

### **ZNEO32! Family of Microcontrollers**

# **Z32F128 MCU**

**Product Specification** 

PS034503-0516

PRELIMINARY

Warning: DO NOT USE THIS PRODUCT IN LIFE SUPPORT SYSTEMS.

#### LIFE SUPPORT POLICY

ZILOG'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS PRIOR WRITTEN APPROVAL OF THE PRESIDENT AND GENERAL COUNSEL OF ZILOG CORPORATION.

#### As used herein

Life support devices or systems are devices which (a) are intended for surgical implant into the body, or (b) support or sustain life and whose failure to perform when properly used in accordance with instructions for use provided in the labeling can be reasonably expected to result in a significant injury to the user. A critical component is any component in a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system or to affect its safety or effectiveness.

# **Revision History**

Each instance in this document's revision history reflects a change from its previous edition. For more details, refer to the corresponding page(s) or appropriate links furnished in the table below.

Date	Revision Level	Description	Page
May 2016	03	Added Quadrature Encoder Interface information. Corrected bit positions of the Status and Interrupt Enable registers.	122 113, 114
Apr 2016	02	Added timing information for peripherals; global edits for clarity.	All
Nov 2015	01	Original issue.	

# 1. Overview

### Introduction

Zilog's Z32F128 MCU, a member of the ZNEO32! Family of microcontrollers is a cost-effective and high-performance 32-bit microcontroller. The Z32F128 MCU provides 3-phase PWM generator units which are suitable for inverter bridges, including motor drive systems. The two built-in channels of these generators control two inverter motors simultaneously.

Three 12-bit high speed ADC units with 16-channel analog multiplexed inputs are included to gather information from the motor. The Z32F128 MCU can control up to two inverter motors or one inverter motor and the Power Factor Correction (PFC) function simultaneously. Four on-chip operational AMPs and four analog comparators are available to measure analog input signals. The operational amplifier can amplify the input signal to the proper signal range and transfer it to the ADC input channel. The comparator monitors external signals and helps create an internal emergency signal. Multiple powerful external serial interface engines communicate with on-board sensors.

Figure 1.1 shows a block diagram of the Z32F128 MCU.

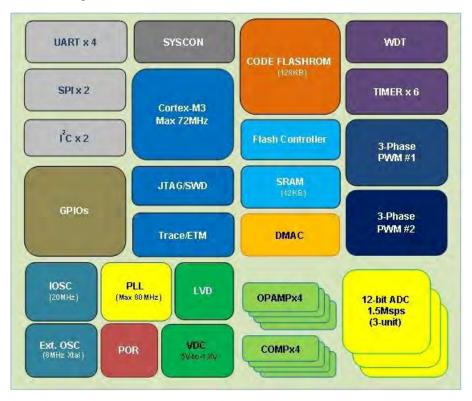

Figure 1.1. Z32F128 MCU Block Diagram

Figure 1.2 and Figure 1.3 show the pin layouts.

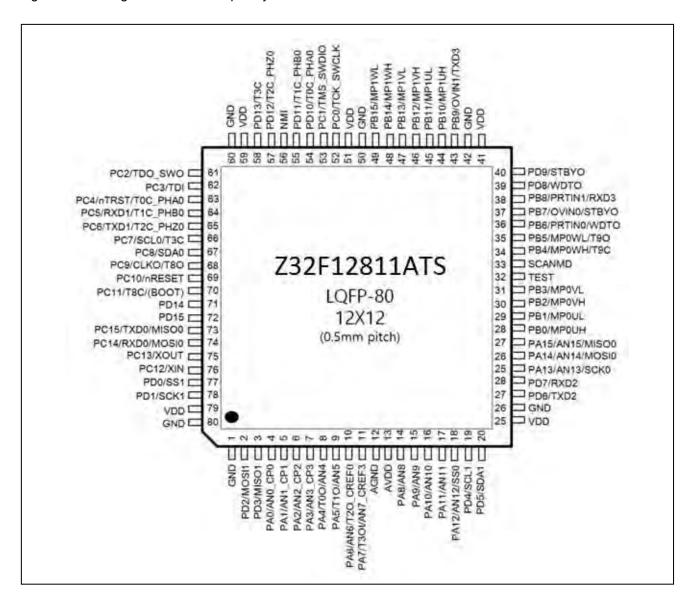

Figure 1.2. Pin Layout (LQFP-80)

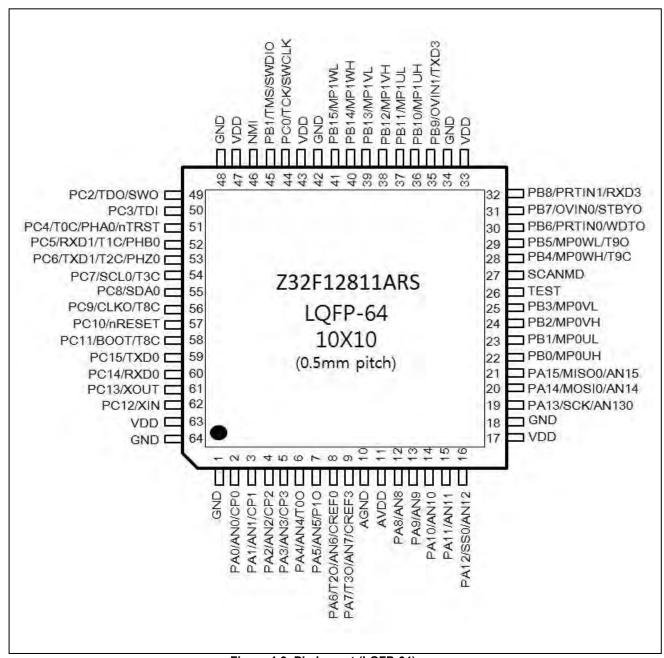

Figure 1.3. Pin Layout (LQFP-64)

### **Product Features**

The Z32F128 MCU offers the following features:

- High performance low-power Cortex-M3 core
- 128 KB code Flash memory with cache function
- 12 KB SRAM
- 3-Phase Motor PWM with ADC triggering function
  - o 2 channels
- 1.5Msps high-speed ADC with burst conversion function
  - o 2 or 3 units with 16 channel input
- Built-in Programmable Gain Amplifier (PGA) for ADC inputs
  - o 4 channels
    - 3 channels for 3 shunt resistor configuration
    - 1 channel for 1 shunt resistor configuration
- Built-in analog comparator
  - o 4 channels
    - 3 channels for 3 shunt resistor configuration
    - 1 channel for 1 shunt resistor configuration
- · System fail-safe function by clock monitoring
- XTAL OSC fail monitoring
- Precision internal oscillator clock (20MHz ±3%)
- Watchdog timer
- Six general purpose timers
- · Quadrature encoder interface counter
- External communication ports: 4 UARTs, 2 I<sup>2</sup>Cs, 2 SPIs
- High current driving port for UART photo couplers
- Debug and emergency stop function
- · Real-time monitoring function support for more effective development
- JTAG and Serial Wire Debug (SWD) in-circuit debugger
- Various memory size and package options
  - o LQFP-80, LQFP-64
- Industrial grade operating temperature (-40 ~ +85 °C)

Table 1.1. Device Type

Part Number	Flash	SRAM	UART	SPI	I2C	MPWM	ADC	I/O PORT	PKG
Z32F12811ATS	128KB	12KB	4	2	2	2	3-unit	68	LQFP-80
Z32F12811ARS		IZND	2	2	1	2	16 ch	48	LQFP-64

## **Architecture**

## **Block Diagram**

An internal block diagram of the Z32F128 MCU is shown in Figure 1.4.

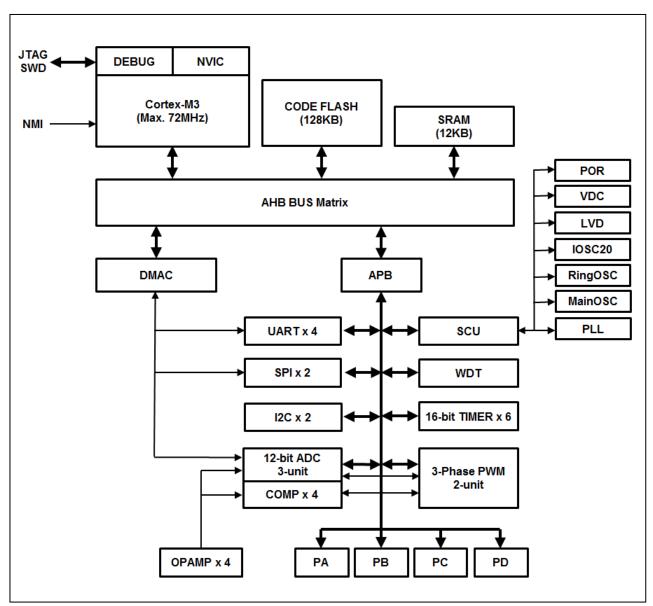

Figure 1.4. Internal Block Diagram

### **Functional Description**

The following section provides an overview of the features of the Z32F128 microcontroller.

#### ARM Cortex-M3

- ARM powered Cortex-M3 Core based on v7M architecture, which is optimized for small size
  and low-power systems. On core system timer (SYSTICK) provides a simple 24-bit timer that
  makes it easy to manage the system operations
- Thumb-compatible Thumb-2 only instruction set processor core makes code high-density
- Hardware division and single-cycle multiplication
- Integrated Nested Vectored Interrupt Controller (NVIC) provides deterministic interrupt handling
- Full featured debug solutions JTAG and SWD, FPB, DWT, ITM, and TPIU
- Maximum 72 MHz operating frequency with zero wait execution

### **Nested Vector-Interrupt Controller (NVIC)**

- The ARM Nested Vectored Interrupt Controller (NVIC) on the ARM Cortex-M3 core handles all internal and external exceptions. When an interrupt condition is detected, the processor state is automatically stored to the stack and automatically restored from the stack at the end of the interrupt service routine.
- The vector is fetched in parallel to the state saving, which enables efficient interrupt entry.
- The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoring.

### 128 KB Internal Code Flash Memory

- The Z32F128 MCU provides internal 128 KB code Flash memory and its controller. This is
  enough to program the motor algorithm and control the system. Self-programming is available
  and ISP and JTAG programming is also supported in Boot or Debugging Mode.
- Instruction and data cache buffer overcome the limitations of low-bandwidth Flash memory. The CPU can execute from Flash memory with zero wait state up to 72 MHz bus frequency.

### 12 KB Zero-wait Internal SRAM

 On chip 12 KB zero-wait SRAM can be used for working memory space and program code can be loaded on this SRAM.

#### **Boot Logic**

 The smart boot logic supports Flash programming. The Z32F128 MCU can be entered by external boot pin and UART and SPI programming are available in Boot Mode. UART0 or SPI0 is used in Boot mode communication.

### System Control Unit (SCU)

 The SCU block manages internal power, clock, reset and operation mode. It also controls analog blocks (INTOSC, VDC and LVD).

### 32-bit Watchdog Timer (WDT)

 The watchdog timer performs the system monitoring function. It generates an internal reset or interrupt to notice an abnormal status of the system.

#### Multi-purpose 16-bit Timer

- Six-channel 16-bit general purpose timers support:
  - o Periodic timer mode
  - o Counter mode
  - o PWM mode
  - Capture mode

#### **PWM Generator**

- Two channels of the 3-phase PWM generator are implemented. 16 bit up/down counter with prescaler supports triangular and saw tooth waveforms.
- The PWM generates an internal ADC trigger signal to measure the signal on time.
- Dead time insertion and emergency stop functionality ensure that the chip and system operate under safe conditions.

### Serial Peripheral Interface (SPI)

- Synchronous serial communication is provided by the SPI block. The Z32F128 MCU has 2 channel SPI modules. The DMA function is supported by the DMA controller. Transfer data is moved to/from the memory area without CPU operation.
- Boot mode uses this SPI block to download the Flash program.

### Inter-Integrated Circuit Interface (I<sup>2</sup>C)

• The Z32F128 MCU has a 2-channel I<sup>2</sup>C block and it supports up to 400 kHz I<sup>2</sup>C communication. Master and the slave modes are supported.

### Universal Asynchronous Receiver/Transmitter (UART)

- The Z32F128 MCU includes a 4-channel UART block. For accurate baud rate control, a fractional baud rate generator is provided.
- The DMA function is supported by the DMA controller. Transfer data is moved to/from memory area without CPU operation.

#### General PORT I/Os

- 16-bit PA, PB, PC, PD ports are available and provide multiple functionality:
- General I/O port
- Independent bit set/clear function
- External interrupt input port
- Pull-up/Open-drain
- On chip debounce Filter

### 12-bit Analog-to-Digital Converter (ADC)

• 3 built-in ADCs can convert analog signal up to 1usec conversion rate. 16-channel analog mux and OP-AMP provides various combinations from external analog signals.

### **Analog Front End (AFE)**

- Operational Amplifier (OPAMP)
  - o 4 built-in OPAMPs amplify analog signals up to x8.74 gain
- Analog Comparator (COMP)
  - 4 built-in analog comparators

# **Pin Description**

The pin configurations are shown in Table 1.2. 16 pins are reserved for power/ground pair and dedicated pins.

Figure 1.7. Peripheral Memory Map

# 2. CPU

### **Cortex-M3 Core**

The CPU core is supported by the ARM Cortex-M3 processor which provides a high-performance, low-cost platform. For more information about Cortex-M3, refer to document number DDI337 from ARM.

# **System Timer**

The System Timer (SYSTICK) is a 24-bit timer and is part of the Cortex-M3 core. The system timer can be configured either through the registers (see the Cortex-M3 Technical Reference Manual) or through the provided functions defined in <code>core\_cm3.h</code>. There is an interrupt vector for the system timer. To configure the system timer, call <code>SysTickConfig()</code> with the number of system clocks in between interrupt intervals (up to a maximum of 24 bits).

# **Interrupt Controller**

The Nested Vectored Interrupt Controller (NVIC) is part of the core Cortex-M3 MCU. The NVIC controls system exceptions and peripheral interrupts and is closely coupled with the core to provide low latency and efficient processing of late arriving interrupts. The NVIC maintains knowledge of the nested interrupts to enable tail-chaining of interrupts.

The Z32F128 MCU supports 64 peripheral interrupts (of which 25 are not used) and 16 system interrupts. The NVIC also allows setting software interrupts and resetting the system.

Interrupts can be assigned a PRIORITY GROUP (common interrupts with the same priorities) as well as individual priorities. There are 8 priority levels available. For an interrupt to be active, it must be enabled in the peripheral and the NVIC registers. For more information on NVIC, see the Cortex M3 Technical Reference Manual.

The system includes functions to set the NVIC registers which are defined in core cm3.h.

**Table2.1. Interrupt Vector Map** 

Interrupt Number	Vector Address	Interrupt Source

# 3. Boot Mode

### **Boot Mode Pins**

The Z32F128 MCU has a Boot Mode option to program internal Flash memory. When the BOOT pin is pulled low, the system will start up in the BOOT area  $(0x1FFF\_0000)$  instead of the default Flash area  $(0x0000\_0000)$ . This provides the ability to flash the part using either UART or SPI interfaces. The BOOT pin has an internal pull up resistor. Therefore, when the BOOT pin is not connected, it rides high (normal state).

Boot Mode uses the UART0 port and the SPI0 ports for the interface. The JTAG and SW interfaces can also be used, which provide the ability to recover from a bad Flash update that prevents the JTAG or SW debugger from attaching.

The pins for Boot Mode are listed in Table 3.1.

Table 3.1. Boot Mode Pin List

Block	Pin Name	Dir	Description
SYSTEM	nRESET/PC10	I	Reset Input signal
SISIEW	BOOT/PC11	I	'0' to enter Boot mode
UART0	RXD0/PC14	I	UART Boot Receive Data
UARIU	TXD0/PC15	0	UART Boot Transmit Data
	SS0/PA12	I	SPI Boot Slave Select
SPI0	SCK0/PA13	I	SPI Boot Clock Input
3710	MOSI0/PA14	I	SPI Boot Data Input
	MISO0/PA15	0	SPI Boot Data Output

# **Boot Mode Connections**

The target board can be designed using either of the Boot Mode ports – UART or SPI.

Figure 3.1 and Figure 4.1Figure 3.2 show sample connection diagrams in Boot Mode.

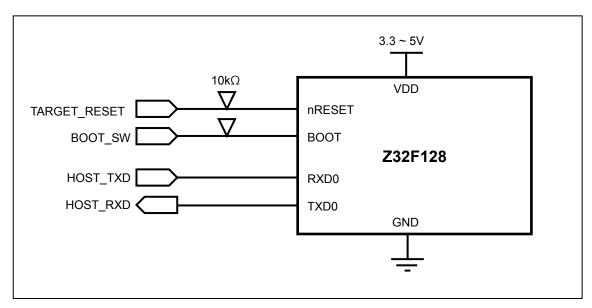

Figure 3.1. Connection Diagram of UART Boot

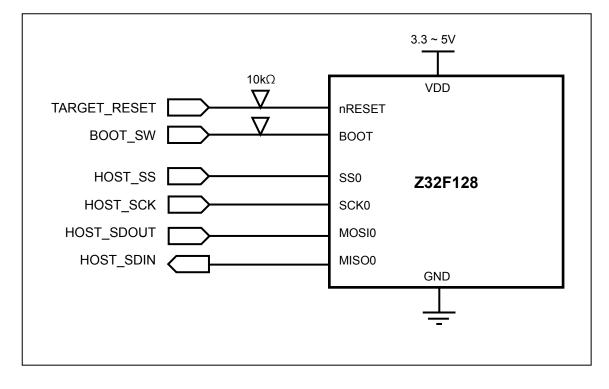

Figure 3.2. Connection Diagram of SPI Boot

# 4. System Control Unit

### **Overview**

The Z32F128 MCU has a built-in intelligent power control block which manages system analog blocks and operating modes. Internal reset and clock signals are controlled by the SCU block to maintain optimal system performance and power dissipation.

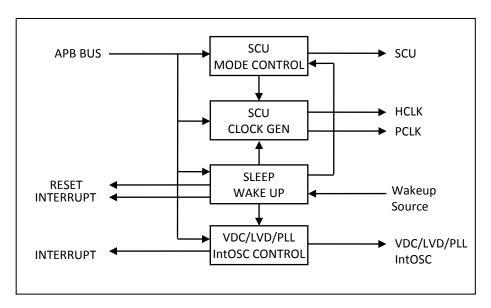

Figure 4.1. SCU Block Diagram

## **Clock System**

The Z32F128 MCU contains two main operating clocks – HCLK, which supplies the clock to the CPU and the AHB bus system; and PCLK, which supplies the clock to the peripheral systems. Users can control the clock system variation by software. Figure 4.2 shows the clock system of the chip. Table 4.1 lists the clock source descriptions.

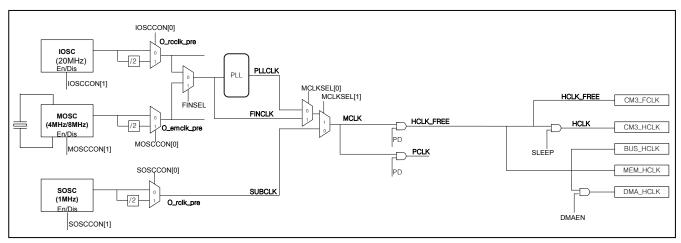

Figure 4.2. System Clock Configuration

Each of the registers to switch the clock source has a glitch-free circuit. Therefore, the clock can be switched without the risk of glitches.

Table 4.1. Clock Sources

Clock name	Frequency	Description
IOSC20	20MHz	Internal OSC
MOSC	XTAL(4MHz~8MHz)	External Crystal IOSC
PLL Clock	8MHz ~ 80MHz	On Chip PLL
ROSC	1MHz	Internal RING OSC

The PLL can synthesize the PLLCLK clock up to 80 MHz with the FIN reference clock. It also has an internal pre-divider and post-divider.

### **HCLK Clock Domain**

The HCLK clock feeds the clock to the CPU and AHB bus. The Cortex-M3 CPU requires two clocks related with HCLK clock – FCLK and HCLK. FCLK is the free running clock and it is always running except in Power-down mode. HCLK can be stopped in Idle mode.

### **Miscellaneous Clock Domain for Cortex-M3**

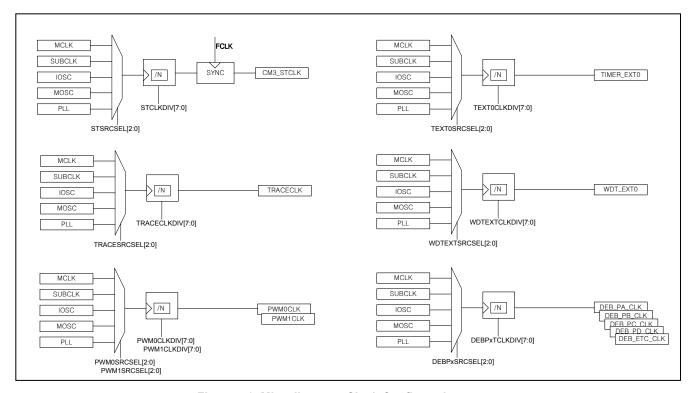

Figure 4.3. Miscellaneous Clock Configuration

### **PCLK Clock Domain**

PCLK is the master clock of all the peripherals. It can be stopped in Power-down mode. Each peripheral clock is generated by the PCER register set.

