCU to the other.

The SIPI module implements both the initiator part of the protocol and the recipient part of the protocol. The module implements four SIPI Initiator channels that can run independently of each other and can run simultaneously. The SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the initiating MCU, SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

The initiator part of the module is connected to the DMA controller and is able to generate DMA requests as a command is completed. This allows a series of read or write commands to be queued in the Initiator MCU and executed by DMA and SIPI without CPU intervention at either Initiator or Target MCU.

## 46.5 Zipwire interconnections

LFAST has the following connections:

- Tx and Rx configuration is controlled by LFAST Control registers.
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.

- Tx Data Port/Rx Data Port — Directly connected to the SIPI module. Allows received data to be efficiently transferred to SIPI and transmit data to be transferred from SIPI.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers.
- DMA connections — Allows SIPI command sequences to be queues and initiated without CPU intervention.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

## 46.6 Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Initiator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

### 46.6.1 Read performance

A Zipwire read operation consists of three stages:

- Initiator sends SIPI Read command to Target.

- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data
- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in a LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes 278 ns ( $= 89 \times 3.13$  ns).

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of  $6 \times$  XBAR cycles to read different memories.
- XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, time for SIPI to read an address location is:

$$(13 \times 50 \text{ MHz clocks}) + (6 \times 100 \text{ MHz clocks}) = 320 \text{ ns}$$

### 46.6.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simultaneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

$$\text{Read Bandwidth} = 4 \text{ bytes in } 320 \text{ ns} = 12.5 \text{ MB/second}$$

### 46.6.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

$$\text{Read Latency} = 278 \text{ ns} + 320 \text{ ns} + 278 \text{ ns} = 876 \text{ ns}$$

## 46.6.2 Write performance

A Zipwire write operation consists of three stages:

- Initiator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address

- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header
- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32-bit (acknowledge)
- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is 320 Mbaud which yields a bit time of 3.13 ns

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes 378 ns
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes 178 ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of  $5 \times$  XBAR cycles to write different memories.
- XBAR clocked at 100 MHz
- SIPI clocked at 50 MHz

Therefore, the time for SIPI to write an address location is:

$$(13 \times 50 \text{ MHz clocks}) + (5 \times 100 \text{ MHz clocks}) = 310 \text{ ns}$$

#### **46.6.2.1 Write bandwidth**

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simultaneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

$$\text{Write Bandwidth} = 4 \text{ bytes in } 378 \text{ ns} = 10.6 \text{ MB/second}$$

#### **46.6.2.2 Write latency**

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

$$\text{Write Latency} = 378 \text{ ns} + 310 \text{ ns} + 178 \text{ ns} = 866 \text{ ns}$$

# Chapter 47

## Serial Interprocessor Interface (SIPI)

### 47.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The Serial Interprocessor Interface (SIPI) is an application layer protocol which runs on top of the LFAST (LVDS Fast Asynchronous Serial Transmission) module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

#### 47.1.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multimaster, multi-channel memory interface between 2 devices using few interconnecting signals. But the protocol is designed in such a way that a subset of the protocol can be implemented, where die area is more important than features.

Main scalable features:

- Number of concurrent channels:
  - Full Implementation = 4
  - Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum implementation either Initiator or Target.
- Full Implementation includes a block transfer feature, but this feature is optional.

The rest of this section describes a full implementation of SIPI which includes:

- Advanced High-Performance Bus (AHB-Lite) master interface
- Direct Memory Access (DMA) interface
- LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS)

## 47.2 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the SIPI\_CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

**Figure 47-1. Interprocessor communication diagram**

**Figure 47-2. SIPI module**

## 47.3 SIPI block diagram

<sup>1</sup> Finite State Machine

**Figure 47-3. SIPI block diagram**

## 47.4 Feature description

This section describes the features of the SIPI module.

### 47.4.1 Main features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability

- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface which is used by target node to access shared memory
- Target node contains a set of nine 32-bit internal registers to store commands
- Up to two outstanding requests are supported at initiator

### 47.4.2 Standard features

- IPS bus interface (PBRIDGE)
- SPP DMA2x bus interface
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

## 47.5 SIPI operation from reset

When the SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

## 47.6 Functional description

### 47.6.1 External signals

The SIPI has no chip external signals.

## 47.6.2 Frame format

All frames have the same general format:

- 16 bit header
- Address, Address and Data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID. The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

### 47.6.2.5 Streaming write request

Figure 47-8. Streaming write request format

#### NOTE

Direct write operations are used to set the streaming address.

Streaming data write is performed using the format shown in [Figure 47-8](#).

### 47.6.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

#### 47.6.2.6.1 SIPI header coding

[Figure 47-9](#), [Table 47-1](#), [Figure 47-10](#), and [Table 47-2](#) show how the SIPI header bits are coded.

**Figure 47-9. SIPI header coding**

Table 47-1 shows the command coding for the bits[12:8] of the header.

**Table 47-1. SIPI header command coding**

| b[12:8]<br>(hex) | Command                         | Payload Size |
|------------------|---------------------------------|--------------|
| 00               | Read 8 bits                     | 64           |
| 01               | Read 16 bits                    | 64           |
| 02               | Read 32 Bits                    | 64           |
| 03               | Reserved                        | —            |
| 04               | Write 8 bits with ACK           | 96           |
| 05               | Write 16 bits with ACK          | 96           |
| 06               | Write 32 bits with ACK          | 96           |
| 07               | Reserved                        | —            |
| 08               | ACK – OK                        | 32           |
| 09               | ACK – Fault                     | 32           |
| 0A               | Read Answer – OK                | 64           |
| 0B               | Reserved                        | —            |
| 0C               | Trigger comm and with ACK       | 32           |
| 0D               | Reserved                        | —            |
| ...              | ...                             | ...          |
| 11               | Reserved                        | —            |
| 12               | ID Register Read Request        | 32           |
| 13               | Reserved                        | —            |
| ...              | ...                             | ...          |
| 16               | Reserved                        | —            |
| 17               | Stream Data with ACK (32 bytes) | 288          |
| 18               | Reserved                        | —            |
| ...              | ...                             | ...          |
| 1F               | Reserved                        | —            |

Figure 47-10 shows the channel number field in the header and Table 47-2 shows the channel number coding.

**Figure 47-10. SIPI header channel field**

**Table 47-2. SIPI header channel number coding**

| SIPI channel name | Channel number coding in header(s)                 |                                        | Comment  |
|-------------------|----------------------------------------------------|----------------------------------------|----------|
|                   | SIPI channel coding select field (SIPI_MCR[CHNSB]) |                                        |          |
|                   | Code table I<br>(SIPI_MCR[CHNSB] = 1)              | Code table II<br>(SIPI_MCR[CHNSB] = 0) |          |
| 0 (Channel A)     | 000b                                               | 100b                                   | In use   |
| 1 (Channel B)     | 001b                                               | 101b                                   | In use   |
| 2 (Channel C)     | 010b                                               | 110b                                   | In use   |
| 3 (Channel D)     | 011b                                               | 111b                                   | In use   |
| 4 (Channel E)     | 100b                                               | 000b                                   | Reserved |

| 7 (Channel H)     | 111b                                               | 011b                                   | Reserved |

### 47.6.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

### 47.6.2.8 Payload field

Table 47-3 shows the payload sizes of LFAST frames.

**Table 47-3. Payload size of LFAST channel frame**

| LFAST Code | SIPI Code | LFAST Payload Size (bits) | LFAST Payload Size (bytes) |
|------------|-----------|---------------------------|----------------------------|
| 000b       | —         | 8                         | 1                          |
| 001b       | —         | 32                        | 4                          |
| 010b       | 010b      | 64                        | 8                          |
| 011b       | 011b      | 96                        | 12                         |
| 100b       | 100b      | 128                       | 16                         |

*Table continues on the next page...*

**Table 47-3. Payload size of LFAST channel frame (continued)**

| LFAST Code | SIPI Code | LFAST Payload Size (bits) | LFAST Payload Size (bytes) |
|------------|-----------|---------------------------|----------------------------|
| 101b       | 101b      | 256                       | 32                         |
| 110b       | 110b      | 512                       | 64                         |
| 111b       | 111b      | 288                       | 36                         |

Table 47-4 shows the converted coding of LFAST for a given SIPI code.

**Table 47-4. Converted coding of LFAST channel code for SIPI headers**

| LFAST Code | SIPI Code | Channel (hex) <sup>1</sup> |
|------------|-----------|----------------------------|
| 0100b      | 100b      | A                          |
| 0101b      | 101b      | B                          |
| 0110b      | 110b      | C                          |
| 0111b      | 111b      | D                          |
| 1000b      | 000b      | E (not used by SIPI)       |
| 1001b      | 001b      | F (not used by SIPI)       |
| 1010b      | 010b      | G (not used by SIPI)       |
| 1011b      | 011b      | H (not used by SIPI)       |

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.  
 SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.  
 SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.  
 SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

### 47.6.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome ( $x^{16} + x^{12} + x^5 + 1$ ). MSB is sent first in the data stream.

#### 47.6.2.9.1 CRC field examples

##### 47.6.2.9.1.1 Example 1 – 32 bit write on channel 1 with ID1

- Header = 260Ah
- Address = 1122\_3344h
- Data = CCDD\_EEFFh
- CRC = BF7Dh

#### **47.6.2.9.1.2 Example 2 – 32 bit read on channel 2 with ID2**

- Header = 420Ch
- Address = 89AB\_CDEFh
- CRC = 6B80h

#### **47.6.2.9.1.3 Example 3 – Event command on channel 3 with ID3**

- Header = 6C0Eh
- CRC = B286h

## **47.7 Transfer types**

This section describes the available transfer types of the SIPI module. The SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

### **47.7.1 Read transfer**

A Read transfer can be of two types:

- Read Request Transfer (at initiator node)
- Read Response Transfer (at target node)

#### **47.7.1.1 Register read request transfer**

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in [Figure 47-11](#).

Figure 47-11. Read request transfer

### 47.7.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see [Figure 47-12](#)). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see [Figure 47-13](#)).

Figure 47-12. Read answer transfer

**Figure 47-13. Data allocation****Note**

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as halfword enable.
  - Bit[0]:
    - 0 - halfword 1 enabled (MSB)
    - 1 - halfword 0 enabled (LSB)

**47.7.3 Register Write transfer**

Register Write transfer can be of two types:

- Normal write transfer - channels 0, 1, 2 and 3
- Streaming data transfer - channel 2 only

A Register Write transfer can be done through Normal Write transfer on channels 0, 1, 2 and 3 (see [Normal write transfer](#)) as shown in [Figure 47-14](#).

**Figure 47-14. Register write transfer (showing LFAST frame encapsulation)**

### 47.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and CRC as shown in [Figure 47-15](#).

**Figure 47-15. Write transfer (LFAST frame encapsulation is not shown)**

### Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
  - Bit[0]:
    - 0 - half-word 1 enabled (MSB)
    - 1 - half-word 0 enabled (LSB)

## 47.7.3.2 Streaming write transfer

Streaming write transfer has 256 bits of payload.

### 47.7.3.2.1 Streaming write transfer with address

Setting the address is performed using a direct write transfer. The SIPI Maximum Count Register (SIPI\_MAXCR) and SIPI Address Reload Register (SIPI\_ARR) are written before the SIPI Address Count Register (SIPI\_ACR). This is to avoid unwanted behavior of the SIPI attempting to access non-shared memory. This is only true for the very first streaming command, subsequent streaming command(s) may not need to write the SIPI\_MAXCR and SIPI\_ARR (see [SIPI Max Count Register \(SIPI\\_MAXCR\)](#), [SIPI Address Count Register \(SIPI\\_ACR\)](#) and [SIPI Address Reload Register \(SIPI\\_ARR\)](#)).

### 47.7.3.2.2 Streaming transfer with data

[Figure 47-16](#) shows the packet structure of the streaming transfer containing data.

Figure 47-16. Streaming transfer with data

#### 47.7.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see [Write Acknowledge transfer](#)). The CRC bits are calculated on the header field.

Figure 47-17. Write Acknowledge transfer (LFAST encapsulation is not shown)

#### 47.7.5 ID request response

### 47.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in [Figure 47-18](#).

Figure 47-18. ID request transfer (LFAST encapsulation is not shown)

### 47.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in [Figure 47-19](#).

Figure 47-19. ID request response transfer

#### Note

The ID request response contains the value of the CHIP ID in place of data.

## 47.8 Transfer API and flow charts

\*Note: TC = Transmit Command

**Figure 47-20. SIPI single register write API**

Implement the following steps to generate a single Write Transfer Request (Figure 47-20):

1. Configure data and SIPI\_CCR $n$  at the initiator node.
2. Configure SIPI\_CAR $n$  at the initiator node.

As soon as the channel address register (SIPI\_CAR $n$ ) is written and if CCR $n$ [CHEN] = 1, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.

3. Software polls the status register bits (SIPI\_CSR $n$ ) to determine when the request completes, SIPI\_CSR $n$ [ACKR] = 1. An interrupt will be generated if the corresponding SIPI\_CIR $n$ [ACKIE] = 1.

On a single Write transfer request reception (Figure 47-21):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process is completed, the target node will generate an acknowledge frame and send it back to the LFAST.

Figure 47-21. SIPI Single Register Write API – Flow Chart

**Figure 47-22. SIPI Multiple Register Write API**

For multiple write transfer request generation (Figure 47-22):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write `SIPI_CCRn[CHEN] = 1` and `SIPI_CCRn[DAN] = 1`.
3. SIPI will start copying data into the `SIPI_CDRn` through its DMA interface, depending on the transfer count and data registers size. `SIPI_CDR2_0` should be written with the MSB.
4. When the copying process is complete, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST.
5. Software should poll the `SIPI_CSRn` status register bits to determine if the request has completed. If `SIPI_CSRn[ACKR] = 1`, an interrupt will be generated (if the corresponding `SIPI_CIRn[ACKIE] = 1`).
6. If `SIPI_CCRn[DEN] = 1`, the SIPI request will transfer to the DMA controller. If not, the state machine goes idle.
7. Steps 4–7 will be repeated.

On Multiple Write transfer request reception (Figure 47-22):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process is completed, target node will generate an acknowledge frame and send it back to the LFAST.

**Figure 47-23. SIPI Single Register Read API**

For Single Read Transfer Request generation ([Figure 47-23](#)):

1. Software/DMA will configure  $\text{SIPI\_CCR}_n$  and  $\text{SIPI\_CDR}_n$ , with the last step by writing  $\text{CAR}_n$ .
2. As soon as  $\text{SIPI\_CAR}$  is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll  $\text{CSR}_n$  to determine when the request has completed. If  $\text{SIPI\_CSR}_n[\text{RAR}] = 1$ , an interrupt will be generated (if  $\text{SIPI\_CIR}_n[\text{RAIE}] = 1$ ). If  $\text{SIPI\_CSR}_n[\text{RAR}]$  does not set then  $\text{SIPI\_ERR}[\text{TOEN}] = 1$  which indicates a timeout has occurred.
4. If  $\text{SIPI\_CSR}_n[\text{RAR}] = 1$  then software can read the data register, or can other necessary action if  $\text{SIPI\_CSR}_n[\text{RAR}] = 0$ .

On Single Read transfer request reception (Figure 47-23):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process is completed, target node will send read response back to LFAST.

**Figure 47-24. SIPI multiple register read API**

For multiple read transfer request generation (Figure 47-24):

1. Software/DMA will configure SIPI\_CCR<sub>n</sub> and SIPI\_CDR<sub>n</sub>, with the last step by writing SIPI\_CAR<sub>n</sub>.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then starts transmitting data to the LFAST.
3. Software should poll SIPI\_CSR<sub>n</sub> to determine when the request has completed. If SIPI\_CSR<sub>n</sub>[RAR] = 1 and SIPI\_CIR<sub>n</sub>[RAIE] = 1 an interrupt will be generated. If SIPI\_CSR<sub>n</sub>[RAR] does not set, then SIPI\_ERR[TOEn] = 1 which indicates a timeout.
4. Steps 2–3 will be repeated for multiple requests.

On Multiple Read transfer request reception (Figure 47-24):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

Figure 47-25, Figure 47-26, Figure 47-27 and Figure 47-28 show the SIPI data streaming of data.

Figure 47-25. SIPI data stream model

Figure 47-26. SIPI data stream model - Initiator

Figure 47-27. SIPI data stream model - Target

Figure 47-28. SIPI data stream with acknowledge trigger

## 47.9 DMA programming sequence

The DMA programming sequence is as follows:

1. Software configures TCD (DMA data).
2. DMA transfers from RAM to SIPI registers.
3. SIPI starts transferring the data through LFAST Tx ports.
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. If SIPI has received a read response, and error flags are not set on the LFAST Rx port, SIPI will assert `ipd_request`. In case of error, move to Step 8.
6. As soon as `ipd_request` is asserted, DMA transfer starts between the SIPI registers and RAM.
7. If DMA transfer minor loop/major loop is complete, and the request is negated, `ipd_request` is negated.
8. If an error occurs:

- The SIPI generates an interrupt
- Software takes control of the SIPI

9. Steps 5 – 8 are repeated until the transfer is finished.

## 47.10 Modes of operation

SIPI has three operating modes:

- Initialization
- Normal
- Module Disable

After hardware reset the SIPI is in module disable mode, which helps reduce power consumption.

### 47.10.1 Initialization mode

To enter Initialization mode software writes SIPI\_MCR[INIT]=1 (SIPI\_MCR[MOEN] must be set before attempting to write SIPI\_MCR[INIT]). To exit Initialization mode software writes SIPI\_MCR[INIT]=0 (see [SIPI Module Configuration Register \(SIPI\\_MCR\)](#)).

All message transfers are stopped when in Initialization mode. If software invokes Initialization mode when a bus transfer is in progress, the transfer will be aborted immediately even if the transfer has not completed.

#### Note

It is recommended that software checks the state of SIPI (SIPI\_MCR[MOEN]) before setting SIPI\_MCR[INIT].

### 47.10.2 Normal mode

Once software has completed initialization of SIPI (SIPI\_MCR[INIT]=1), it can enter Normal mode by writing SIPI\_MCR[INIT]=0. SIPI needs to be in Normal mode for all data transfers (see [SIPI Module Configuration Register \(SIPI\\_MCR\)](#)).

#### Note

SIPI must be enabled before attempting to write SIPI\_MCR[INIT] (SIPI\_MCR[MOEN]=1).

### 47.10.3 Module Disable (MD)

MD mode in the SIPI is used to help reduce power consumption. By default, SIPI is in Disable mode, SIPI\_MCR[MOEN]=0, and is exited by writing SIPI\_MCR[MOEN]=1 (see [SIPI Module Configuration Register \(SIPI\\_MCR\)](#)). All the activities on the SIPI Tx and Rx ports are immediately stopped in Module Disable mode.

## 47.11 Errors

This section describes the potential errors that can occur during SIPI operation.

### 47.11.1 Timeout error

A timeout error is generated at the initiator node when the acknowledge/response is not received within the time configured in the corresponding CTOR<sub>n</sub>[TOR] field setting (see [SIPI Channel Timeout Register 0 \(SIPI\\_CTOR0\)](#), [SIPI Channel Timeout Register 1 \(SIPI\\_CTOR1\)](#), [SIPI Channel Timeout Register 2 \(SIPI\\_CTOR2\)](#) and [SIPI Channel Timeout Register 3 \(SIPI\\_CTOR3\)](#)). A timeout error is indicated when ERR[TOE<sub>n</sub>]=1 (see [SIPI Error Register \(SIPI\\_ERR\)](#)).

#### Note

SIPI should not drop the response even after a timeout occurs. Software will poll both error and status flags after the transfer to see if there was a timeout error. If there was a timeout error the response received may then be discarded.

### 47.11.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match the calculated CRC, and the SR[GCRCE] is set (see [SIPI Status Register \(SIPI\\_SR\)](#)). An interrupt will be asserted if MCR[CRCIE]=1 (see [SIPI Module Configuration Register \(SIPI\\_MCR\)](#)).

#### Note

The target node will not send an acknowledge to the initiator node when a CRC error is generated. An interrupt will be generated on the target side if the corresponding interrupt

enable bit is set. The initiator node will detect a timeout and take necessary action.

### 47.11.3 Maximum count reached error

The maximum count reached error is only generated at the target node. It is generated when the value of the SIPI\_ACR is equal to the SIPI\_MAXCR (see [SIPI Max Count Register \(SIPI\\_MAXCR\)](#) and [SIPI Address Count Register \(SIPI\\_ACR\)](#)). When the maximum count is reached, SIPI\_SR[MCR] = 1 (see [SIPI Status Register \(SIPI\\_SR\)](#)). An interrupt will be generated if SIPI\_MCR[MCRIE] = 1 (see [SIPI Module Configuration Register \(SIPI\\_MCR\)](#)).

### 47.11.4 Transaction ID error

The Transaction ID (TID) error is always generated at the initiator node only. It is generated when header bits 15–13 do not match SIPI\_CSR $n$ [TID] (transaction ID bits, see [SIPI Channel Status Register 0 \(SIPI\\_CSR0\)](#), [SIPI Channel Status Register 1 \(SIPI\\_CSR1\)](#), [SIPI Channel Status Register 2 \(SIPI\\_CSR2\)](#), and [SIPI Channel Status Register 3 \(SIPI\\_CSR3\)](#)). SIPI\_CSR $n$ [TIDE] = 1 when a TID error is detected, and an interrupt will be generated if SIPI\_CIR $n$ [TIDIE] = 1 (see [SIPI Channel Interrupt Register 0 \(SIPI\\_CIR0\)](#), [SIPI Channel Interrupt Register 1 \(SIPI\\_CIR1\)](#), [SIPI Channel Interrupt Register 2 \(SIPI\\_CIR2\)](#), and [SIPI Channel Interrupt Register 3 \(SIPI\\_CIR3\)](#)).

### 47.11.5 Acknowledge error

An incorrect acknowledge is received only from the initiator. When the acknowledge received is incorrect, SIPI\_ERR[ACKR $n$ ] will be set (see [SIPI Error Register \(SIPI\\_ERR\)](#)). An interrupt will be generated if SIPI\_CIR $n$ [WAIE]=1 (see [SIPI Channel Interrupt Register 0 \(SIPI\\_CIR0\)](#), [SIPI Channel Interrupt Register 1 \(SIPI\\_CIR1\)](#), [SIPI Channel Interrupt Register 2 \(SIPI\\_CIR2\)](#), and [SIPI Channel Interrupt Register 3 \(SIPI\\_CIR3\)](#)).

## 47.12 CRC calculation

Example: If header is AABBh, address is 1122\_3344h and data is CCDD\_EEFFh. Then CRC calculation will take place as follows:

- 1) The CRC seed is initialized by FFFF\_FFFFh.

- 2) All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).
- 3) So the header will be sent as DD55\_0000h.
- 4) Address will be sent as 22CC\_4488h.
- 5) Data will be sent as FF77\_BB33h.

### 47.13 Interrupt logic

A description of the interrupt logic can be found in the following figure.

Figure 47-29. Interrupt description

## 47.14 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

Figure 47-30. SIPI control and status overview – Register transfer

## 47.15 Memory map and register definition

### SIPI memory map

| Address offset (hex) | Register name                                 | Width (in bits) | Access | Reset value | Section/ page                |
|----------------------|-----------------------------------------------|-----------------|--------|-------------|------------------------------|

### 47.15.1 SIPI Channel Control Register 0 (SIPI\_CCR0)

#### NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI\_CSR0[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI\_CSR0[CB] = 0).

**PRIORITY SCHEDULING:** The channel whose SIPI\_CAR $n$  is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

#### NOTE

This register is only writable in Initialization mode (SIPI\_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI\_CSR $n$ [CB] = 1 (see [SIPI Channel Status Register 0 \(SIPI\\_CSR0\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI\_CAR $n$  (see [SIPI Channel Address Register 0 \(SIPI\\_CAR0\)](#)).

| 0–23<br>Reserved | This field is reserved.                                                                                                                                                                                                                 |
| 24–31<br>TOR     | Timeout value for transmitted requests.<br>Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR].<br><b>NOTE:</b> Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1). |

47.15.5 SIPI Channel CRC Register 0 (SIPI\_CCRC0)

SIPI\_CCRCn is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 14h offset = 14h

SIPI\_CCRC0 field descriptions

| Field         | Description                              |
|---------------|------------------------------------------|
| 0–15<br>CRCI  | Reflects received CRC value at initiator |
| 16–31<br>CRCT | Reflects received CRC value at target    |

47.15.6 SIPI Channel Address Register 0 (SIPI\_CAR0)

SIPI\_CAR0 is the address target for data transmission.

