

LOW DROPOUT REGULATOR

FEATURES

- Up to 5 A Output Current Capability With External PNP Transistor
- Internal Short Circuit Protection
- Excellent Load Regulation
- CMOS/TTL-Compatible On/Off Switch
- Internal Reverse Bias Current Protection Switch
- Internal Thermal Shutdown
- Broad Operating Voltage Range
- High Impedance V_{SENSE} Pin (Off Mode)
- Continuous and Pulsed Current Modes

DESCRIPTION

The TK732xx is a controller IC for a low dropout voltage regulator. The TK732xx and the external PNP power transistor provide standard output voltages from 2 to 11 V and output current from 100 mA to 5 A. By utilizing an external PNP power transistor, low dropout voltage at high current can be readily achieved. The internal electronic switch can be controlled by TTL or CMOS logic levels. The device is in the "on" state when the control pin is pulled to a high logic level. A pin for a bypass capacitor, which connects to the internal circuitry, is provided to lower the overall output noise level.

The current limit characteristics can be configured as continuous (constant current) or pulsed (cycling). An internal thermal shutdown circuit limits the junction temperatures to below 150 °C. In the "off" mode, the output of the regulator becomes a high impedance. This prevents the output capacitor from being rapidly discharged for backup to the load.

APPLICATIONS

- Battery Powered Systems
- Cellular/Cordless Telephones
- Radio Control Systems
- Wireless Communications Systems
- Portable Instrumentations
- Portable Computers
- Personal Digital Assistants
- Local Area Network (LAN) Receivers
- Lithium Ion Battery Chargers
- Power Recovery for Microprocessors

DEFINITION AND EXPLANATION OF TECHNICAL TERMS

OUTPUT VOLTAGE (V_{OUT})

The output voltage is specified with $V_{IN} = (V_{OUT(TYP)} + 1 \text{ V})$ and $I_{OUT} = 30 \text{ mA}$.

DROPOUT VOLTAGE (V_{DROP})

The dropout voltage is the difference between the input voltage and the output voltage at which point the regulator starts to fall out of regulation. Below this value, the output voltage will fall as the input voltage is reduced. It is dependent upon the load current, the external transistor and the junction temperature.

BASE CONTROL CURRENT (I_{BASE})

The base control current is the drive current for the base of the external transistor.

OUTPUT CURRENT (I_{OUT})

The output current depends on the characteristics of the external transistor and current limit setting.

LINE REGULATION (Line Reg)

Line regulation is the ability of the regulator to maintain a constant output voltage as the input voltage changes. The line regulation is specified as the input voltage is changed from $V_{IN} = V_{OUT(TYP)} + 1 \text{ V}$ to $V_{IN} = V_{OUT(TYP)} + 6 \text{ V}$.

LOAD REGULATION (Load Reg)

Load regulation is the ability of the regulator to maintain a constant output voltage as the load current changes. It is a pulsed measurement to minimize temperature effects. Load regulation depends on the external transistor.

QUIESCENT CURRENT (I_Q)

The quiescent current is the current which flows through the ground terminal under no load conditions ($I_{OUT} = 0 \text{ mA}$) and excludes the control pin current.

GROUND CURRENT (I_{GND})

Ground current is the current which flows through the ground pin(s). It is defined as $I_{IN} - I_{OUT}$, excluding control current.

RIPPLE REJECTION RATIO (RR)

Ripple rejection is the ability of the regulator to attenuate the ripple content of the input voltage at the output. It is specified with 100 mVrms, 400 Hz superimposed on the input voltage, where $V_{IN} = V_{OUT(TYP)} + 1.5 \text{ V}$. The output decoupling capacitor is set to $10 \mu\text{F}$, the noise bypass capacitor is set to $0.1 \mu\text{F}$, and the load current is set to 30 mA. Ripple rejection is the ratio of the ripple content of the output vs. the input and is expressed in dB.

STANDBY CURRENT (I_{STBY})

Standby current is the current which flows into the regulator when the output is turned off by the control function ($V_{CONT} = 0 \text{ V}$). It is measured with $V_{IN} = 8 \text{ V}$ (9 V for the 8 V output device).

REMOTE SENSING (V_{SENSE})

The V_{SENSE} pin is the output voltage sensing pin. If the voltage drop to the load caused by the PCB etch resistance cannot be disregarded, the voltage drop can be compensated by connecting the V_{SENSE} pin as shown below.

The length of the V_{SENSE} etch should be limited to 30 cm (11.8 in.) maximum.

DEFINITION AND EXPLANATION OF TECHNICAL TERMS (CONT.)

SENSOR CIRCUITS

Overcurrent Sensor

The overcurrent sensor protects the device if the output is shorted to ground.