### **Clock Configuration**

After power up, the default system clock is fed by the RINGOSC (1MHz) clock. RINGOSC is enabled by default during the power up sequence. The other clock sources are enabled by user controls with the RINGOSC system clock.

The MOSC clock can be enabled by the CSCR register. Before enabling the MOSC block, the pin mux configuration should be set for XIN, XOUT function. PC12 and PC13 pins are shared with MOSC's XIN and XOUT function - PCCMR and PCCCR registers should be configured properly. After enabling the MOSC block, you must wait for more than 1 msec to ensure stable operation of crystal oscillation.

The PLL clock can be enabled by the PLLCON register. After enabling the PLL block, you must wait for the PLL lock flag. When the PLL output clock is stable, you can select MCLK for your system requirement. Before changing the system clock, set Flash access wait to the maximum value. After the system clock is changed, set the desired Flash access wait time.

Figure 4.4 shows a flow chart outlining the process to configure the system clock.

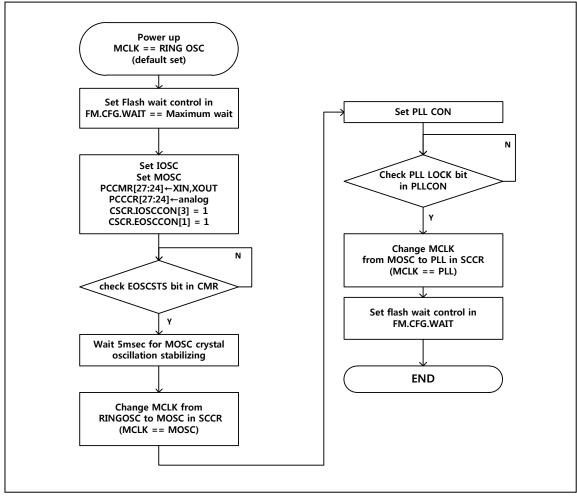

Figure 4.4. Clock Configuration Procedure Flowchart

When you speed up the system clock up to the maximum operating frequency, check the Flash wait control configuration. The CLK3 and CLK4 bit fields in the FMCR register can control the wait time. Flash read access time is one of the limiting factors that can impact performance.

The wait control recommendation is provided in Table 4.2.

**Table 4.2. Flash Wait Control Recommendation** 

FMCR	Flash Access Wait	Available Max System Clock Frequency
CLK3	3 Clock Wait	~48MHz
CLK4	4 Clock Wait	~72MHz

### Reset

The Z32F128 MCU has two system resets:

- Cold reset by POR which is effective during power up or down sequence
- Warm reset which is generated by several reset sources.

The reset event causes the chip to return to its initial state.

Cold reset has only one reset source, which is POR. Warm reset has the following reset sources:

- nRESET pin
- WDT reset
- LVD reset
- MCLK Fail reset
- MOSC Fail reset
- S/W reset
- · CPU request reset

### **Cold Reset**

The cold reset is an important feature of the chip when power is up. This characteristic affects the system boot globally. Internal VDC is enabled when VDD power is turned on. The internal VDD level slope is followed by the external VDD power slope. The boot operation is started when the internal PoR trigger level is 1.4V of the internal VDC voltage out level. The RINGOSC clock is enabled and counts 4 msec to stabilize the internal VDC level. During this time, the external VDD voltage level should be higher than the initial LVD level (2.3V). After counting 4 msec, the CPU reset is released and the operation is started.

Figure 4.5 shows the power up sequence and internal reset waveform.

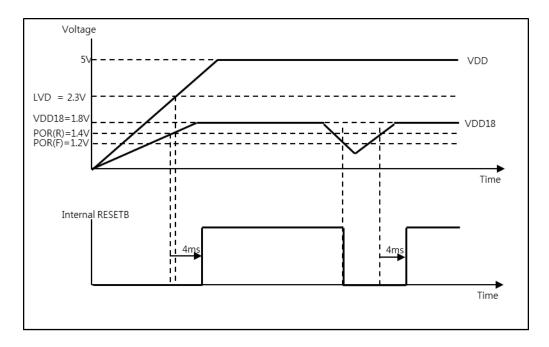

Figure 4.5. Power Up POR Sequence

The RSSR register shows the POR reset status. The last reset comes from POR. RSSR.PORST is set to "1". After power up, this bit is always "1". If an abnormal internal voltage drop occurs during normal operation, the system is reset and this bit is also set to "1".

When a cold reset is applied, the entire chip returns to its initial state.

### Warm Reset

The warm reset event has several reset sources and some parts of the chip return to initial state when a warm reset condition occurs.

The warm reset source is controlled by the RSER register and the status appears in the RSSR register. The reset for each peripheral block is controlled by the PRER register. The reset can be masked independently.

The CM3 SYSRESETN signal resets the processor, excluding debug logic in the processor.

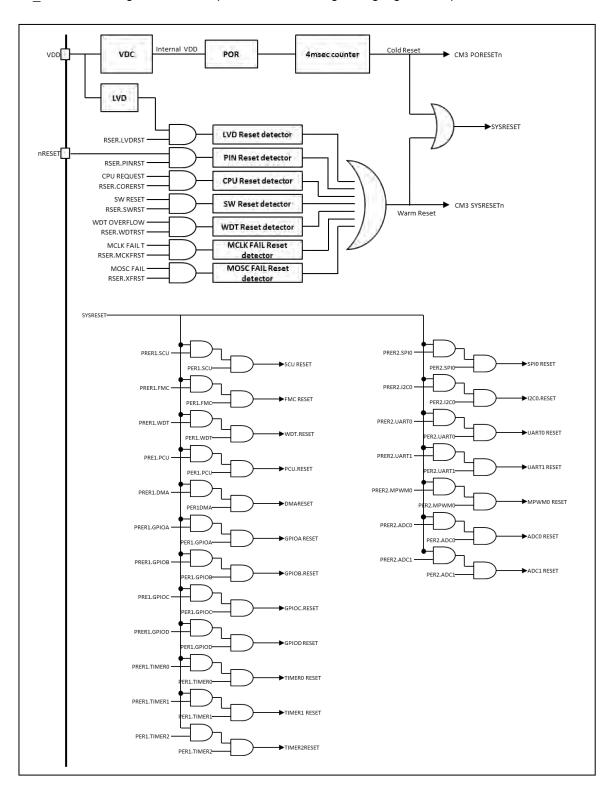

Figure 4.6. Reset Configuration

# **Operation Mode**

Three operational states are available in addition to the Initialization state (INIT). When the reset is asserted (brought low), the Z32F128 MCU runs at 1 MHz, driven by the ROSC. All the other clocks are disabled and peripheral power and clocks are reset.

The RUN mode is designed to run at maximum performance of the CPU with a high-speed clock system. The IOSC must be enabled in order to enable the MOSC. The SLEEP mode is designed to run in Low Power consumption mode by halting the processor core and any unused peripherals.

Figure 4.7 shows the operation mode transition diagram.

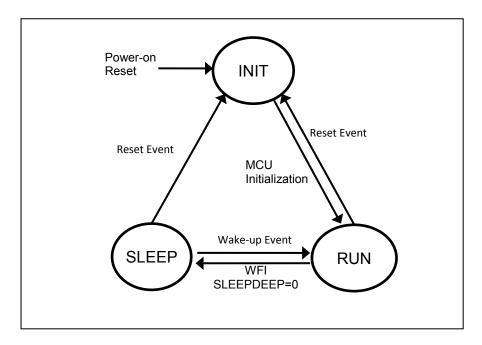

Figure 4.7. Operating Mode

### **RUN Mode**

This mode operates the MCU core and the peripheral hardware by using the high-speed clock. After reset, followed by the INIT state, the system can be configured to enter into RUN mode.

### **SLEEP Mode**

Only the CPU is stopped in this mode. Each peripheral function can be enabled by the function enable and clock enable bit in the PER and PCER registers. To enter sleep mode, configure the system for the desired low power state then use the "wfi" instruction. When exiting sleep mode, the clock will be set to the RING oscillator.

# **Pin Description**

## **WUER Wakeup Source Enable Register**

This is the enable wakeup source. The source of chip wakeup should be enabled in each bit field. If the source will be used as the wakeup source, write 1 to its enable bit. If the source will not be used as the wakeup source, write 0 into its enable bit. This register is a 16-bit register.

#### WUER=-0x4000\_0010

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		0 Not used for wakeup source
		1 Enable the wakeup event generation
0	LVDWUE	Enable wakeup source of LVD event
		0 Not used for wakeup source
		1 Enable the wakeup event generation

## **WUSR Wakeup Source Status Register**

When the system is woken up by any wakeup source, the wakeup source is identified by reading this register. When the bit is set to 1, the related wakeup source issues the wakeup to the SCU. The bit will be cleared when the event is cleared by the software.

### WUSR=0x4000\_0014

12	GPIOEWU	Status of wakeup source of GPIOE port pin change event
12	dilozwo	0 No wakeup event
		1 Wakeup event was generated

0	LVDWU	Status of wakeup source of LVD event
		0 No wakeup event
		1 Wakeup event was generated

## **RSER Reset Source Enable Register**

The reset source which will generate the reset event can be selected by the RSER register. Write 1 in the bit field of each reset source to transfer the reset source event to the reset generator. Write 0 in the bit field of each reset source to mask the reset source event, and therefore, not generate the reset event.

#### RSER=0x4000\_0018

## **RSSR** Reset Source Status Register

The RSSR shows the reset source information when a reset event occurs. For a given reset source, 1 indicates that a reset event exists and 0 shows that a reset event does not exist. When a reset source is found, writing 1 to the corresponding bit will clear the reset status. This register is an 8-bit register.

## PRER1 Peripheral Reset Enable Register 1

The reset of each peripheral by an event reset can be masked by user settings. The PRER1/2 register controls enabling of the event reset. If the corresponding bit is 1, the peripheral corresponding to this bit accepts the reset event. Otherwise, the peripheral is protected from the reset event and maintains its current operation.

#### PRER1=0x4000 0020

## PRER2 Peripheral Reset Enable Register 2

The reset of each peripheral by an event reset can be masked by user settings. The PRER1/2 register controls enabling of the event reset. If the corresponding bit is 1, the peripheral corresponding to this bit accepts the reset event. Otherwise, the peripheral is protected from the reset event and maintains its current operation.

#### PRER2=0x4000 0024

### PCER2

## Peripheral Clock Enable Register 2

To use a peripheral unit, activate its clock by writing **1** to the corresponding bit in the PCER1/2 register. The peripheral will not operate correctly until its clock is enabled.

To stop the clock of the peripheral unit, write **0** to the corresponding bit in the PCER1/2 register.

		0	- 0	X Stop Exter	nal Crystal oscill	ator					

## **SCCR System Clock Control Register**

The Z32F128 MCU has multiple clock sources to generate internal operating clocks. Each clock source can be controlled by the SCU CSCR register. The MOSC must be running and stable before setting the FINSEL bit.

#### SCCR=0x4000 0044

		1 M	CLKSEL	Syste 0X 10 11	em clock sele Internal sul PLL bypass PLL output	o oscillator ed clock		

**Note:** When changing FINSEL, both internal OSC and external OSC should be alive, otherwise the chip will malfunction.

CMR=0x4000 0048

## **CMR** Clock Monitoring Register

To monitor the internal clock and external oscillator, the MCLKMNT/EOSCMNT bits must be set before the MCLK and EOSC bits are valid. The Clock Monitoring Register is a 16-bit register.

**Note:** The EOSC bit only checks for the EOSC oscillation, not its stability. When the system detects an MCLKFAIL interrupt, the MCLKREC bit determines if the system dies or will auto-recover using the ROSC. The system usually auto-recovers so that it can continue running.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCLKREC								MCLKMNT	MCLKIE	MCLKFAIL	MCLKSTS	EOSCMNT	EOSCIE	EOSCFAIL	EOSCSTS
0	0	0	0	0	0	0	0	1	0	0	1	0	0	1	1
RW								RW	RW	RC1	RC1	RW	RW	RC1	RC1

15	MCLKREC	MCLK fail auto recovery										
		0 MCLK is changed to RINGOSC by default when										
		MCLKFAIL issued										
		1 MCLK auto recovery is disabled										
7	MCLKMNT	MCLK monitoring enable										
		0 MCLK monitoring disabled										
		1 MCLK monitoring enabled										
6	MCLKIE	MCLK fail interrupt enable										
		0 MCLK fail interrupt disabled										
		1 MCLK fail interrupt enabled										
5	MCLKFAIL	MCLK fail interrupt										
		0 MCLK fail interrupt not occurred										
		1 Read: MCLK fail interrupt is pending										
		Write : Clear pending interrupt										
4	MCLKSTS	MCLK clock status										
		0 No clock is present on MCLK										
		1 Clock is present on MCLK										
3	EOSCMNT	External oscillator monitoring enable										
		0 External oscillator monitoring disabled										
		1 External oscillator monitoring enabled										
2	EOSCIE	External oscillator fail interrupt enable										
		0 External oscillator fail interrupt disabled										
		1 External oscillator fail interrupt enabled										
1	EOSCFAIL	External oscillator fail interrupt										
		0 External oscillator fail interrupt not occurred										
		1 Read : External oscillator fail interrupt is pending										
		Write : Clear pending interrupt										
0	EOSCSTS	External oscillator status										
		0 Not oscillate										
		1 External oscillator is working normally										

The clock monitoring function cannot cover all malfunction cases. It is just used for the reference. Figure 4.8 shows the operational diagram for the clock monitoring function.

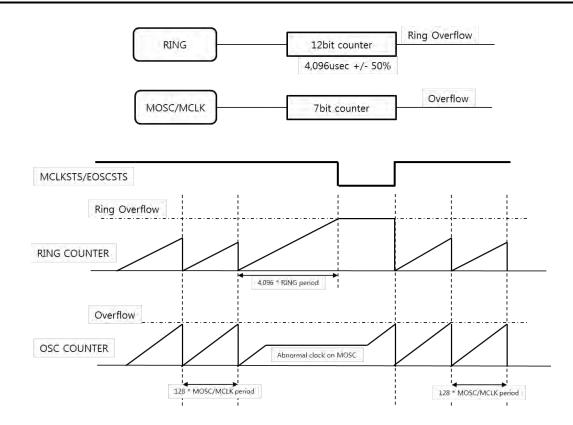

Figure 4.8. Clock Monitoring Function Diagram

## **NMIR NMI Control Register**

Non-Maskable Interrupt pin configuration provides the ability to enable/disable and set the debounce of the NMI pin. It also provides the ability to monitor the interrupt and status of the NMI pin.

													NMI	R=0x400	00_004		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## **COR** Clock Output Register

The clock output register controls the enabling/disabling of the clock signal and provides a divider for the clock output. In order to output the clock signal, you must enable the Clock out function pin. For more information, see Chapter 5, Port Control Unit.

#### COR=0x4000\_0050

7	6	5	5	4	3	2	1	0
	-			CLKOEN		CLK	ODIV	
	000			0		1	111

		3	CLKODI	V	Clock output div			
					CLKO = MCLK	(CLKODIV = 0)	0)	
					CLKO =	MCLK 2 * (CLKODIV +	1) (CLKODIN	y > 0)

### **PLLCON**

### **PLL Control Register**

Integrated PLL can synthesize the high speed clock for extremely high performance of the CPU from either the internal oscillator (IOSC) or the external oscillator (MOSC). The PLL Control register provides the configuration for the PLL system. By default, the PLL system is in reset mode and disabled. You must negate the reset and enable the PLL to operate (bits 14 and 15 must be set). The Bypass bit must be set to output the PLL clock. The active clock is defined in SCCR bit 2 (FIN).

To calculate the PLL output:

PLL Out = ((Active clock / PREDIV) \* FBCTRL) / POSTDIV

For example:

Using MOSC (assuming it is running at 8 MHz and selected):

PREDIV set to 1 (FIN / 2)
FBCTRL set to 0x05 (M=18)
POSTDIV set to 0x00 (N=1)

((8 MHz / 2) \* 18) = 72 MHz

#### PLLCON=0x4000\_0060

### **VDCCON**

## **VDC Control Register**

The On-chip VDC control register, VDCTRIM, is used for the trim value of VDC output. To modify the VDCTRIM bit, write 1 to VDCTE. The VDCWDLY value can be written when writing 1 to the VDCDE bit simultaneously.

#### VDCCON=0x4000\_0064

31	BMRTE	Reference BGR trim write enable.
		0 BMRTRIM field is not updated by writing
		1 BMRTRIM filed can be updated by writing
26	BMRTRIM	Reference BGR output voltage trim value
24		
23	VDCTE	VDCTRIM value write enable. Write only with VDCTRIM
		value.
		0 VDCTRIM field is not updated by writing
		1 VDCTRIM filed can be updated by writing
19	VDCTRIM	VDC output voltage trim value
16		
8	VDCDE	VDCWDLY value write enable. Write only with VDCWDLY
		value
		0 Disable writing warm-up delay count value
		1 Enable writing warm-up delay count value
7	VDCWDLY	VDC warm-up delay count value.
0		When SCU is woken up from power-down mode, the warm-up
		delay is inserted to stabilize VDC output.
		The amount of delay can be defined with this register value
		7F: 2msec

#### LVDCON

## **LVD Control Register**

The LVD Control Register is an on-chip brown-out detector control register. There are four voltage levels that can be set for the Low Voltage Detect monitoring and the ability to trim the monitoring voltages. This register is a 32-bit register.

#### LVDCON=0x4000\_0068

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		1 LVD level is detected
0	LVDEN	LVD Function enable
		0 LVD is not enabled
		1 LVD is enabled

### **IOSCTRIM**

## **Internal OSC Trim Register**

This is the internal oscillator frequency trim register, which is a 32-bit register.

#### IOSCTRIM=0x4000\_006C

23	TSLEN	TSL trim value write enable. Write only with TSL trim value.
		0 TSL field is not updated by writing

		1 TSL filed can be updated by writing
18	TSL[2:0]	TSL trim value
16		
15	LTEN	LTM/LT value write enable. Write only with LTM/LT value
		0 LT field is not updated by writing
		1 LT filed can be updated by writing
13	LTM/LT	Internal oscillator LT trim value
8		Not recommended strongly to write into this field
7	UDCEN	UDCH/UDCL value write enable. Write only with UDC value
		0 UDC field is not updated by writing
		1 UDC filed can be updated by writing
4	UDCH/UDCL	Internal oscillator UDC trim value
0	·	Not recommended strongly to write into this field

All trim bits are writable when Trim mode is enabled.

### **EOSCR**

## **External Oscillator Control Register**

The External Oscillator control register provides the configuration of the external oscillator connections. The current and amplification types can be modified. The external main crystal oscillator has two characteristics. For noise immunity, the NMOS amp type is recommended and for the low power characteristic, the INV amp type is recommended. This register is a 16-bit register.

#### EOSCR=0x4000 0080

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		110 External Main OSC
		111 PLL Clock
7	ETCDDIV	ETC Debounce Clock N divider
0		ETC clock = Clock source / ETCDDIV
		(If ETCDDIV is 0, input clock will be stopped)

## **Functional Description**

#### System Clock Setup Procedure Example for the Internal Clock with PLL

- Configure the FM.CR (after selecting CFG mode through FM.MR) register to the maximum wait
- Enable the internal clock IOSC in the CSCR register.
- Write 0x02 to the SCCR register (system clock control register) to select the IOSC as the PLL source (FIN) with bypassing the PLL output
- In the PLLCON register, Set bits 14,15 to enable PLL, clear bit 13 to bypass PLL output and configure bits 0-8 to the PREDIV/FBCTRL/POSTDIV for desired PLL output. For full speed, the PLLCON register would be set to 0xC110
- Wait for the PLL to be locked by monitoring the LOCK bit (bit 12) in the PLLCON register.
- Set bit 13 of the PLLCON register to enable the PLL output
- Set bit 0 of SCCR to enable the PLL for the system clock
- Set the FM.CR (after selecting CFG mode through FM.MR) register for the appropriate Flash Wait states for the speed selected.

#### System Clock Setup Procedure Example for the External Clock with PLL

- Enable the Port C peripheral and clock in the SCU PER1 and PCER1 registers
- Unlock the Port Controller using the PORTEN register as defined in PORT CONTROL UNIT (PCU)
- Enable the Alternative function 01b for pins 12 and 13 on PORT C through the PCC MR register
- Set the Pin type for pins 12 and 13 on PORT C to analog (11b)
- Lock the Port Controller by writing any value to PORTEN register
- Configure the FM.CR (after selecting CFG mode through FM.MR) register to the maximum wait
- If not already enabled, enable Internal oscillator in CSCR
- Set bit 3 in the CMR register to monitor External Oscillator
- Enable External Oscillator in CSCR register
- Wait for bit 0 of the CMR register to be set. Note: if the external oscillator does not start, this bit will never be set.
- Wait for an additional time (more than 1 ms) to allow the oscillator to stabilize
- Write 0x06 to the SCCR register (system clock control register) to select the External Oscillator as the PLL source (FIN)
- Set PLLCON high byte (8-15) to 0xC and low byte (0-7) to the FBCTRL/POSTDIV for desired PLL output.
- Wait until bit 12 of PLLCON is set. Note: if the PLL does not lock, this bit will never be set.
- Set bit 13 to enable the PLL output
- Set bit 0 of SCCR to enable the PLL for the system clock
- Set the FM.CR (after selecting CFG mode through FM.MR) register for the appropriate Flash Wait states for the speed selected.