Address: 0h base + 18h offset = 18h

SIPI\_CAR0 field descriptions

| Field       | Description                                        |
|-------------|----------------------------------------------------|
| 0–31<br>CAR | These bits contain the address of the target node. |

### 47.15.7 SIPI Channel Data Register 0 (SIPI\_CDR0)

SIPI\_CDR0 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 1Ch offset = 1Ch

SIPI\_CDR0 field descriptions

| Field       | Description                                                                  |
|-------------|------------------------------------------------------------------------------|
| 0–31<br>CDR | Data register bits. Contains the data that will be transmitted, or received. |

### 47.15.8 SIPI Channel Control Register 1 (SIPI\_CCR1)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI\_CSR1[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI\_CSR1[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI\_CAR<sub>n</sub> is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

**NOTE**

This register is only writable in Initialization mode (SIPI\_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI\_CSR $n$ [CB] = 1 (see [SIPI Channel Status Register 1 \(SIPI\\_CSR1\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI\_CAR $n$  (see [SIPI Channel Address Register 1 \(SIPI\\_CAR1\)](#)).

Address: 0h base + 20h offset = 20h

### 47.15.12 SIPI Channel CRC Register 1 (SIPI\_CCRC1)

SIPI\_CCRC $n$  is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 34h offset = 34h

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**SIPI\_CAR1 field descriptions**

| Field       | Description                                        |
|-------------|----------------------------------------------------|
| 0–31<br>CAR | These bits contain the address of the target node. |

47.15.14 SIPI Channel Data Register 1 (SIPI\_CDR1)

SIPI\_CDR1 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 3Ch offset = 3Ch

SIPI\_CDR1 field descriptions

| Field    | Description                                                                  |
|----------|------------------------------------------------------------------------------|
| 0–31 CDR | Data register bits. Contains the data that will be transmitted, or received. |

47.15.15 SIPI Channel Control Register 2 (SIPI\_CCR2)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI\_CSR2[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI\_CSR2[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI\_CAR<sub>n</sub> is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

**NOTE**

This register is only writable in Initialization mode (SIPI\_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI\_CSR $n$ [CB] = 1 (see [SIPI Channel Status Register 2 \(SIPI\\_CSR2\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI\_CAR $n$  (see [SIPI Channel Address Register 2 \(SIPI\\_CAR2\)](#)).

Address: 0h base + 40h offset = 40h

## SIPI\_CTOR2 field descriptions

| Field            | Description                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–23<br>Reserved | This field is reserved.                                                                                                                                                                      |
| 24–31<br>TOR     | Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR].<br><b>NOTE:</b> Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1). |

### 47.15.19 SIPI Channel CRC Register 2 (SIPI\_CCRC2)

SIPI\_CCRC $n$  is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 54h offset = 54h

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|------|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit   | 0    | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16   | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
| R     | CRCI |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    | CRCT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0    | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |    |

**SIPI\_CCRC2 field descriptions**

| Field         | Description                              |
|---------------|------------------------------------------|
| 0–15<br>CRCI  | Reflects received CRC value at initiator |
| 16–31<br>CRCT | Reflects received CRC value at target    |

### 47.15.20 SIPI Channel Address Register 2 (SIPI\_CAR2)

SIPI\_CAR2 is the address target for data transmission. For streaming operations this register is the start address.

Address: 0h base + 58h offset = 58h

|       |     |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|-----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit   | 0   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
| R     | CAR |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| W     |     |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset | 0   | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |    |

**SIPI\_CAR2 field descriptions**

| Field       | Description                                        |
|-------------|----------------------------------------------------|
| 0–31<br>CAR | These bits contain the address of the target node. |

47.15.21    **SIPI Channel Data Register 2 (SIPI\_CDR2\_n)**

SIPI\_CDR2\_n contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 5Ch offset + (4d × i), where i=0d to 7d

SIPI\_CDR2\_n field descriptions

| Field        | Description                                                                  |
|--------------|------------------------------------------------------------------------------|
| 0–31<br>CDR2 | Data register bits. Contains the data that will be transmitted, or received. |

47.15.22    **SIPI Channel Control Register 3 (SIPI\_CCR3)**

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI\_CSR3[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI\_CSR3[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI\_CARn is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

**NOTE**

This register is only writable in Initialization mode (SIPI\_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI\_CSR $n$ [CB] = 1 (see [SIPI Channel Status Register 3 \(SIPI\\_CSR3\)](#)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI\_CAR $n$  (see [SIPI Channel Address Register 3 \(SIPI\\_CAR3\)](#)).

Address: 0h base + 7Ch offset = 7Ch

| 24–31<br>TOR     | Timeout value for transmitted requests.<br><br>Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR].<br><br><b>NOTE:</b> Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1). |

### 47.15.26 SIPI Channel CRC Register 3 (SIPI\_CCRC3)

SIPI\_CCRC $n$  is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 90h offset = 90h

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| 0–15<br>CRCI  | Reflects received CRC value at initiator |
| 16–31<br>CRCT | Reflects received CRC value at target    |

### 47.15.27 SIPI Channel Address Register 3 (SIPI\_CAR3)

SIPI\_CAR3 is the address target for data transmission.

Address: 0h base + 94h offset = 94h

|-------------|----------------------------------------------------|
| 0–31<br>CAR | These bits contain the address of the target node. |

### 47.15.28 SIPI Channel Data Register 3 (SIPI\_CDR3)

SIPI\_CDR3 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 98h offset = 98h

SIPI\_CDR3 field descriptions

| Field    | Description                                                                  |
|----------|------------------------------------------------------------------------------|
| 0–31 CDR | Data register bits. Contains the data that will be transmitted, or received. |

## 47.15.29 SIPI Module Configuration Register (SIPI\_MCR)

The SIPI\_MCR is a global 32-bit configuration register.

Address: 0h base + 9Ch offset = 9Ch

| 23–26<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                     |
| 27<br>CHNSB       | Channel coding select bit.<br>0 Code Table II (see <a href="#">Table 47-2</a> )<br>1 Code Table I (see <a href="#">Table 47-2</a> )                                                                                                                                                                                                         |
| 28<br>TEN         | Target Enable<br>Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in "streaming without ACK" mode. This bit has to be enabled for the transmission operations also.                                           |
| 29<br>INIT        | Initialization Mode<br>Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits can't be enabled together.<br>0 Normal Mode<br>1 Initialization Mode |
| 30<br>MOEN        | Module Enable<br>This bit should be set or cleared by software. When this bit is negated, all SIPI operations are immediately stopped.                                                                                                                                                                                                      |
| 31<br>SR          | Soft Reset<br>Setting this bit clears all status and error registers, and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.                                                                                                                                                 |

47.15.30 SIPI Status Register (SIPI\_SR)

The SIPI\_SR is the global status register of SIPI.

Address: 0h base + A0h offset = A0h

SIPI\_SR field descriptions

|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>FRZACK | Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited. |

**SIPI\_ARR field descriptions**

| Field             | Description                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–29<br>ADRLD     | ADRLD contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator. |
| 30–31<br>Reserved | This field is reserved.                                                                                                                         |

**47.15.33 SIPI Address Count Register (SIPI\_ACR)**

This register reflects the count value of address counter at target node. It should be configured by direct write request from initiator. This register can be read/written by software anytime.

**NOTE**

SIPI\_ARR, SIPI\_ACR and SIPI\_MAXCR will be configured by direct write operation through the initiator.

**NOTE**

When a streaming write command is received, the target will start the write operation from the address present in SIPI\_ACR (address count register).

**NOTE**

After each 32-bit write has completed, SIPI\_ACR[ADCNT] is compared against SIPI\_MAXCR[MXCNT]. If they are equal, SIPI\_ACR[ADCNT] is loaded with the value stored in SIPI\_ARR[ADRLD]. If they are not equal, the SIPI\_ACR[ADCNT] will increment by 4, decrement by 4 or remain the same (depending on configuration). In both cases, the SIPI\_ACR[ADCNT] will contain the address at which the next streaming write will occur.

Address: 0h base + ACh offset = ACh

| 30–31<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                     |

## 47.15.34 SIPI Error Register (SIPI\_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate errors.

Address: 0h base + B0h offset = B0h

## **Chapter 48**

# **LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications**

## **48.1 Introduction**

### **NOTE**

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

## **48.2 Block diagram**

The following figure depicts LFAST interaction with other modules on the device.

Figure 48-1. LFAST block diagram

## 48.3 External signals

LFAST is a five pin interface with the following signals :

- lfast\_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface.

### 48.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps ( $\text{lfast\_sysclk} \div 4$  or  $\text{lfast\_sysclk} \div 2$ ) is referred to as low data rate, and the high data rate is in the Data Sheet.

## 48.4 LFAST frame structure

A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See [Figure 48-2](#) for details of the LFAST frame.

LFAST frame structure

Figure 48-2. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

**Figure 48-3. Serial frame structure**

The frame structure is shown in [Figure 48-3](#) and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010\_1000\_0100\_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in [Table 48-1](#) :

**Table 48-1. Header payload sizes**

| b7-b5(bin) | Payload Size | Frame Size |
|------------|--------------|------------|
| 000        | 8            | 32         |
| 001        | 32           | 56         |
| 010        | 64           | 88         |
| 011        | 96           | 120        |
| 100        | 128          | 152        |
| 101        | 256          | 280        |
| 110        | —            | —          |
| 111        | 288          | 312        |

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.
- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

## 48.5 Features

- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer up to the maximum data rate shown in the product Data Sheet.
- Transmits and receives data, CTS, ICLC and unsolicited frames.
- Receives ICLC frames
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation in slave mode.
- Supports for detection of unsupported channel number and unsupported payload size.

## 48.6 Memory map and register definition

All registers are 32 bits wide.

### NOTE

Read/Write accesses to all unimplemented registers and write accesses to Read only register will return a Transfer Error.

### LFAST memory map

| Address offset (hex) | Register name                                           | Width (in bits) | Access | Reset value                 | Section/ page                |
|----------------------|---------------------------------------------------------|-----------------|--------|-----------------------------|------------------------------|

### LFAST\_ICR field descriptions

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–13<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                          |
| 14<br>ICLCSEQ     | ICLC enabled. This bit should be set whenever the S/W is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frames request are ignored.<br><br>0 Single ICLC frame transfer.<br>1 S/W is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0.                              |
| 15<br>SNDICLC     | ICLC frame request. This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. Set by user software and cleared by system hardware.<br><br>0 No Valid ICLC frame for transfer.<br>1 Valid ICLC frame for transfer. |
| 16–23<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 24–31<br>ICLCPLD  | ICLC Payload. This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. This field can only be written when ICR[SNDICLC] = 0 ( see <a href="#">Table 48-8</a> for supported ICLC payloads).                                                                                                                                                                                           |

### 48.6.9 LFAST Ping Control Register (LFAST\_PICR)

Address: 0h base + 20h offset = 20h

**LFAST\_UNSRDR<sub>n</sub> field descriptions**

| Field         | Description                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>UNRXD | Unsolicited Receive Data. This represents 9 registers for Unsolicited received data. It is read only register.<br>The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload. |

**48.7 Functional description****48.7.1 Startup procedure**

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

**48.7.1.1 LFAST master interface startup procedure**

1. After reset the SLCR and RCDRCR are programmed according to the LVDS parameters in the device data sheet.
2. The PLLCR is programmed with configuration parameters for the PLL.

3. The LCR is programmed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. Write ICR[SNDICLC] = 1 and ICR[ICLCSEQ] = 1.
9. Write MCR[TXARBD] = 0.
10. The ICLC transmission is confirmed by verifying one of the following:
  - ICR[SNDICLC] = 0.
  - TISR[TXICLCF] = 1.
11. Write ICR[ICLCPLD] = 00h to check the LFAST slaves status.
12. Write ICR[SNDICLC] = 1.
13. The LFAST slave status is confirmed by occurrence of one of the following:
  - LFAST slave is enabled if RIISR[ICPSF] = 1. Proceed to step 14.
  - LFAST slave is disabled if RIISR[ICPFF] = 1. The LFAST master must wait and restart from Step 7.

**Speed mode change:**

14. Write PLLCR[SWPON] = 1 to enable the LFAST masters PLL.
15. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
16. Write ICR[SNDICLC] = 1.
17. The ICLC transmission is confirmed by occurrence of one of the following:
  - ICR[SNDICLC] = 0.
  - TISR[TXICLCF] = 1.
18. To change LFAST masters Tx interface speed both of the following operations are performed:

**Note**

(The slaves Rx interface speed should be changed first.)

- Write ICR[ICLCPLD] = 10h for Tx data fast frame.
- Write ICR[SNDICLC] = 1.

19. Both of the following operations are performed to change the LFAST masters Rx interface speed:

**Note**

(The slaves Tx interface speed mode should be changed first)

- Write ICR[ICLCPLD] = 80h to select Rx data fast frame.
- Write ICR[SNDICLC] = 1.

20. The ICLC transmission is confirmed by the occurrence of one of the following:

- ICR[SNDICLC] = 0
- TISR[TXICLCF] = 1.

21. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.

22. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.

23. Write ICR[ICLCPLD] = 00h to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.

24. Write ICR[SNDICLC] = 1

25. Write MCR[TXARBD] = 1, after some delay to ensure the step 24 ICLC frame is send but no other frame is sent to arbitration.

26. The LFAST slaves speed mode is confirmed by the occurrence of the following:

- If RIISR[ICPSF] = 1. The LFAST slave is in High Speed mode.
- If RIISR[ICPFF] = 1. The LFAST slave is in Low Speed mode.

27. If RIISR[ICPSF] = 1, then all frame arbitration is enabled by both of the following operations:

- Write ICR[ICLCSEQ] = 0.
- Write MCR[TXARBD] = 0.

28. If RIISR[ICPFF] = 1 modifying the LFAST slaves speed needs to be repeated by:

- Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
- Write MCR[TXARBD] = 0, to enable frame transmission.
- The operations from step 14 need to be executed again.

#### 48.7.1.2 LFAST slave interface startup procedure

1. After reset the SLCR and RCDCCR are programed according to the LVDS datasheet.
2. The PLLCR is programed with the configuration parameters for the PLL.
3. The LCR is programed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signal and LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following are true:
  - When an ICLC frame with payload 31h is received the H/W will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
  - MCRMCR[TXEN] = 1.
8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
  - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h frame is received. H/W writes [ICRPF] = 1.
  - PICR[PNGREQ] = 1.

#### **Speed mode change:**

9. The PLL will start when one of the following conditions is met:

- When an ICLC frame with payload 02h is received. H/W writes RIISR[IPONF] = 1.
- Write PLLCR[SWPON] = 1.

10. The speed of the Tx interface is changed on one of the following conditions:

- When SCR[DRMD] = 1 and an ICLC frame with payload 80h is received. H/W writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
- SCR[TDR] = 1, when SCR[DRMD] = 0.

11. The speed of the Rx interface is changed on one of the following conditions:

- When SCR[DRMD] = 1 and an ICLC frame with payload 10h is received. H/W writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
- SCR[RDR] = 1, when SCR[DRMD] = 0.

12. A Ping Frame is sent on one of the following conditions:

- When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h is received. H/W writes RIISR[ICRPF] = 1.
- Write PICR[PNGREQ] = 1.
- Write PICR[PNGREQ] = .

## 48.7.2 Line Receiver

This section describes the Line Receiver.

### 48.7.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data

type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 48-4 shows the block diagram of Uplink Controller.

Figure 48-4. Top Level Receive Controller

### 48.7.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

#### 48.7.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

#### 48.7.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 48-5 shows the block diagram of Hunt Correlation mode.

Figure 48-5. Hunt Correlation mode

#### 48.7.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

#### 48.7.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

**Figure 48-6. High Speed 8 Phase Selection**

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

**Figure 48-7. High Speed 8 Phase Clock Alignment Example**

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in [Figure 48-8](#) and [Figure 48-9](#).

**Figure 48-8. High Speed 4 Phase Clock Alignment Example**

**Figure 48-9. Low speed 4 phase clock alignment example**

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

## Functional description

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in [Table 48-2](#), [Table 48-3](#), and [Table 48-4](#) before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

**Table 48-2. High speed 8 phase selection - sampling procedure**

| Samplers | InitialSample | Intermediate Sample | Final Sample |
|----------|---------------|---------------------|--------------|
| 0        | Phase 0       | Phase 0             | Phase 0      |
| 1        | Phase 1       | Phase 0             | Phase 0      |
| 2        | Phase 2       | Phase 0             | Phase 0      |
| 3        | Phase 3       | Phase 0             | Phase 0      |
| 4        | Phase 4       | Phase 2             | Phase 0      |
| 5        | Phase 5       | Phase 2             | Phase 0      |
| 6        | Phase 6       | Phase 4             | Phase 0      |
| 7        | Phase 7       | Phase 4             | Phase 0      |

**Table 48-3. High speed 4 phase selection - sampling procedure**

| Samplers | InitialSample Phase | Intermediate Sample Phase | Final Sample Phase |
|----------|---------------------|---------------------------|--------------------|
| 0        | Phase 0             | Phase 0                   | Phase 0            |
| 1        | Disabled            | Disabled                  | Disabled           |
| 2        | Phase 2             | Phase 0                   | Phase 0            |
| 3        | Disabled            | Disabled                  | Disabled           |
| 4        | Phase 4             | Phase 2                   | Phase 0            |
| 5        | Disabled            | Disabled                  | Disabled           |
| 6        | Phase 6             | Phase 4                   | Phase 0            |
| 7        | Disabled            | Disabled                  | Disabled           |

For High speed 4 Phase selection, See [Table 48-3](#), Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

**Table 48-4. Low speed 4 phase selection - sampling procedure**

| Samplers | InitialSample Phase | Intermediate Sample Phase | Final Sample Phase |
|----------|---------------------|---------------------------|--------------------|
| 0        | Phase 0             | Phase 0                   | Phase 0            |

*Table continues on the next page...*

**Table 48-4. Low speed 4 phase selection - sampling procedure (continued)**

| Samplers | InitialSample Phase | Intermediate Sample Phase | Final Sample Phase |
|----------|---------------------|---------------------------|--------------------|
| 1        | Phase 1             | Phase 0                   | Phase 0            |
| 2        | Phase 2             | Phase 0                   | Phase 0            |
| 3        | Phase 3             | Phase 0                   | Phase 0            |
| 4        | Disabled            | Disabled                  | Disabled           |
| 5        | Disabled            | Disabled                  | Disabled           |
| 6        | Disabled            | Disabled                  | Disabled           |
| 7        | Disabled            | Disabled                  | Disabled           |

For low speed 4 Phase selection, See [Table 48-4](#), Samplers 4, 5, 6, 7 are disabled. The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

#### 48.7.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

## Functional description

**Figure 48-10. 8 Samplers, each Sampler has 3 Registers**

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

Figure 48-11. Sampler 5 Logic

### 48.7.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the [Figure 48-12](#).

**Figure 48-12. Extracting Header and Payload from the 16-bit output from Auto correlation.**

### 48.7.3 Transmit Controller

This section describes the Transmit Controller.

#### 48.7.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, CTS, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

**Figure 48-13. Transmit Controller Connections**

### 48.7.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in [Table 48-5](#)

**Table 48-5. Priority Levels for the Transmit Controller**

| Request                         | LFAST MasterPriority | LFAST SlavePriority | Triggering Conditions<br>(at least one of the listed)                                                                                                                                                                                                               |
|---------------------------------|----------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LFAST interface enable          | 1                    | 1                   | <ul style="list-style-type: none"> <li>• LFAST interface enable is asserted</li> <li>• LFAST interface enable is negated</li> </ul>                                                                                                                                 |
| Tx Interface disabled           | 2                    | 2                   | <ul style="list-style-type: none"> <li>• MCR[DRFEN] = 0</li> <li>• MCR[TXEN] = 0</li> <li>• MCR[DRFRST] = 1</li> <li>• MCR[TXARBD] = 1</li> <li>• LFAST Slave: ICLC frame with payload for "Disable Rx interface" received</li> </ul>                               |
| Tx Interface speedmode change   | 3                    | 3                   | <ul style="list-style-type: none"> <li>• SCR[TDR] is modified</li> <li>• LFAST Slave: ICLC frame with payload for changing Rx interface speed received</li> </ul>                                                                                                   |
| Loopback frame in Loopback mode | 4                    | 4                   | <ul style="list-style-type: none"> <li>• TMCR[LPON] = 1Dig</li> <li>• RF Slave: ICLC frame with payload for loopback mode enable received</li> </ul> <p><b>Note:</b> Valid only for following TMCR[LPMOD] settings:<br/>LPMOD[2:0] = 011b<br/>LPMOD[2:0] = 100b</p> |
| ICLC frame request              | 5                    | -                   | <ul style="list-style-type: none"> <li>• LFAST Master: ICR[SNDICLC] = 1</li> <li>• LFAST Master: ICR[ICLCSEQ] = 1</li> </ul>                                                                                                                                        |
| Ping response request           | -                    | 5                   | <ul style="list-style-type: none"> <li>• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1</li> <li>• LFAST Slave: PICR[PNGREQ] = 1</li> </ul>                                                                                   |

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

### 48.7.3.3 Line Driver digital connections

#### 48.7.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication. The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to  $V_{cm}$  (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

**Figure 48-14. Example of Sleep mode**

As shown in [Figure 48-14](#) before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. If the LD is not enabled, and the framer is activated,

and has a frame to transmit, an interrupt (TISR[TXIEF]) will be generated. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

**Table 48-6. Line Driver States**

| LD State | LFAST Master Triggers                                                                                                                        | LFAST Slave Triggers                                                                                                                                                                                                                        |

#### 48.7.4 CTS mode support

LFAST module supports flow control methods. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

##### CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write  $MCR[CTSEN] = 1$  then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device doesn't want the peer device to send data. The CTS bit of all frame are sent 0 untill the Rx FIFO pointer reaches the lower threshold, as described below.

- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 untill the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frame sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

### **CTS Reception:**

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed untill a frame with CTS bit 1 is received.

**Figure 48-15. CTS generation**

## **48.7.5 Frames supported**

Table 48-7 provides the frames supported and their permissible payload sizes

**Table 48-7. Frames supported by LFAST interfaces**

| Frame Type        | LCT Code      | Supported by 1.<br>LFAST Master Tx2.<br>LFAST Slave Rx | Supported by1.<br>LFAST Slave Tx2.<br>LFAST Master Rx | Payload Size (bits)             |
|-------------------|---------------|--------------------------------------------------------|-------------------------------------------------------|---------------------------------|
| Data Frame        | 0100b – 1011b | YES                                                    | YES                                                   | 32, 64, 96, 128, 256, 288       |
| Unsolicited Frame | 0001b         | YES                                                    | YES                                                   | 8, 32, 64, 96, 128, 256 and 288 |
| ICLC Frame        | 0000b         | YES                                                    | NO <sup>1</sup>                                       | 8                               |
| CTS Frame         | 0011b         | YES                                                    | YES                                                   | 8                               |
| Reserved          | All others    | —                                                      | —                                                     | —                               |

1. Except the ICLC PING response frame.

If logical channel type (LCT) code other than the above mentioned are received then the interrupt flag  $RISR[RXLCEF] = 1$ . If the payload size received does not match any value in [Table 48-7](#) then the flag  $RISR[RXSZF] = 1$ . In both these error conditions the received frame is ignored. The S/W may have to take the necessary steps to recover from such an error.

## 48.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

### 48.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

#### 48.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The  $MCR[DATAEN]$ ,  $MCR[DRFEN]$  and  $MCR[TXEN]$  bits, should be set to enable the transfer of Tx data.