Thermal Sensor

The thermal sensor protects the device if the junction temperature exceeds the safe value ($T_j = 150\text{ }^{\circ}\text{C}$). This temperature rise can be caused by extreme heat, excessive power dissipation caused by large output voltage drops, or excessive output current. The regulator will shut off when the temperature exceeds the safe value. As the junction temperature decreases, the regulator will begin to operate again. Under sustained fault conditions, the regulator output will oscillate as the device turns off then resets. Damage may occur to the device under extreme fault conditions.

Reverse Voltage Protection

Reverse voltage protection prevents damage due to the output voltage being higher than the input voltage. This fault condition can occur when the output capacitor remains charged and the input is reduced to zero, or when an external voltage higher than the input voltage is applied to the output side.

PACKAGE POWER DISSIPATION (P_D)

This is the power dissipation level at which the thermal sensor is activated. The IC contains an internal thermal sensor which monitors the junction temperature. When the junction temperature exceeds the monitor threshold of $150\text{ }^{\circ}\text{C}$, the IC is shut down. The junction temperature rises as the difference between the input power ($V_{IN} \times I_{IN}$) and the output power ($V_{OUT} \times I_{OUT}$) increases. The rate of temperature rise is greatly affected by the mounting pad configuration on the PCB, the board material, and the ambient temperature. When the IC mounting has good thermal conductivity, the junction temperature will be low even if the power dissipation is great. When mounted on the recommended mounting pad, the power dissipation of the SOT-23L-8 is increased to 600 mW. For operation at ambient temperatures over $25\text{ }^{\circ}\text{C}$, the power dissipation of the SOT-23L-8 device should be derated at $4.8\text{ mW}/^{\circ}\text{C}$. To determine the power dissipation for shutdown when mounted, attach the device on the actual PCB and

deliberately increase the output current (or raise the input voltage) until the thermal protection circuit is activated. Calculate the power dissipation of the device by subtracting the output power from the input power. These measurements should allow for the ambient temperature of the PCB. The value obtained from $P_D / (150\text{ }^{\circ}\text{C} - T_A)$ is the derating factor. The PCB mounting pad should provide maximum thermal conductivity in order to maintain low device temperatures. As a general rule, the lower the temperature, the better the reliability of the device. The thermal resistance when mounted is expressed as follows:

$$T_j = \theta_{jA} \times P_D + T_A$$

For Toko ICs, the internal limit for junction temperature is $150\text{ }^{\circ}\text{C}$. If the ambient temperature (T_A) is $25\text{ }^{\circ}\text{C}$, then:

$$150\text{ }^{\circ}\text{C} = \theta_{jA} \times P_D + 25\text{ }^{\circ}\text{C}$$

$$\theta_{jA} = 125\text{ }^{\circ}\text{C} / P_D$$

P_D is the value when the thermal sensor is activated. A simple way to determine P_D is to calculate $V_{IN} \times I_{IN}$ when the output side is shorted. Input current gradually falls as temperature rises. You should use the value when thermal equilibrium is reached.

The range of usable currents can also be found from the graph below.

Procedure:

- 1) Find P_D
- 2) P_{D1} is taken to be $P_D \times$ (Note: It is not necessary to connect a ceramic capacitor in parallel with an aluminum or tantalum output capacitor. ($\sim 0.8 - 0.9$))

DEFINITIONS AND TERMS (CONT.)

- 3) Plot P_{D1} against 25 °C
- 4) Connect P_{D1} to the point corresponding to the 150 °C with a straight line.
- 5) In design, take a vertical line from the maximum operating temperature (e.g., 75 °C) to the derating curve.
- 6) Read off the value of P_D against the point at which the vertical line intersects the derating curve. This is taken as the maximum power dissipation, D_{PD} .

The maximum operating current is:

$$I_{OUT} = (D_{PD} / (V_{IN(MAX)} - V_{OUT}))$$

SOT-23L-8 POWER DISSIPATION CURVE

APPLICATION INFORMATION

INPUT-OUTPUT CAPACITORS

The output capacitor is necessary for stable operation. The regulator may oscillate if the output capacitor is too small or missing. The output capacitor size is determined by load, transient response and external transistor used. Evaluation in the circuit is recommended to ensure performance requirements are satisfied. A minimum of 4.7 μ F is necessary for stability, with twice that value recommended. The minimum recommended input capacitor is 1 μ F. Problems do not occur with larger values of capacitance. However, extremely low ESR may result in unstable operation. Thus, the use of large value ceramic capacitors is not recommended on the output.

BOARD LAYOUT

SOT-23L-8 BOARD LAYOUT

APPLICATION INFORMATION (CONT.)