#### To Enable Clock Out for monitoring actual clock output

- Enable the Port C peripheral and clock in the SCU PER1 and PCER1 registers
- Unlock the Port Controller using the PORTEN register as defined in PORT CONTROL UNIT (PCU)
- Enable the Alternative function 01b for pin 9 on PORT C through the PCC MR register
- Set the Pin type for pin 9 on PORT C to output (00b)
- Lock the Port Controller by writing any value to PORTEN register
- Set bit 4 of the COR register (Clock Output Register) to enable the output
- Configure the CLKODIV to the desired output divider

## 5. Port Control Unit

## **Overview**

The Port Control Unit (PCU) controls the external I/O configuration to:

- Set the multiplex state of each pin (for alternative functions)
- Set external signal type (Analog / Push-Pull output /Open Drain output /Input)
- Set enable/monitor/trigger type for interrupts for each pin
- Set internal pull-up register control for each pin
- Set debounce for each pin

**Note:** You must enable both the Port Peripheral and the Port Peripheral Clock in PER1/PCER1/ to use the pins of the port.

Figure 5.1 shows a block diagram of the PCU. Figure 5.2 and Figure 5.3 show I/O Port Block diagrams.

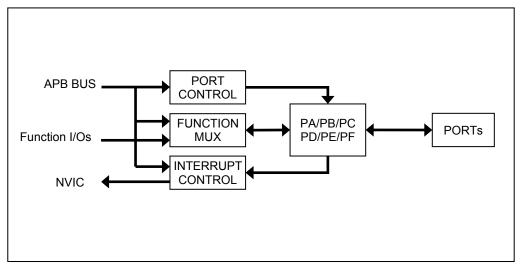

Figure 5.1. PCU Block Diagram

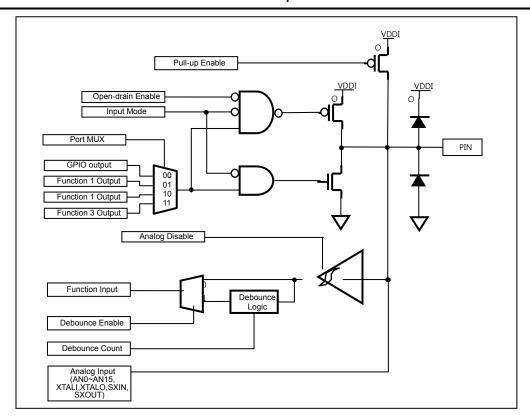

Figure 5.2. I/O Port Block Diagram (ADC and External Oscillator Pins)

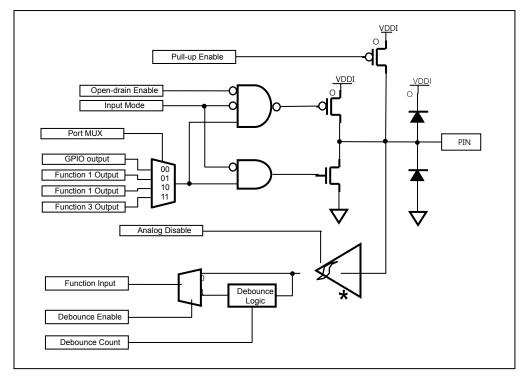

Figure 5.3. I/O Port Block Diagram (General I/O Pins)

# **Pin Multiplexing**

GPIO pins have alternative function pins. Table 5.1 shows the pin multiplexing information.

### **PORTEN**

# **Port Access Enable Register**

The Port Access Enable register enables the register writing permission of all PCU registers.

PORTEN=0x4000\_1FF0

7	PORTEN	Writing the sequence of 0x15 and 0x51 in this register									
0		enables writing to PCU registers, and writing other values									
		protects all PCU registers from writing.									

PS034503-0516 PRELIMINARY 73

# **Functional Description**

All the GPIO pins can be configured for different operations – inputs, outputs, and triggered interrupts (both level and edge) through the PDU. The system is also able to disable ports by setting the PER1 and PCER1 registers in the SCU. By default, all pins are disabled (except for UART0/SPI0) so the developer must enable these to operate.

All configuration parameters are protected by the Port Access Enable register. You must write the sequence in order  $(0 \times 15, 0 \times 51)$  to the PORTEN register to configure any pin(s). Once the configuration is complete, write any other value to the PORTEN register to lock it.

Note: Do not read in between the sequence; it will prevent the configuration registers from being unlocked.

When the input function of I/O port is used by the Pin Control Register, the output function of I/O port is disabled. The Port Function differs according to the Pin Mux Register. The Input Data Register captures the data present on the I/O pin or debounced input data at every GPIO clock cycle.

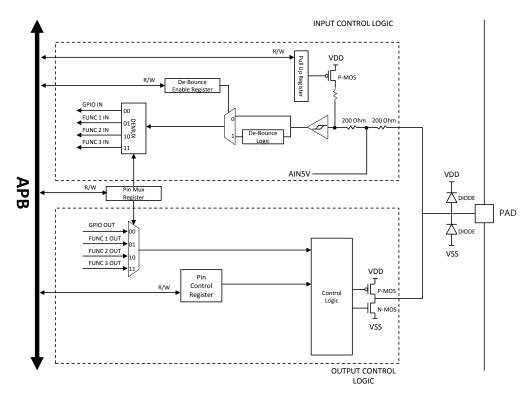

Figure 5.4. Port Diagram

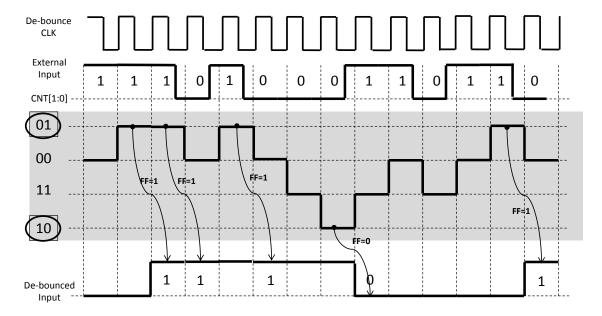

Figure 5.5. Debounce Diagram

When the debounce function of input data is used by the Debounce Enable Register, the external input data is captured by the debounce clock.

- If CNT value is "01", debounced input data is "1".
- If CNT Value is "10", debounced input data is "0"

It is possible to change the Debounce CLK of each port group used by the DBCLK Registers.

# 6. General Purpose I/O

### **Overview**

Most pins, except the dedicated function pins, can be used as general I/O ports. General input/output ports are controlled by the GPIO block.

- Output signal level (H/L) select
- Input signal level
- Output Set/Clear pin by writing a 1

# **Functional Description**

The GPIO registers provide the input/output condition of the GPIO pins. The input data registers give the states of the pins of the ports. The output data register is used to set the port pins. The Set and Clear registers control the pins at the individual level.

When configured as output, the value written to the GPIO Output Data Register is output on the I/O Pin. When setting the Bit Set Register, set the GPIO Output Data Register high. When setting the Bit Clear Register, set the GPIO Output Data Register low.

The Input Data Register captures the data present on the I/O pin or debounced input data at every GPIO clock cycle.

# 7. Flash Memory Controller

## Introduction

Flash Memory Controller is an internal Flash memory interface controller with the following features:

- 128 KB Flash code memory
- 32-bit read data bus width
- · Code cache block for fast access mode
- 128-byte page size
- Support page erase and macro erase
- 128-byte unit program

Table 7.1. Internal Flash Specification

Item	Description							
Size	128KB							
Start Address	0x0000_0000							
End Address	0x0001_FFFF							
Page Size	128-byte							
Total Page Count	1,024 pages							
PGM Unit	128-byte							
Erase Unit	128-byte							

Figure 7.1 shows a block diagram of the Flash Memory Controller.

PS034503-0516 PRELIMINARY 86

#### **BOOTCR**

### **Boot ROM Remap Clear Register**

The Boot ROM remap clear register is an 8-bit register.

# **Functional Description**

Flash Memory Controller is an internal Flash memory interface controller which primarily controls the programming of Flash memory and preparing read data to be requested from the bus.

### Flash Organization

The 128 Kbytes code Flash memory consists of 1,024 pages which have a uniform 128 bytes page size. The Flash controller allows reading or writing of Flash memory data. This memory is located at  $0 \times 0000 - 0000$  address on the system memory map. The system boot address is  $0 \times 0000 - 0000$ ; therefore, this Flash memory is boot memory. The code data which is programmed in Flash memory will boot up the device after the boot ROM sequence is completed.

### Flash Read Operation

The Flash data read operation is requested from the bus. The Flash controller responds to the request. The wait time should be correctly defined because the bus speed is usually faster than Flash data access time.

The normal read operation is not available in Flash mode in the ACODE.FM.MR field.

## Flash Program Operation

The erase and program access of Flash memory is available only in Flash mode in the ACODE.FM.MR field. Therefore, self-programming is not supported. The Flash program/erase operation should be performed by the execution program on the SRAM memory.

The Flash program operation writes one page to the target address selected by the FM.AR register. At first, users should write the program data into the page buffer. Page buffer write is performed by word write access to the FM.DR register at FM.AR address. After filling the page buffer, users can begin the Flash write operation and should wait for the IDLE bit to be set.

Figure 7.2 shows the page buffer loading operation.

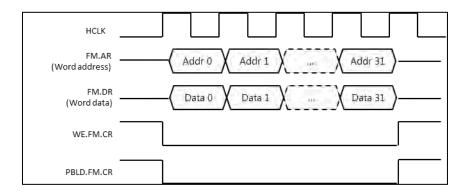

Figure 7.2. Page Buffer Load Timing Diagram

The Flash write of page buffer data is done by the PRGM.FM.CR command. A safe writing operation requires the correct program time. The tPGM program time is defined by the FM.TMR register. When the timer is activated (TIMER.FM.CR bit is set), the IDLE.FM.MR bit is cleared and the Flash controller will start counting the HCLK pulses until the pulse count matches the value in the FM.TMR. When the count is reached, the Flash controller will set the IDLE.FM.MR bit to show the time has elapsed. In this page write operation, the target page address should be written in the FM.AR register.

Figure 7.3 shows the page write operation.

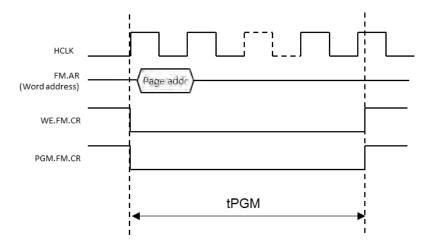

Figure 7.3. Page Write Timing Diagram

### Flash Erase Operation

The erase and program access of Flash memory is available only in Flash mode in the ACODE.FM.MR field. Therefore, self-programming is not supported. The Flash program/erase operation should be performed by the execution program on the SRAM memory.

Two types of Flash erase operations are supported – Page erase and Bulk erase. The page erase operation erases one page to the target address selected by the FM.AR register. User starts the Flash write operation and should wait for the IDLE bit to be set. The bulk erase operation erases the entire Flash memory data and the FM.AR address is ignored. The process is the same between page and bulk erase with the exception of the AE.FM.CR bit. When the AE.FM.CR bit is set, the Flash controller will perform a bulk erase.

Figure 7.4 shows the page erase operation.

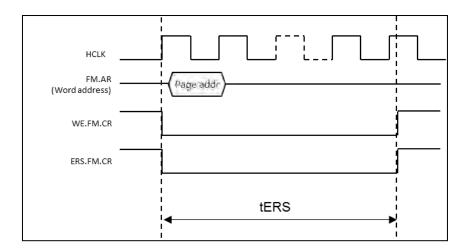

Figure 7.4. Page Erase Timing Diagram

Flash erase is done by the ERS.FM.CR command. A safe writing operation requires the correct program time. The tERS erase time is defined by the FM.TMR register. When the timer is activated (TIMER.FM.CR bit is set), the IDLE.FM.MR bit is cleared and the Flash controller will start counting the HCLK pulses until the pulse count matches the value in the FM.TMR. When the count is reached, the Flash controller will set the IDLE.FM.MR bit to show the time has elapsed.

Figure 7.5 shows the bulk erase operation.

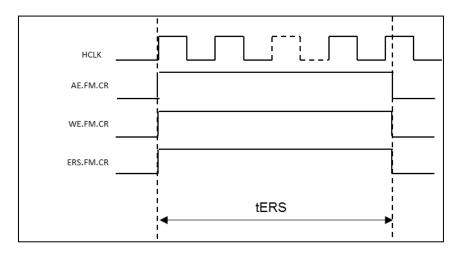

Figure 7.5. Bulk Erase Timing Diagram

The Flash area can be read from directly via the memory address. Writing of Flash memory can be done through Boot mode or in-application programming. The execution for the writing of Flash must occur from the RAM area. The Flash controller cannot read Flash memory (including instructions) once the program bit has been set.

**Caution:** If the vector table is not placed in RAM, you MUST disable interrupts so as to prevent reading the interrupt service routine in Flash.

To write to Flash memory:

- 1. Disable the Watch Dog Timer (if enabled).
- 2. Set the clock to internal oscillator ( 20 MHz ).
- 3. Write configuration sequence to the MR register to enable Control Register upper bits (24-31).
- 4. Configure upper bits of the Control Register (HRESPD and Flash access of 4 cycles).
- 5. Lock the Flash controller by writing 0x00 to the MR register.

- 6. Write the Flash sequence to the MR register.
- 7. Clear the DRTY register.
- 8. Set the PMODE bit in the CR register to set Program Mode.
- 9. Wait until the IDLE bit in MR register is set.
- 10. Reset the page buffer (setting and clearing PBR bit in CR register).
- 11. Set the PBLD bit in the CR register to allow the page buffer to be written to.
- 12. Write to the page buffer by loading the DR register with each 32-bit word of the page.
- 13. Clear the PBLD bit in the CR register.
- 14. Write the address to which the page buffer will be written (in 32-bit words) to the AR register.
- 15. Set the PGM bit in the CR register.
- 16. Set the WE bit in the CR register to start writing.
- 17. Wait until the IDLE bit in MR register is set.
- 18. Clear the WE bit in the CR register.
- 19. Clear the PGM bit in the CR register. If there are additional pages to write, repeat the process, starting at step 10.
- 20. Load 2500 into the TMR register (2.5mS).
- 21. Set the TIMER bit in the CR register to start the timer.
- 22. Wait until the IDLE bit in the MR register is set.
- 23. Clear the Timer bit in the CR register to stop the timer.
- 24. Clear the PMODE bit in the CR register to take out of Program Mode.
- 25. Lock the Flash controller by writing 0x00 to the MR Register.
- 26. Write the configuration sequence to the MR register to enable the Control Register upper bits (24-31).
- 27. Restore the upper bits of the Control Register.
- 28. Lock the Flash controller by writing 0x00 to the MR register.
- 29. Reset the system clock to normal operations.
- 30. Enable the Watch Dog timer (if desired).

#### To erase Flash memory:

- 1. Disable the Watch Dog Timer (if enabled).
- 2. Set the clock to internal oscillator (20 MHz).
- 3. Write the configuration sequence to the MR register to enable Control Register upper bits (24-31).
- 4. Configure upper bits of the Control Register (HRESPD and Flash access of 4 cycles).
- 5. Lock the Flash controller by writing 0x00 to the MR register.
- 6. Write the Flash sequence to the MR register.
- 7. Clear the DRTY register.
- 8. Set the PMODE bit in the CR register to set Program Mode.
- 9. Wait until the IDLE bit in the MR register is set.
- 10. If erasing all the Flash, set the AE bit in the CR register; otherwise, load the page address in the AR register.
- 11. Set the ERS bit in the CR register.
- 12. Set the WE bit in the CR register to start the erase operation.
- 13. Wait until the IDLE bit in the MR register is set.
- 14. Clear the WE, ERS and AE bits.
- 15. Load 2500 into the TMR register (2.5mS).
- 16. Set the TIMER bit in the CR register to start the timer.
- 17. Wait until the IDLE bit in the MR register is set.
- 18. Clear the Timer bit in the CR register to stop the timer.

- 19. Clear the PMODE bit in the CR register to take out of Program Mode.
- 20. Lock the Flash controller by writing 0x00 to the MR Register.
- 21. Write the configuration sequence to the MR register to enable the Control Register upper bits (24-31).
- 22. Restore the upper bits of the Control Register.
- 23. Lock the Flash controller by writing 0x00 to the MR register.
- 24. Reset the system clock to normal operations.
- 25. Enable the Watch Dog timer (if desired).

The CRC16 function allows a CRC check on the Flash bytes to a known value.

To run a CRC16 check on Flash bytes (must be done in memory, since every read, including instructions, would be part of the CRC16 calculations).

- 1. Disable the Watch Dog Timer (if enabled).
- 2. Set the CRCINIT bit in the CR register.
- 3. Clear the CRCINIT bit in the CR register.
- 4. Read the Flash memory that is to be processed.
- 5. When completed, the CRC value is located in the CRC register.

# 8. Internal SRAM

### **Overview**

The Z32F128 MCU implements zero-wait on the chip's SRAM. The size of SRAM is 12 KB. The SRAM base address is 0x2000 0000.

The SRAM memory area is usually used for data memory and stack memory. Sometimes, the code is dumped into the SRAM memory for fast operation or Flash erase/PGM operation.

This device does not support a memory remap strategy; therefore, a jump and return is required to execute the code in the SRAM memory area.

Figure 8.1 shows a block diagram of the SRAM.

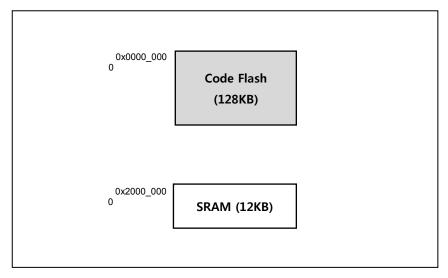

Figure 8.1. SRAM Block Diagram

# 9. Direct Memory Access Controller

## Introduction

The Direct Memory Access (DMA) controller includes the following features:

- 15 channels
- Single transfer only
- Supports 8/16/32-bit data size
- Supports multiple buffers with the same size
- Interrupt condition is transferred through a peripheral interrupt

A block diagram of the DMA controller is shown in Figure 9.1.

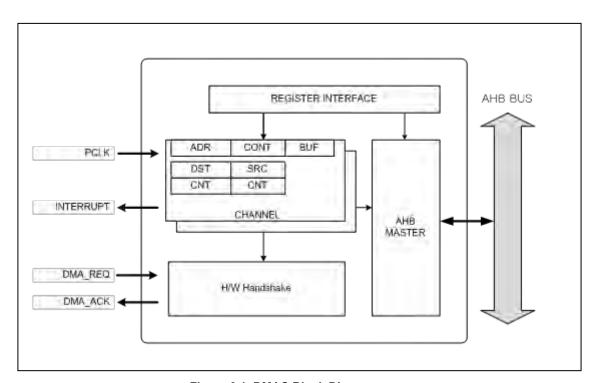

Figure 9.1. DMAC Block Diagram

# **Pin Description**

There are no external interface pins.

# **Registers**

The base address of the DMA controller is shown in Table 9.1.

**Table 9.1. DMA Controller Base Address** 

Ch. No.	BASE ADDRESS	Assigned Peripheral
DMACH0	0x4000_0400	UARTO RX
DMACH1	0x4000_0410	UART0 TX
DMACH2	0x4000_0420	UART1 RX
DMACH3	0x4000_0430	UART1 TX
DMACH4	0x4000_0440	UART2 RX
DMACH5	0x4000_0450	UART2 TX
DMACH6	0x4000_0460	UART3 RX

0		Address is automatically incremented according to SIZE bits
		when each transfer is done.

# **Functional Description**

The DMA controller performs direct memory transfer by sharing the system bus with the CPU core. The system bus is shared by two AHB masters following the round-robin priority strategy. Therefore, the DMA controller can share half of the system bandwidth.

The DMA controller can be triggered only by a peripheral request. When a peripheral requests the transfer to the DMA controller, the related channel is activated and accesses the bus to transfer the requested data from memory to the peripheral data buffer or from the peripheral data buffer to memory space.

The transfer process involves the following steps:

- 1. User sets the peripheral and memory addresses.
- 2. User configures the DMA operation mode and transfer count.
- 3. User enables the DMA channel.
- 4. The peripheral sends a DMA request.
- 5. DMA activates the channel that was requested.
- 6. DMA reads data from the source address and saves it to the internal buffer.
- DMA writes the buffered data to the destination address.
- 8. The transfer count number is decreased by 1.
- 9. When the transfer count becomes 0, the EOT flag is set and a notice is sent to the peripheral to issue the interrupt.
- 10. DMA does not have an interrupt source; the interrupt-related DMA status can be shown from the assigned peripheral interrupt.