If  $MCR[DATAEN] = 0$ , then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO. Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

#### 48.7.6.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTE] = 1 after each frame transfer
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

#### 48.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception. When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

#### 48.7.6.2 Unsolicited flow

### 48.7.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programmed into the Unsolicited Data and Control registers. Once the Payload is programmed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

#### 48.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programming of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
  - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
    - UNSTCR[USNDRQ] = 0
    - TISR[TXUNSF] = 1
  - If UNSTCR[USNDRQ] = 0 then:
    - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
    - Program the unsolicited frame header in UNSTCR[UNSHDR].
    - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

### 48.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.

3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

### 48.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

#### 48.7.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see [Table 48-8](#) for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

**Table 48-8. Supported ICLC Payloads**

| ICLC Code(hex) | ICLC Function                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------|
| 00             | Ping Request from LFAST Master to LFAST Slave                                                          |
| 01             | Reserved                                                                                               |
| 02             | Start PLL in preparation for High Speed mode                                                           |
| 04             | Stop PLL<br>Fallback to low speed mode                                                                 |
| 08             | Select TxData Slow (LFAST Slave Rx Interface)                                                          |
| 10             | Select TxData Fast (LFAST Slave Rx Interface)                                                          |
| 20             | Select RxData Slow (LFAST Slave Tx Interface)                                                          |
| 40             | Not Supported                                                                                          |
| 80             | Select RxData Fast (LFAST Slave Tx Interface)                                                          |
| 31             | Enable RxData Interface (LFAST Slave Tx Interface)                                                     |
| 32             | Disable RxData Interface (LFAST Slave Tx Interface)                                                    |
| 34             | Clock Test mode<br>Send 101010... continuously using the currently configured clock rate (slow, fast); |
| FF             | Turn payload loopback on                                                                               |
| 38             | Turn Test mode (Loopback and Clock Test) off                                                           |

**Programing model for ICLC frame transmit:**

1. Set the ICR[ICLCSEQ] bit (optional)
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the [Table 48-8](#).
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exist.

### Note

ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in [Table 48-8](#).

#### 48.7.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in [Table 48-8](#) will cause RISR[RXICF] = 1.

##### 48.7.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

##### 48.7.6.3.2.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

**48.7.6.3.2.3 LFAST Slaves TxData Interface Slow/Fast ICLC**

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

**48.7.6.3.2.4 Enable/Disable LFAST Slaves TxData Interface ICLC**

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

**48.7.6.3.2.5 Clock Test mode ICLC**

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

**48.7.6.3.2.6 Loopback payload on ICLC**

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

**48.7.6.3.2.7 Test mode off ICLC**

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable.

#### 48.7.6.3.2.8 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

### 48.7.6.4 CTS flow

#### 48.7.6.4.1 CTS Tx flow

The CTS frame, if enabled by the S/W, indicates the status of the Receive Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

##### Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

#### 48.7.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frame with LCT type CTS are not stored in the LFAST.

## 48.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

### 48.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

**Table 48-9. Loopback modes**

| LPMOD[2:0] | Mode Selected                                               |
|------------|-------------------------------------------------------------|
| 000        | Rx Loopback (default)                                       |
| 001        | Rx LVDS Loopback                                            |
| 010        | Tx Loopback without Automatic frame generation              |
| 011        | Tx Loopback with Automatic frame generation                 |
| 100        | Tx LVDS Loopback (external) with Automatic frame generation |

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.

- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

#### 48.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 48-16. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
  - S/W programs TMCR[LPON] = 1.
  - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs  $\text{TMCR}[\text{LPON}] = 0$
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

#### 48.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 48-17. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs  $\text{TMCR}[\text{LPMOD}] = 001b$ .
2. Loopback can be turned ON by either of the following methods:

- S/W writes  $\text{TMCR}[\text{LPON}] = 1$ .
- For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs  $\text{TMCR}[\text{LPON}] = 0$ .
- For LFAST Slave:
  - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.

#### 48.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

**Figure 48-18. Tx LoopBack mode without automatic frame generation**

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs  $\text{TMCR}[\text{LPMOD}] = 010b$ .
2. Loopback can be turned on by either of the following methods:
  - S/W programs  $\text{TMCR}[\text{LPON}] = 1$ .
  - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs  $\text{TMCR}[\text{LPON}] = 0$ .
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

#### 48.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- $\text{ALCR}[\text{LPCNTEN}]$  defines whether fixed number of auto loopback frames to be transmitted
- $\text{ALCR}[\text{LPFMCNT}]$  defines the number of loopback frames to be transmitted if  $\text{ALCR}[\text{LPCNTEN}] = 1$ .

The Status signals and register used for these modes are:

- $\text{GSR}[\text{LPCSDV}]$ : Valid Synchronization received.
- $\text{GSR}[\text{LPCHDV}]$ : Frame with Header of 13h received.
- $\text{GSR}[\text{LPCPDV}]$ : Frame with Payload of CBh received.
- $\text{GSR}[\text{LPTXDN}]$ : Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to  $\text{ALCR}[\text{LPFMCNT}]$ .

**Figure 48-19. Automatic Loopback Test status signal timings**

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

#### **48.7.7.1.4.1 Tx loopback mode with automatic frame generation**

When **TMCR[LPMOD] = 011b** (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

**Figure 48-20. Tx LoopBack mode with automatic frame generation**

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
  - S/W programs TMCR[LPON] = 1.
  - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

#### **48.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation**

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

**Figure 48-21. Tx LVDS loopback (external) mode with automatic frame generation**

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs  $\text{TMCR}[\text{LPMOD}] = 100\text{b}$ .
2. Loopback can be turned on by either of the following methods:
  - S/W programs  $\text{TMCR}[\text{LPON}] = 1$ .
  - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by the following method:

- S/W programs  $\text{TMCR}[\text{LPON}] = 0$ .

#### 48.7.7.2 Clock test mode

The bit  $\text{TMCR}[\text{CLKTST}]$  enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs  $\text{TMCR}[\text{CLKTST}]$ .

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs  $\text{TMCR}[\text{CLKTST}] = 0$ .
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

## 48.7.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC receive interrupt

Each interrupt is asserted when any one of their status conditions is met.

### 48.7.8.1 Transmit complete interrupt

This interrupt indicates a transfer completion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

### 48.7.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

**Table 48-10. Recommended transmit exception handling**

| Exception | Recommendation                                                                                                                                                                                                                                                                                                                                        |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TXOVF     | <ul style="list-style-type: none"> <li>• MCR[TXEN] = 0</li> <li>• The system level interfaces transmit is reseted and enabled again</li> <li>• For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set</li> <li>• For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent</li> </ul> |
| TXIEF     | <ul style="list-style-type: none"> <li>• The MCR[TXEN] should be set</li> </ul>                                                                                                                                                                                                                                                                       |

### 48.7.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

#### 48.7.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RXMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

**Table 48-11. Recommended receive exception handling mechanism**

| Exception | Recommendation                                                                                                                                                                                 |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RXLCEF    | The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet                                                                                                |
| RXICF     | No action required                                                                                                                                                                             |
| RXSZF     | The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet                                                                                                |
| RXOFF     | <ul style="list-style-type: none"> <li>• The MCR[RXEN] may be cleared</li> <li>• The system level interfaces receive may be reset and enabled, as current transfer may be corrupted</li> </ul> |
| RXUFF     | No action required                                                                                                                                                                             |
| RXMXF     | The system level interfaces receive should be enabled, if not enabled                                                                                                                          |
| RXMNF     | No action required                                                                                                                                                                             |
| RXUNSF    | No action required                                                                                                                                                                             |

### 48.7.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

## 48.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has its own dedicated buffer, and they are not shared between each other.

**Table 48-12. Frames Supported by LFAST interfaces**

| Frame Type        | Tx Buffer(in bits)                 | Rx Buffer(in bits)                 | Memory Type                          |
|-------------------|------------------------------------|------------------------------------|--------------------------------------|
| Data Frame        | 38 × 32<br>max 6 packets           | 38 × 32<br>max 6 packets           | FIFO                                 |
| Unsolicited Frame | 9 × 32<br>max 1 packet             | 9 × 32<br>max 1 packet             | Registers<br>UNSTD[8-0], UNSRDR[8-0] |
| ICLC Frame        | 1 × 7<br>max 1 packet <sup>1</sup> | 1 × 8<br>max 1 packet <sup>2</sup> | Registers<br>ICR, PISR               |
| CTS Frame         | N/A                                | N/A                                | N/A                                  |

1. Only for MCR[MSEN] = 1

2. Only for ping response data when MCR[MSEN] = 1

## 48.9 Resets

The various blocks in LFAST are reset as described in the table below.

**Table 48-13. Recommended receive exception handling mechanism**

| Reset                                           | Blocks Reset                                                                                                                                                                                                                                                                                                                                                                                            |

## 48.10 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

### 48.10.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of `lfast_sysclk`, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

**Figure 48-22. LFAST module clock domains**

## 48.10.2 Slow speed clock

### 48.10.2.1 External muxing

The Clock Control Module will receive `lfast_sysclk` from the clocking subsystem as shown in [Figure 48-23](#), [Figure 48-24](#) and [Figure 48-25](#).

**Figure 48-23. External clock muxing of lfast\_sysclk**

All the reference clocks will be muxed first to provide lfast\_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in [Figure 48-23](#).

The lfast\_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast\_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency  $\text{lfast\_sysclk}/4$  when  $\text{MCR}[\text{LSSEL}] = 1$ . If lfast\_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 48-24](#) (selected clock path shown in green).

**Figure 48-24. External clock muxing of lfast\_sysclk of 20/26 MHz**

In this case, lfast\_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast\_sysclk/2 when MCR[LSSEL] = 0. If lfast\_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 48-25 (selected clock path selected shown in magenta).

**Figure 48-25. External clock muxing of lfast\_sysclk of 10 MHz**

### 48.10.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if `lfast_sysclk` is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using `lfast_sysclk`.

Figure 48-26. Slow speed 4 phases generation

## 48.10.3 Rx Controller Clocks

### 48.10.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

**Figure 48-27. Clock enables and clock paths**

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

## 48.10.5 Clock module requirements for low speed phases

### 48.10.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 48-14. Rx clocks summary

| Rx Speed mode | Source       |
|---------------|--------------|
| Low Speed     | lfast_sysclk |
| High Speed    | PLL          |

48.10.6 Tx Controller Clocks

48.10.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast\_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 48-15. Tx clocks summary

| Tx Speed mode | Source       |
|---------------|--------------|
| Low Speed     | lfast_sysclk |
| High Speed    | PLL          |

48.10.6.2 Transmit Clock Muxing

Figure 48-28. Transmit Clocks Muxing

### **48.10.6.3 Tx Request Clock Control**

The Tx phase 0 clock is enabled when all the resets are negated.

# Chapter 49

## Serial Peripheral Interface (SPI)

### 49.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device.

#### 49.1.1 Block Diagram

The block diagram of this module is as follows:

Figure 49-1. SPI Block Diagram

## 49.1.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 5 entries
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 5 entries
- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues

- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - four transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 16 bits
    - SPI frames longer than 16 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
- 8 peripheral chip selects (PCSeS), expandable to 256 with external demultiplexer
- Deglitching support for up to 128 peripheral chip selects (PCSeS) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - Transfer of current frame complete (TCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
- Global interrupt request line
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
  - Support for Stop mode

### 49.1.3 Interface configurations

#### 49.1.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

Figure 49-2. SPI with queues and DMA

#### 49.1.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode

- Slave mode
- Module Disable mode
- Chip-specific modes:
  - External Stop mode
  - Debug mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

#### 49.1.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- SOUT
- PCS[x]

#### 49.1.4.2 Slave Mode

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{\text{SS}}$  signals are configured as inputs and driven by an SPI bus master.

#### 49.1.4.3 Module Disable Mode

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

#### 49.1.4.4 External Stop Mode

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

#### 49.1.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the chip is in debug mode.
- If the bit is cleared, the chip debug mode has no effect on the module.

## 49.2 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

**Table 49-1. Module signal descriptions**

| Signal                         | Master mode                                             | Slave mode       | I/O |
|--------------------------------|---------------------------------------------------------|------------------|-----|
| PCS0/SS                        | Peripheral Chip Select 0 (O)                            | Slave Select (I) | I/O |
| PCS[1:3]                       | Peripheral Chip Selects 1–3                             | (Unused)         | O   |
| PCS4                           | Peripheral Chip Select 4                                | (Unused)         | O   |
| PCS5/ $\overline{\text{PCSS}}$ | Peripheral Chip Select 5 /Peripheral Chip Select Strobe | (Unused)         | O   |
| PCS[6:7]                       | Peripheral Chip Selects 6–7                             | (Unused)         | O   |
| SCK                            | Serial Clock (O)                                        | Serial Clock (I) | I/O |
| SIN                            | Serial Data In                                          | Serial Data In   | I   |
| SOUT                           | Serial Data Out                                         | Serial Data Out  | O   |

### 49.2.1 PCS0/SS—Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

### 49.2.2 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 49.2.3 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 49.2.4 PCS5/ $\overline{\text{PCSS}}$ —Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

### 49.2.5 PCS6–PCS7—Peripheral Chip Selects 6–7

Master mode: Peripheral Chip Selects 6–7 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

### 49.2.6 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

### 49.2.7 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

### 49.2.8 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

#### NOTE

Serial Data Out output buffers are controlled through SIU (or SIUL) and cannot be controlled through the module.

## 49.3 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Write access to the POPR and RXFRn also results in a transfer error.

**SPI memory map**

| Address offset (hex) | Register name                                                            | Width (in bits) | Access | Reset value | Section/page                |
|----------------------|--------------------------------------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Module Configuration Register (SPI_MCR)                                  | 32              | R/W    | 0000_4001h  | <a href="#">49.3.1/1584</a> |

49.3.1 Module Configuration Register (SPI\_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: 0h base + 0h offset = 0h

**SPI\_MCR field descriptions (continued)**

| Field | Description      |
|-------|------------------|
| 0     | Start transfers. |
| 1     | Stop transfers.  |

**49.3.2 Transfer Count Register (SPI\_TCR)**

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: 0h base + 8h offset = 8h

**SPI\_TCR field descriptions**

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>SPI_TCNT  | SPI Transfer Counter<br><br>Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero. |
| 16–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                    |

**49.3.3 Clock and Transfer Attributes Register (In Master Mode) (SPI\_CTAR<sub>n</sub>)**

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

## Memory Map/Register Definition

When the module is configured as an SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

Address: 0h base + Ch offset + (4d × i), where i=0d to 3d

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p>The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. There is a constraint on the minimum allowable Frame size, which depends on the ratio of the Register Read/Write clock to the Protocol clock. The minimum Frame size (FMSZ + 1) is determined by the following equation. Upper Ceiling must be applied for non-integer values.</p> $\text{Minimum Frame Size} = ( (4 \times f_p) + (3 \times f_r) ) / (n \times f_r)$ <p><math>f_p</math> = Protocol clock frequency<br/> <math>f_r</math> = Register interface clock frequency<br/> <math>n = (\text{PBR} \times \text{BR}) / (1 + \text{DBR})</math> = Multiple of protocol clock required to get Baud (SCK) Clock</p> <p>However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Also note that 'fp' can be equal to, less than or greater than 'fr' purely based on user requirement.</p> |
| 5<br>CPOL     | <p>Clock Polarity</p> <p>Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge.</p> <p><b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.</p> <p>0 The inactive state value of SCK is low.<br/> 1 The inactive state value of SCK is high.</p>                                                                                                                                                                                                                                                                    |
| 6<br>CPHA     | <p>Clock Phase</p> <p>Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.</p> <p>0 Data is captured on the leading edge of SCK and changed on the following edge.<br/> 1 Data is changed on the leading edge of SCK and captured on the following edge.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 7<br>LSBFE    | <p>LSB First</p> <p>Specifies whether the LSB or MSB of the frame is transferred first.</p> <p>0 Data is transferred MSB first.<br/> 1 Data is transferred LSB first.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 8–9<br>PCSSCK | <p>PCS to SCK Delay Prescaler</p> <p>Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. | 12–13<br>PDT   | <p>Delay after Transfer Prescaler</p> <p>Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer <a href="#">Delay after Transfer (t<sub>DT</sub>)</a> for more details.</p> <p>00 Delay after Transfer Prescaler value is 1.<br/> 01 Delay after Transfer Prescaler value is 3.<br/> 10 Delay after Transfer Prescaler value is 5.<br/> 11 Delay after Transfer Prescaler value is 7.</p>                                                                                                                                                                                                                    |             |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |
| 14–15<br>PBR   | <p>Baud Rate Prescaler</p> <p>Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate.</p> <p>00 Baud Rate Prescaler value is 2.<br/> 01 Baud Rate Prescaler value is 3.<br/> 10 Baud Rate Prescaler value is 5.<br/> 11 Baud Rate Prescaler value is 7.</p>                                                                                                                                                                                                                                                                                                                                                |             |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |
| 16–19<br>CSSCK | <p>PCS to SCK Delay Scaler</p> <p>Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation:</p> $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$ <p>The following table lists the delay scaler values.</p> <p style="text-align: center;"><b>Table 49-3. 49.3.5 Status Register (SPI\_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

**SPI\_SR field descriptions (continued)**

| Field              | Description                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14<br>RFDF         | <p>Receive FIFO Drain Flag</p> <p>Provides a method for the module to request that entries be removed from the RX FIFO. The bit is set while the RX FIFO is not empty. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty.</p> <p>0 RX FIFO is empty.<br/>1 RX FIFO is not empty.</p> |
| 15<br>Reserved     | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                        |
| 16–19<br>TXCTR     | <p>TX FIFO Counter</p> <p>Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHX is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.</p>                                                                                       |
| 20–23<br>TXNXTPTR  | <p>Transmit Next Pointer</p> <p>Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.</p>                                                                                                                                       |
| 24–27<br>RXCTR     | <p>RX FIFO Counter</p> <p>Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.</p>                                                                                                                       |
| 28–31<br>POPXNTPTR | <p>Pop Next Pointer</p> <p>Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPXNTPTR is updated when the POPR is read.</p>                                                                                                                                                                                              |

### 49.3.6 DMA/Interrupt Request Select and Enable Register (SPI\_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: 0h base + 30h offset = 30h

**49.3.7 PUSH TX FIFO Register In Master Mode (SPI\_PUSHR)**

Specifies data to be transferred to the TX FIFO. An 8- or 16-bit write access transfers all 32 bits to the TX FIFO. In Master mode, the register transfers 16 bits of data and 16 bits of command information. A read access of PUSHR returns the topmost TX FIFO entry.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: 0h base + 34h offset = 34h

## 49.3.9 POP RX FIFO Register (SPI\_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: 0h base + 38h offset = 38h

49.3.11 Receive FIFO Registers (SPI\_RXFRn)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO. The field MCR[MDIS] must be 0 when RXFR is read.

NOTE

Accessing the SPI\_RXFRn register will cause all subsequent SPI register accesses to be incorrect. Hence, the user should only read received data through, [SPI\\_POPR](#).

Address: 0h base + 7Ch offset + (4d × i), where i=0d to 4d

## 49.4 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module has the following configuration

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPI<sub>x</sub>\_MCR is 0b00.

The CTAR<sub>n</sub> registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See [Clock and Transfer Attributes Register \(In Master Mode\) \(SPI\\_CTAR<sub>n</sub>\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

**Figure 49-3. Serial protocol overview**

Generally, more than one slave device can be connected to the module master. 8 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The SPI configuration shares transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

### **49.4.1 Start and Stop of module transfers**

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

## 49.4.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

### 49.4.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(SPI\\_PUSHR\)](#) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

### 49.4.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

### 49.4.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS\_TXF] bit disables the TX FIFO, and setting the MCR[DIS\_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO is disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

### 49.4.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 5 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

#### 49.4.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO by writing to the PUSHHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller

indicates that a write to PUSHHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

#### 49.4.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR\_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

#### 49.4.2.5 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 5 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

#### 49.4.2.5.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

#### 49.4.2.5.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX\_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

### 49.4.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

**Figure 49-4. Communications clock prescalers and scalers**

### 49.4.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

**Table 49-5. Baud rate computation example**

| $f_p$   | PBR  | Prescaler | BR     | Scaler | DBR | Baud rate |
|---------|------|-----------|--------|--------|-----|-----------|
| 100 MHz | 0b00 | 2         | 0b0000 | 2      | 0   | 25 Mb/s   |
| 20 MHz  | 0b00 | 2         | 0b0000 | 2      | 1   | 10 Mb/s   |

#### NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 49.4.3.2 PCS to SCK Delay ( $t_{csc}$ )

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 49-6](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR<sub>x</sub> registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

**Table 49-6. PCS to SCK delay computation example**

| $f_{sys}$ | PCSSCK | Prescaler | CSSCK  | Scaler | PCS to SCK Delay |
|-----------|--------|-----------|--------|--------|------------------|
| 100 MHz   | 0b01   | 3         | 0b0100 | 32     | 0.96 $\mu$ s     |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 49.4.3.3 After SCK Delay ( $t_{ASC}$ )

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 49-6](#) and [Figure 49-7](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR<sub>x</sub> registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

**Table 49-7. After SCK Delay computation example**

| $f_p$   | PASC | Prescaler | ASC    | Scaler | After SCK Delay |
|---------|------|-----------|--------|--------|-----------------|
| 100 MHz | 0b01 | 3         | 0b0100 | 32     | 0.96 $\mu$ s    |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 49.4.3.4 Delay after Transfer ( $t_{DT}$ )

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 49-6](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR<sub>x</sub> registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

**Table 49-8. Delay after Transfer computation example**

| $f_p$   | PDT  | Prescaler | DT     | Scaler | Delay after Transfer |
|---------|------|-----------|--------|--------|----------------------|
| 100 MHz | 0b01 | 3         | 0b1110 | 32768  | 0.98 ms              |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the  $t_{DT}$  delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

### 49.4.3.5 Peripheral Chip Select Strobe Enable ( $\overline{\text{PCSS}}$ )

The  $\overline{\text{PCSS}}$  signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR,  $\overline{\text{PCSS}}$  provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the  $\overline{\text{PCSS}}$  signal relative to PCS signals.

**Figure 49-5. Peripheral Chip Select Strobe timing**

The delay between the assertion of the PCS signals and the assertion of  $\overline{\text{PCSS}}$  is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_P} \times \text{PCSSCK}$$

At the end of the transfer, the delay between  $\overline{\text{PCSS}}$  negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_P} \times \text{PASC}$$

The following table shows an example of how to compute the  $t_{\text{pcssck}}$  delay.

**Table 49-9. Peripheral Chip Select Strobe Assert computation example**

| $f_P$   | PCSSCK | Prescaler | Delay before Transfer |
|---------|--------|-----------|-----------------------|
| 100 MHz | 0b11   | 7         | 70.0 ns               |

The following table shows an example of how to compute the  $t_{\text{pasc}}$  delay.

**Table 49-10. Peripheral Chip Select Strobe Negate computation example**

| $f_P$   | PASC | Prescaler | Delay after Transfer |
|---------|------|-----------|----------------------|
| 100 MHz | 0b11 | 7         | 70.0 ns              |

The  $\overline{\text{PCSS}}$  signal is not supported when Continuous Serial Communication SCK mode is enabled.

**NOTE**

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

**49.4.4 Transfer formats**

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

#### 49.4.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

**Figure 49-6. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)**

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the  $t_{CSC}$  delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signals. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 49.4.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

**Figure 49-7. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)**

The master initiates the transfer by asserting the PCS signal to the slave. After the  $t_{CSC}$  delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signal. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

#### 49.4.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI\_MCR[SMPL\_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL\_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- $T_{csc}$  - PCS to SCK assertion delay
- $T_{acs}$  - After SCK PCS negation delay
- $T_{su_{ms}}$  - master SIN setup time
- $T_{hd_{ms}}$  - master SIN hold time
- $T_{vd_{sl}}$  - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$  - data setup time on slave data input
- $T_{hd_{sl}}$  - data hold time on slave data input
- $T_{sys}$  - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and  $F_{sys}/F_{sck} = 4$ . Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

## Functional description

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

### Note

In the following diagrams,  $f_{\text{sys}}$  represents the protocol clock frequency from which the Baud frequency  $f_{\text{sck}}$  is derived.

**Figure 49-8. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{\text{sck}} = f_{\text{sys}}/4$ )**

Figure 49-9. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/2$ )

Figure 49-10. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/3$ )

#### 49.4.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT

signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

Figure 49-11. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/2$ )

Figure 49-12. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/3$ )

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

**Figure 49-14. Example of non-continuous format (CPHA=1, CONT=0)**

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers ( $t_{DT}$ ) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

**Figure 49-15. Example of continuous transfer (CPHA=1, CONT=1)**

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX\_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

### NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

## 49.4.5 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT\_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT\_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer ( $t_{DT}$ ) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

### NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR\_TXF] field before initiating transfer.

**Figure 49-16. Continuous SCK Timing Diagram (CONT=0)**

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

**Figure 49-17. Continuous SCK timing diagram (CONT=1)**

### 49.4.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the  $\overline{SS}$  signal is asserted and any time when transmit data is ready and  $\overline{SS}$  signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the  $\overline{SS}$  negates before that last SCK edge, the data from shift register is lost.