PULSE CURRENT LIMIT MODE

The equation for the pulse output current limit is as follows:

$$I_{SET} \text{ (mA)} = 90 \text{ (mV)} / R_{IPK} \text{ (}\Omega\text{)}$$

During the initial turn-on, charge (surge) current flows to the output capacitor. This IC has a possibility for the current limit to operate and to turn off the output by the charge current of the output capacitor. Therefore, the relationship between C_L and C_P is set as shown in the graph below:

CONTINUOUS CURRENT LIMIT MODE

In the continuous current limit mode, the C_{PULSE} pin (pin 3) is directly connected to ground. The output current limit is set by R_{IPK} according to the following equation:

$$I_{SET} \text{ (mA)} = 100 \text{ (mV)} / R_{IPK} \text{ (}\Omega\text{)}$$

If the continuous current limit mode is also used for output short circuit protection, the I_{SET} value is set 50% to 100% more than the maximum operating current. The current transistor is selected from the I_{SET} value. The output voltage drops when the output current exceeds the I_{SET} value. However, the output voltage returns to normal once the output current decreases below the I_{SET} value.

APPLICATION INFORMATION (CONT.)

EXTERNAL PNP POWER TRANSISTOR

This IC can use any kind of external transistor. The external transistor selection is a function of the load current, H_{fe} and power dissipation. See following chart:

LOAD CURRENT	RECOMMENDED EXTERNAL TRANSISTOR	RECOMMENDED $R_{IPK} (\Omega)$
0 ~ 180 mA	2SB624, 2SB1115, 2SB799 (NEC), 2SB970 (Matushita)	0.33 ~ 0.39
0 ~ 300 mA	2SB1115, 2SB799 (NEC)	0.22 ~ 0.27
0 ~ 500 mA	2SB1114, 2SB1115 (NEC), 2SB1302 (Sanyo), 2SA1203, 2SA1213, 2SA1734 (Toshiba)	0.12 ~ 0.15
0 ~ 1 A	2SA1242, 2SA1736 (Toshiba), 2SB1302, 2SA1896 (Sanyo)	0.056 ~ 0.068
0 ~ 2 A	2SA1451, 2SA1242 (Toshiba)	0.033 ~ 0.039
0 ~ 3 A	2SA1451 (Toshiba), 2SA1645 (NEC)	0.022 ~ 0.027
0 ~ 4 A	2SA1451 (Toshiba), 2SB904 (Sanyo), 2SA1645 (NEC)	0.012 ~ 0.015

HIGH-SIDE SWITCHING

High-side switching should not be implemented by an external transistor as shown above. This results in additional voltage drop and loss of accuracy.

The high output voltage accuracy and low dropout voltage are maintained when the IC is turned ON/OFF by using the control pin as illustrated above.

APPLICATION INFORMATION (CONT.)

VOLTAGE BACKUP OPERATION (HOLDUP TIME)

C_L becomes the backup power supply when the microprocessor is reset with the voltage detector IC simultaneously with turning OFF the TK732xx. C_L provides the holdup time necessary to do an orderly shutdown of the microprocessor.

PARALLEL ON/OFF CONTROL OPERATION

The figure above illustrates multiple regulators being controlled by a single ON/OFF control signal. The series resistor R is put in the input line of the low output voltage regulator in order to prevent overdissipation. The voltage dropped across the resistor reduces the large input-to-output voltage across the regulator, reducing the power dissipation in the device.

OUTPUT VOLTAGE ADJUST

When a highly accurate output voltage is necessary, the output can be adjusted. As shown above, higher output resolution can be achieved by putting a resistor (R_{ADJ}) in the V_{SENSE} pin in parallel with a 1000 pF capacitor. A value of 2 K provides an adjustment of 50 mV typically. Note: using this technique, the output voltage can only be adjusted higher.

BATTERY CHARGER

Continuous Current Limit Mode:

$$I_{SET} \text{ (mA)} = 100 \text{ (mV)} / R_{IPK} \text{ (}\Omega\text{)}$$

APPLICATION INFORMATION (CONT.)

I_{SET} (Continuous Current Limit Mode) is set to the desired charging current.

circuit condition, T_{r1} is turned "off." This converts the circuit into the pulse current limit mode of operation, reducing the power dissipation in the pass transistor. The transition between the continuous and pulse current limit modes can be controlled by adjusting the operating point of T_{r1} by the value of resistor R .

LITHIUM ION BATTERY CHARGER WITH OVERDISSIPATION PROTECTION OF EXTERNAL TRANSISTOR (SHORT CIRCUIT MODE) (RECOMMENDED WITH TK732xxMCLH)

During normal operation, T_{r1} is turned ON, connecting pin 3 (C_{PULSE}) to ground. This provides the continuous current limit mode for normal operating conditions. During a short