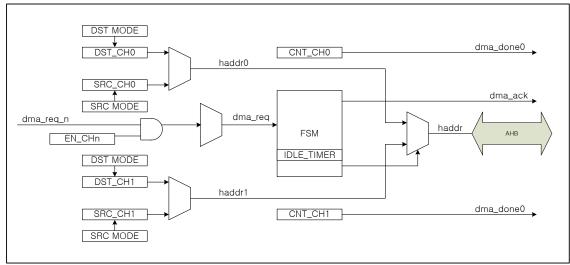

Figure 9.2. DMA Controller Block Diagram

Figure 9.3 shows the functional timing diagram of the DMA controller. The transfer request from the peripheral is pended internally and it invokes source data read transfer on the AHB bus. The read data from the source address is stored in the internal buffer. This data is transferred to the destination address when the AHB bus is available.

The timing diagram for a DMA transfer from peripheral to memory is shown in Figure 9.3. A 4-clock cycle latency exists when accessing the peripheral. If the bus is occupied by a different bus master, the number of bus waiting cycles increase until the bus is available.

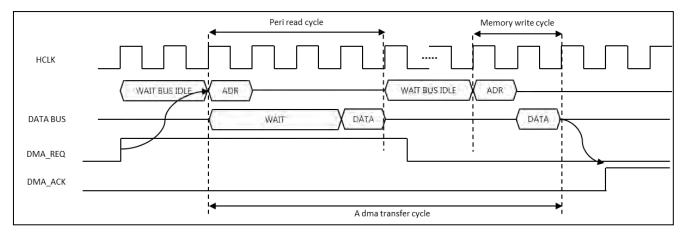

Figure 9.3. DMA Transfer from Peripheral to Memory

The timing diagram for a DMA transfer from memory to peripheral is shown in Figure 9.4. A 4-clock cycle latency exists while accessing the peripheral. If the bus is occupied by a different bus master, the number of bus waiting cycles increase until the bus is available.

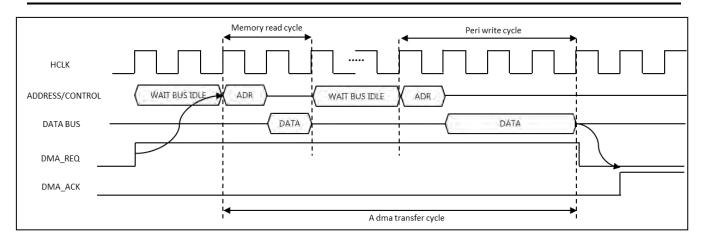

Figure 9.4. DMA Transfer from Memory to Peripheral

Figure 9.5 is an example of N data transfers with the DMA. The DMA transfer is started when DCnSR.DMAEN is set and will be cleared when all transfers are completed.

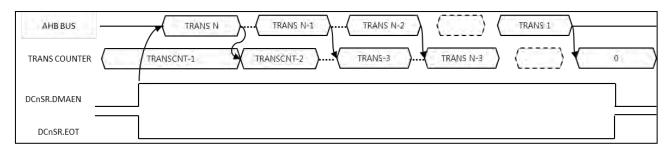

Figure 9.5. N DMA Transfer Example

# 10. Watch-Dog Timer

### **Overview**

The Watchdog Timer can monitor the system and generate an interrupt or a reset. It has a 32-bit down-counter. The Miscellaneous Clock Control Register 3 provides base clock options with clock dividers to drive the WDT clock. This can be selected in the WDTCON register. To prevent the WDT from firing, reload the LR register with the appropriate value before the WDT times out.

#### Features include:

- 32-bit down counter (WDTCVR)
- Select reset or periodic interrupt
- Count clock selection
- Dedicated prescaler
- · Watchdog overflow output signal

Figure 10.1 shows a block diagram of the Watch-dog Timer.

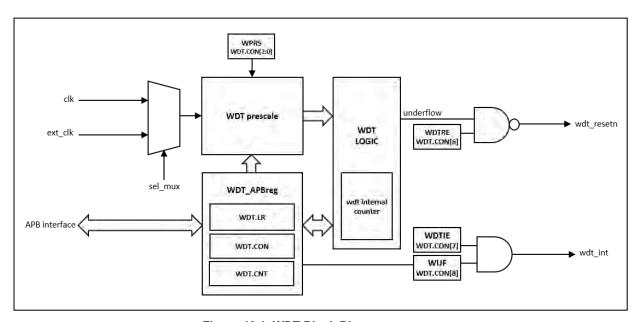

Figure 10.1. WDT Block Diagram

# Registers

The base address of the watch-dog timer is  $0x4000\_0200$  and the register map is described in Table 10.1. The initial watch-dog time-out period is set to 2000-miliseconds.

Table 10.1. Watchdog Timer Register Map

Name	Offset	R/W	Description	Reset
WDTLR	0x0000	R/W	WDT Load register	0x00000000
WDTCNT	0x0004	R	WDT Current counter register	0x0000FFFF
WDTCON	0x0008	R/W	WDT Control register	0x0000805C

### WDTLR Watchdog Timer Load Register

The WDTLR register is used to update the WDTCVR register. To update the WDTCVR register, the WDTEN bit of WDTCON should be set to **1** and written into the WDTLR register with target value of WDTCVR.

WDTLR=0x4000\_0200

# **Functional Description**

The watchdog timer count can be enabled by WDTEN (WDT.CON[4]) to 1. As the watchdog timer is enabled, the down counter will start counting from the Load Value. If WDTRE (WDT.CON[6]) is set to 1, WDT reset will be asserted when the WDT counter value reaches 0 (underflow event) from the WDTLR value. Before the WDT counter goes down to 0, the software can write a certain value to the WDTLR register to reload the WDT counter.

### **Timing Diagram**

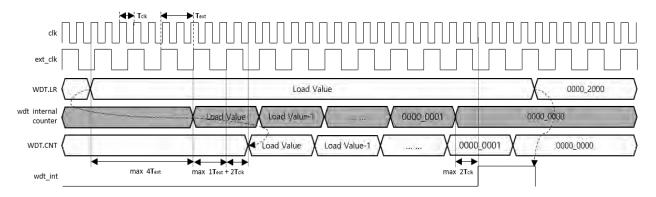

Figure 10.2. Timing Diagram in Interrupt Mode Operation when WDT clock is External Clock

In WDT interrupt mode, after WDT underflow occurs, a certain count value is reloaded to prevent the next WDT interrupt in a short time period. This reloading action is only activated when the watchdog timer counter is set to Interrupt mode (set WDTIE of WDT.CON). It takes up to 5 cycles to go from the Load value to the CNT value. The WDT interrupt signal and CNT value data may be delayed by a maximum of 2 system bus clocks in synchronous logic.

#### **Prescale Table**

The WDT includes a 32-bit down counter with programmable pre-scaler to define different time-out intervals.

The clock sources of the watchdog timer can be the peripheral clock (PCLK) or one of 5 external clock sources. The external clock source can be enabled by CKSEL (WDT.CON[3]) set to '1'. The external clock source was chosen in the MCCR3 register of the SCU block.

To make the WDT counter base clock, users can control the 3-bit pre-scaler WPRS [2:0] in the WDT.CON register and the maximum pre-scaled value is "clock source frequency/256". The pre-scaled WDT counter clock frequency values are listed in Table 10.2.

Selectable clock source (40 kHz  $\sim$  16 MHz) and the time out interval when 1 count Time out period = {(Load Value) \* (1/pre-scaled WDT counter clock frequency) + max  $5T_{ext}$ } + max  $4T_{clk}$ 

Table 10.2. Pre-scaled WDT Counter Clock Frequency

# 11. 16-Bit Timer

#### **Overview**

The timer block consists of 6 channels of 16-bit general-purpose timers. They can support periodic timer, PWM pulse, one-shot timer, and capture mode.

#### Features include:

- 16-bit up-counter
- Periodic timer mode
- One-shot timer mode
- PWM pulse mode
- Capture mode
- 10-bit prescaler

Figure 11.1 shows a block diagram of the 16-bit timer.

#### **TnPRS**

## Timer n Prescaler Register

Timer Prescaler Register sets the pre-scale of the input clock for the timer counter.

T0PRS=0x4000\_3008, T1PRS=0x4000\_3028 T2PRS =0x4000\_3048, T3PRS=0x4000\_3068 T8PRS=0x4000\_3108, T9PRS=0x4000\_3128

9	PRS	Pre-scale value of count clock
0		$TCLK = CLOCK_IN/(PRS+1)$
		(CLOCK_IN is a selected timer input clock in TnCR1[CKSEL])

#### **TnGRA**

## Timer n General Register A

Timer General Register A is a 16-bit register.

T0GRA=0x4000\_300C, T1GRA=0x4000\_302C

											RA =0x4 RA=0x4	_	•		_

#### **TnGRB**

#### Timer n General Register B

Timer General Register B is a 16-bit register. This register is used for the Timer in PWM modes.

T0GRB=0x4000\_3010, T1GRB=0x4000\_3030 T2GRB=0x4000\_3050, T3GRB=0x4000\_3070 T8GRB=0x4000\_3110, T9GRB=0x4000\_3130

modes.

## Capture mode

Read current timer count value

Set count value

- Rising edge of TnC port will capture the count value when rising edge clear mode

Match interrupt is requested only in PWM and one-shot

- Falling edge of TnC port will capture the count value when falling edge clear mode

#### **TnCNT Timer n Count Register**

Timer Count Register is a 16-bit register.

T0CNT=0x4000\_3014, T1CNT=0x4000\_3034 T2CNT=0x4000 3054, T3CNT=0x4000 3074 T8CNT=0x4000\_3114, T9CNT=0x4000\_3134

## TnSR Timer n Status Register

Timer Status Register is a 16-bit register. This register indicates the current status of the timer module.

T0SR=0x4000\_3018, T1SR=0x4000\_3038 T2SR=0x4000\_3058, T3SR=0x4000\_3078 T8SR=0x4000\_3118, T9SR=0x4000\_3138

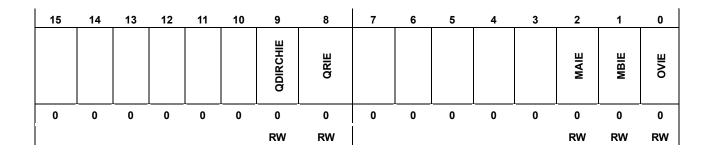

10	QDIR	Current Direction
		0 Phase A leading Phase B (clockwise)
		1 Phase B leading Phase A (counterclockwise)
9	QDIRCH	Quadrature direction change
		0 No direction change
		1 Direction is changed. Write '1' to this bit for clear
8	QRF	Quadrature revolution flag
		0 No revolution flag
		1 Revolution flag is detected. Write '1' to this bit for clear
2	MFA	GRA Match flag
		0 Not match with GRA
		1 Match flag with GRA. Write '1' to this bit for clear
1	MFB	GRB Match flag
		0 Not match with GRB
		1 Match flag with GRB. Write '1' to this bit for clear
0	OVF	Counter overflow flag
		0 No overflow event
		1 Counter overflowed. Write '1' to this bit for clear

## **TnIER Timer n Interrupt Enable Register**

The Timer Interrupt Enable Register is a 16-bit register. Each status flag of the timer block can issue the interrupt. To enable the interrupt, write 1 in the corresponding bit in the TnIER register.

T0IER=0x4000\_301C, T1IER=0x4000\_303C T2IER=0x4000\_305C, T3IER=0x4000\_307C T8IER=0x4000\_311C, T9IER=0x4000\_313C

9	QDIRCHIE	Quadrature direction change interrupt enable
		0 Disable direction change interrupt
		1 Enable direction change interrupt
8	QRIE	Quadrature revolution interrupt enable
		0 Disable revolution flag interrupt
		1 Enable revolution flag interrupt
2	MAIE	GRA Match interrupt enable
		0 Disable match register A interrupt
		1 Enable match register A interrupt
1	MBIE	GRB Match interrupt enable
		0 Disable match register B interrupt
		1 Enable match register B interrupt
0	OVIE	Counter overflow interrupt enable
		0 Disable counter overflow interrupt
		1 Enable counter overflow interrupt

**Note:** The QMOD in the TGECR register must be set before enabling the Quadrature interrupts.

#### **TGECR**

## **Timer Group Encoder Control Register**

The Timer Group Encoder Control Register is a 16-bit register. Timer0, Timer1, Timer2, and Timer3 can be used for quadrature encoder interface function.

#### TGECR=0x4000\_3140

15	14	13	12	11	10	9	8	7 6	3	5	4	3	2	1	0

		1 Quadrature decoder count mode
		Timer0 is phase A counter
		Timer1 is phase B counter
		Timer2 is position counter
		Timer3 is revolution counter

## **Functional Description**

#### **Basic Operation of Timer**

In Figure 11.2, TMCLK is a reference clock for operation of the timer. Divide this clock by the prescaler setting to operate the counting clock. The following images show the starting point of the counter and the ending of the period point of the counter in normal periodic mode.

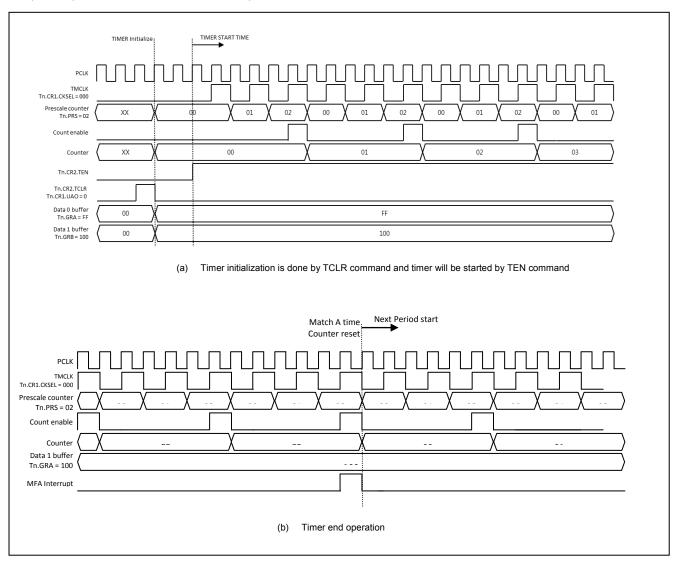

Figure 11.2. Basic Start and Match Operation

The timer count period can be calculated as follows:

The period = TMCLK Period \* Tn.GRA value

Match A interrupt time = TMCLK Period \* Tn.GRA value

When you change the timer setting and restart the timer with the new setting, Zilog recommends that you write the CR2.TCLR command before the CR2.TEN command.

#### **Normal Periodic Mode**

Figure 11.3 shows the timing diagram in normal periodic mode. The Tn.GRA value decides the timer period. The Tn.GRM register value does not matter.

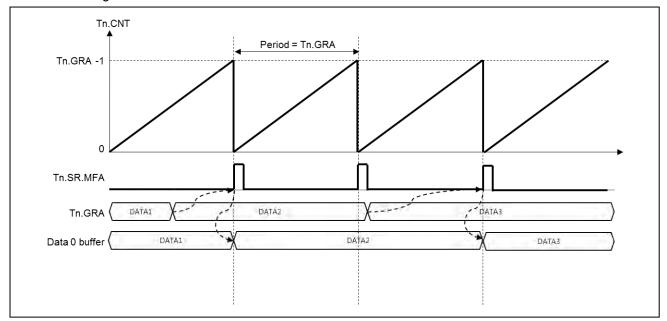

Figure 11.3. Normal Periodic Mode Operation

The timer count period can be calculated as follows:

The period = TMCLK Period \* Tn.GRA value

Match A interrupt time = TMCLK Period \* Tn.GRA value

If Tn.GRA = 0, the timer cannot be started even if TnCR2.TEN is "1" because the period is "0".

The values in Tn.GRA and Tn.GRB are loaded into the internal compare data buffer 0 when the loading condition occurs. In this periodic mode, the Tn.CR2.TCLR write operation and the GRA match event will load the compare data buffers.

#### **One Shot Mode**

Figure 11.4 shows the timing diagram in one shot mode. The Tn.GRB value decides the one shot period. An additional comparison point is provided with the Tn.GRA register value.

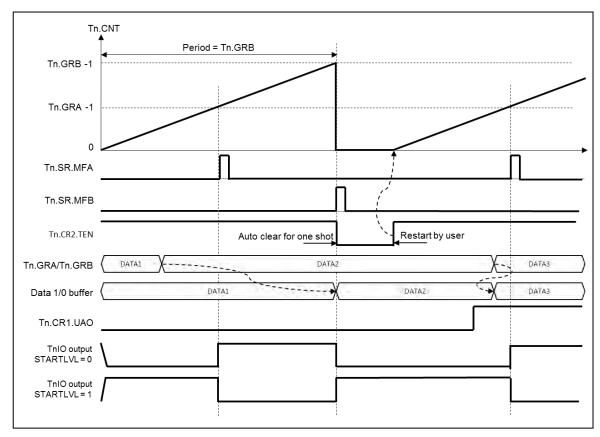

Figure 11.4. One Shot Mode Operation

The one shot count period can be calculated as follows:

The period = TMCLK Period \* Tn.GRB value

Match A interrupt time = TMCLK Period \* Tn.GRA value

If Tn.GRB = 0, the timer cannot be started even if TnCR2.TEN is "1" because the period is "0".

The values in Tn.GRA and Tn.GRB are loaded into the internal compare data buffers 0 and 1 when the loading condition occurs. In this mode, the Tn.CR2.TCLR write operation and the GRB match event will load the data buffer.

The TnIO output signal format is the same as PWM mode. The Tn.GRB value defines the output pulse period and the Tn.GRA value defines the pulse width of one shot pulse.

#### **PWM Timer Output Examples**

Figure 11.5 shows the timing diagram of PWM output mode. The Tn.GRB value decides the PWM pulse period. An additional comparison point is provided with the Tn.GRA register value which defines the pulse width of PWM output.

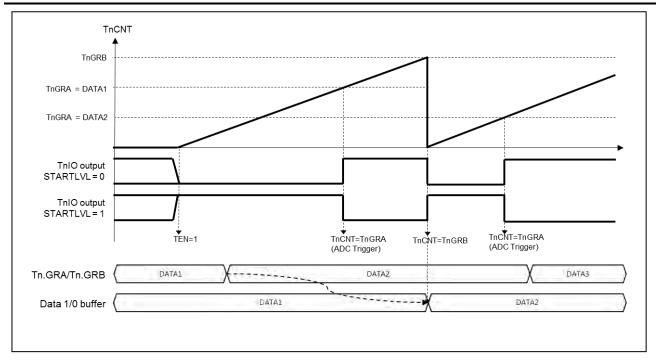

Figure 11.5. PWM Output Operation

The PWM pulse period can be calculated as follows:

The period = TMCLK Period \* Tn.GRB value

Match A interrupt time = TMCLK Period \* Tn.GRA value

If Tn.GRB = 0, the timer cannot be started even if TnCR2.TEN is "1" because the period is "0".

The values in Tn.GRA and Tn.GRB are loaded into the internal compare data buffers 0 and 1 when the loading condition occurs. In this mode, the Tn.CR2.TCLR write operation and the GRB match event will load the data buffer.

The TnIO output signal generates a PWM pulse. The Tn.GRB value defines the output pulse period and the Tn.GRA value defines the pulse width of one shot pulse. The active level of PWM pulse can be controlled by the Tn.CR1.STARTLVL bit value.

ADC Trigger generation is available at Match A interrupt time.

## **Capture Mode**

Figure 11.6 shows the timing diagram in capture mode operation. The TnIO input signal is used for the capture pulse. Both rising and falling edges can capture the counter values in each capture condition.

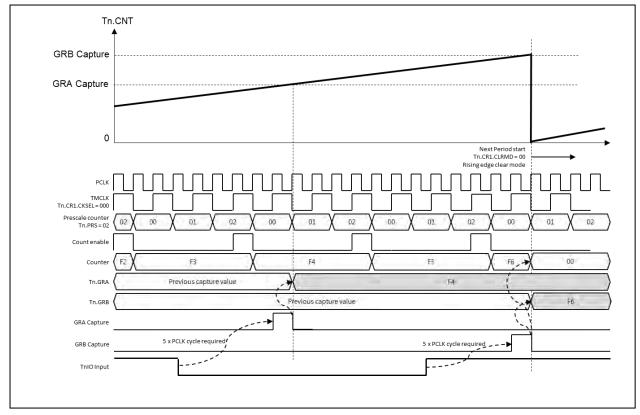

Figure 11.6. Capture Mode Operation

A 5 PCLK clock cycle is required internally. Therefore, the actual capture point is after the 5 PCLK clock cycle from the rising or falling edge of the TnIO input signal.

The internal counter can be cleared in multiple modes. The TnCR1.CLRMD field controls the counter clear mode. Rising edge clear mode, falling edge clear mode, both edge clear mode and none clear mode are supported.

## **ADC Trigger Function**

The timer module can generate ADC start trigger signals. One timer can be one trigger source of the ADC block. Trigger source control is performed by the ADC control register.

Figure 11.7 shows the ADC trigger function.

The conversion rate must be shorter than the timer period; else an overrun situation can occur. ADC acknowledge is not required because the trigger signal is cleared automatically after 3 PCLK clock pulses.