### 49.4.7 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

**Table 49-11. Interrupt and DMA request conditions**

| Condition          | Flag | Interrupt | DMA |
|--------------------|------|-----------|-----|
| End of Queue (EOQ) | EOQF | Yes       | -   |
| TX FIFO Fill       | TFFF | Yes       | Yes |
| Transfer Complete  | TCF  | Yes       | -   |
| TX FIFO Underflow  | TFUF | Yes       | -   |

*Table continues on the next page...*

**Table 49-11. Interrupt and DMA request conditions (continued)**

| Condition        | Flag | Interrupt | DMA |
|------------------|------|-----------|-----|
| RX FIFO Drain    | RFDF | Yes       | Yes |
| RX FIFO Overflow | RFOF | Yes       | -   |

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

#### 49.4.7.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF\_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

#### 49.4.7.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF\_RE bit in the RSER is set. The TFFF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

#### NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

### 49.4.7.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF\_RE bit is set in the RSER.

### 49.4.7.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF\_RE bit in the RSER is set, an interrupt request is generated.

### 49.4.7.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF\_RE bit in the RSER is set. The RFDF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

### 49.4.7.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF\_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

## 49.4.8 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

#### 49.4.8.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

#### 49.4.8.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS\_TXF and DIS\_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

### 49.5 Initialization/application information

This section describes how to initialize the module.

### 49.5.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO by writing a 1 to the CLR\_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR\_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI\_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

### 49.5.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR\_TXF and CLR\_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

### 49.5.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

### 49.5.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

#### NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

**Table 49-12. Baud rate values (bps)**

|                         |      | Baud rate divider prescaler values |       |       |       |
|-------------------------|------|------------------------------------|-------|-------|-------|
|                         |      | 2                                  | 3     | 5     | 7     |
| Baud Rate Scaler Values | 2    | 25.0M                              | 16.7M | 10.0M | 7.14M |
|                         | 4    | 12.5M                              | 8.33M | 5.00M | 3.57M |
|                         | 6    | 8.33M                              | 5.56M | 3.33M | 2.38M |
|                         | 8    | 6.25M                              | 4.17M | 2.50M | 1.79M |
|                         | 16   | 3.12M                              | 2.08M | 1.25M | 893k  |
|                         | 32   | 1.56M                              | 1.04M | 625k  | 446k  |
|                         | 64   | 781k                               | 521k  | 312k  | 223k  |
|                         | 128  | 391k                               | 260k  | 156k  | 112k  |
|                         | 256  | 195k                               | 130k  | 78.1k | 55.8k |
|                         | 512  | 97.7k                              | 65.1k | 39.1k | 27.9k |
|                         | 1024 | 48.8k                              | 32.6k | 19.5k | 14.0k |
|                         | 2048 | 24.4k                              | 16.3k | 9.77k | 6.98k |

*Table continues on the next page...*

**Table 49-12. Baud rate values (bps) (continued)**

|  |       | Baud rate divider prescaler values |       |       |       |
|--|-------|------------------------------------|-------|-------|-------|
|  |       | 2                                  | 3     | 5     | 7     |
|  | 4096  | 12.2k                              | 8.14k | 4.88k | 3.49k |
|  | 8192  | 6.10k                              | 4.07k | 2.44k | 1.74k |
|  | 16384 | 3.05k                              | 2.04k | 1.22k | 872   |
|  | 32768 | 1.53k                              | 1.02k | 610   | 436   |

### 49.5.5 Delay settings

The following table shows the values for the Delay after Transfer ( $t_{DT}$ ) and CS to SCK Delay ( $T_{CSC}$ ) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

#### NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

**Table 49-13. Delay values**

|                     |       | Delay prescaler values |               |               |               |
|---------------------|-------|------------------------|---------------|---------------|---------------|
|                     |       | 1                      | 3             | 5             | 7             |
| Delay scaler values | 2     | 20.0 ns                | 60.0 ns       | 100.0 ns      | 140.0 ns      |
|                     | 4     | 40.0 ns                | 120.0 ns      | 200.0 ns      | 280.0 ns      |
|                     | 8     | 80.0 ns                | 240.0 ns      | 400.0 ns      | 560.0 ns      |
|                     | 16    | 160.0 ns               | 480.0 ns      | 800.0 ns      | 1.1 $\mu$ s   |
|                     | 32    | 320.0 ns               | 960.0 ns      | 1.6 $\mu$ s   | 2.2 $\mu$ s   |
|                     | 64    | 640.0 ns               | 1.9 $\mu$ s   | 3.2 $\mu$ s   | 4.5 $\mu$ s   |
|                     | 128   | 1.3 $\mu$ s            | 3.8 $\mu$ s   | 6.4 $\mu$ s   | 9.0 $\mu$ s   |
|                     | 256   | 2.6 $\mu$ s            | 7.7 $\mu$ s   | 12.8 $\mu$ s  | 17.9 $\mu$ s  |
|                     | 512   | 5.1 $\mu$ s            | 15.4 $\mu$ s  | 25.6 $\mu$ s  | 35.8 $\mu$ s  |
|                     | 1024  | 10.2 $\mu$ s           | 30.7 $\mu$ s  | 51.2 $\mu$ s  | 71.7 $\mu$ s  |
|                     | 2048  | 20.5 $\mu$ s           | 61.4 $\mu$ s  | 102.4 $\mu$ s | 143.4 $\mu$ s |
|                     | 4096  | 41.0 $\mu$ s           | 122.9 $\mu$ s | 204.8 $\mu$ s | 286.7 $\mu$ s |

## 49.5.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 49-18. TX FIFO pointers and counter

### 49.5.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXTPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

#### 49.5.6.2 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

## FlexRay Communication Controller (FlexRay)

### 50.1 Introduction

#### NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information.

This section provides a high-level summary of module features.

#### 50.1.1 Reference

The following documents are referenced.

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*<sup>1</sup>
  - Refer to this document for the all of the FlexRay related informaton including the configuration parameters and the allowed parameter ranges.
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0*

#### 50.1.2 Glossary

This section provides a list of terms used in this chapter.

---

1. The FlexRay Specifications have been developed for automotive applications. The FlexRay Specifications have been neither developed nor tested for non-automotive applications.

Table 50-1. List of terms

| Term                          | Definition                                                                                                                                                                                                                 |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BCU                           | Buffer Control Unit. Handles message buffer access.                                                                                                                                                                        |
| BMIF                          | Bus Master Interface. Provides master access to FlexRay memory area.                                                                                                                                                       |
| CC                            | Communication Controller                                                                                                                                                                                                   |
| CDC                           | Clock Domain Crosser                                                                                                                                                                                                       |
| CHI                           | Controller Host Interface                                                                                                                                                                                                  |
| Cycle length in $\mu\text{T}$ | The actual length of a cycle in $\mu\text{T}$ for the ideal controller (+/- 0 ppm)                                                                                                                                         |
| EBI                           | External Bus Interface                                                                                                                                                                                                     |
| FlexRay Memory Area           | Memory area to store the physical message buffer payload data, frame header, frame and slot status, and synchronization frame related tables.                                                                              |
| FSS                           | Frame Start Sequence                                                                                                                                                                                                       |
| HIF                           | Host Interface. Provides host access to controller.                                                                                                                                                                        |
| Host                          | The FlexRay CC host MCU                                                                                                                                                                                                    |
| Keyslot                       | Key slot is used to transmit the startup frame, sync frame, or designated single slot frame.                                                                                                                               |
| LUT                           | Look Up Table. Stores message buffer header index value.                                                                                                                                                                   |
| LRAM                          | Look Up Table RAM. Module internal memory to store message buffer configuration data and data field offsets for individual message buffers and receive shadow buffers.                                                     |
| MB                            | Message Buffer                                                                                                                                                                                                             |
| Mini-slot                     | An interval of time within the dynamic segment of the communication cycle that is of constant duration (in terms of microticks) and that is used by the synchronized FTDMA media access scheme to manage media arbitration |
| MBIDX                         | Message Buffer Index: the position of a header field entry within the header area. If the header area is accessed as an array, this is the same as the array index of the entry.                                           |
| MBNum                         | Message Buffer Number: Position of message buffer configuration registers within the register map. For example, Message Buffer Number 5 corresponds to the MBCCS5 register.                                                |
| MCU                           | Microcontroller Unit                                                                                                                                                                                                       |
| $\mu\text{T}$                 | Microtick                                                                                                                                                                                                                  |
| MT                            | Macrotick                                                                                                                                                                                                                  |
| MTS                           | Media Access Test Symbol                                                                                                                                                                                                   |
| message frame                 | Frame with <i>Null Frame Indicator</i> set to 1                                                                                                                                                                            |
| normal frame                  | null frame or message frame with both <i>Sync Frame Indicator</i> and <i>Startup Frame Indicator</i> set to 0                                                                                                              |
| null frame                    | frame with <i>Null Frame Indicator</i> set to 0                                                                                                                                                                            |
| NIT                           | Network Idle Time                                                                                                                                                                                                          |
| PE                            | Protocol Engine                                                                                                                                                                                                            |
| POC                           | Protocol Operation Control. Each state of the POC is denoted by POC:state                                                                                                                                                  |
| Rx                            | Reception                                                                                                                                                                                                                  |
| Slot                          | An interval of time during which access to a communication channel is granted exclusively to a specific node for the transmission of a frame with a frame ID corresponding to the slot.                                    |
| SEQ                           | Sequencer Engine                                                                                                                                                                                                           |
| SU                            | Status update                                                                                                                                                                                                              |

**Table 50-1. List of terms (continued)**

| Term          | Definition                                                                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------|
| SECEDED       | Single-bit error correction, double-bit error detection                                                       |
| System Memory | Memory that contains the FlexRay Memory Area.                                                                 |
| System Bus    | Bus that connects the controller and System Memory                                                            |
| sync frame    | null frame or message frame with <i>Sync Frame Indicator</i> set to 1                                         |
| startup frame | null frame or message frame with both <i>Sync Frame Indicator</i> and <i>Startup Frame Indicator</i> set to 1 |
| TCU           | Time Control Unit                                                                                             |
| Tx            | Transmission                                                                                                  |

### 50.1.3 Overview

The CC is a FlexRay communication controller that implements the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

The CC has three main components:

- *Controller host interface (CHI)*
- *Protocol engine (PE)*
- *Clock domain crossing unit (CDC)*

A block diagram of the CC with its surrounding modules is given in the below figure.

**Figure 50-1. FlexRay block diagram**

The protocol engine has two transmitter units TxA and TxB and two receiver units RxA and RxB for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the PE is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, and the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the CHI clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the System Memory Base Address Register (FR\_SYMBADHR and

FR\_SYMBADLR). All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

### Note

The CC does not provide a memory protection scheme for the FlexRay memory area.

## 50.1.4 Features

The CC provides the following features:

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A compliant protocol implementation*
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0 compliant bus driver interface*
- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B.
- Dual channel support
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 64 configurable message buffers with
  - individual frame ID filtering
  - individual channel ID filtering
  - individual cycle counter filtering
- Message buffer header, status and payload data stored in dedicated FlexRay memory area
  - allows for flexible and efficient message buffer implementation
  - consistent data access ensured by means of buffer locking scheme
  - application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0 up to 254 bytes
- Two independent message buffer segments with configurable size of payload data section

- each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
  - applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
  - receive message buffer
  - transmit message buffer
- Individual message buffer reconfiguration supported
  - means provided to safely disable individual message buffers
  - disabled message buffers can be reconfigured
- Two independent receive FIFOs
  - one receive FIFO per channel
  - up to 255 entries for each FIFO
  - global frame ID filtering, based on both value/mask filters and range filters
  - global channel ID filtering
  - global message ID filtering for the dynamic segment
- 4 configurable slot error counters
- 4 dedicated slot status indicators
  - used to observe slots without using receive message buffers
- Measured value indicators for the clock synchronization
  - internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- 1 absolute timer
- 1 timer that can be configured to absolute or relative

- Error correction and error detection (SECDED ECC) for protocol engine data RAM
- Error detection (SECDED ECC) for CHI lookup table RAM

## 50.1.5 Modes of Operation

This section describes the basic operational power modes of the CC.

### 50.1.5.1 Disabled Mode

The CC enters the Disabled Mode during hard reset or when the host clears the ‘MEN’ field in the Module Configuration Register (FR\_MCR). The host can clear this field by writing ‘0’ and only when the module is in POC:default config mode. The Disabled mode can be checked by reading the module enable field, MEN, in the Module Configuration Register (FR\_MCR).

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled Mode* can be accessed for writing as stated in the Memory Map and Register Description section.

The application configures the CC by accessing the configuration bits and fields in the Module Configuration Register (FR\_MCR) as described in [Module Initialization](#).

#### 50.1.5.1.1 Leave Disabled Mode

The CC leaves the Disabled Mode and enters the Normal Mode, when the application writes 1 to the module enable bit MEN in the Module Configuration Register (FR\_MCR)

#### Note

Once the CC is enabled, it can only be disabled during POC: default config.

### 50.1.5.2 Normal Mode

In this mode the CC is fully functional. The CC indicates that it is in Normal Mode by asserting the module enable bit MEN in the Module Configuration Register (FR\_MCR).

### 50.1.5.2.1 Enter Normal Mode

This mode is entered when the application requests the CC to leave the Disabled Mode. If the Normal Mode was entered by leaving the Disabled Mode, the application has to perform the protocol initialization described in [Protocol Initialization](#) to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB bits in the Module Configuration Register (FR\_MCR), the corresponding FlexRay bus driver ports are enabled and driven.

## 50.2 External Signal Description

This section lists and describes the CC signals connected to external pins. These signals are summarized in the following table and described in detail in the Detailed Signal Descriptions section below.

### NOTE

Please refer the device configuration of the reference manual for the exact module pin names.

### NOTE

The off chip signals FR\_A\_RX, FR\_A\_TX, and  $\overline{\text{FR\_A\_TX\_EN}}$  are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

**Table 50-2. External Signal Properties**

| Name                              | Direction | Active | Reset | Function                  |
|-----------------------------------|-----------|--------|-------|---------------------------|
| FR_A_RX                           | Input     | —      | —     | Receive Data Channel A    |
| FR_A_TX                           | Output    | —      | 1     | Transmit Data Channel A   |
| $\overline{\text{FR\_A\_TX\_EN}}$ | Output    | Low    | 1     | Transmit Enable Channel A |
| FR_B_RX                           | Input     | —      | —     | Receive Data Channel B    |
| FR_B_TX                           | Output    | —      | 1     | Transmit Data Channel B   |
| $\overline{\text{FR\_B\_TX\_EN}}$ | Output    | Low    | 1     | Transmit Enable Channel B |
| FR_DBG[0]                         | Output    | —      | 0     | Debug Strobe Signal 0     |
| FR_DBG[1]                         | Output    | —      | 0     | Debug Strobe Signal 1     |
| FR_DBG[2]                         | Output    | —      | 0     | Debug Strobe Signal 2     |
| FR_DBG[3]                         | Output    | —      | 0     | Debug Strobe Signal 3     |

## 50.2.1 Detailed Signal Descriptions

This section provides a detailed description of the CC signals, connected to external pins.

### 50.2.1.1 FR\_A\_RX — Receive Data Channel A

The FR\_A\_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

### 50.2.1.2 FR\_A\_TX — Transmit Data Channel A

The FR\_A\_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

### 50.2.1.3 $\overline{\text{FR\_A\_TX\_EN}}$ — Transmit Enable Channel A

The  $\overline{\text{FR\_A\_TX\_EN}}$  signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

### 50.2.1.4 FR\_B\_RX — Receive Data Channel B

The FR\_B\_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

### 50.2.1.5 FR\_B\_TX — Transmit Data Channel B

The FR\_B\_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver.

### 50.2.1.6 $\overline{\text{FR\_B\_TX\_EN}}$ — Transmit Enable Channel B

The  $\overline{\text{FR\_B\_TX\_EN}}$  signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

### 50.2.1.7 FR\_DBG[3], FR\_DBG[2], FR\_DBG[1], FR\_DBG[0] — Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection refer to the [Strobe Signal Support](#).

## 50.3 Controller Host Interface Clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

The first constraint corresponds to the number of utilized message buffers and is specified in [Number of Usable Message Buffers](#).

The second constraint corresponds to the value of the TIMEOUT field in the System Memory Access Time-Out Register (FR\_SYMATOR) and is specified in [Configure System Memory Access Time-Out Register \(FR\\_SYMATOR\)](#).

## 50.4 Protocol Engine Clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select bit CLKSEL in the Module Configuration Register (FR\_MCR).

### Note

See the Device clocking details for the exact clock sources used.

### 50.4.1 Oscillator Clocking

If the protocol engine is clocked by the internal crystal oscillator, a crystal or CMOS compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

## 50.4.2 PLL Clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately and provided to the PE.

For more details, see the clocking chapter of the device reference manual.

## 50.5 Register Descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

**Table 50-3. Register Access Conventions**

| Convention | Description                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------|
|            | Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.    |
| R*         | Reserved bit or field, will not be changed. Application must not write any value different from the reset value. |
| FIELDNAME  | Identifies the field. Its presence in the read or write row indicates that it can be read or written.            |

**Table 50-4. Register Field Types**

| Convention         | Description                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------|
| rwm                | A read/write bit that may be modified by a hardware in some fashion other than by a reset.             |
| w1c                | Write one to clear. A flag bit that can be read, is cleared by writing a one, writing 0 has no effect. |
| <b>Reset Value</b> |                                                                                                        |
| 0                  | Resets to zero.                                                                                        |
| 1                  | Resets to one.                                                                                         |
| -                  | Not defined after reset and not affected by reset.                                                     |

### 50.5.1 Register Reset

All registers except the [Message Buffer Cycle Counter Filter Register \(FR\\_MBCCFR<sub>n</sub>\)](#), [Message Buffer Frame ID Register \(FR\\_MBFIDR<sub>n</sub>\)](#), and [Message Buffer Index Register \(FR\\_MBIDXR<sub>n</sub>\)](#) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For

some register fields, additional reset conditions exist. These additional reset conditions are mentioned in the detailed description of the register. The additional reset conditions are explained in the table below.

**Table 50-5. Additional Register Reset Conditions**

| Condition              | Description                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol RUN Command   | The register field is reset when the application writes to RUN command "0101" to the POCCMD field in the <a href="#">Protocol Operation Control Register (FR_POCR)</a> .                                                                                                                                                               |
| Message Buffer Disable | The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants the disable to the application by clearing the FR_MBCCSRn[EDS] bit. |

## 50.5.2 Register Write Access

This section describes the write access restriction terms that apply to all registers.

### 50.5.2.1 Register Write Access Restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the table below. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

**Table 50-6. Register Write Access Restrictions**

| Condition     | Indication                       | Description                                                 |
|---------------|----------------------------------|-------------------------------------------------------------|
| Any Time      | -                                | No write access restriction.                                |
| Disabled Mode | FR_MCR[MEN] = 0                  | Write access only when CC is in Disabled Mode.              |
| Normal Mode   | FR_MCR[MEN] = 1                  | Write access only when CC is in Normal Mode.                |
| POC:config    | FR_PSR0[PROTSTAT E] = POC:config | Write access only when Protocol is in the POC:config state. |
| MB_DIS        | FR_MBCCSRn[EDS] = 0              | Write access only when related Message Buffer is disabled.  |
| MB_LCK        | FR_MBCCSRn[LCKS] = 1             | Write access only when related Message Buffer is locked.    |
| IDL           | FR_EEIRICR[BSY] = 0              | Write access only when ECC configuration is idle.           |

### 50.5.2.2 Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

### 50.5.2.3 Internal Register Access

The following memory mapped registers are used to access multiple internal registers.

- *Strobe Signal Control Register (FR\_STBSCR)*
- *Slot Status Selection Register (FR\_SSSR)*
- *Slot Status Counter Condition Register (FR\_SSCCR)*
- *Receive Shadow Buffer Configuration Data*

Each of these memory mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If the WMD bit is set to 0 during the write access, all fields of the internal register are updated. If the WMD bit set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

## 50.6 Memory map and register definition

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU. Address offset - 0x0Ah,0xDEh-0xE0h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at these offset/s.

### NOTE

The following registers are 16-bit write accessible only.

Strobe Signal Control Register (FR\_STBSCR)

PE DRAM Access Register (FR\_PEDRAR)

PE DRAM Data Register (FR\_PEDRDR)

Sync Frame ID Rejection Filter Register (FR\_SFIDRFR)

Slot Status Selection Register (FR\_SSSR)

Slot Status Counter Condition Register (FR\_SSCCR)

Receive Shadow Buffer Index Register (FR\_RSBIR)

Receive FIFO Range Filter Configuration Register  
(FR\_RFRFCFR)

Message Buffer Cycle Counter Filter Register (FR\_MBCCFRn)

Message Buffer Frame ID Register (FR\_MBFIDRn)

Message Buffer Index Register (FR\_MBIDXRn)

Message Buffer Data Field Offset Register (FR\_MBDORn)

LRAM ECC Error Test Register (FR\_LEETRn)

### FR memory map

| Address offset (hex) | Register name                                                     | Width (in bits) | Access | Reset value | Section/ page                |
|----------------------|-------------------------------------------------------------------|-----------------|--------|-------------|------------------------------|
| 0                    | Module Version Register (FR_MVR)                                  | 16              | R      | A468h       | <a href="#">50.6.1/1667</a>  |

| 109A                 | LRAM ECC Error Test Register (FR_LEETR5) | 16              | R/W    | <a href="#">See section</a> | <a href="#">50.6.117/1772</a> |

**50.6.1 Module Version Register (FR\_MVR)**

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Address: 0h base + 0h offset = 0h

|       |        |   |   |   |   |   |   |   |       |   |    |    |    |    |    |    |
|-------|--------|---|---|---|---|---|---|---|-------|---|----|----|----|----|----|----|
| Bit   | 0      | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8     | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| Read  | CHIVER |   |   |   |   |   |   |   | PEVER |   |    |    |    |    |    |    |
| Write |        |   |   |   |   |   |   |   |       |   |    |    |    |    |    |    |
| Reset | 1      | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0     | 1 | 1  | 0  | 1  | 0  | 0  | 0  |

**FR\_MVR field descriptions**

| Field         | Description                                                                                  |
|---------------|----------------------------------------------------------------------------------------------|
| 0–7<br>CHIVER | CHI Version Number. This field provides the version number of the controller host interface. |
| 8–15<br>PEVER | PE Version Number. This field provides the version number of the protocol engine.            |

## 50.6.2 Module Configuration Register (FR\_MCR)

This register defines the global configuration of the CC.

Address: 0h base + 2h offset = 2h

|       |     |      |     |     |     |      |      |          |

### 50.6.3 System Memory Base Address High Register (FR\_SYMBADHR)

#### NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR\_SYMBADHR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR\_SYMBADHR register contains the most significant bits of the base address.

Address: 0h base + 4h offset = 4h

| Field        | Description                                                                                                                                                                                                                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>SMBA | System Memory Base Address high. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address. |

**50.6.4 System Memory Base Address Low Register (FR\_SYMBADLR)****NOTE**

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR\_SYMBADLR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR\_SYMBADLR register contains the least significant bits of the base address.

Address: 0h base + 6h offset = 6h

**50.6.5 Strobe Signal Control Register (FR\_STBSCR)**

This register is used to assign the individual protocol timing related strobe signals given in [Table 50-8](#) to the external strobe ports. Each strobe signal can be assigned to at most one strobe port . Each write access to registers overwrites the previously written ENB and STBPSEL values for the signal indicated by SEL . If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port . If no strobe signal is assigned to a strobe port, the strobe port carries logic 0 . For more detailed and timing information refer to [Strobe Signal Support](#) .

**NOTE**

In single channel device mode, channel B related strobe signals are undefined and should not be assigned to the strobe ports.

Address: 0h base + 8h offset = 8h

**50.6.6 Message Buffer Data Size Register (FR\_MBDSR)**

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

**50.6.8 PE DRAM Access Register (FR\_PEDRAR)**

The PEDRAR register is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this registers initiates a read or write operation on the PE DRAM. The access done status bit DAD is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR\_PEDRDR are written into the PE DRAM, read back from the PE DRAM and are stored into the FR\_PEDRDR.

In case of an PE DRAM read access, the requested data are read from PE DRAM and stored into the FR\_PEDRDR.

For a detailed description refer to [Memory Content Fault Detection](#)

**FR\_PEDRDR field descriptions**

| Field        | Description                                                                                              |
|--------------|----------------------------------------------------------------------------------------------------------|
| 0–15<br>DATA | Data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR. |

**50.6.10 Protocol Operation Control Register (FR\_POCR)**

The application uses this register to issue

- protocol control commands
- external clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see [Protocol Control Command Execution](#).