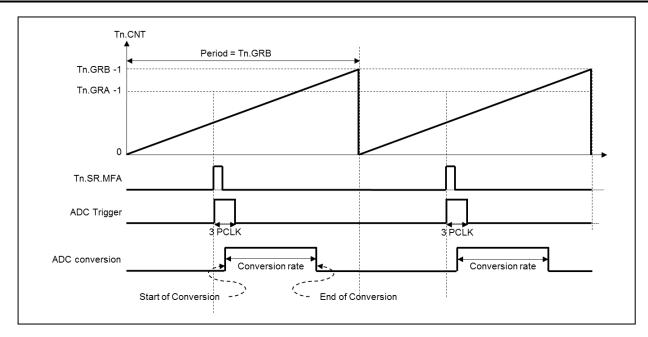

Figure 11.7. ADC Trigger Function Timing Diagram

#### Setup Example: Using the 16-bit Timer0 for Continuous Mode Operation

- 1. Enable the Timer0 peripheral by writing the appropriate value to the Peripheral Enable Register (PER1).
- 2. Enable the Timer0 peripheral clock by writing the appropriate value to the Peripheral Clock Enable Register (PCER).
- 3. Stop Timer0 before modifying the Timer0 registers by resetting bit0 in the Timer Control Register2 (TnCR2).
- 4. In Timer Control Register1 (TnCR1), write the appropriate value to enable the Timer0 Normal Period Operation Mode (e.g. 0x0000).
- 5. Write the appropriate Timer prescalar value to the Timer Prescalar Register (TnPRS).
- 6. Write the appropriate Timer count match value to the Timer General Register A (TnGRA) register. This timer count match value is compared to the actual count value in the Timer Count Register (TnCNT).
- 7. Write the appropriate value to Timer Interrupt Enable Register (TnIER) to enable or disable the Timer interrupt.
- 8. Start the Timer by setting bit0 and bit1; Timer Control Register2 (TnCR2) is enabled and initialized.

**Note:** Timer General Register A (TnGRA) is used for normal Timer operations. Timer General Register B (TnGRB) is used for Timer PWM modes.

#### **Quadrature Encoder Interface**

To use the Quadrature Encoder Interface Mode, Timer 0–Timer 3 are used for the input signals, holding the counter information and issuing the interrupts as necessary. The Timer mode for each of the timers used must be Capture Mode (TnCR1.MODE).

The Quadrature Encoder Interface peripheral receives pulses from the input of Timer 0 (Phase A), Timer 1 (Phase B) and Timer 2 (Phase Z) and processes the information to determine position, direction, and optionally, speed. The input for Timer 3 is not used. The position and revolution counters both use the Timer 2 input (as the Phase Z, or Index input).

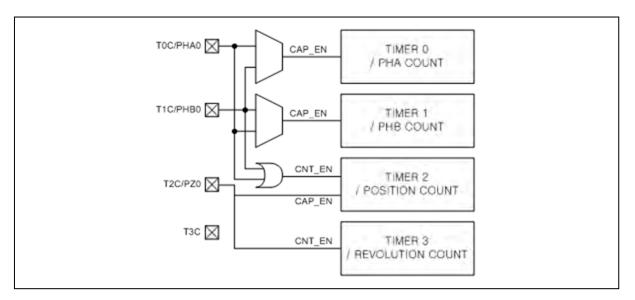

Figure 11.8. Quadrature Encoder Interface Counter Block

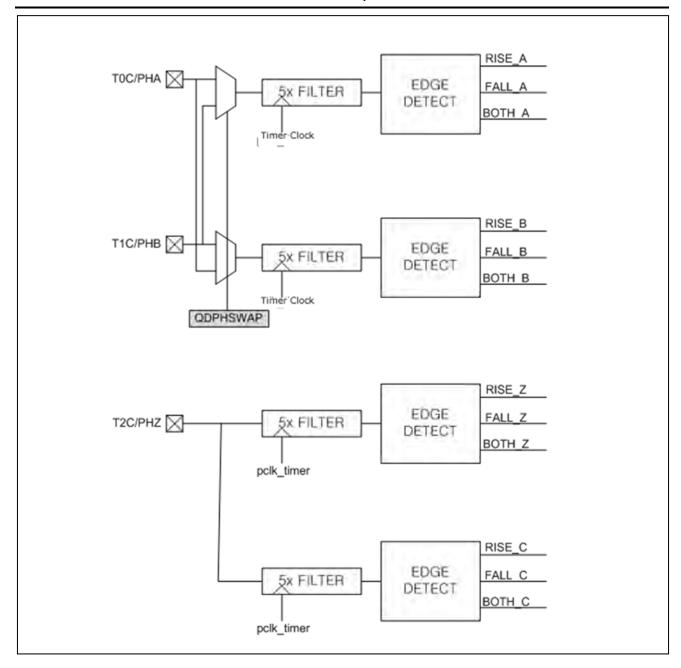

Figure 11.9. Quadrature Encoder Interface Input Block

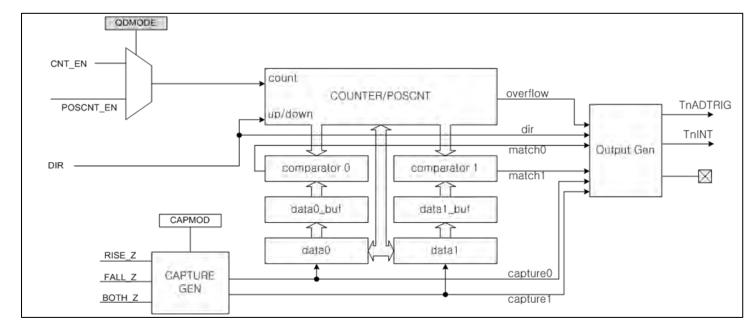

Figure 11.10. Quadrature Encoder Interface Block

The Phase A and Phase B inputs are controlled by the timer clock configuration (TnCR1.CKSEL). The GRA register contains the pulse count from the latest pulse and GRB register contains the previous pulse count. When the MFx interrupt is received, the MFx register has been updated. Depending on how TnCR1.CLRMOD and TnCR1.CKSEL are configured, this value could either be the pulse count or the time between pulses (up to the 16-bit count).

Phase A and Phase B can generate interrupts for QRF (Pulse received), QDIRCH (Direction changed). The QDIR status bit is set or cleared depending on the direction calculated from the last set of pulses from Phase A compared to Phase B.

Timer 2 (Position counter) counts the pulses from Phase A and Phase B. The GRB register contains the number of Phase A + Phase B pulses for each Phase Z input received. The CNT register is the current Phase A + Phase B pulses (giving the position within the Phase Z revolutions).

Timer 3 (Revolution counter) counts the pulses from the Phase Z input. Timer 3 only generates the QRF interrupt on receiving the Phase Z pulse.

To enable the Quadrature Encoder Interface interrupts, TGECR.QDMOD must be set before the desired interrupts in the TnIER register can be set.

# 12. Universal Asynchronous Receiver/Transmitter

#### **Overview**

4-Channel Universal Asynchronous Receiver/Transmitter (UART) modules are provided. Dedicated DMA support exists to transfer data between the memory buffer and the Transmit or Receive buffer of the UART block.

The UART operation status, including error status, can be read from the status register. The prescaler which generates the correct baud rate, exists for each UART channel. The prescaler can divide the UART clock source, PCLK/2, from 1 to 65535. The baud rate is generated by the clock which is internally divided by 16 of the prescaled clock and 8-bit precision clock tuning function.

A programmable interrupt generation function helps control communication via the UART channel.

#### Features of the UART include:

- Compatible with 16450
- Supports DMA transfer
- Standard asynchronous control bit (start, stop, and parity) configurable
- Programmable 16-bit fractional baud generator
- Programmable serial communication
- 5-, 6-, 7,- or 8- bit data transfer
- Even, odd, or no-parity bit insertion and detection
- 1-, 1.5,- or 2-stop bit-insertion and detection
- 16-bit baud rate generation with 8-bit fraction control
- Hardware inter-frame delay function
- Stop bit error detection
- · Detail status register
- Loop-back control

Figure 12.1 shows a block diagram of the UART.

#### **UnliR**

#### **UART Interrupt ID Register**

The UART Interrupt ID Register is an 8-bit register.

U0IIR=0x4000\_8008, U1IIR=0x4000\_8108 U2IIR=0x4000\_8208, U3IIR=0x4000\_8308

3	IID	Interrupt source ID					
1		See interrupt source ID table					
0	IPEN	Interrupt pending bit					
		0 Interrupt is pending					
		1 No interrupt is pending.					

UART supports 3-priority interrupt generation. The interrupt source ID register shows one interrupt source which has the highest priority among pending interrupts. The priority is defined as:

- Receive line status interrupt
- · Receive data ready interrupt
- Transmit hold register empty interrupt
- Tx/Rx DMA complete interrupts

Table 12.4. Interrupt ID and Control

	DMA	OMA IID		IPEN	Interrupt sources

6	BREAK	When this bit is set, TxD pin will be driven at low state in order to				
		notice the alert to the receiver.				
		0 Normal transfer mode				
		1 Break transmit mode				
5	STICKP	Force parity and it will be effective when PEN bit is set. See Table 9.5				
		0 Parity stuck is disabled				
		1 Parity stuck is enabled				
4	PARITY	Parity mode selection bit and stuck parity select bit				
		0 Odd parity mode				
		1 Even parity mode				
3	PEN	Parity bit transfer enable				
		0 The parity bit disabled				
		1 The parity bit enabled				
2	STOPBIT	The number of stop bit followed by data bits.				
		0 1 stop bit				
		1 1.5 / 2 stop bit				
		In case of 5 bit data case, 1.5 stop bit is added. In case of 6,7 or				
		8 bit data, 2 stop bit is added				
1	DLEN	The data length in one transfer word.				
0		00 5 bit data				
		01 6 bit data				
		10 7 bit data				
		11 8 bit data				

The parity bit is generated according to bits 3,4,5 of the UnLCR register. Table 12.5 shows the variation of parity bit generation.

Table 12.5. Variation of Parity Bit Generation

STICKP	STICKP PARITY PEN		Parity		
Х	Х	0	No Parity		
0	0 0 1		Odd Parity		
0	0 1 1		Even Parity		
1	1 0 1		Force parity as "1"		
1 1		1	Force parity as "0"		

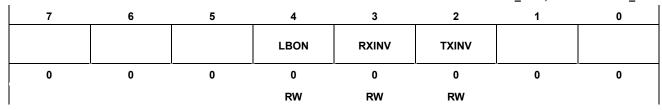

#### **UnDCR**

## **UART Data Control Register**

The UART Data Control Register is an 8-bit register.

U0DCR=0x4000\_8010, U1DCR=0x4000\_8110 U2DCR=0x4000\_8210, U3DCR=0x4000\_8310

4	LBON	Local loopback test mode enable
		0 Normal mode
		1 Local loopback mode (TxD connected to RxD internally)
3	RXINV	Rx Data Inversion Selection
		0 Normal RxData Input
		1 Inverted RxData Input
2	TXINV	Tx Data Inversion Selection
		0 Normal TxData Output
		1 Inverted TxData Output

#### **UnLSR**

#### **UART Line Status Register**

The UART Line Status Register is an 8-bit register.

This register provides the status of data transfers between the transmitter and the receiver. Users can get the line status information from this register to handle the next process. Bits 1,2,3,4 will raise the line status interrupt when the RLSIE bit in UnIEN register is set. Other bits can generate its interrupt when its interrupt enable bit in the UnIEN register is set.

0

#### **UnBDR**

#### **Baud rate Divisor Latch Register**

The UART Baud rate Divisor Latch Register is a 16-bit register.

U0BDR=0x4000\_8020, U1BDR=0x4000\_8120 U2BDR=0x4000 8220, U3BDR=0x4000 8320

ī										UZE	SDR=UX4	1000_82	20, U3BL	)K=0X40	00_8320
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
							В	DR							
							0x0	0000							
							R	w							
				15 0	BDR		I	Baud rat	e Divide	r latch v	alue				

To establish communication with the UART channel, the baud rate should be set properly. The programmable baud rate generator UnBDR provides the 16-bit dividers values. The 16 bit divider register (UnBDR) should be written for the expected baud rate.

The baud rate calculation formula is:

$$BDR = \frac{PCLK / 2}{16 \times BaudRate}$$

For a speed of 72 MHz PCLK, the divider value and error rate is described in Table 12.6.

Table 12.6. Example of Baud Rate Calculation

PCLK=72 MHz								
Baud rate	Divider (BDR)	Error (%)						
1200	1875	0.00%						
2400	937	0.05%						
4800	468	0.16%						
9600	234	0.16%						
19200	117	0.16%						
38400	58	1.02%						
57600	39	0.16%						
115200	19	2.79%						

is operating. Fraction counter is incremented by FCNT.

#### **UnBFR**

#### **Baud Rate Fraction Counter Register**

The Baud Rate Fraction Counter Register is an 8-bit register.

U0BFR=0x4000\_8024, U1BFR=0x4000\_8124 U2BFR=0x4000\_8224, U3BFR=0x4000\_8324

						_ ′	_
7	6	5	4	3	2	1	0
			ВЕ	R			
			0x	00			
			R\	N			
		7 BFI	R <u>F</u>	ractions counte	r value.		
		0	0	Fraction co	unter is disable	ed	
			N	Fraction co	unter enabled.	Fraction comper	sation mode

Table 12.7. Example of Baud Rate Calculation with BFR

	PCLK=72 MHz								
Baud rate	Divider (BDR)	FCNT (BFR)	Error (%)						
1200	1875	0	0.0%						
2400	937	128	0.0%						
4800	468	192	0.0%						
9600	234	96	0.0%						
19200	117	48	0.0%						
38400	58	152	0.0%						
57600	39	16	0.0%						
115200	19	136	0.0%						

$$FCNT = Float * 256$$

The 8-bit fractional counter counts up by FCNT value every (baud rate)/16 period and whenever the fractional counter overflows, the divisor value increments by 1. Therefore, this period will be compensated. In the next period, the divisor value returns to the original set value.

For example, if 9600 bps,

$$\frac{\textit{PCLK} / 2}{16 \times \textit{BaudRate}} = \frac{72000000 / 2}{16 \times 9600} = 234.375 \ \textit{Divider} = 234, \textit{Float} = 0.375$$

$$FCNT = Float * 256 = 0.375 * 256 = 96$$

BDR = 234, BFR = 96

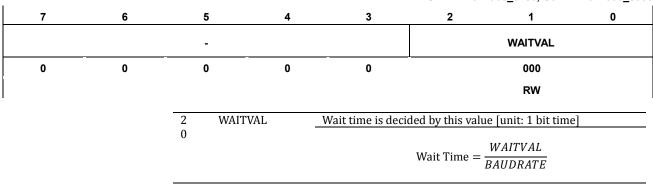

#### **UnIDTR**

#### **Inter-frame Delay Time Register**

The UART Inter-frame Time Register is an 8-bit register. A dummy delay can be inserted between 2 continuous transmits.

U0IDTR=0x4000\_8030, U1IDTR=0x4000\_8130 U2IDTR=0x4000 8230, U3IDTR=0x4000 8330

## **Functional Description**

The PER2 and PCER2 registers must be configured to enable the UART peripheral and UART peripheral clock. The UART module is compatible with 16450 UART. Additionally, dedicated DMA channels and fractional baud rate compensation logic are provided.

Because there is no internal FIFO block, data transfers are established interactively or by using DMA support. The DMA operation is described here.

2 DMA channels are provided for each UART module — TX transfer and RX transfer. Each channel has a 32-bit memory address register and a 16-bit transfer counter register. Prior to the DMA operation, the DMA Memory Address register and the Transfer Count register should be configured. For the RX operation, the memory address will be the destination memory address and for the TX operation, the memory address will be the source memory address.

The transfer counter register will store the number of transfer data. When a single transfer is done, the counter will be decremented by 1. When the counter reaches zero, the DMA done flag will be delivered to the UART control block. If the interrupt is enabled, this flag will generate the interrupt.

## **Receiver Sampling Timing**

The UARTs operate per the following timing:

If the falling edge is on the receive line, UART judges it as the start bit. From the start timing, the UART oversamples 16 times of 1-bit and detects the bit value at the 7th sample of 16 samples.

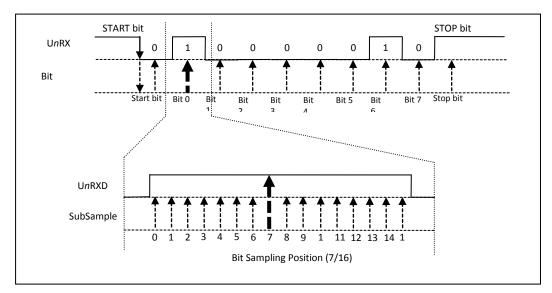

Figure 12.2. Sampling Timing of UART Receiver

**Note:** Zilog recommends enabling of debounce settings in the PCU block to reinforce the immunity of external glitch noise.

#### **Transmitter**

The transmitter's function is to transmit data. The start bit, data bits, optional parity bit, and stop bit are serially shifted, with the least significant bit first. The number of data bits is selected in the DLAN[1:0] field of the Un.LCR register.

The parity bit is set according to the PARITY and PEN bit field of the Un.LCR register. If the parity type is even, it depends on the one bit sum of all data bits. For odd parity, the parity bit is the inverted sum of all data bits.

The number of stop bits is selected in the STOPBIT field of the Un.LCR register.

An example of transmit data format is shown in Figure 12.3.

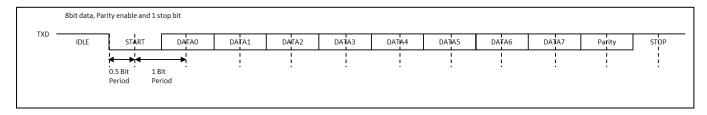

Figure 12.3. Transmit Data Format Example

### **Inter-frame Delay Transmission**

The inter-frame delay function allows the transmitter to insert an idle state on the TXD line between two characters. The width of the idle state is defined in the WAITVAL field of the Un.IDTR register. When this field is set to 0, zero time-delay is generated. Otherwise, the transmitter holds a high level on TXD after each transmitted character during the number of bit periods defined in the WATIVAL field.

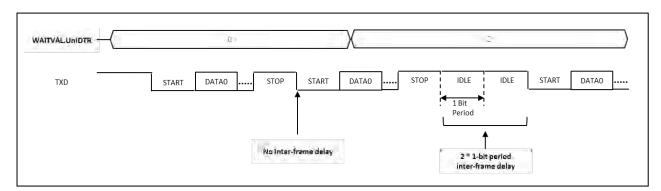

Figure 12.4. Transmit Data Format Example

#### **Transmit Interrupt**

The transmit operation generates interrupt flags. When the transmitter holding register is empty, the THRE interrupt flag is set. When the transmitter shifter register is empty, the TXE interrupt flag is set. Users can select the interrupt timing that is best for the application.

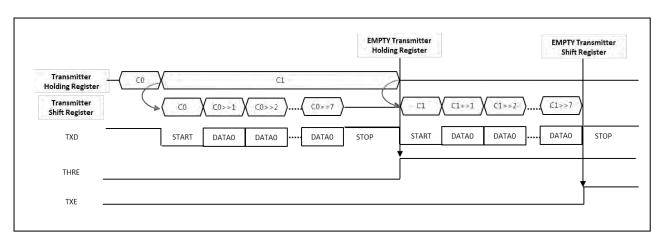

Figure 12.5. Transmit Data Format Example

#### **DMA Transfers**

The UART supports the DMA interface function. It is optionally provided depending on the device. The start memory address for transfer data and the length of transfer data are programmed in the registers in the DMA block.

The end of transfer is notified by the related transfer done flag. The transmit with DMA operation invokes the DMA TX done flag DTX.UnIIR and sets the DMA TX done interrupt ID when all the transmit data is written to the transmit holding register. Two transmit data values remain in the UART block registers after the DMA transfer done interrupt.

The Receive with DMA operation invokes the DMA RX done flag RXT.UnIIR and sets the DMA RX done interrupt ID when all the receive data is written to the destination memory. Therefore, the UART RXD signal is already in Idle state when the DMA RX done interrupt is issued.

# 13. Serial Peripheral Interface

#### **Overview**

2-channel serial interface is provided for synchronous serial communication with external peripherals. The SPI block supports master and slave modes. 4 signals are used for SPI communication – SS, SCK, MOSI, and MISO.

#### Features include:

- Master or slave operation
- Programmable clock polarity and phase
- 8,9,16,17-bit wide transmit/receive register
- 8,9,16,17-bit wide data frame
- Loop-back mode
- Programmable start, burst, and stop delay time
- DMA transfer operation.

Figure 13.1 shows the SPI Block Diagram.

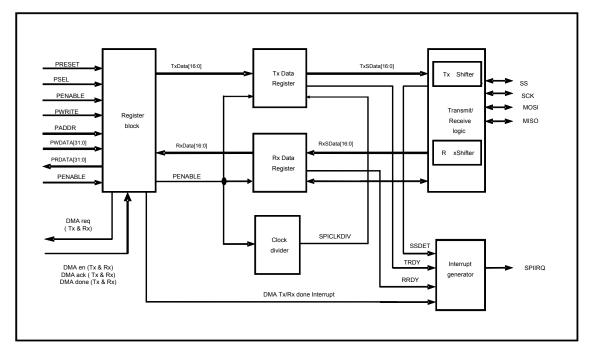

Figure 13.1. SPI Block Diagram

# **Pin Description**

Table 13.1. External Pins

PIN NAME	TYPE	DESCRIPTION
SS0	I/O	SPI0 Slave select (Master output, Slave input)
SCK0	I/O	SPI0 Serial clock (Master output, Slave input)
MOSI0	I/O	SPI0 Serial data (Master output, Slave input)
MISO0	I/O	SPI0 Serial data (Master input, Slave output)
SS1	I/O	SPI1 Slave select (Master output, Slave input)
SCK1	I/O	SPI1 Serial clock (Master output, Slave input)
MOSI1	I/O	SPI1 Serial data (Master output, Slave input)
MISO1	I/O	SPI1 Serial data (Master input, Slave output)

# **Registers**

The base address of SPI is  $0x4000\_9000$  and the register map is described in Table 13.2 and Table 13.3.

Table 13.2. SPI Base Address

Channel	Base address
SPI0	0x4000_9000

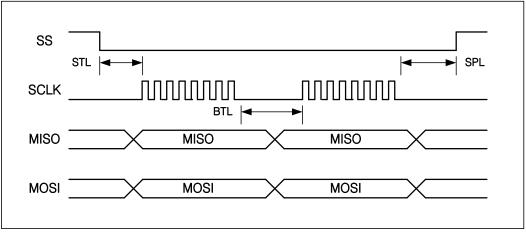

Figure 13.2. SPI waveform (STL, BTL, and SPL)

## **Functional Description**

The SPI Transmit and Receive blocks share the Clock Gen Block; however, they are independent of each other. The Transmit and Receive blocks have double buffers and SPI is available for back-to-back transfer operations.

## **SPI Timing**

The SPI has four modes of operation. These modes essentially control the way data is clocked in or out of an SPI device. The configuration is done by two bits in the SPI Control Register (SPnCR). The clock polarity is specified by the CPOL control bit, which selects an active high or active low clock. The clock phase (CPHA) control bit selects one of two fundamentally different transfer formats. To ensure proper communication between master and slave, both devices have to run in the same mode. This may require a reconfiguration of

the master to match the requirements of different peripheral slaves.

The clock polarity has no significant effect on the transfer format. Switching this bit causes the clock signal to be inverted (active high becomes active low and idle low becomes idle high). However, the settings of the clock phase select one of two different transfer timings, which are described in further detail in the next two chapters. Since the MOSI and MISO lines of the master and the slave are directly connected to each other, the diagrams show the timing of both these devices. The nSS line is the slave select input of the slave. The nSS pin of the master is not shown in the diagrams. It has to be inactivated by a high level on this pin (if configured as an input pin) or by configuring it as an output pin.

The timing of an SPI transfer where CPHA is zero is shown in Figure 13.3 and Figure 13.4. Two wave forms are shown for the SCK signal - one for CPOL equals zero and another for CPOL equals one.

When the SPI is configured as a slave, the transmission starts with the falling edge of the /SS line. This activates the SPI of the slave and the MSB of the byte stored in its data register (SPnTDR) is output on the MISO line. The actual transfer is started by a software write to the SPnTDR of the master. This causes the clock signal to be generated. If the CPHA equals zero, the SCLK signal remains zero for the first half of the first SCLK cycle. This ensures that the data is stable on the input lines of both the master and the slave. The data on the input lines is read with the edge of the SCLK line from its inactive to its active state. The edge of the SCLK line from its active to its inactive state (falling edge if CPOL equals zero and rising edge if CPOL equals one) causes the data to be shifted one bit further so that the next bit is output on the MOSI and MISO lines.

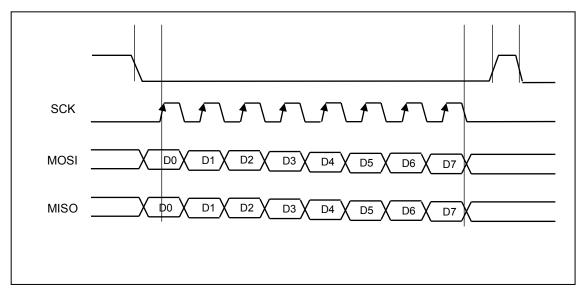

Figure 13.3. SPI Transfer Timing 1/4 (CPHA=0, CPOL=0, MSBF=0)

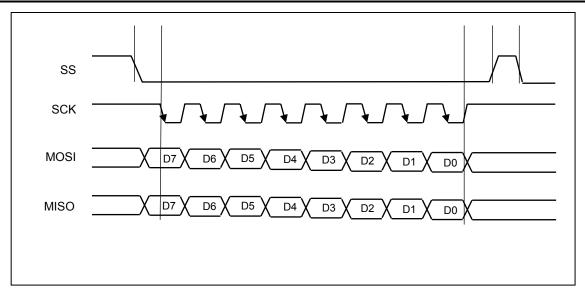

Figure 13.4.SPI Transfer Timing 2/4 (CPHA=0, CPOL=1, MSBF=1)

The timing of an SPI transfer where CPHA is one is shown in Figure 13.5 and Figure 13.6. Two wave forms are shown for the SCLK signal - one for CPOL equals zero and another for CPOL equals one.

As in the previous scenarios, the falling edge of the nSS lines selects and activates the slave. However, in contrast to the previous cases, where CPHA equals zero, the transmission is not started and the MSB is not output by the slave at this stage. The actual transfer is started by a software write to the SPnTDR of the master which causes the clock signal to be generated. The first edge of the SCLK signal from its inactive to its active state (rising edge if CPOL equals zero and falling edge if CPOL equals one) causes both the master and the slave to output the MSB of the byte in the SPnTDR.

As shown in Figure 13.3 and Figure 13.4, there is no delay of half a SCLK-cycle. The SCLK line changes its level immediately at the beginning of the first SCLK-cycle. The data on the input lines is read with the edge of the SCLK line from its active to its inactive state (falling edge if CPOL equals zero and rising edge if CPOL equals one). After eight clock pulses, the transmission is complete.

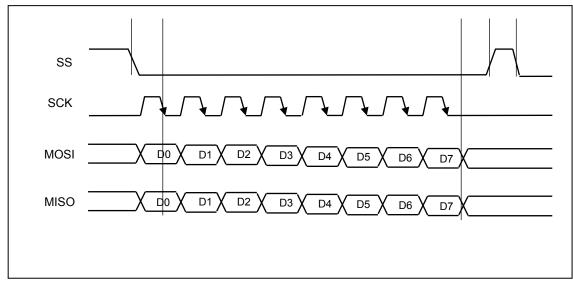

Figure 13.5.SPI Transfer Timing 3/4 (CPHA=1, CPOL=0, MSBF=0)

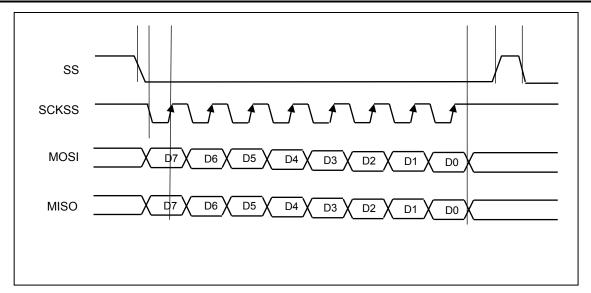

Figure 13.6.SPI Transfer Timing 4/4 (CPHA=1, CPOL=1, MSBF=1)

#### **DMA Handshake**

SPI supports the DMA handshaking operation. To operate a DMA handshake, DMA registers should be set first (see Chapter 9, Direct Memory Access Controller). SPI0 has 2 DMA channels – Channel 8 for the receiver and Channel 9 for the transmitter. SPI1 has Channel 10 for the receiver and Channel 11 for the transmitter. Because the transmitter and receiver are independent of each other, SPI can operate the two channels at the same time.

After the DMA channel for receiver is enabled and the receive buffer is filled, SPI sends Rx request to DMA to empty the buffer and waits for an ACK signal from DMA. If the Receive buffer is filled again after the ACK signal, SPI sends an Rx request. If DMA Rx DONE becomes high, RXDMAF (SPnSR[8]) is 1 and an interrupt is serviced when RXDIE (SPnCR[17]) is set.

Similarly, if the transmit buffer is empty after the DMA channel for transmitter is enabled, SPI sends a Tx request to the DMA to fill the buffer and waits for an ACK signal from the DMA. If the transmit buffer is empty again after the ACK signal, SPI sends a Tx request. If DMA Tx DONE becomes high, TXDMAF (SPnSR[9]) is 1 and an interrupt is serviced when TXDIE(SPnCR[18]) is set.

The slave transmitter sends dummy data at the first transfer (8~17 SCLKs) in DMA handshake mode.

Figure 13.7 shows a flowchart of the DMA handshaking process.

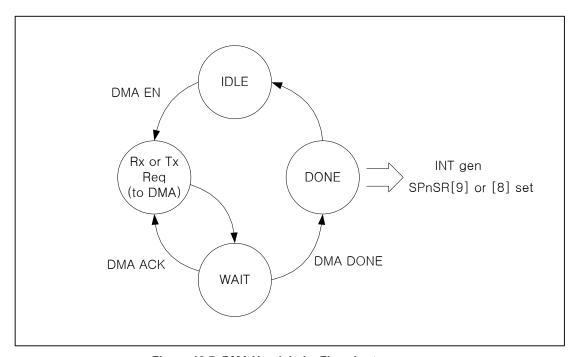

Figure 13.7. DMA Handshake Flowchart

# 14. I<sup>2</sup>C Interface

### **Overview**

The Inter-Integrated Circuit ( $I^2C$ ) bus serves as an interface between the microcontroller and the serial  $I^2C$  bus. It provides two wires, a serial bus interface to a large number of popular devices and allows parallel-bus systems to communicate bi-directionally with the  $I^2C$ -bus.

#### Features include:

- · Master and slave operation
- Programmable communication speed
- Multi-master bus configuration
- 7-bit addressing mode
- Standard data rate of 100/400 kbps
- STOP signal generation and detection
- START signal generation
- ACK bit generation and detection

Figure 14.1 shows the I<sup>2</sup>C block diagram.

# ICnDR I<sup>2</sup>C Data Register

ICnDR is an 8-bit read/write register. It contains a byte of serial data to be transmitted or a byte which has just been received.

7	6	5	4	3	2	1	0				
			D	R							
0xFF											
			R	W							
	7 ICI	OR '	The most recently	received data of	or data to be tran	ismitted.					
	0										

PS034503-0516 PRELIMINARY 153

### **ICnSR**

# I<sup>2</sup>C Status Register

ICnSR is an 8-bit read/write register. It contains the status of the  $I^2C$  bus interface. Writing to the register clears the status bits.

#### IC0SR=0x4000\_A008, IC1SR=0x4000\_A008

7	6	6 5		3	2	1	0
GCALL	TEND	STOP	SSEL	MLOST	BUSY	TMOD	RXACK
0	0	0 0		0 0		0	0
RW	RW	RW	RW	RW	RW	RW	RW

7	GCALL	This bit has different meaning depending on whether I <sup>2</sup> C is master or slave
		When I <sup>2</sup> C is a master, this bit represents whether it received AACK(Address
		ACK) from slave.
		When I <sup>2</sup> C is slave, this bit is used to indicate general call.
		0 No AACK is received (master mode)
		1 AACK is received (master mode).
		0 General call is not detected (slave mode)
		1 General call is detected (slave mode)
6	TEND	1 Byte transmission complete flag
		0 The transmission is working or not completed.
		1 The transmission is completed.
5	STOP	STOP flag
		0 STOP is not detected.
		1 STOP is detected.
4	SSEL	Slave flag
		0 Slave is not selected.
		1 Slave is selected.
3	MLOST	Mastership lost flag
		0 Mastership is not lost.
		1 Mastership is lost.
2	BUSY	BUSY flag
		0 I <sup>2</sup> C bus is in IDLE state.
		1 I <sup>2</sup> C bus is busy.
1	TMOD	Transmitter/Receiver mode flag
		0 Receiver mode.
		1 Transmitter mode.
0	RXACK	Rx ACK flag
		0 Rx ACK is not received.
		1 Rx ACK is received.

When an I<sup>2</sup>C interrupt occurs, except for the STOP interrupt, the SCL line is held LOW. To release SCL, write an arbitrary value to ICnSR. When ICnSR is written, the TEND, STOP, SSEL, MLOST, and RXACK bits are cleared.

## **ICnSAR**

# I<sup>2</sup>C Slave Address Register

ICnSAR is an 8-bit read/write register. It shows the address in slave mode.

#### IC0SAR=0x4000\_A00C, IC1SAR=0x4000\_A10C

7	6	5	4	3	2	1	0				
			SVAD				GCEN				
		0x00									
		RW									
	7 1	SVAD	7-bit Slave Addre								
	0	GCEN	General call enab	le bit							
			0 General ca	all is disabled.							

General call is enabled.

# ICnCR I<sup>2</sup>C Control Register

ICnCR is an 8-bit read/write register. This register can be set to configure  $I^2C$  operation mode and simultaneously allows for  $I^2C$  transactions to be kicked off.

#### IC0CR=0x4000\_A014, IC1CR=0x4000\_A114

7	6	5	4	3	2	1	0
IIF		SOFTRST	INTEN	ACKEN		STOP	START
0	0	0	0	0	0	0	0
RW		RW	RW	RW		RW	RW

7	IIF	Interrupt flag bit
		0 No interrupt is generated or interrupt is cleared
		1 Interrupt is generated
5	SOFTRST	Soft Reset enable bit.
		0 Soft Reset is disabled.
		1 Soft Reset is enabled
4	INTEN	Interrupt enabled bit.
		0 Interrupt is disabled.
		1 Interrupt is enabled.
3	ACKEN	ACK enable bit in Receiver mode.
		0 ACK is not sent after receiving data.
		1 ACK is sent after receiving data.
1	STOP	Stop enable bit.
		When this bit is set as "1" in transmitter mode, next transmission will be
		stopped even though ACK signal has been received.
		0 Stop is disabled.
		1 Stop is enabled.
		When this bit is set, transmission will be stopped.
0	START	Transmission start bit in master mode.
		0 Waits in slave mode.
		1 Starts transmission in master mode.

## **ICnSCLL**

# I<sup>2</sup>C SCL LOW Duration Register

ICnSCLL is a 16-bit read/write register. SCL LOW time can be set by writing this register in master mode.

ICOSDLL=0x4000	Δ018	IC1SDL	=0x4000	Δ118
IOOODEE OXTOO	_~~,	.0.00	_ 0x-000_	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SCLL														
	0xFFFF														
							R	W							

15	SCLL	SCL LOW duration value.
		SCLL = (PCLK * SCLL[15:0]) + 2*PCLKs
0		Default value is 0xFFFF.

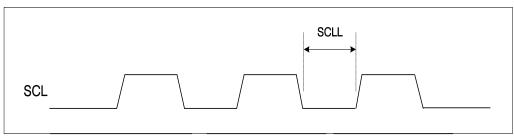

Figure 14.2.SCL LOW Timing

## ICnSCLH I<sup>2</sup>C SCL HIC

# I<sup>2</sup>C SCL HIGH duration Register

ICnSCLH is a 16-bit read/write register. SCL HIGH time will be set by writing this register in master mode.

ICOSDLH=0x4000	A01C, IC1SDLH=0x4	000 A11C
	, .v . v, . v . v = = v	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SCLH														
	0xFFFF														
							R	W							

15	SCLH	SCL HIGH duration value.
		SCLH = (PCLK * SCLH[15:0]) + 3 PCLKs
0		Default value is 0xFFFF.

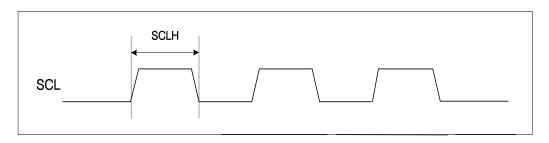

Figure 14.3.SCL HIGH Timing

## **ICnSDH**

## **SDA Hold Register**

ICnSDH is a 15-bit read/write register. SDA HOLD time will be set by writing this register in master mode.

IC0SDH=0x4000_	A020,	IC1SDH=0x4000	_A120

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SDH														
								SDH							
	0x7FFF														
								RW							

14	SDH	SDA HOLD time setting value.
		SDH = (PCLK * SDH[14:0]) + 4 PCLKs
0		Default value is 0x7FFF.

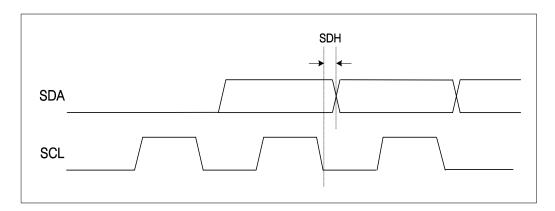

Figure 14.4.SDA HOLD Timing

# **Functional Description**

# I<sup>2</sup>C Bit Transfer

The data on the SDA line must be stable during the "H" period of the clock. The "H" or "L" state of the data line can only change when the clock signal on the SCL line is "L" as shown in Figure 14.5.

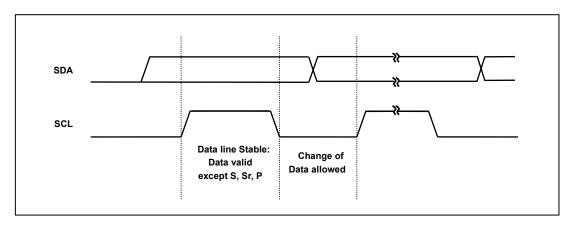

Figure 14.5. I<sup>2</sup>C Bus Bit Transfer

### START/Repeated START/STOP

Within the procedure of the  $I^2$ C-bus, unique situations arise which are defined as START(S) and STOP(P) conditions; see Figure 14.6.

An "H" to "L" transition on the SDA line while SCL is "H" is one such unique case. This situation indicates a START condition. An "L" to "H" transition on the SDA line while SCL is "H" defines a STOP condition.

START and STOP conditions are always generated by the master. The bus is considered to be busy after the START condition. The bus is considered to be free again a certain time after the STOP condition.

The bus is busy if a repeated START(Sr) is generated instead of a STOP condition. In this respect, the START(S) and repeated START(Sr) conditions are functionally identical. Therefore, for the remainder of this document, the S symbol will be used as a generic term to represent both the START and repeated START conditions, unless Sr is particularly relevant.

Detection of START and STOP conditions by devices connected to the bus is easy if they incorporate the necessary interfacing hardware. However, microcontrollers with no such interface have to sample the SDA line at least twice per clock period to sense the transition.

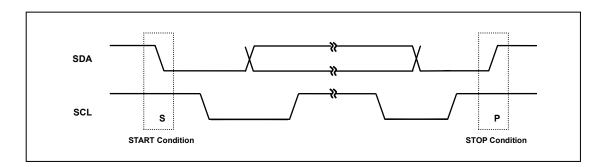

Figure 14.6. START and STOP Condition

#### **Data Transfer**

Every byte put on the SDA line must be 8-bit long. The number of bytes that can be transmitted per transfer is unrestricted. Each byte has to be followed by an acknowledge bit. Data is transferred with the most significant bit (MSB) first; see Figure 14.7. If a slave can't receive or transmit another complete byte of data until it has performed some other function, for example servicing an internal interrupt, it can hold the clock line SCL "L" to force the master into a wait state. Data transfer then continues when the slave is ready for another byte of data and releases clock line SCL.

A message which starts with such an address can be terminated by generation of a STOP condition, even during the transmission of a byte. In this case, no acknowledge is generated.

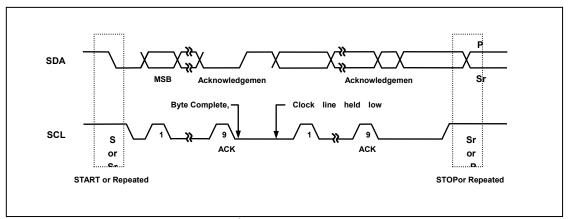

Figure 14.7. I<sup>2</sup>C Bus Data Transfer

### **Acknowledge**

Data transfer with acknowledge is obligatory. The acknowledge-related clock pulse is generated by the master. The transmitter releases the SDA line (HIGH) during the acknowledge clock pulse.

The receiver must pull down the SDA line during the acknowledge clock pulse so that it remains stable "L" during the "H" period of this clock pulse as shown in Figure 14.8. Set-up and hold times must also be taken into account.

When a slave doesn't acknowledge the slave address (for example, it is unable to receive or transmit because it is performing a real-time function), the data line must be left "H" by the slave. The master can then generate either a STOP condition to abort the transfer, or a repeated START condition to start a new transfer.

If a slave-receiver does acknowledge the slave address but, sometime later in the transfer cannot receive any more data bytes, the master must again abort the transfer. This is indicated by the slave generating the not-acknowledge on the first byte to follow. The slave leaves the data line "H" and the master generates a STOP or a repeated START condition.

If a master-receiver is involved in a transfer, it must signal the end of data to the slave-transmitter by not generating an acknowledge signal on the last byte that was clocked out of the slave. The slave-transmitter must release the data line to allow the master to generate a STOP or repeated START condition.