External clock correction commands are issued by writing to the EOC\_AP and ERC\_AP fields. For more information on external clock correction, refer to [External Clock Synchronization](#).

Address: 0h base + 14h offset = 14h

### 50.6.11 Global Interrupt Flag and Enable Register (FR\_GIFER)

This register provides the means to control some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables. The generation scheme for these flags is depicted in [Figure 50-33](#). For more details on interrupt generation, see [Interrupt Support](#). These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Address: 0h base + 16h offset = 16h

**FR\_GIFER field descriptions (continued)**

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | 0 No Wakeup symbol received on FlexRay bus<br>1 Wakeup symbol received on FlexRay bus                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 4<br>FAFBIF | Receive FIFO Channel B Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs<br>a) the current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or<br>b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires.<br>0 no such event<br>1 FIFO B almost full event has occurred                                                                                                                                                                                                                            |
| 5<br>FAFAIF | Receive FIFO Channel A Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs<br>a) the current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or<br>b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires.<br>0 no such event<br>1 FIFO A almost full event has occurred                                                                                                                                                                                                                            |
| 6<br>RBIF   | Receive Message Buffer Interrupt Flag. This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application can not clear this interrupt flag directly, instead it is cleared by the CC when all of the interrupt flags MBIF of the individual receive message buffers are cleared by the application or if the application has cleared the related interrupt enables bit MBIE.<br>0 None of the individual receive message buffers has the MBIF and MBIE flag set.<br>1 At least one individual receive message buffer has the MBIF and MBIE flag set.                      |
| 7<br>TBIF   | Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application can not clear this interrupt flag directly, instead, this interrupt flag is cleared by the CC when either all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application or the application has cleared the related interrupt enables bit MBIE.<br>0 None of the individual transmit message buffers has the MBIF and MBIE flag set.<br>1 At least one individual transmit message buffer has the MBIF and MBIE flag set. |
| 8<br>MIE    | Module Interrupt Enable. This bit controls if the Module Interrupt line is asserted when the MIF flag is set.<br>0 Disable interrupt line<br>1 Enable interrupt line                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 9<br>PRIIE  | Protocol Interrupt Enable. This bit controls if the Protocol Interrupt line is asserted when the PRIF flag is set.<br>0 Disable interrupt line<br>1 Enable interrupt line                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

*Table continues on the next page...*

**FR\_GIFER field descriptions (continued)**

| Field        | Description                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10<br>CHIE   | CHI Interrupt Enable. This bit controls if the CHI Interrupt line is asserted when the CHIF flag is set.<br><br>0   Disable interrupt line<br>1   Enable interrupt line                                                    |
| 11<br>WUPIE  | Wakeup Interrupt Enable. This bit controls if the Wakeup Interrupt line is asserted when the WUPIF flag is set.<br><br>0   Disable interrupt line<br>1   Enable interrupt line                                             |
| 12<br>FABIE  | Receive FIFO Channel B Almost Full Interrupt Enable. This bit controls if the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set.<br><br>0   Disable interrupt line<br>1   Enable interrupt line |
| 13<br>FAFAIE | Receive FIFO Channel A Almost Full Interrupt Enable. This bit controls if the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set.<br><br>0   Disable interrupt line<br>1   Enable interrupt line |
| 14<br>RBIE   | Receive Message Buffer Interrupt Enable. This bit controls if the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set.<br><br>0   Disable interrupt line<br>1   Enable interrupt line              |
| 15<br>TBIE   | Transmit Message Buffer Interrupt Enable. This bit controls if the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set.<br><br>0   Disable interrupt line<br>1   Enable interrupt line            |

**50.6.12 Protocol Interrupt Flag Register 0 (FR\_PIFR0)**

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 18h offset = 18h

|       |         |         |         |         |         |        |        |        |

**FR\_PIFR0 field descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>FATL_IF | <p>Fatal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. The fatal protocol errors are:</p> <p>1) pLatestTx violation, as described in the MAC process of the FlexRay protocol</p> <p>2) transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol</p> <p>0 No such event.<br/>1 Fatal protocol error detected.</p>                                                                                                                                                                                                                              |
| 1<br>INTL_IF | <p>Internal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error.</p> <p>0 No such event.<br/>1 Internal protocol error detected.</p>                                                                                                                                                                                                                                                                                   |
| 2<br>ILCF_IF | <p>Illegal Protocol Configuration Interrupt Flag. This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the POC:halt state immediately.</p> <p>The protocol engine checks the listen_timeout value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of listen_timeout is equal to zero, the protocol configuration setting is considered as illegal.</p> <p>0 No such event.<br/>1 Illegal protocol configuration detected.</p> |
| 3<br>CSA_IF  | <p>Cold Start Abort Interrupt Flag. This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3).</p> <p>0 No such event.<br/>1 Cold start aborted and no more coldstart attempts allowed.</p>                                                                                                                                                                                                                                                                                                                         |
| 4<br>MRC_IF  | <p>Missing Rate Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle.</p> <p>0 No such event<br/>1 Insufficient number of measurements for rate correction detected</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 5<br>MOC_IF  | <p>Missing Offset Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol.</p> <p>0 No such event.<br/>1 Insufficient number of measurements for offset correction detected.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| 6<br>CCL_IF  | <p>Clock Correction Limit Reached Interrupt Flag. This flag is set when the internal calculated offset or rate calculation values have reached or exceeded its configured thresholds as given by the offset_coorection_out field in the Protocol Configuration Register 9 (FR_PCR9) and the rate_correction_out field in the Protocol Configuration Register 14 (FR_PCR14).</p> <p>0 No such event.<br/>1 Offset or rate correction limit reached.</p>                                                                                                                                                                                                                                                                                |

## FR\_PIFR0 field descriptions (continued)

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>MXS_IF   | <p>Max Sync Frames Detected Interrupt Flag. This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the node_sync_max field in the Protocol Configuration Register 30 (FR_PCR30).</p> <p><b>NOTE:</b> Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account.</p> <p>0 No such event.<br/>1 More than node_sync_max sync frames detected.</p> |
| 8<br>MTX_IF   | <p>Media Access Test Symbol Received Interrupt Flag. This flag is set when the MTS symbol was received on channel A or channel B.</p> <p>0 No such event.<br/>1 MTS symbol received.</p>                                                                                                                                                                                                                                                                                                  |
| 9<br>LTXB_IF  | <p>pLatestTx Violation on Channel B Interrupt Flag. This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation, as described in the MAC process of the FlexRay protocol.</p> <p>0 No such event.<br/>1 pLatestTx violation occurred on channel B.</p>                                                                                                                              |
| 10<br>LTXA_IF | <p>pLatestTx Violation on Channel A Interrupt Flag. This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation as described in the MAC process of the FlexRay protocol.</p> <p>0 No such event.<br/>1 pLatestTx violation occurred on channel A.</p>                                                                                                                               |
| 11<br>TBVB_IF | <p>Transmission across boundary on channel B Interrupt Flag. This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol.</p> <p>0 No such event.<br/>1 Transmission across boundary violation occurred on channel B.</p>                                                                                                             |
| 12<br>TBVA_IF | <p>Transmission across boundary on channel A Interrupt Flag. This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol.</p> <p>0 No such event.<br/>1 Transmission across boundary violation occurred on channel A.</p>                                                                                                             |
| 13<br>TI2_IF  | <p>Timer 2 Expired Interrupt Flag. This flag is set whenever timer 2 expires.</p> <p>0 No such event.<br/>1 Timer 2 has reached its time limit.</p>                                                                                                                                                                                                                                                                                                                                       |
| 14<br>TI1_IF  | <p>Timer 1 Expired Interrupt Flag. This flag is set whenever timer 1 expires.</p> <p>0 No such event<br/>1 Timer 1 has reached its time limit</p>                                                                                                                                                                                                                                                                                                                                         |
| 15<br>CYS_IF  | <p>Cycle Start Interrupt Flag. This flag is set when a communication cycle starts.</p> <p>0 No such event<br/>1 Communication cycle started.</p>                                                                                                                                                                                                                                                                                                                                          |

### 50.6.13 Protocol Interrupt Flag Register 1 (FR\_PIFR1)

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 1Ah offset = 1Ah

|       |        |        |         |        |         |         |         |         |

**FR\_CHIERFR field descriptions (continued)**

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12<br>SPL_EF  | Static Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding protocol configuration register field payload_length_static in the Protocol Configuration Register 19 (FR_PCR19).<br><br>0 No such error occurred<br>1 Static payload length error occurred                                            |
| 13<br>NML_EF  | Network Management Length Error Flag. This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLRL). In this case the received part of the Network Management Vector will be used to update the Network Management Vector.<br><br>0 No such error occurred<br>1 Network management length error occurred |
| 14<br>NMF_EF  | Network Management Frame Error Flag. This flag is set if a received message in the static segment with a Preamble Indicator flag PP asserted has its Null Frame indicator flag NF asserted as well. In this case, the Global Network Management Registers (see Network Management Vector Registers (FR_NMVR0-FR_NMVR5)) are not updated.<br><br>0 No such error occurred<br>1 Network management frame error occurred                                                                                                         |
| 15<br>ILSA_EF | Illegal System Bus Address Error Flag. This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (see <a href="#">System Bus Illegal Address Access</a> ).<br><br>0 No such event<br>1 Illegal system bus address accessed                                                                                                                                                                                                                                    |

**50.6.17 Message Buffer Interrupt Vector Register (FR\_MBIVEC)**

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their interrupt status flag MBIF and interrupt enable MBIE bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Address: 0h base + 22h offset = 22h

| 2–7<br>TBIVEC   | Transmit Buffer Interrupt Vector. This field provides the number of the lowest numbered enabled transmit message buffer that has its interrupt status flag MBIF and its interrupt enable bit MBIE set. If there is no transmit message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.    |
| 8–9<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                |
| 10–15<br>RBIVEC | Receive Buffer Interrupt Vector. This field provides the message buffer number of the lowest numbered receive message buffer which has its interrupt flag MBIF and its interrupt enable bit MBIE asserted. If there is no receive message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0. |

**50.6.18 Channel A Status Error Counter Register (FR\_CASERCR)**

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see [Slot Status Monitoring](#).

Address: 0h base + 24h offset = 24h

**FR\_CASERCR field descriptions**

| Field             | Description                                                                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>CHAERSCNT | Channel A Status Error Counter. This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment. |

### 50.6.19 Channel B Status Error Counter Register (FR\_CBSERCR)

This register provides the channel status error counter for channel B. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring see [Slot Status Monitoring](#).

| 10<br>FRZ      | Freeze Occurred. protocol related variable: vPOC!Freeze This status bit is set when the CC has reached the POC:halt state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state.<br><br>0 No such event<br>1 Immediate halt due to FREEZE or internal error condition                                                                |
| 11–15<br>APTAC | Allow Passive to Active Counter. protocol related variable: vPOC!vAllowPassivetoActive<br><br>This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the POC:normal passive state due to an application configured delay to enter POC:normal active state. This delay is defined by the allow_passive_to_active field in the Protocol Configuration Register 12 (FR_PCR12). |

**50.6.22 Protocol Status Register 2 (FR\_PSR2)**

This register provides a snapshot of status information about the Network Idle Time NIT, the Symbol Window and the clock synchronization. The NIT related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The Symbol Window related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol window related status bits remain in their reset state. The clock synchronization related CLKCORRFailCnt is updated by the CC after the end of the static segment and before the end of the current communication cycle.

| 12–15<br>CKCORFCNT | <p>Clock Correction Failed Counter. protocol related variable: vClockCorrectionFailed This field provides the number of consecutive even/odd communication cycle pairs that have passed without clock synchronization having performed an offset or a rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in the Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the POC:normal active state, or when both the rate and offset correction terms have been calculated successfully.</p> |

### 50.6.23 Protocol Status Register 3 (FR\_PSR3)

This register provides aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception. It provides accrued information for the symbol window, the NIT, and the wakeup status.

Address: 0h base + 2Eh offset = 2Eh

If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0).<br><br><b>NOTE:</b> If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated. |

**50.6.30 Combined Interrupt Flag Register (FR\_CIFR)**

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in [Figure 50-35](#). The individual interrupt flags WUIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR\_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR\_GIFER).

**NOTE**

The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR\_GIFER).

**FR\_SYMATOR field descriptions**

| Field           | Description                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                      |
| 8–15<br>TIMEOUT | System Memory Access Time-Out. This value defines when a system bus access timeout is detected. For a detailed description see <a href="#">Configure System Memory Access Time-Out Register (FR_SYMATOR)</a> and <a href="#">System Bus Access Timeout</a> . |

**50.6.32 Sync Frame Counter Register (FR\_SFCNTR)**

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 MT after offset correction start.

**NOTE**

If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

**NOTE**

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the values SFODB and SFODA.

Address: 0h base + 40h offset = 40h

|       |       |   |   |   |       |   |   |   |       |   |    |    |       |    |    |    |

### 50.6.33 Sync Frame Table Offset Register (FR\_SFTOR)

This register defines the FlexRay memory area related offset for sync frame tables. For more details, see [Sync Frame ID and Sync Frame Deviation Tables](#).

Address: 0h base + 42h offset = 42h

|       |            |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

#### FR\_SFTOR field descriptions

| Field              | Description                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–14<br>SFT_OFFSET | Sync Frame Table Offset. The offset of the Sync Frame Tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus STF_OFFSET[0] is always 0. |
| 15<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                |

### 50.6.34 Sync Frame Table Configuration, Control, Status Register (FR\_SFTCCSR)

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see [Sync Frame ID and Sync Frame Deviation Tables](#).

Address: 0h base + 44h offset = 44h

### 50.6.38 Network Management Vector Register (FR\_NMVRn)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR\_NMVLR). If FR\_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR\_NMVR0-FR\_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Address: 0h base + 4Ch offset + (2d × i), where i=0d to 5d

### 50.6.39 Network Management Vector Length Register (FR\_NMVLRL)

This register defines the length of the network management vector in bytes.

Address: 0h base + 58h offset = 58h

### 50.6.40 Timer Configuration and Control Register (FR\_TICCR)

This register is used to configure and control the two timers T1 and T2. For timer details, see [Timer Support](#) . The Timer T1 is an absolute timer. The Timer T2 can be configured as an absolute or relative timer.

#### NOTE

Both timers are deactivated immediately when the protocol enters a state different from POC:normal active or POC:normal passive.

**50.6.41 Timer 1 Cycle Set Register (FR\_TI1CYSR)**

This register defines the cycle filter value and the cycle filter mask for timer T1. For a detailed description of timer T1, refer to [Absolute Timer T1](#).

**NOTE**

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

### 50.6.44 Timer 2 Configuration Register 0 (Relative Timer Configuration) (FR\_TI2CR0\_REL)

The content of this register depends on the value of the T2\_CFG bit in the Timer Configuration and Control Register (FR\_TICCR). For a detailed description of timer T2, refer to [Relative Timer T2](#).

#### NOTE

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

### 50.6.47 Slot Status Selection Register (FR\_SSSR)

This register is used to access the four internal non-memory mapped slot status selection registers FR\_SSSR0 to FR\_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding Slot Status Registers (FR\_SSR0-FR\_SSR7) according to [Slot Status Selection Register \(FR\\_SSSR\)](#) . For a detailed description of slot status monitoring, refer to [Slot Status Monitoring](#) .

**Table 50-10. Mapping Between FR\_SSSRn and FR\_SSRn**

| Internal Slot Status Selection Register | Write the Slot Status of the Slot Selected by FR_SSSRn for each |                     |                         |                     |
|-----------------------------------------|-----------------------------------------------------------------|---------------------|-------------------------|---------------------|
|                                         | Even Communication Cycle                                        |                     | Odd Communication Cycle |                     |
|                                         | For Channel B<br>to                                             | For Channel A<br>to | For Channel B<br>to     | For Channel A<br>to |

| 5–15<br>SLOTNUMBER | Slot Number. This field specifies the number of the slot whose status will be saved in the corresponding slot status registers.<br><br><b>NOTE:</b> If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start. |

### 50.6.48 Slot Status Counter Condition Register (FR\_SSCCR)

This register is used to access and program the four internal non-memory mapped Slot Status Counter Condition Registers FR\_SSCCR0 to FR\_SSCCR3. Each of these four internal slot status counter condition registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR\_SSCR0-FR\_SSCR3). The correspondence is given in [Slot Status Counter Condition Register \(FR\\_SSCCR\)](#) . For a detailed description of slot status counters, refer to [Slot Status Counter Registers](#) .

**Table 50-11. Mapping between internal FR\_SSCCRn and FR\_SSCRn**

| Condition Register | Condition Defined for Register |
|--------------------|--------------------------------|
| FR_SSCCR0          | FR_SSCR0                       |
| FR_SSCCR1          | FR_SSCR1                       |
| FR_SSCCR2          | FR_SSCR2                       |
| FR_SSCCR3          | FR_SSCR3                       |

## 50.6.49 Slot Status Register (FR\_SSRn)

Each Slot Status Register (SSR) holds the status vector of the slot specified in the corresponding internal slot status selection register, which can be programmed using the Slot Status Selection Register (FR\_SSSR). Each register is updated after the end of the corresponding slot as shown in [Figure 50-31](#) . The register bits are directly related to the protocol variables and described in more detail in [Slot Status Monitoring](#) .

**50.6.50 Slot Status Counter Register (FR\_SSCR<sub>n</sub>)**

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal slot status counter condition register FR\_SSCCR<sub>n</sub>, which can be programmed by using the Slot Status Counter Condition Register (FR\_SSCCR). For more details, see [Slot Status Counter Registers](#).

### NOTE

If the counter has reached its maximum value 0xFFFF and is in the multicycle mode, i.e. FR\_SSCCRn[MCY] = 1, the counter is not reset to 0x0000. The application can reset the counter by clearing the FR\_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be set into the multicycle mode again.

### NOTE

Address: 0h base + 78h offset + (2d × i), where i=0d to 3d

This field contains the current index of the message buffer header field of the receive shadow message buffer selected by the SEL field. The CC uses this index to determine the physical location of the shadow buffer header field in the FlexRay memory area. The CC will update this field during receive operation. The application provides initial message buffer header index value in the configuration phase.<br><br>CC: Updates the message buffer header index after successful reception.<br><br>Application: Provides initial message buffer header index.<br><br>Legal Values are $0 \leq i \leq 67$ . Illegal values will be detected during the message buffer search. |

## 50.6.54 Receive FIFO Watermark and Selection Register (FR\_RFWMSR)

This register is used to

- select a receiver FIFO for subsequent programming access through the receiver FIFO configuration registers summarized in [Receive FIFO Watermark and Selection Register \(FR\\_RFWMSR\)](#).
- to define the watermark for the selected FIFO.

**Table 50-12. SEL Controlled Receiver FIFO Registers**

| Register                                                                |
|-------------------------------------------------------------------------|
| Receive FIFO Start Index Register (FR_RFSIR)                            |
| Receive FIFO Depth and Size Register (FR_RFDSR)                         |
| Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) |
| Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)  |
| Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)    |
| Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)     |
| Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)           |
| Receive FIFO Range Filter Control Register (FR_RFRFCTR)                 |

Address: 0h base + 86h offset = 86h

| Bit   | 0  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15  |
|-------|----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|-----|

| 0–7<br>FIFO_DEPTH | FIFO_DEPTHA/FIFO_DEPTHB - FIFO Depth<br><br>FIFO Depth. This field defines the depth of the selected FIFO, i.e. the number of entries.<br><br>Note: If the FIFO_DEPTH is configured to 0, FR_RFFIDRFMR[FIDRFMSK] must be configured to 0 too, to ensure that no frames are received into the FIFO. |

Table continues on the next page...

**FR\_RFDSR field descriptions (continued)**

| Field              | Description                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 8<br>Reserved      | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                  |
| 9–15<br>ENTRY_SIZE | ENTRY_SIZEA/ENTRY_SIZEB - Entry Size<br>This field defines the size of the frame data sections for the selected FIFO in 2 byte entities. |

**50.6.57 Receive FIFO A Read Index Register (FR\_RFARIR)**

This register provides the message buffer header index of the next available FIFO A entry that the application can read.

**NOTE**

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Ch offset = 8Ch

|       |   |   |   |   |   |   |       |   |   |   |    |    |    |    |    |    |
|-------|---|---|---|---|---|---|-------|---|---|---|----|----|----|----|----|----|
| Bit   | 0 | 1 | 2 | 3 | 4 | 5 | 6     | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| Read  | 0 |   |   |   |   |   | RDIDX |   |   |   |    |    |    |    |    |    |
| Write |   |   |   |   |   |   |       |   |   |   |    |    |    |    |    |    |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0     | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |

**FR\_RFARIR field descriptions**

| Field           | Description                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 0–5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                  |
| 6–15<br>RDIDX   | Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read. |

**50.6.58 Receive FIFO B Read Index Register (FR\_RFBIR)**

This register provides the message buffer header index of the next available FIFO B entry that the application can read.

**NOTE**

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Eh offset = 8Eh

|       |   |   |   |   |   |   |       |   |   |   |    |    |    |    |    |    |

### 50.6.67 Protocol Configuration Register 0 (FR\_PCR0)

The protocol configuration registers (FR\_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in [Protocol Configuration Register 0 \(FR\\_PCR0\)](#).

**Table 50-13. Protocol Configuration Register (PCR0-30) Fields**

| Name               | Description        | Min | Max | Unit   | FR_PCR |
|--------------------|--------------------|-----|-----|--------|--------|
| coldstart_attempts | gColdstartAttempts |     |     | number | 3      |

50.6.99 Receive FIFO Start Data Offset Register (FR\_RFSDOR)

NOTE

Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses the content of the FR\_RFSDOR corresponds to the start address of payload area of the selected FIFO.

Address: 0h base + E6h offset = E6h

|       |     |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

| Reset | 0   | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |

FR\_RFSDOR field descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>SDO | SDOA/SDOB - Start Data Field Offset<br><br>Start Data Field Offset. This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO's first message buffer header field. For configuration constraints see <a href="#">Configure Data Field Offsets</a> . |

50.6.100 Receive FIFO System Memory Base Address High Register (FR\_RFSYMBADHR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR\_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Address: 0h base + E8h offset = E8h

|       |      |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |

## 50.6.103 Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs

If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, then the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

Address: 0h base + EEh offset = EEh

|       |             | 8-15 PCA  | Pop Count FIFO A - This field defines the number of entries to be removed from FIFO A. |

**50.6.104 ECC Error Interrupt Flag and Enable Register (FR\_EEIFER)**

This register provides the means to control the ECC related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description see [Memory Error Reporting](#).

Address: 0h base + F0h offset = F0h

**50.6.106 ECC Error Report Address Register (FR\_EERAR)**

This register provides the memory identifier, bank, and address for which the memory error is reported.

Address: 0h base + F4h offset = F4h

| 4–15<br>ADDR | Memory Address. This field provides the address of the failing memory location.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                  |           |  |  |     |               |              |           |     |               |                  |           |     |               |                  |           |     |                 |                  |           |     |                 |                  |           |     |                 |                  |           |     |          |          |          |     |

**50.6.107 ECC Error Report Data Register (FR\_EERDR)**

This register provides the data related information of the reported memory read access. The assignment of the bits depends on the selected memory and memory bank as shown in [ECC Error Report Data Register \(FR\\_EERDR\)](#).

**Table 50-16. Valid Bits in FR\_EERDR[DATA] / FR\_EEIDR[DATA] field**

**50.6.110 ECC Error Injection Data Register (FR\_EEIDR)**

This register defines the data distortion pattern for the error injection write. The number of valid bits depends on the selected memory and memory bank as shown in [ECC Error Report Data Register \(FR\\_EERDR\)](#) .

NOTE

The effect of the error injected depends from the LRAM content at the address accessed and from the module internal usage of the data. Refer to [Memory Error Response](#) for details.

Address: 0h base + FCh offset = FCh

### 50.6.112 Message Buffer Configuration, Control, Status Register (FR\_MBCCSR<sub>n</sub>)

The content of these registers is composed of message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in [Individual Message Buffer Functional Description](#).

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Address: 0h base + 800h offset + (8d × i), where i=0d to 63d

**50.6.113 Message Buffer Cycle Counter Filter Register (FR\_MBCCFR<sub>n</sub>)****NOTE**

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to [Message Buffer Cycle Counter Filtering](#).

**NOTE**

If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the message buffer configuration is illegal and the result of the message buffer search is not defined.

**Table 50-17. Channel Assignment Description**

| CHA | CHB | Transmit Message Buffer                  |                            | Receive Message Buffer                                            |                                                                 |

## 50.7 Functional Description

This section provides a detailed description of the functionality implemented in the CC.

### 50.7.1 Message Buffer Concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts, the *message buffer control data* and the *physical message buffer*. The message buffer control data are located in dedicated registers. The structure of the message buffer control data depends on the message buffer type and is described in the Message Buffer Types section. The physical message buffer is located in the FlexRay memory area and is described in the next section.

### 50.7.2 Physical Message Buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area. The structure of a physical message buffer is depicted in the figure below.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

**Figure 50-2. Physical Message Buffer Structure**

### 50.7.2.1 Message Buffer Header Field

The message buffer header field is a contiguous region in the FlexRay memory area and occupies eight bytes. It contains the frame header, and the slot status. Its structure is shown in the above figure. The physical start address *SADR\_MBHF* of the message buffer header field must be 16-bit aligned.

#### 50.7.2.1.1 Frame Header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the usage and the content of the frame header is provided in Frame Header Description section.

#### 50.7.2.1.2 Slot Status

The slot status occupies the last two bytes of the message buffer header field. It provides the slot and frame status related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in the Slot Status Description section.

### 50.7.2.2 Message Buffer Data Field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in the following section.

### 50.7.3 Message Buffer Types

The CC provides three different types of message buffers.

- *Individual Message Buffers*
- *Receive Shadow Buffers*
- *Receive FIFO Buffers*

For each message buffer type the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

### 50.7.3.1 Individual Message Buffers

The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in the Individual Message Buffer Functional Description section.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in the figure below.

Each individual message buffer has a message buffer number  $n$  assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number  $n$  is controlled by the registers FR\_MBCCSR $_n$ , FR\_MBCCFR $_n$ , FR\_MBFIDR $_n$ , and FR\_MBIDXR $_n$ .

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field MBIDX in the Message Buffer Index Registers (FR\_MBIDXR $_n$ ). The start address SADR\_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$\text{SADR\_MBHF} = (\text{FR\_MBIDXR}_n[\text{MBIDX}] \times 8) + \text{SMBA}$$

#### Equation 17

The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX  $i$  the FR\_MBDOR $_i$  contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR\_SYMBADR).

The data field offset is used to determine the start address SADR\_MBDF of the corresponding message buffer data field in the FlexRay memory area according to this equation:

$$\text{SADR\_MBDF} = [\text{DataFieldOffset}] + \text{SMBA}$$

## Equation 18

The FR\_MBDORn are stored in the module internal memory LRAM. Refer to [CHI LRAM Initialization](#) for the setup of the data field offset values.

Figure 50-3. Individual Message Buffer Structure

## 50.7.3.1.1 Individual Message Buffer Segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR). All individual message buffers with a message buffer number  $n \leq \text{FR\_MBSSUTR}[\text{LAST\_MB\_SEG1}]$  belong to the first message buffer segment. All individual message buffers with a message buffer number  $n > \text{FR\_MBSSUTR}[\text{LAST\_MB\_SEG1}]$  belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- *all physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length*
- *the minimum length of the message buffer data field for individual message buffers in the first message buffer segment is  $2 \times \text{FR\_MBDSR}[\text{MBSEG1DS}]$  bytes*
- *the minimum length of the message buffer data field for individual message buffers assigned to the second segment is  $2 \times \text{FR\_MBDSR}[\text{MBSEG2DS}]$  bytes.*

### 50.7.3.2 Receive Shadow Buffers

The receive shadow buffers are required for the frame reception process for individual message buffers. The CC provides four receive shadow buffers, one receive shadow buffer per channel and per message buffer segment.

Each receive shadow buffer consists of two parts, the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in the figure below. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR\_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR\_RSBIR). The start address SADR\_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$\text{SADR\_MBHF} = (\text{FR\_RSBIR}[\text{RSBIDX}] \times 8) + \text{SMBA}$$

#### Equation 19

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR\_RSBIR).

## Functional Description

**Figure 50-4. Receive Shadow Buffer Structure**

### 50.7.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in the Receive FIFO Structure figure, later in this section.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR\_RFSIR), the Receive FIFO Depth and Size Register (FR\_RFDSR), and the Receive FIFO A Read Index Register (FR\_RFARIR) / Receive FIFO B Read Index Register (FR\_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit  $\text{FR\_MCR}[\text{FAM}]$  in the Module Configuration Register.

The start byte address  $\text{SADR\_MBHF}[1]$  of the first message buffer header field that belongs to the receive FIFO is determined according to [Equation 20 on page 1778](#).

$$\text{SADR\_MBHF}[1] = (8 \times \text{FR\_RFSIR}[\text{SIDX}]) + \text{SMBA}$$

**Equation 20**

The start byte address SADR\_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according [Equation 21 on page 1779](#).

$$\text{SADR\_MBHF}[n] = (8 \times (\text{FR\_RFSIR}[\text{SIDX}] + \text{FR\_RFDSR}[\text{FIFO\_DEPTH}])) + \text{SMBA}$$

**Equation 21**

The required information to access the current entry of the FIFO is given in the following registers:

- *The registers Receive FIFO A Read Index Register (FR\_RFARIR) and Receive FIFO B Read Index Register (FR\_RFBIR) provide the index of the physical message buffer belonging to the current entry.*

The data field offset belonging to the current FIFO entry RF\_DFO[X] must be calculated using the current read index i according to the following formula:

$$\text{RF\_DFO}[X] = \text{FR\_RFSIR}[X] + (\text{FR\_RFDSR}[X][\text{ENTRY\_SIZE}] \times 2) \times i - \text{FR\_RFSIDR}[X]$$

**Equation 22**

### Note

The current read index loops up starting at the number given in the FR\_RD[A/B]RDIDX register for the required number of entries.

Refer to [FIFO Update](#) for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR\_RFSIR[SIDX] and FR\_RFDSR[FIFO\_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR\_RFDSR[FIFO\_SIZE].

**Figure 50-5. Receive FIFO Structure**

### Note

The actual values of the data field offsets  $RF\_DFO[A/B]$  need to be calculated according to [Equation 22 on page 1779](#). They are not stored in a register.

## 50.7.3.4 Message Buffer Configuration and Control Data

This section describes the configuration and control data for each message buffer type.

### 50.7.3.4.1 Individual Message Buffer Configuration Data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

#### 50.7.3.4.1.1 Common Configuration Data

The set of common configuration data for individual message buffers is located in the following registers.

- *Message Buffer Data Size Register (FR\_MBDSR)*

*The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.*

- *Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR)*

*The LAST\_MB\_SEG1 and LAST\_MB\_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, see [Individual Message Buffer Segments](#).*

#### 50.7.3.4.1.2 Specific Configuration Data

The set of message buffer specific configuration data for individual message buffers is located in the following registers.

- *Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn)*

*The MTD bit configures the message buffer type.*

- *Message Buffer Cycle Counter Filter Registers (FR\_MBCCFRn)*

*The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.*

- *Message Buffer Frame ID Registers (FR\_MBFIDRn)*

*For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.*

- *Message Buffer Index Registers (FR\_MBIDXRn) This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.*

### 50.7.3.5 Individual Message Buffer Control Data

During normal operation, each individual message buffer can be controlled by the control and trigger bits CMT, LCKT, EDT, and MBIE in the Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn).

### 50.7.3.6 Receive Shadow Buffer Configuration Data

Before frame reception into the individual message buffers can be performed, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR\_RSIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

### 50.7.3.7 Receive FIFO Control and Configuration Data

This section describes the configuration and control data for the two receive FIFOs.

#### 50.7.3.7.1 Receive FIFO Configuration Data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- *Receive FIFO Periodic Timer Register (FR\_RFPTR)*

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- *Receive FIFO Watermark and Selection Register (FR\_RFWMSR)*
- *Receive FIFO Start Index Register (FR\_RFSIR)*
- *Receive FIFO Start Data Offset Register (FR\_RFSDOR)*
- *Receive FIFO Depth and Size Register (FR\_RFDSR)*
- *Receive FIFO Message ID Acceptance Filter Value Register (FR\_RFMIDAFVR)*
- *Receive FIFO Message ID Acceptance Filter Mask Register (FR\_RFMIDAFMR)*
- *Receive FIFO Frame ID Rejection Filter Value Register (FR\_RFFIDRFVR)*

- *Receive FIFO Frame ID Rejection Filter Mask Register (FR\_RFFIDRFMR)*
- *Receive FIFO Range Filter Configuration Register (FR\_RFRFCFR)*

### 50.7.3.7.2 Receive FIFO Control Data

The application can access the FIFOs at any time using the control bits in the following registers:

- *Global Interrupt Flag and Enable Register (FR\_GIFER)*
- *Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR)*

### 50.7.3.7.3 Receive FIFO Status Data

The current status of the receive fifo is provided in the following register:

- *Global Interrupt Flag and Enable Register (FR\_GIFER)*
- *Receive FIFO A Read Index Register (FR\_RFARIR)*
- *Receive FIFO B Read Index Register (FR\_RFBRIR)*
- *Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR)*

## 50.7.4 FlexRay Memory Area Layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR\_MCR[FAM].

### 50.7.4.1 FlexRay Memory Area Layout (FR\_MCR[FAM] = 0)

In the figure given below, shows an example layout for the FIFO address mode FR\_MCR[FAM]=0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is maximum 64 KB.
- The FlexRay memory area starts at a 16 byte boundary

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

Figure 50-6. Example of FlexRay Memory Area Layout (FR\_MCR[FAM] = 0)

### 50.7.4.2 FlexRay Memory Area Layout (FR\_MCR[FAM] = 1)

The following figure shows an example layout for the FIFO address mode FR\_MCR[FAM]=1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

Figure 50-7. Example of FlexRay Memory Area Layout (FR\_MCR[FAM] = 1)

#### 50.7.4.3 Message Buffer Header Area (FR\_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rules apply to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR\_MBHF of each message buffer header field for *individual message buffers* and *receive shadow buffers* must fulfill [Equation 23 on page 1785](#).

$$\text{SADR\_MBHF} = (i \times 8) + \text{FR\_SYMBADR}[\text{SMBA}] \quad (0 \leq i \leq 67)$$

#### Equation 23

2. The start byte address SADR\_MBHF of each message buffer header field for the *FIFO* must fulfill [Equation 23 on page 1785](#).

$$\text{SADR\_MBHF} = (i \times 8) + \text{FR\_SYMBADR}[\text{SMBA}] \quad (0 \leq i \leq 1023)$$

**Equation 24**

$$\text{SADR\_MBHF} = (i \times 8) + \text{FR\_SYMBADR}[\text{SMBA}] \quad (0 \leq i \leq 1023)$$

**Equation 25**

3. The message buffer header fields for each FIFO have to be a contiguous area.

#### 50.7.4.4 Message Buffer Header Area (FR\_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR\_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill [Equation 26 on page 1786](#).

$$\text{SADR\_MBHF} = (i \times 8) + \text{FR\_SYMBADR}[\text{SMBA}] \quad (0 \leq i \leq 67)$$

**Equation 26**

#### 50.7.4.5 FIFO Message Buffer Header Area (FR\_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR\_MBHF of each message buffer header field for the FIFO must fulfill the following equation: [Equation 27 on page 1786](#).

$$\text{SADR\_MBHF} = (i \times 8) + \text{FR\_RFSYMBADR}[\text{SMBA}] \quad (0 \leq i \leq 1023)$$

**Equation 27**

2. The message buffer header fields for each FIFO have to be a contiguous area.

#### 50.7.4.6 Message Buffer Data Area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

### 50.7.4.7 Sync Frame Table Area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to [Sync Frame ID and Sync Frame Deviation Tables](#) for the description of the sync frame table area.

## 50.7.5 Physical Message Buffer Description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer, the message buffer header field and the message buffer data field.

### 50.7.5.1 Message Buffer Protection and Data Consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

### 50.7.5.2 Message Buffer Header Field Description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in [Message Buffer Header Field](#). Each message buffer header field consists of two sections: the frame header section and the slot status section.

#### 50.7.5.2.1 Frame Header Description

Frame header content, access, and checks are discussed in this section.

##### 50.7.5.2.1.1 Frame Header Content

The semantic and content of the frame header section depends on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

## Functional Description

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in the figure below. A detailed description is given in [Table 50-22](#).

**Table 50-18. Frame Header Structure (Receive Message Buffer and Receive FIFO)**

|     | 0 | 1   | 2      | 3   | 4   | 5     | 6 | 7 | 8 | 9      | 10 | 11 | 12 | 13 | 14 | 15 |

1. checked

2. checked if not static

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in the figure below.

**Table 50-20. Frame Header Structure (Transmit Message Buffer for Key Slot)**

|     | 0 | 1          | 2      | 3   | 4   | 5     | 6 | 7 | 8 | 9      | 10 | 11 | 12 | 13 | 14 | 15 |
|-----|---|------------|--------|-----|-----|-------|---|---|---|--------|----|----|----|----|----|----|
| 0x0 | R | PPI        | NUF    | SYF | SUF | FID   |   |   |   |        |    |    |    |    |    |    |
| 0x2 |   |            | CYCCNT |     |     |       |   |   |   | PLDLEN |    |    |    |    |    |    |
| 0x4 |   |            |        |     |     | HDCRC |   |   |   |        |    |    |    |    |    |    |
|     |   | = not used |        |     |     |       |   |   |   |        |    |    |    |    |    |    |

### 50.7.5.2.1.2 Frame Header Access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in the following table. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

**Table 50-21. Frame Header Write Access Constraints (Transmit Message Buffer)**

| Field                    | Static Segment                 | Dynamic Segment |
|--------------------------|--------------------------------|-----------------|
| FID                      | <i>POC:config</i> or MB_DIS    |                 |
| PPI,<br>PLDLEN,<br>HDCRC | <i>POC:config</i> or MB_DIS or | MB_LCK          |

### 50.7.5.2.1.3 Frame Header Checks

As shown in [Table 50-19](#) and [Table 50-20](#) not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR\_MBFIDRn). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag FID\_EF in the CHI Error Flag Register (FR\_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR\_MBFIDRn).

For transmit message buffers assigned to the *static* segment, the PLDLEN value must be equal to the value of the payload\_length\_static field in the Protocol Configuration Register 19 (FR\_PCR19). If this is not fulfilled, the static payload length error flag SPL\_EF in the CHI Error Flag Register (FR\_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload\_length\_static payload words and the payload length field in the transmitted frame header set to payload\_length\_static.

## Functional Description

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the `max_payload_length_dynamic` field in the Protocol Configuration Register 24 (FR\_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL\_EF in the CHI Error Flag Register (FR\_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

**Table 50-22. Frame Header Field Descriptions (Receive Message Buffer and Receive FFO)**

| Field  | Description                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| R      | <b>Reserved Bit</b> — This is the value of the <i>Reserved bit</i> of the received frame stored in the message buffer                              |
| PPI    | <b>Payload Preamble Indicator</b> — This is the value of the <i>Payload Preamble Indicator</i> of the received frame stored in the message buffer. |
| NUF    | <b>Null Frame Indicator</b> — This is the value of the <i>Null Frame Indicator</i> of the received frame stored in the message buffer.             |
| SYF    | <b>Sync Frame Indicator</b> — This is the value of the <i>Sync Frame Indicator</i> of the received frame stored in the message buffer.             |
| SUF    | <b>Startup Frame Indicator</b> — This is the value of the <i>Startup Frame Indicator</i> of the received frame stored in the message buffer.       |
| FID    | <b>Frame ID</b> — This is the value of the <i>Frame ID</i> field of the received frame stored in the message buffer.                               |
| CYCCNT | <b>Cycle Count</b> — This is the number of the communication cycle in which the frame stored in the message buffer was received.                   |
| PLDLEN | <b>Payload Length</b> — This is the value of the <i>Payload Length</i> field of the received frame stored in the message buffer.                   |
| HDCRC  | <b>Header CRC</b> — This is the value of the <i>Header CRC</i> field of the received frame stored in the message buffer.                           |

**Table 50-23. Frame Header Field Descriptions (Transmit Message Buffer)**

| Field  | Description                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R      | <b>Reserved Bit</b> — This bit is not used, the value of the <i>Reserved bit</i> is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .                       |
| PPI    | <b>Payload Preamble Indicator</b> — This bit provides the value of the <i>Payload Preamble Indicator</i> for the frame transmitted from the message buffer.                                                                  |
| NUF    | <b>Null Frame Indicator</b> — This bit is not used, the value of the <i>Null Frame Indicator</i> is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .       |
| SYF    | <b>Sync Frame Indicator</b> — This bit is not used, the value of the <i>Sync Frame Indicator</i> is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> .       |
| SUF    | <b>Startup Frame Indicator</b> — This bit is not used, the value of the <i>Startup Frame Indicator</i> is generated internally according to <i>FlexRay Communications System Protocol Specification, Version 2.1 Rev A</i> . |
| FID    | <b>Frame ID</b> — This field is checked as described in Frame Header Checks.                                                                                                                                                 |
| CYCCNT | <b>Cycle Count</b> — This field is not used, the value of the transmitted <i>Cycle Count</i> field is taken from the internal communication cycle counter.                                                                   |
| PLDLEN | <b>Payload Length</b> — This field is checked and used as described in Frame Header Checks.                                                                                                                                  |

*Table continues on the next page...*

**Table 50-23. Frame Header Field Descriptions (Transmit Message Buffer) (continued)**

| Field | Description                                                                                                                         |
|-------|-------------------------------------------------------------------------------------------------------------------------------------|
| HDCRC | <b>Header CRC</b> — This field provides the value of the <i>Header CRC</i> field for the frame transmitted from the message buffer. |

### 50.7.5.2.2 Slot Status Description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depends on the message buffer type.

#### 50.7.5.2.2.1 Receive Message Buffer and Receive FIFO Slot Status Description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given in the next table.

**Table 50-24. Receive Message Buffer Slot Status Content**

| Receive Message Buffer Type                                                                            | Slot Status Content             |
|--------------------------------------------------------------------------------------------------------|---------------------------------|
| Individual Receive Message Buffer assigned to both channels<br>FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1 | see <a href="#">Table 50-25</a> |
| Individual Receive Message Buffer assigned to channel A<br>FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0     | see <a href="#">Table 50-26</a> |
| Individual Receive Message Buffer assigned to channel B<br>FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1     | see <a href="#">Table 50-27</a> |
| Receive FIFO Channel A Message Buffer                                                                  | see <a href="#">Table 50-26</a> |
| Receive FIFO Channel B Message Buffer                                                                  | see <a href="#">Table 50-27</a> |

The meaning of the bits in the slot status structure is explained in the Receive Message Buffer Slot Status Field Description table below.

**Table 50-25. Receive Message Buffer Slot Status Structure (ChAB)**

#### 50.7.5.2.2.2 Transmit Message Buffer Slot Status Description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given in the table below.

**Table 50-29. Transmit Message Buffer Slot Status Content**

| Transmit Message Buffer Type                                                                            | Slot Status Content             |
|---------------------------------------------------------------------------------------------------------|---------------------------------|
| Individual Transmit Message Buffer assigned to both channels<br>FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1 | see <a href="#">Table 50-30</a> |

*Table continues on the next page...*

**Table 50-29. Transmit Message Buffer Slot Status Content (continued)**

| Transmit Message Buffer Type                                                                        | Slot Status Content             |
|-----------------------------------------------------------------------------------------------------|---------------------------------|
| Individual Transmit Message Buffer assigned to channel A<br>FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0 | see <a href="#">Table 50-31</a> |
| Individual Transmit Message Buffer assigned to channel B<br>FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1 | see <a href="#">Table 50-32</a> |

The meaning of the bits in the slot status structure is described in the Transmit Message Buffer Slot Status Structure Field Descriptions table.

### 50.7.5.3 Message Buffer Data Field Description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in the table below. The structure of the message buffer data field is given in the next figure.

**Table 50-34. Message Buffer Data Field Minimum Length**

| physical message buffer assigned to    | minimum length defined by                 |
|----------------------------------------|-------------------------------------------|
| Individual Message Buffer in Segment 1 | FR_MBDSR[MBSEG1DS]                        |
| Receive Shadow Buffer in Segment 1     | FR_MBDSR[MBSEG1DS]                        |
| Individual Message Buffer in Segment 2 | FR_MBDSR[MBSEG2DS]                        |
| Receive Shadow Buffer in Segment 2     | FR_MBDSR[MBSEG2DS]                        |
| Receive FIFO for channel A             | FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0) |
| Receive FIFO for channel B             | FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1) |

### Note

The CC will not access any locations outside the message buffer data field boundaries given in the table above.

**Table 50-35. Message Buffer Data Field Structure**

|       | 0                   | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8                   | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
|-------|---------------------|---|---|---|---|---|---|---|---------------------|---|----|----|----|----|----|----|
| 0x0   | DATA0 / MID0 / NMV0 |   |   |   |   |   |   |   | DATA1 / MID1 / NMV1 |   |    |    |    |    |    |    |
| 0x2   | DATA2 / NMV2        |   |   |   |   |   |   |   | DATA3 / NMV3        |   |    |    |    |    |    |    |
| ...   | ...                 |   |   |   |   |   |   |   | ...                 |   |    |    |    |    |    |    |
| 0xN-2 | DATA N-2            |   |   |   |   |   |   |   | DATA N-1            |   |    |    |    |    |    |    |

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

### 50.7.5.3.1 Message Buffer Data Field Read Access

For transmit message buffers, the CC will not modify the content of the Message Buffer Data Field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR\_MBIDXRn). While the message buffer is locked, the CC will not update the Message Buffer Data Field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR\_RFARIR) or the Receive FIFO B Read Index Register (FR\_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR) indicate an non-empty FIFO.

### 50.7.5.3.2 Message Buffer Data Field Write Access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in the Frame Data Write Access Constraints table below.

**Table 50-36. Frame Data Write Access Constraints**

| Field          | CC/MB State                           |
|----------------|---------------------------------------|
| DATA, MID, NMV | <i>POC:config</i> or MB_DIS or MB_LCK |

**Table 50-37. Frame Data Field Descriptions**

| Field                                 | Description                                                                                                                                                                                                                                                                                     |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DATA 0,<br>DATA 1,<br>...<br>DATA N-1 | <b>Message Data</b> — Provides the message data received or to be transmitted. For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer.<br><br>For transmit message buffers, the field provides the message data to be transmitted. |
| MID 0,<br>MID 1                       | <b>Message Identifier</b> — If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.                      |

| Field                             | Description                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NMV 0,<br>NMV 1,<br>...<br>NMV 11 | <b>Network Management Vector</b> — If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer.<br><br><b>Note:</b> The MID and NMV bytes replace the corresponding DATA bytes. |

## 50.7.6 Individual Message Buffer Functional Description

The CC provides these basic types of individual message buffers:

1. Transmit Message Buffers
2. Receive Message Buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in [Individual Message Buffer Configuration Data](#).

### 50.7.6.1 Individual Message Buffer Configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

#### 50.7.6.1.1 Common Configuration Data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. These data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST\_MB\_UTIL field in the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST\_MB\_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR\_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR\_RSBIR).

#### 50.7.6.1.2 Specific Configuration Data

The second part of the message buffer configuration data is specific for each message buffer.

These data can be changed only when either

- *the protocol is in the POC:config state or*
- *the message buffer is disabled, i.e.  $FR\_MBCCSRn[EDS] = 0$*

The individual message buffer type is defined by the MTD and MBT bits in the Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn) as given in the following table.

**Table 50-38. Individual Message Buffer Types**

| FR_MBCCSRn |     | Individual Message Buffer Description |
|------------|-----|---------------------------------------|
| MTD        | MBT |                                       |
| 0          | 0   | Receive Message Buffer                |
| 0          | 1   | Reserved                              |
| 1          | 0   | Transmit Message Buffer               |
| 1          | 1   | Reserved                              |

The message buffer specific configuration data are

1. MTD bits in Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn)
2. all fields and bits in Message Buffer Cycle Counter Filter Registers (FR\_MBCCFRn)

3. all fields and bits in Message Buffer Frame ID Registers (FR\_MBFIDRn)
4. all fields and bits in Message Buffer Index Registers (FR\_MBIDXRn)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions in the Transmit Message Buffers section and Receive Message Buffers section.