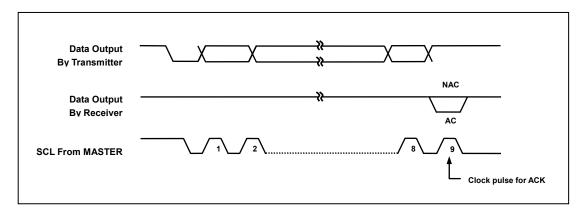

Figure 14.8. I<sup>2</sup>C Bus Acknowledge

### **Synchronization**

All masters generate their own clock on the SCL line to transfer messages on the I<sup>2</sup>C-bus. Data is only valid during the "H" period of the clock. A defined clock is therefore required for the bit-by-bit arbitration procedure to take place.

Clock synchronization is performed using the wires AND connection of I<sup>2</sup>C interfaces to the SCL line. This means that an "H" to "L" transition on the SCL line will cause the devices concerned to start counting off their "L" period and, once a device clock has gone to "L" period, it will hold the SCL line in that state until the clock "H" state is reached as shown in Figure 14.9. However, the "L" to "H" transition of this clock may not change the state of the SCL line if another clock is still within its "L" period by the device with the longest "L" period. Devices with shorter "L" periods enter an "H" wait-state during this time.

When all devices concerned have counted off their "L" period, the clock line will be released and go to "H" state. At this point, there will be no difference between the device clocks and the state of the SCL line, and the devices will start counting their "H" periods. The first device to complete its "H" period will again pull the SCL line "L".

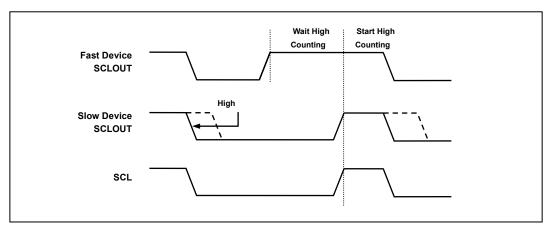

Figure 14.9. Clock Synchronization during the Arbitration Procedure

#### **Arbitration**

A master may start a transfer only if the bus is free. Two or more masters may generate a START condition within the minimum hold time of the START condition which results in a defined START condition to the bus.

Arbitration takes place on the SDA line, while the SCL line is at the "H" level, in such a way that the master which transmits "H" level, while another master is transmitting a "L" level, will switch off its DATA output stage because the level on the bus doesn't correspond to its own level.

Arbitration can continue for many bits. The first stage of arbitration is comparison of the address bits. If the masters are each trying to address the same device, arbitration continues with comparison of the data-bits if they are master-transmitter or acknowledge-bits if they are master-receiver. Because address and data information on the  $I^2$ C-bus is determined by the winning master, no information is lost during the arbitration process.

A master that loses the arbitration can generate clock pulses until the end of the byte in which it loses the arbitration.

If a master also incorporates a slave function and it loses arbitration during the addressing stage, it's possible that the winning master is trying to address it. The losing master must therefore switch over immediately to its slave mode.

Figure 14.10 shows the arbitration procedure for two masters. More masters may be involved, depending on the number of masters connected to the bus. As soon as there is a difference between the internal data level of the master generating Device1 Dataout and the actual level on the SDA line, its data output is switched off, which means that an "H" output level is then connected to the bus. This will not affect the data transfer

initiated by the winning master.

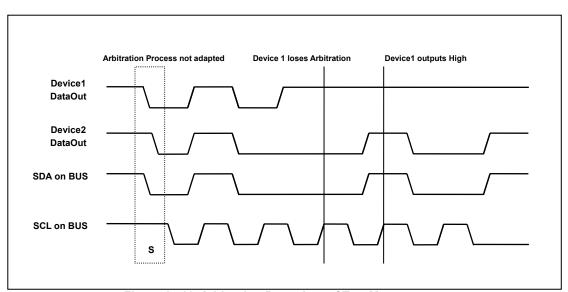

Figure 14.10. Arbitration Procedure of Two Masters

# I<sup>2</sup>C Operation

 $I^2C$  supports the interrupt operation. Once an interrupt is serviced, the IIF (ICnCR[7]) flag is set. ICnSR shows  $I^2C$ -bus status information and the SCL line stays "L" before the register is written as a certain value. The status register can be cleared by writing a zero.

#### **Master Transmitter**

The master transmitter shows the flow of the transmitter in Master Mode as shown in Figure 14.11.

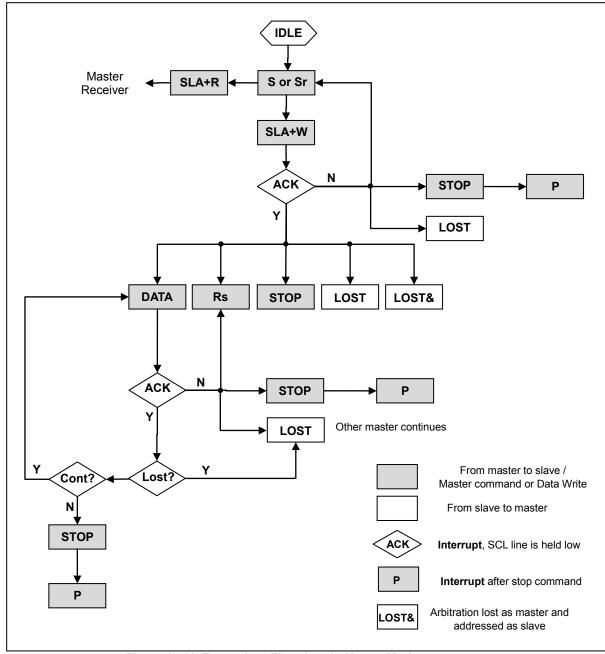

Figure 14.11. Transmitter Flowchart in Master Mode

### **Master Receiver**

The master receiver shows the flow of the receiver in Master Mode as shown in Figure 14.12.

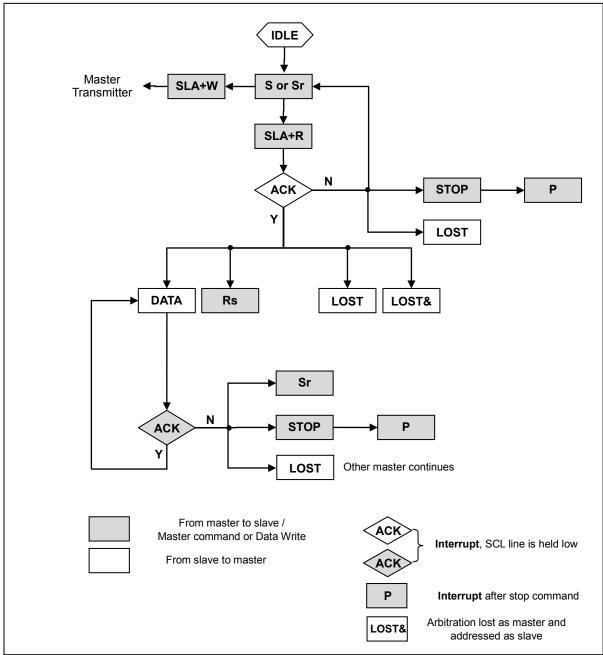

Figure 14.12. Receiver Flowchart in Master Mode

### **Slave Transmitter**

The slave transmitter shows the flow of the transmitter in Slave Mode as shown in Figure 14.13.

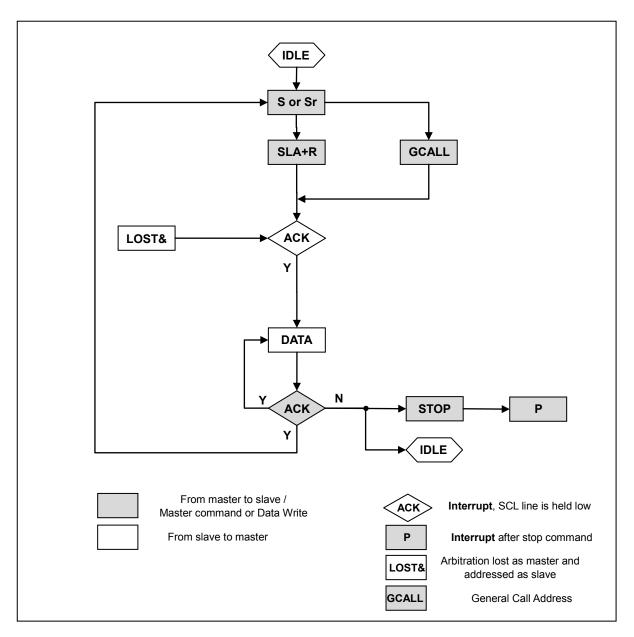

Figure 14.13. Transmitter Flowchart in Slave Mode

### **Slave Receiver**

The slave receiver shows the flow of the receiver in Slave Mode as shown in Figure 14.14.

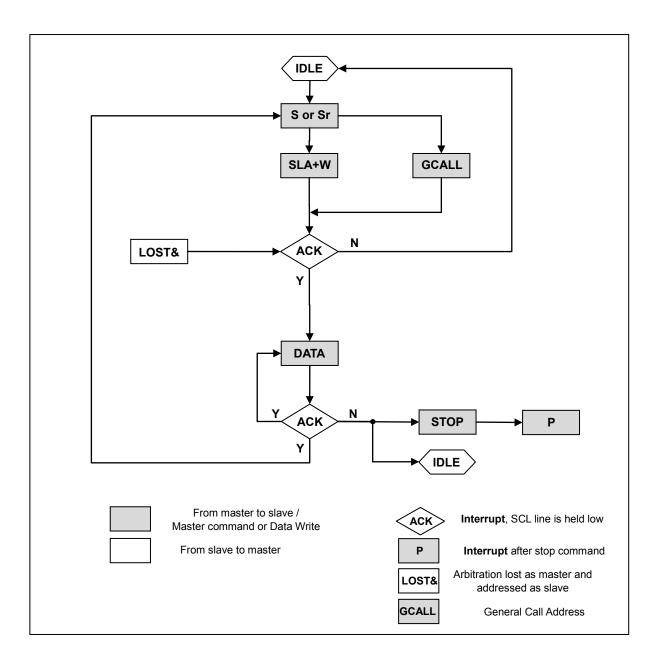

Figure 14.14. Receiver Flowchart in Slave Mode

# 15. Motor Pulse-Width-Modulator

## Introduction

The Motor Pulse Width Modulator (MPWM) is a programmable motor controller. Features include:

- 6-channel output for motor control
- Dead- time zone support
- Protection event and over voltage event handling
- Six ADC trigger outputs
- Interval interrupt mode (period interrupt only)
- Up-down count mode

Figure 15.1 shows the MPWM block diagram.

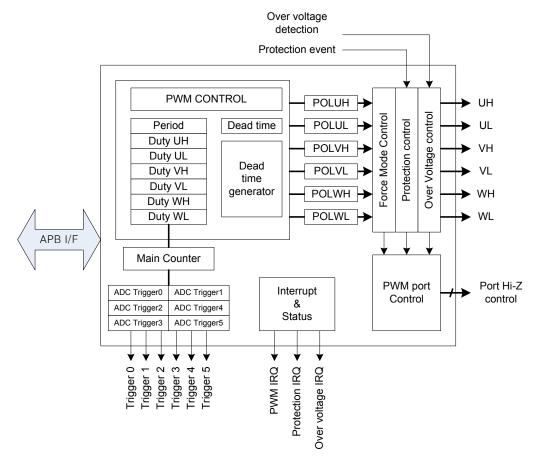

Figure 15.1. MPWM Block Diagram

R							R

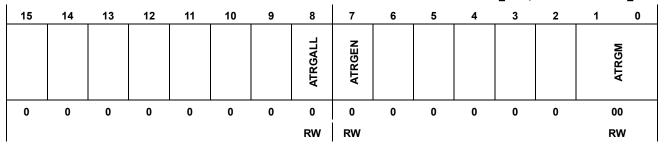

7	OVSTAT	Over voltage protection mode status
0	OVPIN	Over voltage protection input status

#### **MPnATCR**

## **MPWM ADC Trigger Control Register**

The PWM ADC Trigger Control Register is a 16-bit register.

#### MP0ATCR=0x4000\_4054, MP1ATCR=0x4000\_5054

8	ATRGALL	ADC Trigger register 0 match event makes all trigger signals
7	ATRGEN	ADC Trigger mode enable
1	ATRGM	00 Always ADC Trigger enable when TRGEN is high
0		01 ADC Trigger disable in protection state
		10 ADC Trigger disable in over voltage state
		ADC Trigger disable in protection, over voltage state

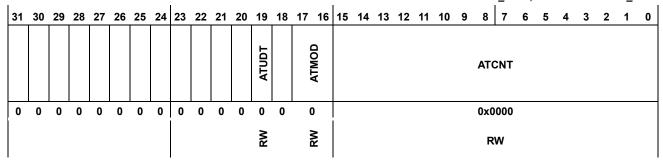

### MPnATRm MPWMn ADC Trigger Counter m Register

MPnATR1	MPWM ADC Trigger Counter 1 Register
MPnATR2	MPWM ADC Trigger Counter 2 Register
MPnATR3	MPWM ADC Trigger Counter 3 Register
MPnATR4	MPWM ADC Trigger Counter 4 Register
MPnATR5	MPWM ADC Trigger Counter 5 Register
MPnATR6	MPWM ADC Trigger Counter 6 Register

The PWM ADC Trigger Counter Register is a 32-bit register.

MP0ATR1=0x4000\_4058, MP1ATR1=0x4000\_5058
MP0ATR2=0x4000\_405C, MP1ATR2=0x4000\_505C
MP0ATR3=0x4000\_4060, MP1ATR3=0x4000\_5060
MP0ATR4=0x4000\_4064, MP1ATR4=0x4000\_5064
MP0ATR5=0x4000\_4068, MP1ATR5=0x4000\_5068
MP0ATR6=0x4000\_406C, MP1ATR6=0x4000\_506C

19	ATUDT	0	Trigger register update mode
			ADC trigger value applied at period match event (at the
			same time with period and duty registers update)
		1	Trigger register update mode
			When this bit set, written Trigger register values are sent
			to trigger compare block after two PWM clocks (through
			synchronization logic)
17	ATMOD	00	ADC trigger Mode register
16			ADC trigger Disable
		01	Trigger out when up count match
		10	Trigger out when down count match
		11	Trigger out when up-down count match
15	ATCNT	ADC	Trigger counter 0 (it should be less than PWM period)
0			

PS034503-0516 PRELIMINARY 186

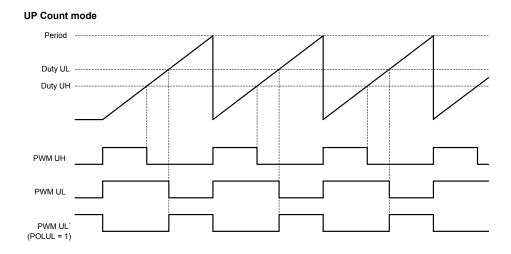

# **Functional Description**

The PWMx module allows users to configure the PWM for different types of modulation schemes described in the previous section. The PER2 and PCER2 registers must be configured to enable the PWMx peripheral and the PWMx peripheral clock.

Setting or resetting the MOTOR bit in the MPnMR register allows users to operate the motor in Independent or Complementary PWM modes. For more information about operating modes, refer to the diagrams in the following section.

# 16. 12-Bit A/D Converter

### Introduction

The ADC block consists of 3 independent ADC units that provide:

- 16 channels of analog inputs
- Single and Continuous conversion mode
- Up to 8 times burst conversion support
- External pin trigger support
- 4 internal trigger sources support (PWMs, timers)
- Adjustable sample & hold time
- ADC clock can be derived from all sources available with configurable dividers

Figure 16.1 shows a block diagram of the 12-bit A/D Converter.

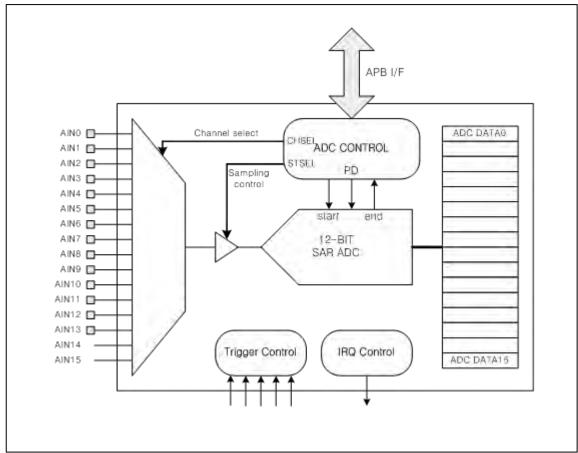

Figure 16.1. 12-bit A/D Converter Block Diagram

R													F	₹	

15	ADDMAR	ADC conversion result data (12-bit)
4		
3	ADMACH	ADC data channel indicator
0		

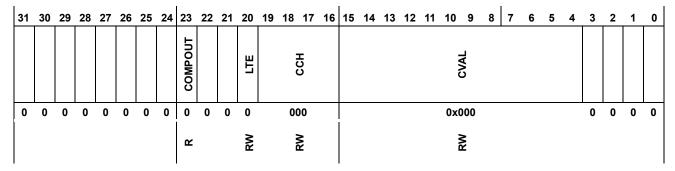

#### ADnCCR

### **ADC Channel Compare Control Register**

ADC Channel Compare Control Registers are 32-bit registers.

#### AD0CCR=0x4000\_B070, AD1CCR=0x4000\_B170, AD2CCR=0x4000\_B270

23	COMPOUT	0 If LTE condition is FALSE
		1 If LTE condition is TRUE (MPWM trigger source)
20	LTE	0 Set compare output when AD conversion value is
		greater than compare value (CVAL)
		1 Set compare output when AD conversion value is less
		than or equal to compare value(CVAL)
19	ССН	Compare channel
16		
15	CVAL	Compare value
4		

### **Functional Description**

The PER2 and PCER2 registers must be configured to enable the ADC peripheral and the ADC peripheral clock. The ADC block provides the ability to convert an analog signal to a digital value. The ADC compares the input channel with the AVDD voltage and provides a 12-bit value.

Voltage value = (ADC Reading / 4096) \* AVDD voltage

The ADC clock can be configured up to 22.5 MHz and be driven from any of the available clocks – System Clock, Ring OSC, Bus Clock, Int OSC, External OSC, or the PLL clock. There is a 6-bit divider available for the system clock (divider must be greater than 1) or the ADC clock can be configured in the MCCR4 register, which provides access to all clocks and the 8-bit divider. The clock is selected in the CR1 register (and optionally configured in the SCU MCCR4 register).

The ADC takes 15 ADC clocks to complete one sample, starting with a single clock, followed by a sample and hold time (minimum of 2 ADC clocks) then 1 clock per bit (12 bits). To increase sample time, configure up to 511 clock sampling time (which would then take 511 + 15 = 526 ADC clocks per sample).

The maximum ADC clock that can be used is calculated as:

ADC Clock = 1.5Msps \* (15 clocks per sample + Sample time)

#### Example (Sampling time = 0):

ADC clock = 1.5Msps \* (15 clocks + 0) = 22.5 MHz

In the above example, if the system clock was running at 72 MHz, the divider cannot be less than 4.

The burst feature allows the programmer to retrieve multiple readings (up to 8) with only one start request. The ADC block automatically goes through all 8 and takes readings without intervention. This feature is best utilized with DMA to store the data. It is also possible to wait a specific time (up to 255 ADC clocks) before starting the next conversion.

To use the burst feature, populate Burst channels 0-7 of the reading you wish to take. They can be the same or different channels. Provide the count of burst operations (number of channels that have been assigned) in the burst count, then modify the ADCMOD to specify burst mode. If desired, populate the BWAIT value with the number of clocks you wish to have between readings and set the BWAITEN bit. You can either manually start it by setting the AStart bit or set a trigger to start it.

#### **BURST Mode Example:**

To take 3 readings of AN0 and AN2 for an average value, set the Burst channels as:

BST1CH = 0x00 (AN0 is ADC Channel 0)

BST2CH = 0x04 (AN2 is ADC Channel 4)

BST3CH = 0x00

BST4CH = 0x04

BST5CH = 0x00

BST6CH = 0x04

Set the BSTCNT in the MR register to 0x06

Set the ADCMOD in the MR register to 0x03

Set the AStart Bit in the CR2 register to take the readings.

It is possible to trigger the burst reading to take the readings when an event occurs.

#### **General ADC Setup Procedure**

- 1. Allow the modification of the I/O pins to use the ADC inputs needed by writing the unlock sequence as described in Port Control Unit (PCU), no pullups enabled.
- 2. Enable the ADC peripherals needed in the PER2 register.
- 3. Enable the ADC peripheral clock in the PCER2 register.
- 4. Select the alternating function for the ADC inputs (Port n MUX registers).
- 5. Configure the ADC mode in the ADCnMODE register and enabled the channel ADCn.
- 6. Configure the ADCnCR1 register and write an appropriate clock divider value.
- 7. Configure TRG0 to enable or disable ADC trigger sources.
- 8. Configure the ADC Burst Mode (ADnBCSR) register for ADC operation with burst mode described below.
- 9. Configure the ADnIER ADC interrupt control register.