### 50.7.6.2 Transmit Message Buffers

The section provides a detailed description of the functionality of single buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number  $n$  is configured to be a transmit message buffer by the following settings:

- $\text{FR\_MBCCSRn[MBT]} = 0(\text{singlebufferedmessagebuffer})$
- $\text{FR\_MBCCSRn[MDT]} = 1(\text{transmitmessagebuffer})$

#### 50.7.6.2.1 Access Regions

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented, which is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in the figure below. A description of the regions is given in [Table 50-40](#). If an region is active as indicated in [Table 50-41](#), the access scheme given for that region applies to the message buffer.

Figure 50-8. Transmit Message Buffer Access Regions

Table 50-39. Transmit Message Buffer Access Regions Description

| Region | Access from |            | Region used for                                   |
|--------|-------------|------------|---------------------------------------------------|
|        | Application | Module     |                                                   |
| CFG    | read/write  | -          | Message Buffer Configuration                      |
| MSG    | read/write  | -          | Message Data and Slot Status Access               |
| NF     | -           | read-only  | Message Header Access for Null Frame Transmission |
| TX     | -           | read/write | Message Transmission and Slot Status Update       |
| CM     | -           | read-only  | Message Buffer Validation                         |
| SR     | -           | read-only  | Message Buffer Search                             |

The trigger bits `FR_MBCCSRn[EDT]` and `FR_MBCCSRn[LCKT]`, and the interrupt enable bit `FR_MBCCSRn[MBIE]` are not under access control and can be accessed from the application at any time. The status bits `FR_MBCCSRn[EDS]` and `FR_MBCCSRn[LCKS]` are not under access control and can be accessed from the CC at any time.

The interrupt flag `FR_MBCCSRn[MBIF]` is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in the next figure. A description of the states is given in [Table 50-40](#), which also provides the access scheme for the access regions.

The status bits FR\_MBCCSRn[EDS] and FR\_MBCCSRn[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

### 50.7.6.2.2 Message Buffer States

This section describes the transmit message buffer states and provides a state diagram.

Figure 50-9. Transmit Message Buffer States

Table 50-40. Transmit Message Buffer State Description (Sheet 1 of 2)

| State    | FR_MBCCSRn |      | Access Region |        | Description                                                                                                                     |
|----------|------------|------|---------------|--------|---------------------------------------------------------------------------------------------------------------------------------|
|          | EDS        | LCKS | Appl.         | Module |                                                                                                                                 |
| Idle     | 1          | 0    | –             | CM,SR  | <b>Idle</b> - Message Buffer is idle. Included in message buffer search.                                                        |
| HDis     | 0          | 0    | CFG           | –      | <b>Disabled</b> - Message Buffer under configuration. Excluded from message buffer search.                                      |
| HDisLck  | 0          | 1    | CFG           | –      | <b>Disabled and Locked</b> - Message Buffer under configuration. Excluded from message buffer search.                           |
| HLck     | 1          | 1    | MSG           | SR     | <b>Locked</b> - Applications access to data, control, and status. Included in message buffer search.                            |
| CCSa     | 1          | 0    | –             | –      | <b>Slot Assigned</b> - Message buffer assigned to next static slot. Ready for Null Frame transmission.                          |
| HLckCCSa | 1          | 1    | MSG           | –      | <b>Locked and Slot Assigned</b> - Applications access to data, control, and status. Message buffer assigned to next static slot |
| CCNf     | 1          | 0    | –             | NF     | <b>Null Frame Transmission</b><br>Header is used for null frame transmission.                                                   |

Table continues on the next page...

**Table 50-40. Transmit Message Buffer State Description (Sheet 1 of 2) (continued)**

| State    | FR_MBCCSRn |      | Access Region |        | Description                                                                                                                                                       |
|----------|------------|------|---------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | EDS        | LCKS | Appl.         | Module |                                                                                                                                                                   |
| HLckCCNf | 1          | 1    | MSG           | NF     | <b>Locked and Null Frame Transmission</b> - Applications access to data, control, and status. Header is used for null frame transmission.                         |
| CCMa     | 1          | 0    | –             | CM     | <b>Message Available</b> - Message buffer is assigned to next slot and cycle counter filter matches.                                                              |
| HLckCCMa | 1          | 1    | MSG           | –      | <b>Locked and Message Available</b> - Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches. |
| CCTx     | 1          | 0    | –             | TX     | <b>Message Transmission</b> - Message buffer data transmit. Payload data from buffer transmitted                                                                  |
| CCSu     | 1          | 0    | –             | TX     | <b>Status Update</b> - Message buffer status update. Update of status flags, the slot status field, and the header index.                                         |

### 50.7.6.2.3 Message Buffer Transitions

Application transitions, module transitions, and transition priorities are discussed in this section.

#### 50.7.6.2.3.1 Application Transitions

The application transitions can be triggered by the application using the commands described in the table below. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

##### 50.7.6.2.3.1.1 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR\_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR\_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

### 50.7.6.2.3.1.2 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR\_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR\_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK\_EF in the CHI Error Flag Register (FR\_CHIERFR) is set.

**Table 50-41. Transmit Message Buffer Application Transitions**

| Transition | Command              | Condition            | Description                                  |
|------------|----------------------|----------------------|----------------------------------------------|
| HE         | FR_MBCCSRn[EDT]:= 1  | FR_MBCCSRn[EDS] = 0  | Application triggers message buffer enable.  |
| HD         |                      | FR_MBCCSRn[EDS] = 1  | Application triggers message buffer disable. |
| HL         | FR_MBCCSRn[LCKT]:= 1 | FR_MBCCSRn[LCKS] = 0 | Application triggers message buffer lock.    |
| HU         |                      | FR_MBCCSRn[LCKS] = 1 | Application triggers message buffer unlock.  |

### 50.7.6.2.3.2 Module Transitions

The module transitions that can be triggered by the CC are described in the following table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

**Table 50-42. Transmit Message Buffer Module Transitions**

| Transition | Condition                                              | Description                                                                                                                  |
|------------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| SA         | slot match and static slot                             | <b>Slot Assigned</b> - Message buffer is assigned to next static slot.                                                       |
| MA         | slot match and Cycle Counter match                     | <b>Message Available</b> - Message buffer is assigned to next slot and cycle counter filter matches.                         |
| TX         | slot start and FR_MBCCSRn[CMT] = 1                     | <b>Transmission Slot Start</b> - Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded. |
| SU         | status updated                                         | <b>Status Updated</b> - Slot Status field and message buffer status flags updated. Interrupt flag set.                       |
| STS        | static slot start                                      | <b>Static Slot Start</b> - Start of static slot.                                                                             |
| DSS        | dynamic slot start or symbol window start or NIT start | <b>Dynamic Slot or Segment Start</b> - Start of dynamic slot or symbol window or NIT.                                        |
| SSS        | slot start or symbol window start or NIT start         | <b>Slot or Segment Start</b> - Start of static slot or dynamic slot or symbol window or NIT.                                 |

### 50.7.6.2.3.3 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of the next table, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and subsequently the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions is given in the second part of the table below.

**Table 50-43. Transmit Message Buffer Transition Priorities**

| State                         | Priorities | Description                                  |
|-------------------------------|------------|----------------------------------------------|
| <b>module vs. application</b> |            |                                              |
| Idle, HLck                    | SA > HD    | Slot Assigned > Message Buffer Disable       |
|                               | MA > HD    | Message Available > Message Buffer Disable   |
| CCMa                          | TX > HL    | Transmission Start > Message Buffer Lock     |
| <b>module internal</b>        |            |                                              |
| Idle, HLck                    | MA > SA    | Message Available > Slot Assigned            |
| CCMa                          | TX > STS   | Transmission Slot Start > Static Slot Start  |
|                               | TX > DSS   | Transmission Slot Start > Dynamic Slot Start |

#### 50.7.6.2.4 Transmit Message Setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit CMT in the Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn). The physical access to the message buffer data field is described in [Individual Message Buffers](#).

As indicated by [Table 50-33](#), the application shall write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in [Table 50-33](#). The state change is indicated through the FR\_MBCCSRn[EDS] and FR\_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa the FR\_MBCCSRn[DVAL] flag is negated.

### 50.7.6.2.5 Message Transmission

As a result of the message buffer search described in [Individual Message Buffer Search](#), the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. the message buffer is in the message available state CCMa
2. the message data are still valid, i.e.  $FR\_MBCCSRn[CMT] = 1$

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in the "Message Transmission Timing" figure below. In this example, the message buffer with message buffer number  $n$  is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid, i.e.  $FR\_MBCCSRn[CMT] = 1$ .

**Figure 50-10. Message Transmission Timing**

**Figure 50-11. Message Transmission from HLck state with unlock**

The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register ( $FR\_MBSSUTR$ ).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register ( $FR\_MBDSR$ )

- the value of the PLDLEN field in the message buffer header field, as described in [Frame Header Description](#)

If a message buffer is assigned to message buffer segment 1, and  $PLDLEN > MBSEG1DS$ , then  $2 \times MBSEG1DS$  bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If  $PLDLEN \leq MBSEG1DS$ , the CC reads and transfers  $2 \times PLDLEN$  bytes. The same holds for segment 2 and  $MBSEG2DS$ .

#### 50.7.6.2.6 Null Frame Transmission

A static slot with slot number  $S$  is assigned to the CC for channel A, if at least one transmit message buffer is configured with the  $FR\_MBFIDRn[FID]$  set to  $S$  and  $FR\_MBCCFRn[CHA]$  set to 1. A Null Frame is transmitted in the static slot  $S$  on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with  $FR\_MBFIDRn[FID] = s$  and  $FR\_MBCCFRn[CHA] = 1$  are either not committed, i.e.  $FR\_MBCCSRn[CMT] = 0$ , or locked by the application, i.e.  $FR\_MBCCSRn[LCKS] = 1$ , or the cycle counter filter is enabled and does not match.

Additionally, the application can clear the commit bit of a message buffer that is in the CCMA state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in [Individual Message Buffer Search](#), the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in the figure below.

**Figure 50-12. Null Frame Transmission from Idle state**

A message buffer timing and state change diagram for null frame transmission from HLck state is given in the following figure.

**Figure 50-13. Null Frame Transmission from HLck state**

If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the next figure.

**Figure 50-14. Null Frame Transmission from HLck state with unlock**

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the figure below.

**Figure 50-15. Null Frame Transmission from Idle state with locking**

#### 50.7.6.2.7 Message Buffer Status Update

After the end of each slot, the PE generates the slot status vector. Depending on the this status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

#### 50.7.6.2.7.1 Message Buffer Status Update after Complete Message Transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer were sent to FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR\_MBCCSRn[MBIF] to indicate the successful message transmission.

Depending on the transmission mode flag FR\_MBCCFRn[MTM], the CC changes the commit flag FR\_MBCCSRn[CMT] and the valid flag FR\_MBCCSRn[DVAL]. If the FR\_MBCCFRn[MTM] flag is negated, the message buffer is in the *event transmission mode*. In this case, each committed message is transmitted only once. The commit flag FR\_MBCCSRn[CMT] is cleared with the SU transition. If the FR\_MBCCFRn[MTM] flag is asserted, the message buffer is in the *state transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR\_MBCCSRn[CMT] flag at the end of transmission and will set the valid flag FR\_MBCCSRn[DVAL] to indicate that the message will be transmitted again.

#### 50.7.6.2.7.2 Message Buffer Status Update after Incomplete Message Transmission

The term incomplete message transmission refers to the fact that not all payload data that should be transmitted were sent to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

In any of these two aforementioned conditions occur, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, the Protocol Engine Communication Failure Interrupt Flag PECF\_IF is set in the Protocol Interrupt Flag Register 1 (FR\_PIFR1).

### 50.7.6.2.7.3 Message Buffer Status Update after Null Frame Transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

### 50.7.6.3 Receive Message Buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used it is required to configure the related receive shadow buffer as described in [Receive Shadow Buffers](#).

A receive message buffer is used to receive a message from the FlexRay Bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application.

1. message data received
2. information about the reception process
3. status information about the slot in which the message was received

A individual message buffer with message buffer number  $n$  is configured as a receive message buffer by the following configuration settings

$$\text{FR\_MBCCSRn[MTD]} = 0(\text{receivemessagebuffer})$$

#### Equation 28

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented that is used to control the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in the figure below. A description of the regions is given in the following table. If a region is active as indicated in the "Receive Message Buffer States and Access (Sheet 2 of 2)" table below, the access scheme given for that region applies to the message buffer.

Figure 50-16. Receive Message Buffer Access Regions

Table 50-44. Receive Message Buffer Access Region Description

| Region | Access from |            | Region used for                                              |
|--------|-------------|------------|--------------------------------------------------------------|
|        | Application | Module     |                                                              |
| CFG    | read/write  | -          | Message Buffer Configuration, Message Data and Status Access |
| MSG    | read/write  | -          | Message Data, Header, and Status Access                      |
| RX     | -           | write-only | Message Reception and Status Update                          |
| SR     | -           | read-only  | Message Buffer Search Data                                   |

The trigger bits `FR_MBCCSRn[EDT]` and `FR_MBCCSRn[LCKT]` and the interrupt enable bit `FR_MBCCSRn[MBIE]` are not under access control and can be accessed from the application at any time. The status bits `FR_MBCCSRn[EDS]` and `FR_MBCCSRn[LCKS]` are not under access control and can be accessed from the CC at any time.

The interrupt flag `FR_MBCCSRn[MBIF]` is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in the figure below. A description of the message buffer states is given in [Table 50-40](#), which also provides the access scheme for the access regions.

The status bits `FR_MBCCSRn[EDS]` and `FR_MBCCSRn[LCKS]` provide the application with the required status information. The internal status information is not visible to the application.

Figure 50-17. Receive Message Buffer States

Table 50-45. Receive Message Buffer States and Access (Sheet 2 of 2)

| State    | FR_MBCCSRn |      | Access from |        | Description                                                                                                                             |
|----------|------------|------|-------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------|
|          | EDS        | LCKS | Appl.       | Module |                                                                                                                                         |
| Idle     | 1          | 0    | –           | SR     | <b>Idle</b> - Message Buffer is idle. Included in message buffer search.                                                                |
| HDis     | 0          | 0    | CFG         | –      | <b>Disabled</b> - Message Buffer under configuration. Excluded from message buffer search.                                              |
| HDisLck  | 0          | 1    | CFG         | –      | <b>Disabled and Locked</b> - Message Buffer under configuration. Excluded from message buffer search.                                   |
| HLck     | 1          | 1    | MSG         | –      | <b>Locked</b> - Applications access to data, control, and status. Included in message buffer search.                                    |
| CCBs     | 1          | 0    | –           | –      | <b>Buffer Subscribed</b> - Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.                   |
| HLckCCBs | 1          | 1    | MSG         | –      | <b>Locked and Buffer Subscribed</b> - Applications access to data, control, and status. Message buffer subscribed for reception.        |
| CCRx     | 1          | 0    | –           | –      | <b>Message Receive</b> - Message data received into related shadow buffer.                                                              |
| HLckCCRx | 1          | 1    | MSG         | –      | <b>Locked and Message Receive</b> - Applications access to data, control, and status. Message data received into related shadow buffer. |
| CCSu     | 1          | 0    | –           | RX     | <b>Status Update</b> - Message buffer status update. Update of status flags, the slot status field, and the header index.               |

### 50.7.6.3.1 Message Buffer Transitions

Application transitions, message buffer enable and disable, message buffer lock and unlock, module transitions, and transition priorities are discussed in this section.

### 50.7.6.3.1.1 Application Transitions

The application transitions that can be triggered by the application using the commands described in Table 50-41. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR\_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

### 50.7.6.3.1.2 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR\_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR\_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCBs, HLckCCBs, or CCRx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

### 50.7.6.3.1.3 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR\_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR\_MBCCSRn[LCKS]. If the command triggers the lock transition HL while the message buffer is in the state CCRx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK\_EF in the CHI Error Flag Register (FR\_CHIERFR) is set.

**Table 50-46. Receive Message Buffer Application Transitions**

| Transition | Host Command         | Condition            | Description                                  |
|------------|----------------------|----------------------|----------------------------------------------|
| HE         | FR_MBCCSRn[EDT]:= 1  | FR_MBCCSRn[EDS] = 0  | Application triggers message buffer enable.  |
| HD         |                      | FR_MBCCSRn[EDS] = 1  | Application triggers message buffer disable. |
| HL         | FR_MBCCSRn[LCKT]:= 1 | FR_MBCCSRn[LCKS] = 0 | Application triggers message buffer lock.    |
| HU         |                      | FR_MBCCSRn[LCKS] = 1 | Application triggers message buffer unlock.  |

### 50.7.6.3.1.4 Module Transitions

The module transitions that can be triggered by the CC are described in the next table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

**Table 50-47. Receive Message Buffer Module Transitions**

| Transition | Condition                                      | Description                                                                                                       |
|------------|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| BS         | slot match and CycleCounter match              | <b>Buffer Subscribed</b> - The message buffer filter matches next slot and cycle.                                 |
| SLS        | slot start                                     | <b>Slot Start</b> - Start of either Static Slot or Dynamic Slot.                                                  |
| SNS        | symbol window start or NIT start               | <b>Symbol Window or NIT Start</b> - Start of either Symbol Window or NIT.                                         |
| SSS        | slot start or symbol window start or NIT start | <b>Slot or Segment Start</b> - Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.                  |
| SU         | status updated                                 | <b>Status Updated</b> - Slot Status field, message buffer status flags, header index updated. Interrupt flag set. |

### 50.7.6.3.1.5 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the table below, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU and can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the buffer subscribed state CCBs and the module triggers the slot start transition SLS at the same time as the application locks the message buffer by the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state HLckCCRx.

**Table 50-48. Receive Message Buffer Transition Priorities**

| State                         | Priorities | Description                                 |
|-------------------------------|------------|---------------------------------------------|
| <b>module vs. application</b> |            |                                             |
| Idle                          | BS > HD    | Buffer Subscribed > Message Buffer Disable  |
| HLck                          | BS > HD    | Buffer Subscribed > Message Buffer Disable  |
| CCRx                          | SSS > HL   | Slot or Segment Start > Message Buffer Lock |

### 50.7.6.3.2 Message Reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to the either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffers assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot the module trigger the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data are written into the shadow buffers. For details on receive shadow buffers, see [Receive Shadow Buffers Concept](#). The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

### 50.7.6.3.3 Message Buffer Update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer was in the locked state HLckCCRx, no update will be performed. The received data are lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA\_EF/FRLB\_EF in the CHI Error Flag Register (FR\_CHIERFR).

If a message buffer was in the CCRx state it is now in the CCSu state. After the evaluation of the slot status provided by the PE the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to. This is described in [Table 50-51](#).

**Table 50-49. Receive Message Buffer Update (Continued)**

| <b>vSS!ValidFrame</b> | <b>vRF!Header!<br/>NFIndicator</b> | <b>Update description</b>                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1                     | 1                                  | <b>Valid non-null frame received.</b> <ul style="list-style-type: none"> <li>- Message Buffer Data Field updated.</li> <li>- Frame Header Field updated.</li> <li>- Slot Status Field updated.</li> <li>- DUP:= 1</li> <li>- DVAL:= 1</li> <li>- MBIF:= 1</li> </ul> |
| 1                     | 0                                  | <b>Valid null frame received.</b>                                                                                                                                                                                                                                    |

*Table continues on the next page...*

**Table 50-49. Receive Message Buffer Update (Continued) (continued)**

| <i>vSS!ValidFrame</i> | <i>vRF!Header!<br/>NFIndicator</i> | Update description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 0                     | x                                  | <p><b>No valid frame received.</b></p> <ul style="list-style-type: none"> <li>- Message Buffer Data Field not updated.</li> <li>- Frame Header Field not updated.</li> <li>- Slot Status Field updated.</li> <li>- DUP:= 0</li> <li>- DVAL <i>not</i> changed.</li> <li>- MBIF:= 1, if the slot was not an empty dynamic slot.</li> </ul> <p><b>Note:</b> An empty dynamic slot is indicated by the following frame and slot status bit values:<br/> <i>vSS!ValidFrame</i> = 0 and <i>vSS!SyntaxError</i> = 0 and <i>vSS!ContentError</i> = 0 and <i>vSS!BViolation</i> = 0.</p> |

### Note

If the number of the last slot in the current communication cycle on a given channel is  $n$ , then all receive message buffers assigned to this channel with  $FR\_MBFIDRn[FID] > n$  will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in the following figure.

**Figure 50-18. Message Reception Timing**

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following two items:

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR\_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR\_MBDSR)
3. the number of bytes received over the FlexRay bus

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than  $2 \times \text{FR\_MBDSR.MBSEG1DS}$ , the CC writes only  $2 \times \text{FR\_MBDSR.MBSEG1DS}$  bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than  $2 \times \text{FR\_MBDSR.MBSEG1DS}$ , the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with  $\text{FR\_MBDSR.MBSEG2DS}$ .

#### 50.7.6.3.4 Received Message Access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in [Individual Message Buffers](#).

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

#### 50.7.6.3.5 Receive Shadow Buffers Concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in [Receive Shadow Buffers](#).

The receive shadow buffers temporarily store the received frame header and message data. After the slot boundary the slot status information is generated. If the slot status information indicates the reception of the valid non-null frame (see [Table 50-49](#)), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR\_MBIDX $R_n$ ) with the content of the corresponding internal shadow buffer index register. In all other cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR\_MBIDXRn). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR\_MBIDXRn).

### 50.7.7 Individual Message Buffer Search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel if a slot  $s$  in a communication cycle  $c$  is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm which is invoked at the following protocol related events:

1. NIT start
2. slot start in the static segment
3. minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot  $n$  searches for message buffers assigned or subscribed to slot  $n+1$ .

In general, the message buffer search for the next slot  $n$  considers only message buffers which are

1. enabled, i.e. FR\_MBCCSRn[EDS] = 1, and
2. matches the next slot  $n$ , i.e. FR\_MBFIDRn[FID] =  $n$ , and

On top of that, for the static segment only those message buffers are considered, that match the condition of at least one row of the "Message Buffer Search Priority (static segment)" table shown below. For the dynamic segment only those message buffers are considered, that match the condition of at least one row of the next "Message Buffer Search Priority (dynamic segment)" table. These message buffers are called *matching* message buffers.

For each enabled channel the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers the message buffers with highest priority according to the "Message Buffer Search Priority (static segment)" table for the static segment and according to the "Message Buffer Search Priority (dynamic segment)" table for the dynamic segment are selected.

**Table 50-50. Message Buffer Search Priority (static segment)**

| Priority    | MT<br>D | LC<br>KS | CM<br>T | CC<br>FM <sup>1</sup> | Description                                                    | Transition |
|-------------|---------|----------|---------|-----------------------|----------------------------------------------------------------|------------|
| (highest) 0 | 1       | 0        | 1       | 1                     | transmit buffer, matches cycle count, not locked and committed | MA         |
| 1           | 1       | -        | 0       | 1                     | transmit buffer, matches cycle count, not committed            | SA         |
|             | 1       | 1        | -       | 1                     | transmit buffer, matches cycle count, locked                   | SA         |
| 2           | 1       | -        | -       | -                     | transmit buffer                                                | SA         |
| 3           | 0       | 0        | n/a     | 1                     | receive buffer, matches cycle count, not locked                | SB         |
| (lowest) 4  | 0       | 1        | n/a     | 1                     | receive buffer, matches cycle count, locked                    | SB         |

1. Cycle Counter Filter Match, see [Message Buffer Cycle Counter Filtering](#).
2. Cycle Counter Filter Match, see [Message Buffer Cycle Counter Filtering](#).

**Table 50-51. Message Buffer Search Priority (dynamic segment)**

| Priority    | MT<br>D | LC<br>KS | CM<br>T | CC<br>FM <sup>1</sup> | Description                                                    | Transition |
|-------------|---------|----------|---------|-----------------------|----------------------------------------------------------------|------------|
| (highest) 0 | 1       | 0        | 1       | 1                     | transmit buffer, matches cycle count, not locked and committed | MA         |
| 1           | 0       | 0        | n/a     | 1                     | receive buffer, matches cycle count, not locked                | SB         |
| (lowest) 2  | 0       | 1        | n/a     | 1                     | receive buffer, matches cycle count, locked                    | SB         |

1. Cycle Counter Filter Match, see [Message Buffer Cycle Counter Filtering](#).
2. Cycle Counter Filter Match, see [Message Buffer Cycle Counter Filtering](#).

If there are multiple message buffer with highest priority, the message buffer with the lowest message buffer number is selected. All message buffer which have the highest priority must have a consistent channel assignment as specified in [Message Buffer Channel Assignment Consistency](#).

Depending on the message buffer channel assignment the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in [Individual Message Buffers](#).

50.7.7.1 Message Buffer Cycle Counter Filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR\_MBCCFRn). This filter determines a set of communication cycles in which the message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled, i.e. CCFE = 0, this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

$$MBCCFRn[CCFE] = 0$$
$$CYCCNT \& MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \& MBCCFRn[CCFMSK]$$

50.7.7.2 Message Buffer Channel Assignment Consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR\_MBCCFRn) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR\_MBCCFRn[CHA] = 1 and transmits or receives on channel B if FR\_MBCCFRn[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The behavior of the message buffer search is not defined, if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in the figure below.

|     |                      |                                          |                                                                                                                 |
|-----|----------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| MB0 | FR_MBFIDR0[FID] = 10 | FR_MBCCFR0[CHA] = 1, FR_MBCCFR0[CHB] = 0 |  single channel assignment |
| MB1 | FR_MBFIDR1[FID] = 10 | FR_MBCCFR0[CHA] = 1, FR_MBCCFR1[CHB] = 1 |                                                                                                                 |

Figure 50-19. Inconsistent Channel Assignment

### 50.7.7.3 Node Related Slot Multiplexing

The term *Node Related Slot Multiplexing* applies to the dynamic segment only and refers to the functionality if there are transmit as well as receive message buffers are configured for the same slot.

According to [Table 50-51](#) the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

### 50.7.7.4 Message Buffer Search Error

There are two kinds of errors which may occur during message buffer search<sup>1</sup>.

#### 50.7.7.4.1 Message Buffer Search Start while Running

If the message buffer search is running in slot  $n-1$  and the next message buffer search start event appears due to the start of slot  $n$ , the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS\_EF is set in the CHI Error Flag Register (FR\_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot  $n$ . Additionally, the search engine will not be started in slot  $n$ , and consequently no individual message buffer is identified for transmission or reception in slot  $n+1$ .

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency see [Number of Usable Message Buffers](#).

#### 50.7.7.4.2 Illegal Message Buffer Index Found

If the message buffer search has finished the message buffer search in slot  $n-1$ , it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS\_EF is set in the CHI Error Flag Register (FR\_CHIERFR) is set and no individual message buffer is identified for transmission or reception in slot

1. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to an search error, the received frame is considered for FIFO reception.

*n.* The legal message buffer index values for the individual and receive shadow buffers are specified in the Receive Shadow Buffer Index Register section (FR\_RSBIR) and the Message Buffer Index Registers sections (FR\_MBIDXRn).

## 50.7.8 Individual Message Buffer Reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data can not be reconfigured when the protocol is out of the *POC:config* state.

### 50.7.8.1 Reconfiguration Schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.

#### 50.7.8.1.1 Basic Type Not Changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR\_MBCCSRn[MTD] are not changed. This type of reconfiguration is denoted by RC1 in Figure 50-20. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

#### 50.7.8.1.2 Buffer Type Not Changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in the figure below. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

Figure 50-20. Message Buffer Reconfiguration Scheme

## 50.7.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

### 50.7.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. One FIFO is assigned to channel A, the other FIFO is assigned to channel B. Both FIFOs work completely independent from each other.

The message buffer structure of each FIFO is described in [Receive FIFO](#). The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- *The FIFO system memory base address*
- *The index of the first FIFO entry given by Receive FIFO Start Index Register (FR\_RFSIR)*
- *The data field offset of the data field belonging to the first FIFO entry given by Receive FIFO Start Data Offset Register (FR\_RFSDOR)*
- *The number of FIFO entries and the length of each FIFO entry as given by Receive FIFO Depth and Size Register (FR\_RFDSR)*

### 50.7.9.2 FIFO Configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO address mode bit FAM in the Module Configuration Register (FR\_MCR).

#### 50.7.9.2.1 Single System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR\_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is System Memory Base Address Register (FR\_SYMBADR).

#### 50.7.9.2.2 Dual System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR\_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is Receive FIFO System Memory Base Address Register (FR\_RFSYMBADR).

The FIFO control and configuration data are given in [Receive FIFO Control and Configuration Data](#). The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details see [FlexRay Memory Area Layout](#).

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

- Configure the FIFO update and address modes in Module Configuration Register (FR\_MCR)
- Configure the FIFO system memory base address
- Configure the Receive FIFO Start Index Register (FR\_RFSIR) with the first message buffer header index that belongs to the FIFO
- Configure the Receive FIFO Start Data Offset Register (FR\_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO
- Configure the Receive FIFO Depth and Size Register (FR\_RFDSR) with FIFO entry size
- Configure the Receive FIFO Depth and Size Register (FR\_RFDSR) with FIFO depth
- Configure the FIFO Filters

### 50.7.9.3 FIFO Periodic Timer

The FIFO periodic timer is used to generate an FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached, but the FIFO is not empty. This can be used to prevent frames from get stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR\_RFPTR). If the periodic timer duration FR\_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR\_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd*, greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

#### 50.7.9.4 FIFO Reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO, if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case the FIFO filter path shown in [Figure 50-21](#) is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR) is incremented. If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

#### 50.7.9.5 FIFO Almost-Full Interrupt Generation

If the fifo fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM, i.e.  $FLA > WM_A$  ( $FLB > WM_B$ ), then the FIFO almost-full interrupt flag FR\_GIFER[FAFAIF] (FR\_GIFER[FAFBIF]) is asserted.

If the periodic timer expires, and FIFOA (FIFOB) is not empty, i.e.  $FLA > 0$  ( $FLB > 0$ ), then the FIFO almost-full interrupt flag FR\_GIFER[FAFAIF] (FR\_GIFER[FAFBIF]) is asserted.

#### 50.7.9.6 FIFO Overflow Error Generation

If the FIFOA (FIFOB) is full, i.e.  $FLA = FIFO\_DEPTH_A$  ( $FLB = FIFO\_DEPTH_B$ ) and the conditions for a FIFO reception as described in [FIFO Reception](#) are fulfilled, then the fifo overflow error flag FR\_CHIERFR[FOVA\_EF] (FR\_CHIERFR[FOVB\_EF]) is asserted.

#### 50.7.9.7 FIFO Message Access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR\_RFARIR) and the

(Receive FIFO B Read Index Register (FR\_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO. The respective read data field offsets can be calculated according to Equation 1-125.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR) is 0, then the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR\_RFARIR) or (Receive FIFO B Read Index Register (FR\_RFBRIR)) point to a message buffer with invalid content. In this case the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR\_RFARIR) (Receive FIFO B Read Index Register (FR\_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to Equation 1-125. The application can access the message data as described in [Receive FIFO](#). When the application has read the message buffer data and status information, it can update the FIFO as described in [FIFO Update](#).

#### 50.7.9.8 FIFO Update

The application updates the FIFOA (FIFOB) by writing a pop count value  $pc$  different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR\_RFFLPCR).

As a result of this operation, the CC removes the oldest  $pc$  entries from FIFOA (FIFOB).

If the specified pop count value  $pc$  is greater than the current fill level  $fl$  provided in FLA (FAB) field, then only  $fl$  entries are removed from the FIFOA (FIFOB), the remaining  $fl - pc$  requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (FR\_RFARIR) (Receive FIFO B Read Index Register (FR\_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR\_RFSIR) automatically.

### 50.7.9.8.1 FIFO Interrupt Flag Update

The FIFO Interrupt Flag Update mode is configured, when the FIFO update mode flag `FR_MCR[FUM]` is set to 0. In this mode FIFOA (FIFOB) will be updated by 1 entry, when the interrupt flag `FR_GIFER[FAFAIF]` (`FR_GIFER[FAFBIF]`) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the Receive FIFO A Read Index Register (`FR_RFARIR`) (Receive FIFO B Read Index Register (`FR_RFBRIR`)) is incremented by 1, if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

### 50.7.9.9 FIFO Filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides three sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in the figure below.

**Figure 50-21. Received Frame FIFO Filter Path**

A received frame passes the FIFO filtering if it has passed all three type of filter.

### 50.7.9.9.1 RX FIFO Frame ID Value-Mask Rejection Filter

The frame ID value-mask rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR\_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR\_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter, i.e. is not rejected.

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-Mask Rejection Filter if [Equation 29 on page 1829](#) is fulfilled.

$$FID \& FR\_RFFIDRFMR[FIDRFMSK] \neq FR\_RFFIDRFVR[FIDRFVAL] \& FR\_RFFIDRFMR[FIDRFMSK]$$

**Equation 29**

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to pass all frames by the following settings.

$$FR\_RFFIDRFVR[FIDRFVAL] = 0x000 \text{ and } FR\_RFFIDRFMR[FIDRFMSK] = 0x7FF$$

**Equation 30**

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to reject all frames by the following settings.

$$FR\_RFFIDRFMR[FIDRFMSK] = 0x000$$

**Equation 31**

Using these settings, [Equation 29 on page 1829](#) can never be fulfilled ( $0 \neq 0$ ) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

### 50.7.9.9.2 RX FIFO Frame ID Range Rejection Filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR\_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR\_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range rejection filters if either no rejection filter is enabled, or, for all of the enabled RX FIFO Frame ID Range rejection filters, i.e.  $FR\_RFRFCTR[FiMD] = 1$  and  $FR\_RFRFCTR[FiEN] = 1$ , [Equation 32 on page 1830](#) is fulfilled.

$$FID < FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \text{ or } (FR\_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

**Equation 32**

Consequently, all frames with a frame ID that fulfills [Equation 33 on page 1830](#) for at least one of the enabled rejection filters will be rejected and thus not pass.

$$FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR\_RFRFCFR_{SEL}[SID_{IBD=1}]$$

**Equation 33**

### 50.7.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR\_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR\_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, for at least one of the enabled RX FIFO Frame ID Range acceptance filters, i.e. FR\_RFRFCTR[FiMD] = 0 and FR\_RFRFCTR[FiEN] = 1, [Equation 34 on page 1830](#) is fulfilled.

$$FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR\_RFRFCFR_{SEL}[SID_{IBD=1}]$$

**Equation 34**

### 50.7.9.9.4 RX FIFO Message ID Acceptance Filter

The RX FIFO Message ID Acceptance Filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR\_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR\_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance Filter if [Equation 35 on page 1830](#) is fulfilled.

$$MID \& FR\_RFMIDAFMR[MIDAFMSK] = FR\_RFMIDAFMR[MIDAFVAL] \& FR\_RFMIDAFMR[MIDAFMSK]$$

**Equation 35**

The RX FIFO Message ID Acceptance Filter can be configured to accept all frames by setting

$$\text{FR\_RFMIDAFMR[MIDAFMSK]} = 0x000$$
**Equation 36**

Using these settings, [Equation 35 on page 1830](#) is always fulfilled and all frames will pass.

**50.7.10 Channel Device Modes**

This section describes the two FlexRay channel device modes that are supported by the CC.

**50.7.10.1 Dual Channel Device Mode**

In the dual channel device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR\_A\_RX, FR\_A\_TX, and FR\_A\_TX\_EN is connected to the physical bus channel A and the FlexRay port consisting of FR\_B\_RX, FR\_B\_TX, and FR\_B\_TX\_EN is connected to the physical bus channel B. The dual channel system is shown in the following figure.

**Figure 50-22. Dual Channel Device Mode**

## 50.7.10.2 Single Channel Device Mode

The single channel device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals `FR_A_RX`, `FR_A_TX`, and `FR_A_TX_EN` and can be connected to either the physical bus channel A (shown in the "Single Channel Device Mode (Channel A)" figure below) or the physical bus channel B (shown in the "Single Channel Device Mode (Channel B)" figure below).

If the device is configured as a single channel device by setting `FR_MCR[SCM]` to 1, only the internal channel A and the FlexRay Port A is used. Depending on the setting of `FR_MCR[CHA]` and `FR_MCR[CHB]`, the internal channel A behaves either as a FlexRay Channel A or FlexRay Channel B. The bit `FR_MCR[CHA]` must be set, if the FlexRay Port A is connected to a FlexRay Channel A. The bit `FR_MCR[CHB]` must be set if the FlexRay Port A is connected to a FlexRay Channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single channel device, the application can access and configure only the registers related to internal channel A.

Figure 50-23. Single Channel Device Mode (Channel A)

Figure 50-24. Single Channel Device Mode (Channel B)

### 50.7.11 External Clock Synchronization

The application of the external rate and offset correction is triggered when the application writes to the EOC\_AP and ERC\_AP fields in the Protocol Operation Control Register (FR\_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in the "External Offset Correction Write and Application Timing" figure and the "External Rate Correction Write and Application Timing" figures below.

#### Note

The values provided in the EOC\_AP and ERC\_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle  $2n+1$  shall be affect by the external offset correction, the EOC\_AP field must be written to after the start of cycle  $2n$  and before the end of the static segment of cycle  $2n+1$ . If this field is written to after the end of the static segment of cycle  $2n+1$ , it is not guaranteed that the external correction value is applied in cycle  $2n+1$ . If the value is not applied in cycle  $2n+1$ , then the value will be applied in the cycle  $2n+3$ . Refer to the following for timing details.

**Figure 50-25. External Offset Correction Write and Application Timing**

If the rate correction for the cycle pair  $[2n+2, 2n+3]$  shall be affected by the external offset correction, the `ERC_AP` field must be written to after the start of cycle  $2n$  and before the end of the static segment start of cycle  $2n+1$ . If this field is written to after the end of the static segment of cycle  $2n+1$ , it is not guaranteed that the external correction value is applied in cycle pair  $[2n+2, 2n+3]$ . If the value is not applied for cycle pair  $[2n+2, 2n+3]$ , then the value will be applied for cycle pair  $[2n+4, 2n+5]$ . Refer to the following for details.

**Figure 50-26. External Rate Correction Write and Application Timing**

## 50.7.12 Sync Frame ID and Sync Frame Deviation Tables

The FlexRay protocol requires the provision of a snapshot of the Synchronization Frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

### Note

Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.

### 50.7.12.1 Sync Frame ID Table Content

The Sync Frame ID Table is a snapshot of the protocol related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

### 50.7.12.2 Sync Frame Deviation Table Content

The Sync Frame Deviation Table is a snapshot of the protocol related variable `zsDev(id)(oe)(ch)!Value`. Each Sync Frame Deviation Table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the Sync Frame ID Table.

Figure 50-27. Sync Table Memory Layout

### 50.7.12.3 Sync Frame ID and Sync Frame Deviation Table Setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in Figure 50-27. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR\_SFTOR).

### 50.7.12.4 Sync Frame ID and Sync Frame Deviation Table Generation

The application controls the generation process of the Sync Frame ID and Sync Frame Deviation Tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR\_SFTCCSR). A summary of the copy modes is given in the table below.

**Table 50-52. Sync Frame Table Generation Modes**

| FR_SFTCCSR |       |       | Description                                                                                      |
|------------|-------|-------|--------------------------------------------------------------------------------------------------|
| OPT        | SDVEN | SIDEN |                                                                                                  |
| 0          | 0     | 0     | No Sync Frame Table copy                                                                         |
| 0          | 0     | 1     | Sync Frame ID Tables will be copied continuously                                                 |
| 0          | 1     | 0     | Reserved                                                                                         |
| 0          | 1     | 1     | Sync Frame ID Tables and Sync Frame Deviation Tables will be copied continuously                 |
| 1          | 0     | 0     | No Sync Frame Table copy                                                                         |
| 1          | 0     | 1     | Sync Frame ID Tables for next even-odd-cycle pair will be copied                                 |
| 1          | 1     | 0     | Reserved                                                                                         |
| 1          | 1     | 1     | Sync Frame ID Tables and Sync Frame Deviation Tables for next even-odd-cycle pair will be copied |

The Sync Frame Table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR\_SFTCCSR[SIDEN] to 1, the CC starts the update of the even cycle related tables after the start of the NIT of the next even cycle. The CC checks if the application has locked the tables by reading the FR\_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR\_SFTCCSR[EVAL]. Once all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR\_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT\_IF in the Protocol Interrupt Flag Register 1 (FR\_PIFR1). If the interrupt enable flag EVT\_IE is set, an interrupt request is generated.

To read the generated tables, the application must lock the tables to prevent the CC from updating these tables. The locking is initiated by writing a 1 to the even table lock trigger FR\_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR\_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding

status information fields SFRA, SFRB in the Sync Frame Counter Register (FR\_SFCNTR). The value in the FR\_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR\_SFCNTR[SFEVA] and FR\_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in Figure 50-27.

After reading all the data from the locked tables, the application must unlock the table by writing to the even table lock trigger FR\_SFTCCSR[ELKT] again. The even table lock status bit FR\_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR\_SFTCCSR[EVAL] and FR\_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR\_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR\_SFCNTR).

**Figure 50-28. Sync Frame Table Trigger and Generation Timing**

### 50.7.12.5 Sync Frame Table Access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in Figure 50-27. During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

#### 50.7.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR\_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

### 50.7.13 MTS Generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol MTS in the symbol window on channel A or channel B.

The application can configure the set of communication cycles in which the MTS will be transmitted over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR\_MTSACFR) and MTS B Configuration Register (FR\_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR\_MTSACFR) or MTS B Configuration Register (FR\_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$\text{FR\_PSR0[PROTSTATE]} = \text{POC: normalactive}$$

#### Equation 37

$$\text{FR\_MTSACRF[MTE]} = 1$$

#### Equation 38

$$\text{CYCCNT} \& \text{FR\_MTSACFR[CYCCNTMSK]} = \text{FR\_MTSACFR[CYCCNTVAL]} \& \text{FR\_MTSACFR[CYCCNTMSK]}$$

#### Equation 39

The MTS is transmitted over channel B in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$\text{FR\_MTSBCRF[MTE]} = 1$$

#### Equation 40

$$\text{CYCCNT} \& \text{FR\_MTSBCFR[CYCCNTMSK]} = \text{FR\_MTSBCFR[CYCCNTVAL]} \& \text{FR\_MTSBCFR[CYCCNTMSK]}$$

#### Equation 41

### 50.7.14 Key Slot Transmission

Key slot assignment, transmission in POC:startup state, and transmission in POC:normal active state are discussed in this section.

### 50.7.14.1 Key Slot Assignment

A key slot is assigned to the CC if the `key_slot_id` field in the Protocol Configuration Register 18 (FR\_PCR18) is configured with a value greater than 0 and less or equal to `number_of_static_slots` in Protocol Configuration Register 2 (FR\_PCR2), otherwise no key slot is assigned.

### 50.7.14.2 Key Slot Transmission in POC:startup

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version 2.1 Rev A .

### 50.7.14.3 Key Slot Transmission in POC:normal active

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in the following table is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see [Message Transmission](#)). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see [Null Frame Transmission](#)).

**Table 50-53. Key Slot Frame Type**

| FR_PCR11[key_slot_used_for_sync] | FR_PCR11[key_slot_used_for_startup] | key slot frame type       |
|----------------------------------|-------------------------------------|---------------------------|
| 0                                | 0                                   | normal frame              |
| 0                                | 1                                   | normal frame <sup>1</sup> |
| 1                                | 0                                   | sync frame                |
| 1                                | 1                                   | startup frame             |

1. The frame transmitted has an semantically incorrect header and will be detected as an invalid frame at the receiver.

## 50.7.15 Sync Frame Filtering

Each received synchronization frame must pass the Sync Frame Acceptance Filter and the Sync Frame Rejection Filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled, i.e. the SF FE control bit in the Module Configuration Register (FR\_MCR) is cleared, all received synchronization

frames are considered for clock synchronization. If a received synchronization frame did not pass at least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

### 50.7.15.1 Sync Frame Acceptance Filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR\_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR\_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if the following equations evaluates to true.

$$\text{FR\_MCR}[\text{SFFE}] = 0$$

**Equation 42**

$$\text{FID} \& \text{FR\_SFIDAFMR}[\text{FMSK}] = \text{FR\_SFIDAFVR}[\text{FVAL}] \& \text{FR\_SFIDAFMR}[\text{FMSK}]$$

**Equation 43**

#### Note

Sync frames are transmitted in the static segment only. Thus  
FID <= 1023.

### 50.7.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR\_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if the following equations evaluates to true.

$$\text{FR\_MCR}[\text{SFFE}] = 0$$

**Equation 44**

$$\text{FID} \neq \text{FR\_SFIDRFR}[\text{SYNFRID}]$$

**Equation 45**

#### Note

Sync frames are transmitted in the static segment only. Thus  
FID <= 1023.

## 50.7.16 Strobe Signal Support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in the Strobe Signal Mapping table, located in the Register Descriptions section.

### 50.7.16.1 Strobe Signal Assignment

Each of the strobe signals listed in the Strobe Signal Mapping table, located in the Register Descriptions section, can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR\_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR\_STBSCR) with appropriate settings.

To read out the current settings for a strobe signal with number N, the application must execute the following sequence.

1. Write to FR\_STBSCR with WMD = 1 and SEL = N. (updates SEL field only)
2. Read STBCSR.

The SEL field provides N and the ENB and STBPSEL fields provides the settings for signal N.

### 50.7.16.2 Strobe Signal Timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.

The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay Bus. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a negative clock offset. An example waveform is given in the following figure.

**Figure 50-29. Strobe Signal Timing (type = pulse, clk\_offset = -2)**

Other signals refer to events that occurred on the FlexRay Bus some cycles before the strobe signal is changed. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a positive clock offset. An example waveform is given in the figure below.

**Figure 50-30. Strobe Signal Timing (type = pulse, clk\_offset = +4)**

## 50.7.17 Timer Support

The CC provides two timers, which run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In the non-repetitive mode, timer stops if it expires. In repetitive mode, timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

### 50.7.17.1 Absolute Timer T1

The absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1\_IF in the Protocol Interrupt Flag Register 0 (FR\_PIFR0) is set at the macrotick start event, if the following equations are fulfilled.

$$\text{CYCTR}[\text{CTCCNT}] \& \text{FR\_THCYSR}[T1\_CYC\_MSK] = \text{FR\_THCYSR}[T1\_CYC\_VAL] \& \text{FR\_THCYSR}[T1\_CYC\_MSK]$$
**Equation 46**

$$\text{FR\_MTCTR}[\text{MTCT}] = \text{FR\_TIIMTOR}[T1\_MTOFFSET]$$
**Equation 47**

If the timer 1 interrupt enable bit TI1\_IE in the Protocol Interrupt Enable Register 0 (FR\_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

The corresponding Interrupt condition (i.e., when the abovementioned equations are fulfilled) also leads to an event out indication on an output port (*fr\_evt\_tim1*) based on the [TIM1\_EE] bit of the Protocol Event Output Enable Register (FR\_PEOER).

### 50.7.17.2 Absolute / Relative Timer T2

The timer T2 can be configured to be an absolute or relative timer by setting the T2\_CFG control bit in the Timer Configuration and Control Register (FR\_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

#### 50.7.17.2.1 Absolute Timer T2

If timer T2 is configured as an absolute timer, it has the same functionality timer T1 but the configuration from Timer 2 Configuration Register 0 (FR\_TI2CR0) and Timer 2 Configuration Register 1 (FR\_TI2CR1) is used. On expiration of timer T2, the interrupt flag TI2\_IF in the Protocol Interrupt Flag Register 0 (FR\_PIFR0) is set. If the timer 1 interrupt enable bit TI1\_IE in the Protocol Interrupt Enable Register 0 (FR\_PIER0) is asserted, an interrupt request is generated.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr\_evt\_tim2*) based on the [TIM2\_EE] bit of the Protocol Event Output Enable Register (FR\_PEOER).

50.7.17.2.2 Relative Timer T2

If the timer T2 is configured as a relative timer, the interrupt flag TI2\_IF in the Protocol Interrupt Flag Register 0 (FR\_PIFR0) is set, when the programmed amount of macroticks MT[31:0], defined by Timer 2 Configuration Register 0 (FR\_TI2CR0) and Timer 2 Configuration Register 1 (FR\_TI2CR1), has expired since the trigger or restart of timer 2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.

The corresponding Interrupt condition for T2 also leads to an event out indication on an output port (*fr\_evt\_tim2*) based on the [TIM2\_EE] bit of the Protocol Event Output Enable Register (FR\_PEOER).

50.7.18 Slot Status Monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per channel base. The content of the slot status vector is described in the "Slot Status Content" table below. The PE provides the slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in the below figure.

Figure 50-31. Slot Status Vector Update

Note

The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 50-54. Slot Status Content

|                      | Status Content      |
|----------------------|---------------------|
| static /dynamic Slot | slot related status |

Table continues on the next page...

**Table 50-54. Slot Status Content (continued)**

|               | Status Content                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