#### **ADC Single Mode Timing Diagram**

ADC conversion is started when ADCn.CR.ASTART is written as '1' in single conversion mode. After ADCnCR.ASTART is set, SOC (start of Conversion) will be activated in 2 ADC clocks; ADCn.SR.SIRQ will be set in 1 ADC clock and 2 PCLKs after the end of conversion.

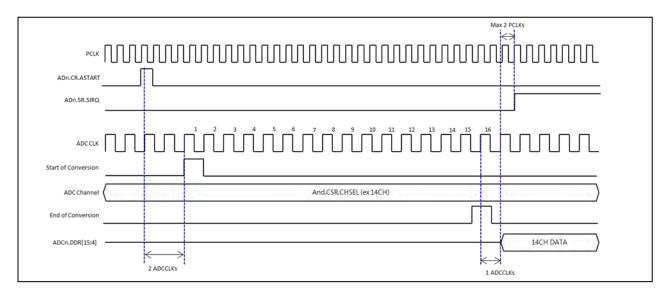

Figure 16.3. ADC Single Mode Timing Diagram

#### **ADC Continuous Mode Timing Diagram**

The ADC conversion in burst mode is almost the same as continuous mode. Burst mode has ADnCR.BWAIT. BWAIT in 8-bit register and can delay the time of SOC. Burst wait counter (BWAIT) in ADC clock domain. ADnSR.BIRQ is set as 1 after the last burst operation; see Figure 16.4

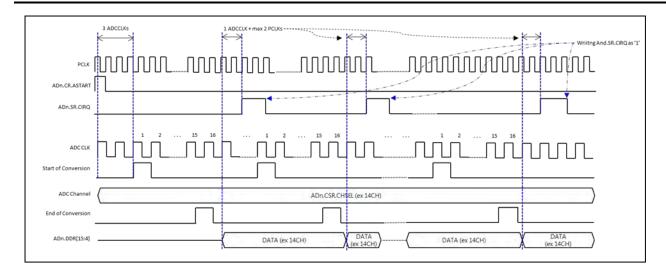

Figure 16.4. ADC Continuous Mode Timing

#### **ADC Burst Mode Timing Diagram**

The ADC conversion in burst mode is almost same as in continuous mode. Burst mode has ADnCR.BWAIT. BWAIT in 8-bit register and can delay the time of SOC. Burst wait counter (BWAIT) in the ADC clock domain. ADnSR.BIRQ is set as 1 after the last burst operation; see Figure 16.5

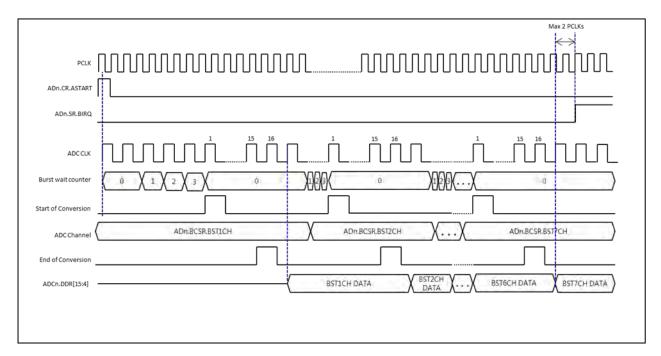

Figure 16.6. ADC Burst Mode Timing (when ADCn.MR.BWAIT = '8'h3' and BSTCNT = '3'b111')

# 17. Analog Front End

## Introduction

Analog Front End (AFE) is the interface controller for OPAMPs and comparators.

#### Features include:

- 4 OPAMPs
- 4 comparators
- OPAMP output can be connected with ADC or comparator
- Internal BGR reference for comparator
- Comparator output debounce function
- · Level and edge interrupt mode support for comparator

Figure 17.1 shows a block diagram of the AFE.

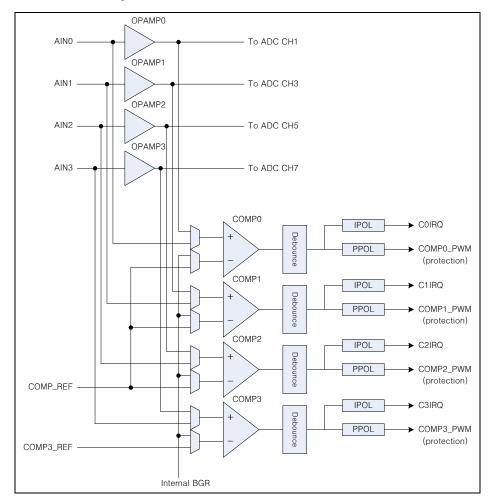

Figure 17.1. Analog Front End Block Diagram

### **Registers**

The base address of AFE is listed in Table 17.2.

Table 17.2. AFE Base Address

	BASE ADDRESS
AFE	0x4000_B300

Table 17.3 shows the register memory map.

Table 17.3. AFE Register Map

Name	Offset	R/W	Description	Reset
OPA0CR	0x0000	R/W	AFE OPAMP 0 control register	0x00
OPA1CR	0x0004	R/W	AFE OPAMP 1 control register	0x00
OPA2CR	0x0004	R/W	AFE OPAMP 2 control register	0x00
OPA3CR	0x000C	R/W	AFE OPAMP 3 control register	0x00
CMP0CR	0x0020	R/W	AFE Comparator 0 control register	0x10
CMP1CR	0x0024	R/W	AFE Comparator 1 control register	0x10
CMP2CR	0x0028	R/W	AFE Comparator 2 control register	0x10
CMP3CR	0x002C	R/W	AFE Comparator 3 control register	0x10
CMPDBR	0x0030	R/W	AFE Comparator debounce register	0x00
CMPICR	0x0034	R/W	AFE Comparator interrupt control	0x00
CMPIER	0x0038	R/W	AFE Comparator interrupt enable	0x00
CMPSR	0x003C	R	AFE Comparator status register	0x00

#### **OPAnCR**

#### **OPAMP 0/1/2/3 Control Registers**

Analog-front-end OPAMP 0/1/2/3 Control Registers are 8-bit registers. All four registers (AFEOPA0~AFEOPA3) have the same functions.

OPA0CR=0x4000\_B300, OPA1CR =0x4000\_B304 OPA2CR =0x4000\_B308, OPA3CR =0x4000\_B30C

7	6	5	4	3	3 2 1						
			OPAEN		G/	MN					
0	0	0	0		02	κ0					
			RW		R	w					

4	OPAEN	0	OPAMP n Disable		
		1	OPAMP n Enable		_
3	GAIN	0000	Gain = $2.19$	1000	Gain = 4.37
0		0001	Gain = 2.33	1001	Gain = 5.0
		0010	Gain = 2.5	1010	Gain = 5.83
		0011	Gain = 2.69	1011	Gain = 7.0
		0100	Gain = $2.92$	1100	Gain = 8.74
		0101	Gain = $3.18$	1101	Reserved
		0110	Gain = 3.5	1110	Reserved
		0111	Gain = 3.89	1111	Gain = 1.00

#### **CMPnCR**

### Comparator 0/1/2/3 Control Register

Analog-front-end Comparator0/1/2/3 Control Registers are 8-bit registers. All four registers (AFECOMP0~AFECOMP3) have the same functions.

CMP0CR=0x4000\_B320,CMP1CR =0x4000\_B324 CMP2CR =0x4000\_B328, CMP3CR =0x4000\_B32C

7	6	5	4	3	3	2	1	0				
			CMPEN				CINSEL	REFSEL				
0	0	0	1	(	0	0	0	0				
			RW				RW	RW				
		4 <b>CM</b>	IPEN	0	Compar	rator 0~3 Enable	<u> </u>					
			_	1	Comparator 0~3 Disable							
		1 CIN	NSEL_		Comparator input selection							
				0	Input fr	om OPAMP 0~3	each					
			_	1	Input fr	om external pin						
					(see pin	n mux table)						
		0 <b>RE</b>	FSEL		Compar	rator reference s	election					
			_	0	Reserve	ed						
			_	1	REF inp	ut from external	pin					
					(see pin	n mux table)						

When OPAMP is disabled, the OPAMP output is unknown (floating). Therefore, the user should set (write 1) CINSELx to choose the external input when OPAMP is an inactive state.

### **CMPDBR**

## **Comparator Debounce Register**

The Analog Front End Comparator Debounce Register is a 32-bit register.

#### CMPDBR=0x4000\_B330

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	3	2	1	0
										DBNCTB					C3DBNC				C2DBNC				C1DBNC						CODENC			
0	0	0	0	0	0	0	0				0x	00					0:	x0			0>	(0			0	x0				0х	0	
											R	w					R	W			R	W			R	W				R۱	W	

23	DBNCTB[3:0]	Debounce time base counter
16		System clock/(DBNCTB *2) becomes shift clock of debounce
		logic
		When DBNCTB is 0, system clock would be debounce clock.
15	CxDBNC[4:0]	Debounce shift Selection
0		When it is 0x0, debounce function is disable
		Shift number of debounce logic is (CxDBNC + 1) when
		CxDBNC is more than 1.

### **CMPICR**

### **Comparator Interrupt Control Register**

The Analog Front End Comparator Interrupt Control Register is a 16-bit register.

#### CMPICR=0x4000\_B334

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
PPOL3	PPOL2	PPOL1	PPOL0	IPOL3	IPOL2	IPOL1	IPOL0	2	СЗІМОБ		O O		<u>2</u>		C1IMOD		COMMOD
-	-	-	-	-	-	-	-	00	)	0	0	0	0	0	0		
R	R	R	R	R	R	R	R	RV	V	R	w	R	w	R	w		

15	PPOL3	0	Comparator outs for PWM protection will not be
14	PPOL2		inverted
13	PPOL1	1	Comparator outs for PWM protection will be inverted (if
12	PPOL0		debounce is enable, debounced output will be inverted)
11	IPOL3	0	When comparator output is high, IRQ bit is set
10	IPOL2		(CxIMODE = 00)
9	IPOL1	1	When comparator output is low, IRQ bit is set (CxIMODE
8	IPOL0		= 00)
3	C3IMODE	00	Comparator interrupt mode
2	C2IMODE		IRQ at level output
1	C1IMODE	01	IRQ at rising edge of comparator output
0	COIMODE	10	IRQ at falling edge of comparator output
		11	IRO at both edge of comparator output

### **CMPIER**

### **Comparator Interrupt Enable Register**

The Analog Front End Interrupt Enable Register is an 8-bit register.

#### CMP0CR=0x4000\_B338

7	6		5	4	3	2	1	0
					CMP3IE	CMP2IE	CMP1IE	CMP0IE
0	0		0	0	0	0	0	0
					RW	RW	RW	RW
		3	CMP3IE		AFE comparator	3 interrupt enab	ole	
					0 -interrupt disa			
					1 -interrupt ena	ble		
		2	CMP2IE		AFE comparator	2 interrupt enab	ole	
					0 -interrupt disa	ıble		
					1 -interrupt ena	ble		
		1	CMP1IE		AFE comparator	1 interrupt enab	ole	
					0 -interrupt disa	able		
					1 -interrupt ena	ble		
		0	CMP0IE		AFE comparator	0 interrupt enab	ole	
					0 -interrupt disa			
					1 -interrupt ena			

#### **CMPSR**

## **Comparator Status Register**

The Analog Front End Status Register is a 16-bit register.

#### CMPSR=0x4000\_B33C

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
C3RAW	C2RAW	C1RAW	CORAW	СЗОИТ	C2OUT	C10UT	COOUT					C3IRQ	C2IRQ	C1IRQ	COIRQ
-	-	-	-	-	-	-	-	0	0	0	0	0	0	0	0
R	R	R	R	R	R	R	R					RC1	RC1	RC1	RC1

15	C3RAW	AFE comparator raw outputs
	C2RAW	These values come from comparator output pin
	C1RAW	(before debouncing)
12	C0RAW	
11	C3OUT	AFE comparator output monitor bit
	C2OUT	These values are debounced outputs.
	C1OUT	
8	COOUT	
3	C3IRQ	AFE comparator interrupt flag
	C3IRQ	(0: no int / 1: int occurred)
	C2IRQ	Write "1" to clear flag
0	COIRQ	

# **Functional Description**

The PER2 and PCER2 registers must be configured to enable the AFE peripheral and the AFE peripheral clock.

# 18. Electrical Characteristics

## **DC Characteristics**

## **Absolute Maximum Ratings**

Absolute maximum ratings are limiting values of operating and environmental conditions which should not be exceeded under the worst possible conditions.

**Table 18.1. Absolute Maximum Ratings** 

Table	7 10.1. ADSU	lute Maximun	i Katiliyə		ı
Parameter		Symbol	min	max	unit
Power Supply (VDD)		VDD	-0.5	+6	V
Analog Power Supply (AVDD)		AVDD	-0.5	+6	V
Input High Voltage			-	VDD+0.5	V
Input Low Voltage			VSS-0.5	-	V
Output Low Current per pin		I <sub>OL</sub>	-	20	mA
Output Low Current Total	80-pin	∑ I <sub>OL</sub>	-	100	mA
Output Low Current Total	64-pin	∑ I <sub>OH</sub>	-	80	IIIA
Output Low Current per pin		I <sub>OH</sub>	-	10	mA
Output Low Current Total	80-pin	∑Ioн	-	100	mA
Output Low Current Total	64-pin	∑Ioн	-	80	IIIA
Power consumption			-	200	mW
Input Main Clock Range			0.4	10	MHz
Operating Frequency			-	72	MHz
Storage Temperature		Tst	-55	+125	°C
Operating Temperature		Тор	-40	+85	°C

### **DC Characteristics**

**Table 18.2. Recommended Operating Conditions** 

Table 10.2. Recommended Operating Conditions								
Parameter	Symbol	Condition	Min	Тур.	Max	unit		
Supply Voltage	VDD		3.0		5.5	V		
Supply Voltage			3.0	5.0	5.5	V		
		MOSC	4		8	MHz		
Operating Frequency	FREQ	INTOSC		20		MHz		
		PLL	4		80	MHz		
Operating Temperature	Тор	Тор	-40		+85	°C		

Table 18.3. DC Electrical Characteristics (VDD = +5V, Ta = 25  $^{\circ}$ C)

Parameter	Symbol	Condition	Min	Тур.	Max	unit
Input Low Voltage	$V_{IL}$	Schmitt input	-	-	0.2VDD	V
Input High Voltage		Schmitt input	0.8VDD	-	-	V
Output Low Voltage	V <sub>OL</sub>	I <sub>OL</sub> = 10mA	-	-	VSS+0.5	V
Output High Voltage	$V_{OH}$	I <sub>OH</sub> = - 3mA	VDD-0.5	-	1	V
Output Low Current	I <sub>OL</sub>		-	-	10	mA
Output High Current	I <sub>OH</sub>		-3	-		mA
Input High Leakage	I <sub>IH</sub>				4	uA
Input Low Leakage	I <sub>IL</sub>		-4			
Pull-up Resister	R <sub>PU</sub>	Rmax:VD D=3.0V Rmin:VD D=5V	30	-	70	kΩ

## **Current Consumption**

Table 18.4. Current Consumption in Each Mode (Temperature: +25℃)

		•		•		
Parameter	Symbol	Condition	Min	Тур.	Max	unit
Normal Operation	IDD <sub>NORMAL</sub>	ROSC=RUN IOSC20=RUN MXOSC=8MHz HCLK=72MHz	-	35	-	mA
Sleep Mode	IDD <sub>SLEEP</sub>	ROSC=RUN IOSC20=RUN MXOSC=STOP HCLK =RUN	-	3	-	mA

### **POR Electrical Characteristics**

Table 18.5. POR Electrical Characteristics (Temperature: -40  $\sim$  +85  $^{\circ}$ C)

Parameter	Symbol	Condition	Min	Тур.	Max	unit
Operating Voltage	VDD18		1.6	1.8	2.0	V
Operating Current	IDD <sub>PoR</sub>	Typ. <6uA If always on	-	60	-	nA
POR Set Level	VR <sub>PoR</sub>	VDD rising (slow)	1.3	1.4	1.55	٧
POR Reset Level	VF <sub>PoR</sub>	VDD falling (slow)	1.1	1.2	1.4	V

### **LVD Electrical Characteristics**

Table 18.6. LVD Electrical Characteristics (Temperature: -40 ~ +85  $\ensuremath{^{\circ}}\xspace$  )

Parameter	Symbol	Condition	Min	Тур.	Max	unit
Operating Voltage	VDD		1.7		5	V
Operating Current	IDD <sub>LVD</sub>	Typ. <6uA when always on	-	1	-	mA
LVD Set Level 0	VLVD0	VDD falling (slow)	1.6	1.8	2.0	٧
LVD Set Level 1	VLVD1	VDD falling (slow)	2.0	2.2	2.5	٧
LVD Set Level 2	VLVD2	VDD falling (slow)	2.5	2.7	3.0	٧
LVD Set Level 3	VLVD3	VDD falling (slow)	3.9	4.3	4.6	V

### **VDC Electrical Characteristics**

Table 18.7. VDC Electrical Characteristics (Temperature: -40  $\sim$  +85  $^{\circ}$ C)

Parameter	Symbol	Condition	Min	Тур.	Max	unit
Operating Voltage	VDD <sub>VDC</sub>		3.0	-	5.5	V
VDC Output Voltage	VOLIT	@RUN	1.62	1.8	1.98	V
VDC Output Voltage	VOUT <sub>VDC</sub>	@STOP	1.4	1.8	2.0	V
Regulation Current	I <sub>OUT</sub>				100	mA
Drop-out Voltage	VDROP <sub>VD</sub>	VDDVDC=3.0 V IOUT=100mA	ı	1	200	mV
Current Consumption	IDD <sub>NORM</sub>	@RUN	-	100	150	uA
	IDD <sub>STOP</sub>	@STOP	-	1	2	uA

### **External OSC Characteristics**

Table 18.8. External OSC Characteristics (Temperature: -40 ~ +85℃)

Parameter	Symbol	Condition	Min	Тур	Max	unit
Operating Voltage	VDD		3.0	-	5.5	V
IDD		@4MHz/5V	-	240		uA
Frequency	OSCF <sub>req</sub>		4	8	10	MHz
Output Voltage	OSC <sub>VOUT</sub>		1.2	2.4	-	V
Load Capacitance	LOAD <sub>CAP</sub>		5	22	35	pF

#### **Internal RC OSC Characteristics**

Table 18.9. Internal RC OSC Characteristics (Temperature: -40  $\sim$  +85  $^{\circ}$ C)

Parameter	Symbol	Condition	Min	Тур	Max	unit
Operating Voltage	VDD		3.0		5.5	V
IDD	losc	@20MHz	-	240		uA
Frequency	IOSCF <sub>req</sub>			20		MHz

### **PLL Electrical Characteristics**

Table 18.10. PLL Electrical Characteristics (Temperature: -40  $\sim$  +85  $^{\circ}$ C)

		10				
Parameter	Symbol	Condition	Min	Тур.	Max	unit
Operating Voltage	VDD <sub>PLL</sub>		3.0		5.5	V
Output Frequency	FOUT		4		80	MHz
Operating Current	IDD <sub>PLL</sub>	@80MHz		1.3		mA
Duty	FOUT <sub>DUTY</sub>		40	-	60	%
P-P Jitter	JITTER	@Lock			500	Ps
VCO	VCO		30		80	MHz
Input Frequency	FIN		4		8	MHz
Locking time	LOCK				1	ms

### **ADC Electrical Characteristics**

Table 18.11. ADC Electrical Characteristics (Temperature: -40  $\sim$  +85  $^{\circ}{\rm C}$ )

Table 10.11. ADC Electrical Characteristics					•••	
Parameter	Symbol	Condition	Min	Тур.	Max	unit
Operating Voltage	AVDD		3.0	5	5.5	V
Reference Voltage	AVREF		3.0	5	5.5	V
Resolution				12		Bit
Operating Current	IDDA				2.8	mA
Analog Input Range			0		AVDD	V
Conversion Rate				-	1.6	Msps
Operating Frequency	ACLK				25	MHz
DC Accuracy	INL			±2.5		LSB
	DNL			±1.0		LSB
Offset Error				±1.5		LSB
Full Scale Error				±1.5		LSB
SNDR	SNDR			68		dB
THD				-70		dB

## **OP-Amp Electrical Characteristics**

Table 18.12. ADC Electrical Characteristics (Temperature: -40 ~ +85℃)

Parameter Symbo		Condition	Min	Тур.	Max	unit
Operating Voltage	AVDD		3.0	5	5.5	V
Operating Current	IDDA				2.2	mA
Analog Input Range			0		AVDD-1.4	V
Slew Rate		@ CL = 20pF		15		V/us
Gain Error		Gain=2.19~4.3 7	-3		+3	%
		Gain=5.0~8.74	-4		+4	%
Common Mode Rejection Ratio			50	70		dB
Power Supply Rejection Ratio			40	70		dB
Gain Bandwidth		@CL=20pF		16		MHz
Open Loop Voltage Gain				100		dB
Open Loop Phase Margin		@CL=20pF		45		o
Closed Loop Phase Margin				70		o
Turn On time				2		us
Gain			2.19		8.74
